I could hear no champing of bits, no snorting of animals. I opened the front door opening to the street, then the back door leading to the yard—all is vacancy and silence, except for that sonorous but inharmonious music of sleep given off from so many organs all over the house. Nor did Ananias himself turn out until six o'clock, and I believe that if he had not to get up to receive payment of accounts from "Comets" and others who had to leave by a train about 7.30 a.m. we might not have seen him then. He coolly answered if the mules did not come soon they must have broken out of the "Curral." (The Ceylon word Kraal comes from this). 8 a.m. no mules—we take breakfast—and by nine they appeared. I do not wish to libel Ananias, for different from his namesake of sacred history he had not a wife to aid him in his sacred councils, but certainly, he gained about four shillings on each of us, by our being so long in starting.

We are at an altitude of about 2,200 feet above the sea, and the air is cool up till nearly mid-day. Our ride was over rather steep roads for three kilometres. At the back of a range of hills, covered with campo grass and chena, we came to the river Rio Pardo—about 10 a.m. This would be 3 miles from Sao José.

The Rio Pardo (Brown River) has a characteristic name, for rising in a range of high mountains—a continuation of the Serra Negra, which I have mentioned before, as dividing the undulating plateaus of Sao Paulo from the rough mountainous campos of Minas Gerães, and although running here slowly, shows by its brown water that it is fed by many a mountain stream, and has already received the drainage of many square leagues of land. Here its width is about 100 yards.

There is a ferry boat here, but a more rickety affair could not be conceived. The construction is of two trees dug out placed parallel, about three feet apart, and a few loose boards crosswise on the top. We were not very confident that the other side would be reached without a ducking. I made sure our mules would object to this mode of crossing, but no; the old negro who acted as ferryman got a hold of the reins and the animal rode, with very little hesitation, jumped aboard, but we could not wish another four-legged passenger, for the loose boards were all curled with the sun and many were broken, and out of place, besides the canoes seemed to get their ballast increased by a considerable addition of water, so we shoved off. To lessen the risk of foundering I had to give the boatman a hand in the rowing of our frail craft and living cargo to the other side. The landing in the mud at the other side was a more serious matter. The only accident however was the soiling of my riding boots and my clothes getting ornamented by some cakes of mud having been thrown up through the foundering of the manle in reaching terra firma. One by one we had to cross, and this delayed us very much, particularly since some of the other animals were either obstinate or not well educated in crossing rivers in such a fragile craft.

After crossing the Rio Pardo we had to ascend a steep hill on patana land. Then we went for five or six miles through some magnificent forest trees with

trunks of large diameter and of colossal height, creeping shrubs with flowers of varied hues, while the singing birds of all sizes and colours had not yet ceased their morning song, and mingling amongst the music of the forest the home of insect tropical life, and the shrill drones of the many crickets and cigaros (a large tree cricket) gave to these parts the enchanting charms which a traveller in the tropics loves to dwell amongst, but can with difficulty describe several hills of forest similar to this alternating with ridges, and plains of campo were crossed. The soil is of the rich Terra Rocha, the finest soil for coffee as yet known. All these forest lands are however in the hands of wealthy owners, and will by-and-by be laid low for planting the favorite coffee bush. There are still many square miles of these forest in these regions. These are not likely to change hands but they will be turned to profitable account by the present proprietors as soon as the labour difficulty is successfully solved.

Game in the bird line was plentiful, both in the forest and on the wide expanses of campos through which we passed that day, but we had started late in the day and had 36 miles to ride before dark, so we could not wait for shooting.

All along this road there were neither resthouses nor bazaars (or vendas as they call them here). We stopped at a native hut by the side of our road and got an old negro woman to make us some coffee, while we discussed some fowls' wings and legs, which Ananias had supplied us with as a bite on the road. The day was cool and, barring the steep sides of hills, the stony fords, and the mud-holes, the journey was agreeable. We reached the end of our day's ride at a town called Guaxupe about an hour before dark. Our route all day had been in a north-westerly direction, the province of Sao Paulo being left behind us at S. José.

Guaxupe is an Indian name, and is given to this small town of some 1,500 inhabitants and which boasts of only one church, while many of the same size in Brazil have three or four. There is an hotel called the "Retiro dos Vigantes" (the Travellers' Retreat). The culinary and eating departments are on one side of the street and the sleeping and travellers' retreating apartments, on the other. Our bath was taken in a large galvanized basin which we considered quite a luxury. A bullock had been that day killed, and we had plenty of rational food for this our first experience of Minas hotels. The hotel happened to be full and my friend and self had to sleep on the floor of the "salle," or sitting-room. Some pleasant days were spent here and I did not get promoted to sleep on a bed all the eight days I stayed at the Retreat.

Coffee planting is the principal agriculture here. The planters have not suffered from the emancipation to the same extent as in many districts, as the principal labour has always been the *camarada* or half-caste between the white and the Indian. Although not slaves they are accustomed to work in gangs.

The landowners here hold only small pieces; the farmer in many cases works with his labourers in the field, and feeds along with them—thus getting the maximum amount of labour out of them. Coffee is dried in the cherry and sent to some central mill, or to some neighbouring proprietor who may have erected coffee cleaning machinery, to be prepared for the market. Many of these seemingly poor farmers are making money owing to the high price of coffee, and the railway coming so near to them. The colonist system of labour is almost unknown here, but will gradually follow after its success in the province of Sao Paulo. As I have some duties in the interim which will occupy some five months I will not be able to return to the Coffee Districts of S. Paulo for that time, when I intend to give a short account of the greatest of Brazil's coffee centres—that of Rebeirao Preto, and these notes will then come to a close.

You will have seen by the European papers that our elections have passed quietly over, the candidates of the Provisional Government having gained all along the line. The Deputies and Senators are now wending their way to the capital, to take their places in Congress which is to meet in a few days.

The Emperor's palace, situated on a nice picturesque piece of ground overlooking the beautiful bay of Rio de Janeiro, is being fitted up for the deliberations of that important body. After some days spent in formal business their duties will be to approve the Constitution, and to elect a President and Vice-President. It is said in some quarters, that, this business done, the two houses will be prorogued until May, by which time each province will have received its constitution and will have thus consolidated the Government by a Republic composed of Federal States. It is expected that after the election of a President all the European powers, which have not as yet done so, will recognise the Estados Unidos do Brazil. The principal acts of the Provisional Government have been generally approved by the nation, but many differences of opinion have been expressed regarding its financial policy. Exchange however is now rising and the value of the milreis is two shillings. All duties have now to be paid in British sovereigns at par or 27 per milreis.

A. SCOTT BLACKLAW.

BARK AND DRUG REPORT.

(From the *Chemist and Druggist*.)

LONDON, Dec. 4th.

ANNATTO.—There have been larger arrivals of seed from Ceylon this week, two vessels bringing 278 packages.

CINCHONA.—The bark supply offered at Tuesday's auctions was a very moderate one, consisting of:—

	Packages	of which	Packages	
Ceylon bark ...	1,064	973	were sold	
East Indian bark ...	684	do	621	do
Java Bark ...	75	do	75	do
South American bark	234	do	171	do
West Coast African	221	do	156	do

Total ... 2,278 do 1,996 do

The assortment was not remarkable in any way, except for the unusually large consignment of bark from the African West Coast included in it. There was a small quantity of good Ledgeriana bark from the Wentworth plantations in India, and also a few lots of fine renewed Succirubra, but most of the bark was of ordinary or medium quality. Competition was brisk, and the improved tone of the market enabled holders to realise a slight advance on the previous auctions, the unit for good barks being 1½d per lb., and the average fully 1½d per lb.

JAVA CINCHONA.—Original: Succirubra stem quills, bold and long, but damaged, 6d to 6½d; dusty stem chips 3½d; ditto root 3d to 3½d per lb.

SOUTH AMERICAN CINCHONA.—Of 230 packages of cultivated Bolivian Calisaya, 171 pkgs. sold at full prices. Quilly chips, 4d to 4½d; medium to long fairly bright stem quill 5½d to 7½d per lb. Four cases (416 lb.) red quill, thin, damaged and colourless, imported via Hamburg, were withdrawn.

WEST COAST AFRICAN CINCHONA.—No less than 221 bales (23,299 lb.) of bark grown in the Island of Sao Thome were offered. The bark was imported in two consignments, via Lisbon, and 156 bales of it (19,169 lb.) sold at comparatively good prices to German quinine makers and French druggists. Calisaya and succirubra hybrid medium quill, fairly bright, but damaged 4½d to 5d; chips and shavings 3½d to 4½d per lb. The greater part of this parcel was slightly damaged. The exports of cinchona from Java during the three months from July 1st to September 30th, have been as follows:—

	1890	1889	1888	1887
Govt. plantations, Amst.	54,208	13,284	148,749	170,295
Private ..	1,595,818	987,641	986,363	864,391

Total 1,650,026 1,170,283 1,065,112 1,034,686

COCOA BUTTER.—At the monthly auctions, which took place here on December 2nd, 300 2-cwt cases of Cadbury's brand sold at prices ranging from 13½d to 12½d, closing at about 13d, the result being a decline of about 1½d per lb as compared with the November auctions. On the same day 70,000 kilos of Van Houten's cocoa butter (A) were sold by auctions in Amsterdam. They realised from 68½ to 70½ cents per ½ kilo, equal to about 12½d to 12½d per lb., or rather less than the prices paid in London.

OILS (ESSENTIAL).—Citronella is worth 13-1½d per oz. on the spot for fair native quality, and for arrival 11½d per lb. o. i. f. is asked for tins. Lemongrass oil on the spot is 1½d per oz., and for arrivals the quotation is 1½d per oz. c. i. o. terms.

OILS (VARIOUS).—Coconut Oil: Ceylon steady, at 31s 6d for fine quality on the spot, while for near at hand 28s

d. c. i. f. terms, is quoted. Cochin has advanced, and is now worth 23s 6d to 34 6d on the spot according to quality, while for distant delivery 52s 6d, c. i. f. terms, is asked.

QUININE.—There has been a somewhat better feeling in the market this week, although the sales reported only amount to about 40,000 oz.—second-hand German bulk at 11½d to 12d per oz., and some Brunswick, from the makers, at 12d per oz. for April-May delivery. There would be further buyers at 12d per oz. for forward delivery now, and also 11½d per oz. spot, but there is nothing to be had at those figures. The B. & S agents have refused all offers below 13d per oz. for January-February, and hold firmly at that quotation.

A PAMPERED RAILWAY COMPANY.

Mr. Geo. W. Christison, a Darjeeling tea-planter and Manager of the Lebong Tea Company, Limited has begun a strenuous agitation against an important public grievance, in regard to which some correspondence has appeared in the *Englishman* lately. Mr Christison, for the first time, tries to bring an organised protest, and Government pressure, if possible, against what has been generally known as the excessive cupidity of the Darjeeling-Himalayan Railway Company, fostered as it is by the indulgence of an over-avish Government. Although subsidised from the public funds to an extent that no railway in the country has been, the public interest is the last thing it seems to look to, payment of a large dividend to shareholders and fat salaries to officers appearing to be its sole concern. The rolling-stock it maintains is far from adequate to the demands of the traffic along the line, so that in busy and rainy seasons goods accumulate at the stations to the great loss of importers and exporters, notwithstanding that bullock carts still carry a good deal of the traffic. The consequence is that, in order to secure a large dividend from a comparatively small traffic, the rates have been kept up from the beginning at exorbitant figures, though it has been amply proved that, with some present sacrifice by laying out money on rolling-stock and improving arrangements, the rates could be considerably reduced without any permanent loss to the income of the Railway.

Passenger fares by the Darjeeling-Himalayan Railway for first and second classes are four times as high as those on the Eastern Bengal State Railway, and third class fares more than six times as high as on the lowest class of the Eastern Bengal State Railway. Parcel rates are higher for 5 miles of the Darjeeling-Himalayan Railway than for 328 miles of the Eastern Bengal State Railway. With regard to goods generally the highness of the scale will be understood when it is known that the price of coal together with freight from Naihati to Silligorie (305 mile) amounts to very much the same as the charge for freight alone over the 51 miles of Darjeeling-Himalayan Railway from Silligorie to Darjeeling.

In response to strong representations for reduction of rates made by the Darjeeling Tea Planters' Association, of which Mr. Geo. W. Christison is a leading member, the Darjeeling-Himalayan Railway has offered a rebate of 5 per cent on coal and 7½ per cent on all other goods. But Mr. Christison regards this to be utterly inadequate to meet the necessities of the case, and he urges upon the Association to press for more, and if accepting the terms offered by the Darjeeling-Himalayan Railway not to bind itself to keep quiet for the next five years, as is stipulated for by the former. In one of his circular letters addressed to the members of the Association through its Secretary, Major Harrison, Mr. Christison writes:—

"It is very evident from the paltry reduction upon coal (the most important of all) where the difficulty lies. If a proper reduction were made, the increase of traffic would be such that the Railway could not carry it. It therefore is the duty of the Association to go to the root of the evil, and induce the Railway to increase its rolling-stock and otherwise improve its arrangements in regard to stations, godowns, cranes, &c., and, if necessary, even

petition Government for this. The line is clearly being worked for the immediate profit of the shareholders, and not for the good of the public. Government has granted the Railway vast concessions in the public interest and would certainly insist upon it making proper arrangements for the public traffic if a strong representation were made in the proper quarter. It is calculated by the best authority that ten lakhs are needed to provide rolling-stock, and otherwise put the line into proper order. The raising of this extra capital might affect the dividends for a time, but the shareholders would ultimately be gainers as well as the public."

The "concessions" referred to in the above paragraph are six very substantial ones, besides others of a minor nature. These are (1).—Free use of the Cart Road between Silligoorie and Darjeeling, said to be one of the best of its kind in the world, for the laying of the lines of the Darjeeling-Himalayan Railway. (2) In regard to the maintenance of this Cart Road the Railway Company is in the position of contractors to the Government, being paid for on a most liberal scale of rates, with 15 per cent. added for tools, plant, and supervision, the landslips being looked after by the Government for the first five years, and still very largely, if not entirely. (3) A most liberal subsidy for the carriage of mails. (4) Free use of Silligoorie Station and appliances till the line makes a clear dividend of $7\frac{1}{2}$ per cent. (5) All materials for the Darjeeling-Himalayan Railway carried at a reduction of 40 per cent. on the minimum rates over the Northern Bengal State Railway. (6) On completion of contract, the Government to take over the line at the market price of shares plus 25 per cent. premium on such market price. The grant of the use of the Cart Road saved the Darjeeling-Himalayan Railway Company 50 lakhs, and it has recently obtained exemption from payment of road and public work cesses.

In view of these concessions from the public funds, and presumably in the public interest, Mr. Christison rightly insists, and hopes that a fair reduction in the rates for goods, particularly for coal, may be obtained, and better arrangements made for the carriage of the traffic. Other railways have borne the whole cost of their construction, and without any such concessions manage to offer rates immeasurably lower, paying themselves fairly and furnishing every necessary convenience to the public. Over and above the high charges, not the least of the inconveniences by the Darjeeling-Himalayan Railway, is the discreditable delay that takes place in the transit of goods owing to the insufficiency of rolling-stock, so that goods are often reported blocked, and goods have to lie exposed in the rains; while a good deal of traffic is carried yet by bullock carts and other modes of conveyance that ought, with fair rates and better arrangements, to go by rail. Mr. Christison suggests that the number of carriages and waggons of the Railway should be increased together with a reduction of rates, and a fourth class should be provided for the poorer classes 50 per cent cheaper than its present third class particularly as so many coolies have to be transported over it. He further declares that instead of the 5 per cent reduction on coal offered by the Darjeeling-Himalayan Railway no less than 33 $\frac{1}{3}$ per cent would be fair, and even 50 per cent would not be unreasonable or out of proportion to the rates for coal charged by other lines, while in place of the 7 $\frac{1}{2}$ per cent general reduction offered under other heads, 10, 18, 20, 25, 40 and even 56 per cent on different goods "would be fair, and nothing more." These contentions are supported by an array of statistics carefully collected and arranged so that there can be no two opinions as to the conclusion they lead to. Mr. Christison points out that the reduction now offered by the Darjeeling-Himalayan Railway Company, so as to draw the Darjeeling planters into an agreement to keep quiet and send all their goods by the Railway for the next five years, is a repetition of Mr. Prestage's old bribe (with an addition of 2 $\frac{1}{2}$ per cent) to get the Darjeeling Carrying Company closed and thus have a monopoly of the traffic over the Cart Road. "The Agreement," remarks Mr.

Christison, "is unworthy of any railway. Certainly, if the Association, as well as the individual members accepting, are to be bound hard and fast for five years, and other routes to be closed, the rebate is not worth the sacrifice." Mr. Christison would rather have the cart traffic revived on its old scale if the Darjeeling-Himalayan Railway does not come to terms. The common rates by bullock carts from Silligoorie to Darjeeling vary from 6 $\frac{1}{2}$ annas to 8 annas per maund—10 annas and upwards in the rains being rather an unusual fare, and 9 annas per maund being rarely paid by those who carry regularly and understand the business. Taking 8 annas as the average rate, it is little over half the charge by the Darjeeling-Himalayan Railway if down traffic (which includes large quantities of tea) be allowed for.

Mr. Christison has taken up a very good cause, and he deserves the support of all sections of the public. He is fighting in the interest not alone of the Darjeeling tea planters, but of the public generally to whom the Darjeeling trade and Darjeeling as a place of business as well as sanitarium, are daily growing to be of greater importance. HOPE.

—*Indian Planters' Gazette.*

TEA CULTIVATION IN JAVA.

The Italian *Bolletino Consolare* gives the following account of the present condition of the tea industry in Java:—

The cultivation of tea in the Dutch Indies is practically confined to the island of Java. It is mainly carried on in the province of Preanger, in the western part of the island, where it is rather a part of horticulture than of agriculture. The industry is in the hands of experienced planters, who are sparing no pains to increase the prominence and quality of the Java teas. Notwithstanding their care, however, as early as in 1887, they could not congratulate themselves on the price of their article. In 1888 it continued to fall, and the planters were forced to expend their utmost energy on saving their plantations from ruin. This was the case not merely with recent enterprises, but with old plantations, that had flourished for many years. The weight of this depression fell, of course, on the native population, which until then had obtained a comfortable livelihood by the cultivation of tea. The quantity produced on the Java tea plantations scarcely fluctuated in the three years, 1886, 1887, and 1888; it remained at about 325,000 kilos. per annum.

In addition to this steady decline in price, the Java tea plantations have been ravaged by an insect (*Helopeltis antonia*), called Boedock Hamand in Malay, and Theluis (tea-lobse) in Dutch, which each year destroys in value hundreds of thousands of florins. It is needless to add that the planters have offered the most liberal rewards to any one who will devise an infallible mode of freeing them from this devastating foe, but hitherto with as little success as in the case of the diseases of the coffee-palm and the sugar-cane.

At the same time there is noticeable a distinct improvement in the quality of the Java teas. Until lately, on account of the quantity of tannin which it contains, the Java tea has only been bought in Europe when mixed with China tea; but the improvement of the quality has now rendered that needless, while the cultivation of Assam plants will presently enable the planters to compete with Ceylon and British India. Nor must it be forgotten that during the last two years great improvements have been introduced in the preparation of the tea. The most recent inventions have been applied, and nothing which is happening in Asia, which can be of any utility to the Java tea planters, is permitted to escape their attention. For many years past it has been proved that the climate and the soil of Java are perfectly adapted to the cultivation of tea, and are powerfully aided by the regular rainfall in that mountainous country, which produces an abundant growth of leaves.—*L. and C. Express*, Nov. 28th.

POTATOES AS PEN WIPERS.

One of the chief woes of the ready writer, be he clerk or what not, consists in the fact that he no sooner gets a pen into good working order than it, like the "dear gazelle," comes to an untimely end from the corrosion caused by the ink. Life is not long enough to use and mend quills, nor to apply with delicate firmness the pen wiper to a steel one. But some genius has now hit on a solution of the difficulty which has the merit of the most extreme simplicity. In many offices, we are informed, a potato is used instead of a pen wiper. The juicy tuber holds the pen steady, removes at once all ink from the nib, and prevents, or at least very greatly delays, the process of corrosion, and spares many a well-loved pen to a ripe old age.—*Pall Mall Gazette.*

CURIOSITIES OF MISNOMER.

Black lead is not lead at all, but a compound of carbon and a small quantity of iron. Brazilian grass is not grass, and never saw Brazil—it is nothing but strips of palm leaf. Burgundy pitch is not pitch, and does not come from Burgundy; the greater part of it is resin and palm-oil. Catgut is made from the entrails of sheep. Cuttle-bone is not bone, but a kind of chalk once enclosed in the fossil remains of extinct specimens of cuttlefish. German silver was not invented in Germany, and does not contain a particle of silver. Cleopatra's Needle (the obelisk now in Central Park) was not erected by the Egyptian Queen who "lost Mark Antony the world," nor in her honor: nor has that other Egyptian monument, known as Pompey's Pillar, any historical connection with Pompey in any way—being erected by or in honor of a very different Roman, Diocletian, and it ought to be known by his name.

Sealing-wax contains no wax at all, but is composed of Venice turpentine, shellac and cinnabar (or red lead). Turkish baths did not originate in Turkey, and are not baths, properly so-called, but rather heated chambers. Whalebone is not bone, although it does come from the leviathan for which Nantucket, New Bedford and Sag Harbor used to make those three-year voyages; moreover, it is said not to possess a single property of bone.

Truly, it seems that the nomenclature of common things is not unlike that celebrated definition which the French Academy of Sciences once made of a crab—"a small red fish which swims backward"—and of which Cuvier remarked that "the crab was not a fish, it was not red, and it did not swim backward—but that otherwise the definition was admirable!"—*Providence Journal.*

SISSAL FIBRE.

Mr. Benson, Assistant Director of Agriculture, Madras, in continuation of previous correspondence, writing on the 8th May said:—"In reply to your letter dated 3rd instant, for which I thank you, I have the honour to inform you that I have communicated the contents thereof to my correspondent, and I will let you know the results. In the meantime you may be interested in reading the following extract from a letter received from the Director, Botanical Department, Northern India, regarding the plant, from which it would appear that there seems to be some doubt as to the Sisal hemp being obtained from a plant not already introduced."

"Extract.—Sisal hemp is said to be yielded by *Agave Sisalana*. This is probably only a variety of the American plant called *Agave vivipara*, which is abundantly cultivated as a hedge plant in various parts of India, and is largely used for fibre in Upper

India. Any number of bulbs or small plants could be sent to you from Saharapore, but as the carriage would be expensive, it would be better to arrange for a supply nearer at hand. It is mentioned on page 118 of Dr. Bidie's catalogue of the Raw Products of Southern India."

Mr. D. Morris, of Kew, writing in April in reply to inquiries, said:—"We have very fully dealt with Sisal Hemp in the *Kew Bulletin*, and last month we gave some additional information in treating of Bombay Aloc fibre. This letter was not before you when you wrote. The greatest difficulty would be experienced in obtaining plants of Sisal hemp from Yucatan or the Bahamas. We have, however, established the fact, that the true Sisal hemp exists in the Turks Islands, dependencies of Jamaica, and also in Florida.....As regards machines there are, no doubt, several in use in different parts of the world. For instance, in Mauritius they have a very simple and apparently satisfactory machine, which has been used for several years. This cleans the leaves of the *Furcraea gigantea*. In Yucatan they have the Death and Ellwood Machines, I believe, but they also use another machine somewhat similar to the Mauritius machines. A full account of this last will appear in the *Kew Bulletin* for May. When the subject is sufficiently advanced to import machines for cleaning Agave leaves on a large scale in India, I have little doubt that either the Mauritius or Yucatan machines will be found to afford adequate results, or failing these, there is a new machine brought out by the Death Fibre Machine Company which is said to be a great improvement on all former machines."

Since Mr. Morris' letter was received, the *Kew Bulletin* for May is to hand, with a description by M. de Chazal of the machines used in Mauritius for cleaning aloë fibre. The subject will receive careful attention, as there can be no doubt that in many parts of the country the species of Agave, common in India, could be made to yield handsome returns, as it will thrive on land unsuited for ordinary crops. One of the members of the Society's Committee remarks as follows about the fibre of this plant:—"Aloë fibre becomes more valuable when the price of Manilla hemp is high, and there is more fluctuation in Manilla hemp than any other fibre. It is not merely supply and demand but, being a centralized and comparatively small business, it is a favourite for speculation, and the price is forced up often 50 per cent., suddenly. It has so happened for the last two years. Just now the price is low. It is when the price of Manilla hemp rises so high from speculation, that other fibres, such as aloë, are more in demand."

No doubt with a large steady supply of the fibre existing in the country, special uses would be found for it. Messrs. Harton & Co. of Calcutta, produce a very lasting and neat matting, somewhat like coir, but finer, from this material, samples of which will be sent to Kew to show what is already done in the country with hand cleaned fibre.

In connection with the subject of aloë fibre, read the following letter to the Deputy Secretary from Messrs. Smith and Neale, Bridgeport, Connecticut:—

"I have seen an article written by you copied in the "Scientific American" relating to Pine-apple fibre. I am thoroughly posted on fibre machinery, and could get you up a simple and good machine for getting the fibre out of the leaf in an expeditious manner; so it would be in good shape to be fed into drawing frames and cards. I can make the machine small and light running, so it can be worked by hand or foot power, horse power, or steam power. It would be necessary for me to know the extreme length of the leaf, and if I had a small quantity of the leaf, I could run it through the machine and send it on to you. I understand it ought to go through green so as to save the fibre. I think I could build a light running foot power machine that would turn out 250 lb. per day, hackles in good shape for the Drawing Frame." In acknowledging Mr. Neal's letter, he was informed that though the Society was not prepared to buy the machine, that should he send one for trial, it would be carefully tested, and a full report sent to him.

Should the machine prove a success, he could be put into communication with people in India who would be willing to negotiate with him for working it commercially.—*Agricultural and Horticultural Society of India.*

HANDBOOK OF AGRICULTURAL AND COMMERCIAL CONCERNS IN NETHERLANDS INDIA.—From Mr. J. H. de Bussy of Amsterdam we have received the third annual issue (for 1890) of the "Handboek voor Cultuur-en Handels-Ondernemingen in Nederlandsch-Indië." This is a most useful work containing information regarding the various estates, firms, &c., in the Dutch East and West Indies arranged in alphabetical order and with indexes of names. The Government regulations for the cultivation of land and the cool ordinances are also given. The whole, however, is in Dutch which to most Ceylon planters is "double Dutch."

THE CALCUTTA INCINERATOR.—Mr. Harrington writes as follows:—The incinerator is to be re-lighted on 6th December. The alterations that have been effected are—(1) The chimney has been heightened from 130 to 200 feet, (2) A powerful smoke crematorium has been constructed, (3) Self-acting hot air blasts have been introduced, which pass through the hottest part of the refuse furnaces on to the smoke crematorium; and the smoke crematorium chamber is so intersected with reverberating cross walls of heat absorbing material that a very high temperature will be maintained therein. After these alterations and when the incinerator has become fairly heated, Mr. Harrington anticipates that there will be but little smoke escaping from the chimney.—*Indian Engineer*, Dec. 6th.

HOW HE PLANTED MY POTATOES.—The piece of ground would be about 150 square yards in area, so rather less than 5 rods, and was sheltered and warm, and had been long under cultivation. The last digging it had got was when the winter frosts had departed, some time late in March. Johann was furnished with the ordinary Croatian hoe, fitted on a handle of about 2 feet 6 inches long, and with the heart-shaped blade, and bending low, was scooping out the shallow basins destined to receive the sets at the stretch of his long legs apart—that is, about 3 feet 6 inches. I could see that the quantity of "seed" required would be much less than by the English mode of planting; but I did not expostulate much with him about it, although I imagined that my crop would be a light one. The sets were duly planted, and the ground made level with the aforesaid hoe. Under the hot sun of Southern Moravia the shoots soon came above ground, and here another surprise awaited me; for when their earthing-up became necessary, my Croat, instead of drawing up the earth in long ridges, in English fashion, made a little rounded hillock around each stem, or bunch of stems, and as the tubers grew, and the hillock distended under the pressure of growth below, more soil was drawn to it; but at the finish each set had its own hillock of mould, independent of its neighbours. This form of earthing-up allowed the haulm, which was strong, to lay on the ground, between the hills, and not on them, so that had disease attacked the Potatos, the spores of the *Peronospora* would have mainly fallen on ground which contained no tubers; moreover, the sun's rays shone on every part of the haulm—a matter of great importance in plant growth, more especially if the growth be of short duration. The crop of Potatos was enormous, and measured from three-quarters to 1 peck at a root, which, at that rate, was 150 pecks for the 5 rods of ground planted. I felt that the foreigner, with his inborn common sense, had taught me a useful lesson; but it was only one among many that had still to be mastered. *Recollections of an Englishman Abroad*—*Gardeners' Chronicle*.

TANK SHIPS IN THE NITRATE TRADE.—A new departure in the construction of ships designed for the nitrate trade was heralded by the launching of the largest sailing ship in the world the other day, says the *London City Leader*. This ship is remarkable, not only for its size, but for the arrangements made to preserve its cargo. Nitrate of soda has a strong attraction for water, absorbing so much of it from the air as to be dissolved by it in large quantities when in bulk. The custom is to discharge this nitrate liquor overboard, and so lose it, but on the new vessel special tanks are fitted in the hold, into which the liquor drains.—*Bradstreet's*.

THE TECHNICAL EXPERTS who, under the direction of Sir Colin Scott Moncrieff, have been to Merv for the purpose of examining the state of the irrigation works carried out by the Russian Administration in Central Asia on the Czar's estate in that region, have returned to St. Petersburg, bringing very unfavourable reports of the condition of affairs. The Administration had proposed to effect the irrigation of about 250,000 acres of land, but from the Engineer's report it appears that there is no hope of irrigating more than about 32,000 acres at the outside.—*O. Mail*.

THE YIELD OF MARIAWATTE, 1,347 LBS. AN ACRE!—This is certainly a splendid record, whether we take the old 100 acre plot or the whole of the large acreage under tea. From our old files we find that the following has been the yield of this far famed field of tea for the past seven years:—

1884	...	1,092	lb. made	tea per	acre.
1885	...	1,178	do.	do.	
1886	...	1,059	do.	do.	
1887	...	1,126	do.	do.	
1888	...	1,033	do.	do.	
1889	...	1,105	do.	do.	
1890	...	1,347	do.	do.	

Average of 7 years 1,133 do. do.

POTATO DISEASE.—Time was when it seemed as if we had no means of arresting or mitigating this plague. But now we know that by proper modes of planting, adequate moulding, the selection of suitable kinds, or the use of sulphate of copper solutions, we have the means of controlling the disease to a large extent. But although each of these methods has been made known widely, very few have availed themselves of them. They are specially suited for the cottager, the allotment gardener, and the cultivator on a small scale, and it is disappointing to see no effort at all made to mitigate the pest. What is still more disheartening is to witness the utter apathy with which even intelligent cultivators allow the disease to be propagated wholesale by their carelessness and their almost incredible negligence, which ensure the best possible means of facilitating the growth and dispersion of the fungus.—*Gardeners' Chronicle*.

CINCHONA PLANTING IN JAVA.—An extraordinary general meeting of the shareholders in the West Java Cinchona Company was held in Amsterdam last week, when the managing director, Mr. M. J. Boissevain, submitted certain proposals which seem to indicate that the undertaking is hardly so prosperous as its proprietors could desire. It was proposed that of the four plantations belonging to the company—viz. Tjiseureuh, Bajabang, Pangairan and Tjidoerian—the two former shall be entirely uprooted. The proceeds of the bark thus obtained are to be used to reduce the share capital of the company. It is estimated that the capital will by this method be reduced by about 30 per cent., and it is hoped that the two remaining plantations will yield a sufficient profit to admit the payment of a fair dividend on the reduced capital. The proposal, which was the result of an investigation of the company's plantations by an expert, was unanimously agreed to.—*Chemist and Druggist*, Dec. 19.

ages ranged from 9d to 1s 2d a range of 5d a lb. This year the figures ranged from 9½d to 1s 0½d, a range of only 2½d. In other words there has been exactly 50 per cent less range this year than last. Indeed, when we examine the monthly averages, we find but little change at all. The lowest was 10½d in March and April, and the highest 11½d in September, October, and November. The figures for monthly averages are as follows:—

MONTHLY AVERAGES DURING 1890.

January	11½d	July	10¾d
February	11½d	August	10½d
March	10½d	September	11½d
April	10½d	October	11½d
May	10½d	November	11½d
June	10¾d	December	11d

These figures take in conjunction with those given below, ought to be of great interest to all our up-country readers. The following are the quantities offered and sold, and the averages realized weekly in London during 1890:—

LANKA PLANTATIONS CO., LD.

Below I would ask you to print the same journal's account of the meeting of the Lanka Plantations Company. In this case, as in that of the P. & O. Company above referred to, my previous letter anticipated nearly all that Sir R. P. Harding had to say to his shareholders. What fell from him, however, will not on that account be less pleasing to your readers:—

The tenth ordinary general meeting of the Lanka Plantations Company (Limited) was held on Wednesday at the offices, Old Jewry, Sir R. P. Harding presided, and in moving the adoption of the report stated that the advices which they received continued to lead them to hope and believe that the current year would certainly not be worse than the year of which they had the accounts before them. He thought that they might fairly consider that the Company had turned the corner, and every year which was added to the age of the tea trees should improve their position. They had 1,400 acres planted with tea, and probably they would soon have 1,500 acres; and if the average yield, when the trees got older, should be only 300lb. per acre, they would have 400,000lb. of made tea a year to dispose of. He had no doubt that this would give them very satisfactory dividends. Very great economy had been practised by their agents and superintendents. They were out of debt, and a debit balance of £1,458 had been discharged. They would be asked to approve the payment of the interim dividend on the preference shares, and to sanction the payment of a dividend on those shares for the second half of the year as well as the payment of a small dividend (3s a share) on the ordinary shares. He trusted that this would be the beginning of a much better state of things than they had experienced for some years. Sir Herbert B. Sandford seconded the motion. Dr. Bayford questioned the advisability of paying the small dividend suggested on the ordinary shares. For several years they had had deficits, and had accumulated a substantial debt, which he thought the credit balances shown this year should have been used in diminishing. He also advised the further planting of tea trees. The chairman, in reply, stated that the coffee which they now had was exceedingly good, and they were advised that the coffee prospects for 1890-1891 were extremely satisfactory. They had gone into tea planting as their resources permitted. They had reduced their indebtedness out of the profits and they had expended £1,900 this year in buildings and in fresh tea planting. They intended to decrease the suspense account, and not to add the capital account any further. The report was adopted and the dividends mentioned were afterwards approved.—London Cor.

"KEW BULLETIN."

The October number contains articles on an edible fungus from New Zealand, *Hirneola polytricha*, which is nearly allied to our common Jew's-ear fungus. It appears that this is in great demand in China, although the analysis, as given by Professor Church, seems to show that its nutritive qualities are feeble, and that unlike most fungi hitherto analysed, it is very deficient in albuminoids or flesh-forming matters. The preparation of Mexican or Istle fibre from *Agave hotenacantha*, is described; the fibre being largely made use of for cheap scrubbing-brushes. The ravages of the moths known as the "Nonnen" (*Liparis monacha*). In the Bavarian forests, are detailed. It appears, that in Bavaria alone the loss to the forest revenue will amount for the year to something like £40,000. Okao fibre, from *Hibiscus esculentus*, and Coconut butter (not to be confounded with Cocoa-butter), receive attention. If this tasteless, fatty substance, can be prepared as suggested from the copra or dried Coconuts of commerce, the supply of material would be almost unlimited. Medical evidence goes to show that the fat in question meets all hygienic requirements, and is "far superior to animal fat and

butter, as well as any of their other substitutes."—The November part contains an article on the Liberian Coffee, introduced to Kew in 1872, and distributed into commerce by Mr. Bull shortly afterwards. On July 22nd 1876, p. 101, Mr. Hiern favoured us with an article on the subject, to accompany a woodcut illustration taken partly from a plant in Mr. Bull's nursery, partly from wild specimens. It was hoped that the West African Coffee would prove more robust, and better able to withstand the attacks of fungus (*Hemileia*). At first, however, these expectations seemed likely to be disappointed but now we learn the tide of opinion in the planting world has set in favouring the Liberian Coffee, and various extracts in support of that opinion are given in the number before us. The African Cola-nut (*Olea acuminata*) is the subject of the next article, which comprises a brief summary of what is known on the natural history and properties of this valuable tree. The nuts contain caffeine and theobromine, and their consumption is stated, on good authority, to enable the natives to undergo great exertions with relatively little fatigue. The bitter Cola, also alluded to in the *Bulletin*, is quite a different thing. A figure of the fruit was given in the *Journal of Botany* for 1875, by Dr. Masters, and the plant was subsequently described under the name *Garcinia Kola* by Heckel, who had had overlooked what had been previously published. The fruits in question have a bitter taste, and are probably destitute of the special virtues of the true Cola.—*Gardeners' Chronicle*, Nov. 22nd.

TEA ON THE NEILGHERRIES

After Coffee, Tea is to the European planter the most important industry on the Neilgherries. It was introduced in the year 1835, but made little progress until after 1860. At first it had to endure the same drawbacks that planting in Assam had, *viz.*, unskilled labour for cultivation and manufacture and inexperienced supervision; on the other hand, it had some advantages, such as choice of land, cheap labour and manure, and high prices for well-manufactured produce. As manufacture improved so did demand with the usual result over production for local consumption. The excess produced was sent to the London market with variable success. Either Neilgherrie Tea did not retain its flavour in England or planters did not receive justice in that quarter, and the latter is suggested by the fact that consumers, to whom expense was a secondary consideration, and who used the better classes of Neilgherrie Teas, preferred getting them from the estate direct to using what they termed "the high-priced flavourless Tea" that they obtained from grocers in England.

As Tea keeps better in large quantities, as sent in chests to the London market, than in small boxes, as sent to private purchasers, the Neilgherrie planter is at a loss to understand why the passing of his Teas through the usual business channels should result in their being classed low and realising little more than "dust" of other Teas. It must be admitted that Neilgherrie Tea is not strong like Assam, and that it is not at all useful for mixing with tasteless China Teas, but it is a good high class drinkable Tea by itself; especially in India, where it keeps with care for a considerable time. The Neilgherrie planter has something yet to learn, since it appears that his Tea does not reach the English market in good condition in lead lined chests, while those of other districts do so.

A few estates have obtained high prices, such as five and ten shillings per pound, notably Brooklands and Glendalo, but these prices were for fancy Teas, and did not represent the ordinary manufacture for commercial purposes. Lately Kodanad obtained high prices for a large consignment; and if this continues, it will be a new departure on the Neilgherries, and help to solve the most difficult problem the Neilgherrie planter has to deal with, and prove conclusively to the most sceptical that climate is not the drawback to the district's Teas realizing good paying prices in the London market.

When tea planting was rushed lands were planted up that should not have been. The plant being hardy grows almost anywhere, and is not easy to eradicate, the small pieces of root left after a tree is dug out often start into new trees even in poor soil. Notwithstanding its hardiness and good growth as a tree, it does not grow so fast as in warmer climates with more rainfall; so that the production is not equal to that of Assam or the favourable Ceylon districts, and it would no doubt have been abandoned ere this only that its fine flavour obtained for it a large sale in India; this, together with cheap labour and a good climate, has been in its favour, and it is probable that the demand for it in England would increase considerably if it could be supplied to consumers in as good condition as it is to the consumers in India. It may be that the passage of Neilgherrie tea through the Customs Department, when it is turned out to be weighed and bulked, and handled in a very different way to what it is in the factory, is too much for its delicate flavour, but which the stronger Assams, Ceylons, and Travancores can probably stand. This seems to be the point where combination among planters may turn a poorly paying industry into a highly remunerative one.

The Tea produced in Southern India is not enough to appreciably affect the general prices in England. The imports of China Tea into England have fallen considerably, but have been amply replaced by increased supplies from India and Ceylon, in both of which countries there is land yet available, and more than enough to produce any demand that may be made from England. The annual increase in supply is quite equal to the increase in consumption as well as to the deficiency in supply from China: so that the prospects of a general rise in prices are not promising for the industry. Great efforts are being made to introduce Indian and Ceylon Teas into America and Russia, but satisfactory efforts are not being made to increase consumption in India. Consumption is increasing amongst the natives slowly but surely, and if it amounted to half a pound per head at the present rate of production, not a pound of tea would be available for England, where consumption is about 5½ lb. per head of population. It will require a very small consumption per head in India to absorb all the increase that takes place annually. A trial is at present being made in Bengal. Perhaps a scheme something like the following might be more successful. Every estate in India to supply to a syndicate at least one per cent. of its produce (will aggregate about 1,000,000 lb.) at cost price, or a little under it, say, an average tea for As. 5 per lb. delivered in the consuming district; the syndicate to add on 20 per cent. to cover expenses and profit, and to pay for the Tea supplied at the end of the year. For this consideration the syndicate to undertake to distribute the teas over the whole country, but in such manner as will not interfere with present important tea dealers, and in, or convenient to every hospital at the prices fixed, say, As. 3 per half lb. packet and As. 1-6 per quarter lb. packet. The teas to be supplied in such packets and properly labelled by the estates with full directions in the vernaculars for preparing the beverage.

No estate can lose much by such a scheme, while it may result in a very large increase in consumption of tea and a reduced consumption of alcohol. It should not be impossible to induce the women of India to indulge in tea who have no national beverage.—*Indian Planters' Gazette*.

SALE OF CEYLON TOBACCO IN LONDON.—Messrs. Grant, Chambers & Co. sold by auction on 11th Dec. 1890, 143 bales Ceylon leaf tobacco, mark N.K., all of which realized 4d per lb.

TOBACCO-GROWING IN GERMANY.—Last year's crop of tobacco in Germany has proved so remunerative that the extent of land under this plant has been increased by upwards of 100,000 acres.—*E. Mail*,

CEYLON GEMMING COMPANIES.

It would seem as if there must have been a very strong divergence of opinion expressed in the Reports of the two experts who were sent from home to examine into the question of Gemming in Ceylon. Every endeavour has been made to keep the nature of these Reports from becoming public, and to a great extent this effort has been successful, for we are without the details of what has been written either by Mr. Barrington Brown or by Mr. Fahey.

As regards the gentleman first mentioned it seems to be certain that he regards the prospect before systematic Gemming in Ceylon to be satisfactory, he having been overheard to express that opinion to Sir Arthur Havelock at the meeting held in London to represent to our then new Governor, the views of those interested in this matter on the Gemming Ordinance passed by Sir Arthur Gordon shortly before his departure. But if the information which had reached our London correspondent may be fully relied upon, Mr. Fahey did not adopt so favourable a view, and the result is that those who sent him out to Ceylon have decided that it is not worth their while to incur further expenditure and have wound up the Syndicate formed to undertake preliminary investigation. In the absence of more authoritative information we must accept the matter as standing in this position. We cannot, of course, argue upon what Mr. Fahey may have reported consequent upon the very simple fact that we are without knowledge of the reasons which determined him upon making a report of the character he appears to have done. We may accept the statement that his Syndicate has closed its venture, as conclusive proof that the expert it employed has expressed an opinion adverse to further attempts by it. We should have much liked to know upon what the different views expressed by the two experts were based. We are told that Mr. Fahey, while admitting the existence of a large number of gems in Ceylon, did not think that the cost of systematic search for them could be repaid, to the extent, at all events, of leaving a margin for profit.

Mr. Barrington Brown, as we have said, is strongly of a contrary opinion. How far he may have reached such a conclusion upon the possible collateral profit to be obtained during the search for other minerals, such for instance as plumbago and mica, we cannot of course say. Little has been done as yet in the way of the importation of machinery for developing the mines formerly existent of the first mentioned of these minerals by the Company working on the Everton and other contiguous estates, but we have been told that time has not sufficed for this. Everything, however, now seems to promise that those who have invested capital in the first actual Gemming Company started will not have done so without profit. The question as it seems to ourselves to stand between the two experts is as to whether the search for gems *per se* can be made to pay, whether that can be attained without the collateral aid to be obtained from the development of other mineral resources possessed by us. While this question remains unanswered, we must be left wholly in doubt as to how far the expert opinions obtained on the prospects of gemming alone are antagonistic to each other, or as to how far they may run on parallel lines. One thing only is certain—that while those who employed Mr. Fahey have abandoned their project, the gentlemen who sent out Mr. Barrington Brown are still hopeful of future success. We suppose there can be no doubt that the latter expert carries

more authority by virtue of special and varied experience. However, it seems probable now, that until full recovery has been made from the financial crisis which has lately overshadowed the London money market, we shall have to wait in our present condition of uncertainty. Much will doubtless depend upon the further success which may be achieved by the Gemming Company now at work. Of profitable returns, it has already secured a certain measure. Whether this will prove sufficient to warrant further investment in Gemming in Ceylon is more than can at present be said. When that Company issues its first Report, we may be in a position to write more certainly of the prospect before us; but at the present time we must hold our judgment in suspense.

TEA LEAD-PAPER.

We call attention to Mr. T. C. Anderson's letter respecting "Clark's Patent Paper Tea Lead" in answer to our remarks of the other day. We had forgotten how many testimonials to its good quality, Clark's patent paper lead had secured. In a private note Mr. Anderson says:—

"I have seen Mr. Seale of Messrs. Somerville & Co., and he says he has never heard of any unfavourable report on the paper lead, and that he uses it for samples. I regret that planters won't give it a fair trial. I do not want to make money out of it, unless it is universally adopted; and anyone may use it provided they use good lead and not ruin the thing by using perforated cheap lead."

In this connection and in regard to several other patents of value to tea planters, would it not be well to form a standing sub-Committee of the Planters' Association for 1891-92, to consider and examine all improved or economical means of cultivating, preparing and shipping tea that might be laid before them. It might be called "The Tea Improvements Committee." Many individual planters cannot afford the time to examine, or fear the risk attaching to, some new and perhaps good thing. Now a report by a disinterested, impartial Committee could not fail to be exceedingly useful as a guide all round.

CEYLON TEA FOR RUSSIA.

A PERMANENT RUSSIAN COMMERCIAL AGENCY IN COLOMBO.

The following translation of an editorial in a leading Russian paper will be read with interest:—

(From the *Novoe Vremya*, Dec. 1st.)

We recently wrote about the development of tea plantations in British India and Ceylon, which we ought to work to our own advantage and the disadvantage of China. We now find a very interesting paragraph in the St. Petersburg *Vedomosti* in connection with that subject. That paper says: "The enormous sums of money which we yearly pay for tea to the China merchants and the London tea brokers, could be profitably spent in arranging to keep up regular communication by our steamers between Russia and Ceylon. The business relations with China are getting each year more and more difficult, as the China men have quite adopted all the ways of usual business speculation, viz., as soon as the so-called tea season begins they all form a sort of confederation buying up all the new teas coming from the hills, increasing at the same time the prices for second qualities and condemned teas, which were not sold the last year. The European Agents getting uneasy about the non-appearance of high quality and new teas in the markets of Foochow, Hankow and Shanghai are easily caught in that trap and buy for high prices condemned or adulterated teas,

believing the assurances of the Chinamen that there are no superior qualities this season to be got. After having sold these lots, the good and now qualities begin to appear in the markets. By these or other tricks the Chinamen almost always succeed in deceiving the European buyers, who have more orders on hand than is possible to execute in a most limited time, and yearly those orders increase in proportion to the fast increasing number of tea-drinkers all over the world.

All this, says the *Vedomosti*, leads us to think seriously of opening new tea markets; and Ceylon appears the most convenient, for all of us drink now already nowares as much Ceylon as China tea, as our London brokers and agents use Ceylon tea most freely, almost half and half, for mixing up all the teas via London for Russia.

Further we must take into consideration that Ceylon may serve also as a market for some of our products. At a Conference which took place recently at the Ministry of Commerce the whole subject (here noticed) was duly talked over, and the Ministry of Commerce came to a resolution to open and confirm in Colombo a permanent commercial agency.

BARK AND DRUG REPORT.

(From the *Chemist and Druggist*.)

LONDON, Dec. 11th.

ANNATTO.—For 50 bags good red seed from Ceylon 2½d per lb was refused. Twelve baskets Pará roll annatto were offered; they were of fresh import, but the quality was common and mouldy. After some bidding 9d per lb was realised for the lot.

COCA LEAVES.—The only lots shown in today's sales were 2 packages Ceylon leaves, good bold dark Huanoco character, undamaged, which sold for 5½d, and 9 packages Java leaves, very small, badly cured, brown and mouldy which were bought in at 6d per lb for the best.

ESSENTIAL OILS.—Two cases fair bright yellow Cinnamon oil realised 1s 4d per oz.; and 17 bottles cataloged as "cinnamon oil," sold without reserve for 3d per oz. For 50 cases Citronella oil in tins, ¾d per oz is asked, but there were no bids.

CEYLON PRODUCE IN RUSSIA.

The following letter addressed to our London Agents, and sent us to deal with, carries its own explanation, and we trust that Mr. Mandel will hear from Colombo merchants with the quotation he asks for: "Orel, Nov. 8th, 1890.—We are indebted for your address to a correspondent of ours and request you kindly to make us offers for Ceylon coconut oil, original tare, delivered at Riga. Kindly send me also samples of tea in ½ and ¼ chests. I have a considerable sale for the above mentioned articles and should be pleased to give you orders should your prices allow me to do so. Hoping to hear from you soon, I remain, Abraham Mandel."

NOTES ON PRODUCE AND FINANCE.

FRAUDULENT TEA MARKS.—Public attention is frequently directed in the Press to the frauds committed in the preparation of tea and the disregard of the Merchandise Marks Act. The *Echo* records the result of an interview with the manager of a leading company which imports and sells the tea from its own gardens. We were shown, says the writer, a row of twenty-seven packages of so-called "pure Ceylon tea," on the labels of which some qualifying words were printed in a far smaller type. It is the poor who chiefly suffer. They are induced to buy dust and sweepings of inferior China tea, mixed with the dust and sweepings of Indian Congou as pure Ceylon tea "blended with choice Indian and China growths." This last sentence is upon most of the labels printed in very small letters, or else at the end of the packet so designed as to mislead the purchaser, while affecting to conform to the letter of the law. Those who wish to lead their sup-

port to British-grown tea might look carefully into these packets and see for themselves what wretched subterfuges are resorted to cheat both the Indian producer and the English consumer. No one is inclined to take up the cudgels for the poor, out of whom a far larger profit is made than that obtained from the well-to-do and educated classes, who know the right quarters to go to. Much the same, in fact, is being done by unprincipled advertisers in the tea market, as by touting brokers in stocks and share. False descriptions and misrepresentations, added to unfairly large profits, will generally carry the day. Government appears powerless to stop the gambling in the one case and the cheating in the other, although both the "bucket-shop" keeper and the preparer of false labels not only err against the spirit but also break the letter of the law.

A TEA RESTORING MACHINE.—The question how to preserve the staying power of Indian and Ceylon teas has for years exercised the minds of planters, brokers, and dealers. The constant cry in the "Lane" has been, "Give us tea which will not 'go off.'" We are glad to learn that Mr. J. D. Cahill, of Sea View, Sandycove, Dublin, a tea planter of experience, has lately patented a process and a machine for not only restoring tea which has "gone off" to its original freshness and briskness, but one which he claims will also materially improve tea which has been badly cured, or which is of inferior quality. We understand plans of the machine are already in the hands of the makers, and we hope shortly to be able to publish a full description of it. We hope that the desirable results claimed by Mr. Cahill may be fully maintained.

PREPARED COCOA.

A leading scientific journal specially devoted to chemical and analytical matters recently gave a short article upon the above subject, in which it was pointed out that cocoa is highly stimulating, but rich and somewhat indigestible, containing a large amount of fat known as cacao butter. To prepare cocoa for the table it is necessary that the amount of this fat should be reduced. This is attained by using one of two methods, namely—(1) the roasted and ground cocoa is mixed with starch and sugar so as to dilute its richness; (2) before grinding the cocoa it is heated and pressed, whereby a considerable amount (generally nearly one-half) of its natural fat is squeezed out. This latter method is decidedly the more desirable one, because not only is the fat removed, but all the other nourishing and stimulating principles are at the same time concentrated. A typical cocoa of English manufacture, which has always been constant in its nature, was recently found to possess the following percentage composition:—Fat=28.12, theobromine=0.95, natural starch, sugar, fibre, &c.,=40.85, soluble albuminoids=6.61, insoluble albuminoids=14.73 (these are the total flesh-formers=21.34), natural mineral matter=4.94, moisture=3.80: total=100.00. To give a still more striking confirmation of these figures let our readers glance at the following average amounts of flesh-forming ingredients present in the substances named:—Natural cocoa, 13.00 per cent; good wheaten flour, 14.00 per cent; cocoa prepared with added starch and sugar, 6.00 per cent; cocoa prepared by extraction of fat, 21.00 per cent.—*Grocer*.

CINCHONA BARK.

(From *C. M. & C. Woodhouse's Report*.)

LONDON, Dec. 18th.

The market during the past month has continued quiet. The Dutch sale held on 13th instant, at Amsterdam, estimated to contain an aggregate of about 13½ tons sulphate quinine or 403 per cent. on the average, sold at easier rates, the unit being quoted 1½d to 1¼d. In London, however, at the auctions held this week, the value

of the unit was fully 1½d, possibly owing in some measures to orders being in the market to buy for speculation. During the past few weeks, meetings of the principal manufacturers of quinine have been held with a view of forming a combination to regulate the price of quinine. The representatives have, however, separated without arriving at any definite understanding. Only small transactions are reported in quinine, the latest sales being at 1½d to 1¼d for German on the spot, and 1¼d for arrival. The Amsterdam public sales of bark, are fixed for the following date next year, viz., 22nd January; 26th February; 2nd April; 14th May; 11th June; 16th July; 3rd September; 8th October; 12th November; 17th December.

COFFEE AND TEA FIGURES CONSIDERED.

TEA: HOME CONSUMPTION.

Ending October 1890, five months.	Then at this rate 12 months 1890-1891 would show as follows.
Indian ... 41,016,071 .. equal to	98,438,570 lb.
Ceylon ... 17,542,380	42,101,712
China, &c. ... 24,938,790	59,853,096
83,497,241	200,393,378 lb.

Take G. W., & S.'s next Circular of 21st Nov. 1890 re Tea exported from United Kingdom for 10 months ending 31st Oct. 1890 and the figures for 12 months at the rate indicated would be.

Indian ... 2,359,629 ... equal to	Say H. C. and export, 12 months.
Ceylon ... 1,328,461	43,430,173
China, &c. ... 31,643,916	91,497,012
35,332,006	235,725,384 lb.

Since compiling the above, G., W. & S.'s figures are to hand in gross, for H. C. and export for 6 months ending November: they are—

Indian ...	50,081,487 lb.
Ceylon ...	22,102,654
China, &c. ...	44,719,286
Java ...	2,098,250

119,001,677 lb.

being in excess of the above estimate and showing a still further advance in the rate of deliveries for Ceylon tea.

With a reduced crop estimate from India (Rucker & Bencraft in a late circular suppose they will receive in London from India 106,000,000; Ceylon 50,000,000, supposition of mine; China 63,000,000,* your Hongkong correspondent's figures—he says it is his estimate for "the whole year"—say 25 per cent less than United Kingdom required last year), U. K. receipts will probably not exceed 220,000,000 lb. against a possible 240,000,000 lb. required, unless the export from the United Kingdom of China tea further shrinks, as it probably will do. No allowance is made here for a very possible increase in the exports of India and Ceylon tea from the United Kingdom.

COFFEE.

British tea planters are apt to leave unstudied the position of their great Rival Coffee in Europe and America—here are some figures showing the gigantic preponderance of coffee over tea in the principal consuming markets of the world.

Rucker & Bencraft in their Circular dated 6th Nov. 1890 (see *Observer* 1st Dec. '90) state that in March 1890, the deliveries in Europe and America were 62,000 tons (i. e. 138,880,000 lb.) which "nearly coincides," they say, "with the total stocks in the two continents" on 6th Nov. 1890.

James Cook & Co. in their Circular dated 22nd Oct. 1890. (See *Observer* 17th Nov. 1890) give total deli-

veries for 9 months ending Sept. 1890 at	
in Europe ...	309,000 tons
„ America ...	159,500 „
Total ..	468,500 „ for 9 months

or at the rate of 624,666 tons for 12 „
i. e.—1,401,000,000 lb. or about 115 million lb. monthly
Strange to say J. Cook & Sons give stocks in EUROPE, on 1st Oct. 1890 at about 60,000 tons—so one of these firms has fallen into an ERROR.

Rucker & Bencraft in their circular of Oct. 9th (see *Ceylon Observer* 30th Oct. 1890) give stocks on 1st Oct. "in Europe" 61,200 tons. In same Circular they say, the "deliveries (Europe and America) have been nominal—about 50,000 tons for the month"—large crops and ever increasing consumption. As far as I remember 8,000,000 bags* is the estimate of the coming Brazil crop, but even if it is on the trees will it ever be picked with labor only just made free? The Brazil planters evidently funk it and were getting some thousands of Chinese to help them, but did not late Rio News inform us that the Rio Government forbid their being landed and in fact ordered the ships with the Chinese on board to leave their shores.

Messrs. Jas. Cook & Co. in their circular of Sept. 24th, 1890 (see *Ceylon Observer*, 21st Oct. 1890) say "the deliveries (Europe and America) for consumption during the 8 months of this year are very good being 10,000 tons above last year, and nearly 17,000 tons in excess of those for 1888—the figures for the United Kingdom, however, are not so encouraging owing to adulteration." The Grand Old Man is mainly responsible for this. He surrendered at discretion, and the grocers carried their right to continue to poison the English working people!—His grand demonstration about pure coffee and tea was—PURE HUMBAG.

P. S.—1 see the new Directory gives a comparison of lb. of coffee and lb. of tea. Your estimated consumption of coffee on Continent of Europe was 405,000 tons, a very close estimate indeed, looking at the actual figures above.

To open freely new tea acreages in India and Ceylon until new markets are more assured of, and China competition can safely be despised, would seem to involve some risk at present, cheap coffee *must* be reckoned with

COFFEE NEWS.

The coffee crop in Hayti this year is reported very large. The *Rio News* says that, generally good news from coffee producing countries this year promises to cause much lower prices for the next year or two.—*American Grocer*, Nov. 12th.

TOBACCO CULTURE PROHIBITED.—The Khedive of Egypt, on June 25th, 1890, issued a decree prohibiting the cultivation of tobacco throughout Egypt, and lands hereafter found to be under such cultivation will be subject to a fine equaling \$1,000 per acre.—*American Grocer*, Nov. 12th.

THE KYROLITE TRADE.—A revival seems to have taken place in the Kryolite trade, the Company which own the quarries at Ivigtut, Greenland, having found a new market for it in Russia. For some time the manufacture of products has been falling off and the Company had disposed of most of their vessels which traded with Copenhagen. Keeping up the supply, however, to Philadelphia where there are also manufactories. The result of the recent revival of the trade has been the re-employment of the Traveller (Captain Alexander Simpson,) of Peterhead, to carry two cargoes to Copenhagen next year, and to take out a cargo of coals. It is six years since this vessel was similarly employed.—*A. F. Press*.

* R. & B. in their last circular, published in the *Observer* of 24th Dec., say 8 to 9 million bags—involving a probable certain export to Europe and America of 7 million bags of 132 lb. each—truly a "bumper" crop.

* Japan too included here I believe.

THE MADRAS AGRICULTURAL OUTLOOK.

A few districts in the Presidency are passing through a grave crisis at the present moment, and much necessarily depends on the state of the weather during the next fortnight, or three weeks. In parts of North Arcot, Chingleput, South Arcot and Tinnevely crops over considerable areas will be lost unless there is an early fall of rain, and Government is already so far anxious as to think it necessary to call for special reports. As we remarked on the 26th ultimo, the distress is partial and local, and the rainfall average for the whole of a district is no indication of the true state of affairs in different portions of it. For instance, from the rainfall statement for October, just issued by the Board of Revenue, we observe that so far as regards the Districts mentioned above, in North Arcot the rainfall up to the end of that month was equal to the average of five years ending 1888-89; in South Arcot it was only three inches below the average; in Chingleput nine inches; and in Tinnevely five inches. The greatest deficiency for a whole district was in Malabar, where it amounted to nineteen inches, while in Madras it amounted to twelve inches. The season has also been unfavourable in the Ombun taluk of Kurnool, where paddy, ragi, and arika are suffering from want of rain. In Cuddapah the paddy is withering in the Badvel taluk, and the ragi in Madanapalle taluk. In Coimbatore the wet crops of Palladam, and the dry crops in parts of Coimbatore, Erode, Udampalpet, Palladam, Pollachi, Srtyamangalam and Kollegal, are being spoilt by the drought, and the same is the case in the Uttakarai taluk of the Salem district. Altogether there appears to be cause for disquietude over considerable areas of the Presidency. If within the next few weeks the rainfall is not more general in considerable amount of distress will, we fear, ensue.—*M. Mail*, Dec. 11th.

ANALYSES OF TEA SOILS, MANURES, &c.

In quoting the following details from the proceedings of the A. and H. Society of India we would suggest that our Ceylon planters might avail themselves of the opportunity to have tea soils, &c., analysed:—

Mr. Francis Y. Ede, of Silchar, Cachar, wrote as follows:—I notice in the Journal of the above Society, Vol. VIII, Part IV, N.S., a memorandum on the analyses of Tea plants, Soils, &c. During the last ten years I have had occasion to draw some hundreds of samples of soil, analyse and report on the same with reference to their suitability for Tea gardens, their probable yield, &c. I have taken numerous samples from all the different kinds of land in Assam, Cachar and Sylhet and have kept, where available, a record of the amount of tea yielded by these soils and the condition under which the yield was obtained. If you think it would interest the subscribers to your journal, I could send you a few notes and memoranda on soils, their treatment, &c., in the tea districts.

Mr. Ede's offer was accepted with the Society's best thanks, and it is hoped that his good example will be followed by the many experienced Planters who are in a position to throw much light on many of the problems both in the culture and manufacture of tea which still remain unsolved. In a subsequent communication Mr. Ede wrote:—"I have to thank you for your letter of October 11th, and I quite agree with you as to the necessity of collecting and printing all information available with regard to the culture of the tea plant. It has been my opinion, for many years, that the application of a little science or technical knowledge would greatly benefit the tea industry. I have been working in a small way on those lines myself, and have been often astonished to find the good results produced; in some instances I have succeeded in doubling the yield of the plant. I am very glad that such a well known and much

appreciated Society should take this matter up; there is plenty of scope, and I have no doubt there will be numbers of men who will voluntarily aid in the investigation. I for one shall be most happy to render any assistance in my power. It remains for your Society to determine the best method of carrying out these investigations and compiling and recording the information it may obtain from the various districts, in such a manner that it may remain as a permanent record for the benefit of all interested. This investigation must be carried out with thoroughness and exactitude in all the tea districts, only absolute facts and reliable observations being recorded. I should be happy to let you have my views on the way in which district investigations should be carried out."

Since the receipt of the foregoing letter from Mr. Ede, Mr. Bamber has arrived in the country. This gentleman has been engaged by the Society, in conjunction with the Indian Tea Association, to conduct the inquiries relating to Tea soils, Manures and Tea manufacture as sketched in the Memorandum published in the last number of the Society's Journal (Vol. VIII, Part IV.). Mr. Bamber holds the Diploma and Gold Medal of the Royal Agricultural College of which he has also been elected a Life Member. In addition to the original research, which it is proposed to conduct, it is hoped that much valuable information will be obtained from gentlemen like Mr. Ede, and that the collating and tabulating of such information will add much to the present knowledge of many obscure points connected with the production of Tea.

The control of the inquiries is vested in a committee nominated by the Indian Association and the Society and which consists of the following gentlemen:—Chairman, Mr. C. B. Garrett. Members, Messrs. J. N. Stuart, W. O. Bell Irving D. Cruickshank, Drs. Warden and King. Secretary, Mr. R. Blechynden.

An inquiry was received from Messrs. Mc Dougall Clark & Co., for books dealing with analyses of tea soils. They were informed that some analyses had been published in the *Tropical Agriculturist* and in other papers, but as they referred to individual gardens, they were not enough to generalize upon; and the action now being taken was alluded to:

PLANTING AND SHOOTING IN PEERMAAD.

The South-West monsoon has been, as I prophesied it would be, one of the lightest on record, and though the North-East, with its attendant cyclone, did its level best to make up for any shortcomings on the part of its elder brother, the total rainfall up to the end of last month only amounts to 104.80 inches; our average being about double this amount. To both coffee and tea, the mildness of the monsoon has been favourable; to the former especially so and—if I had one—I would bet my bottom dollar, that a few successive years of mild monsoons, would effect a radical change for the better in the productiveness of the coffee estates in this district. The season's crop, which is now being gathered, is, with one or two exceptions, decidedly short, owing chiefly to the high winds and storms that prevailed during the blossoming season, but the general appearance of the estates is satisfactory, and the outlook for next year decidedly promising. An instance of the wonderful effect produced on struck coffee by the judicious planting of belts is worth recording. One of the oldest properties up here, planted early in the "Sixties," was some years ago well-nigh played out; crops had become beautifully less, and the proprietor's heart was sad within him; a happy thought, however, struck him to try belts, and he promptly set to work, and planted up rows of *Grevillea Robusta* over a large portion of the estate. These have now grown into fine trees, and the effect on the coffee has been simply marvellous. It seems to have taken quite a new lease of life, and though, doubtless, the shelter and partial shade afforded by the belts has been highly beneficial, there can be no possible doubt that there is something in the *Grevillea* that acts on coffee as a most

wonderful tonic. With the gloomy accounts one hears from various coffee districts, it is chesering to have to record the fact that some new clearings for "Coffea Arabica" are to be opened up during the coming season, thus proving that in spite of past years of leaf disease and short crops, there are some, at any rate, who have not lost their faith in the old King—"So mote it be." The steady increase in the yield of tea, and the good averages obtained are highly satisfactory. Farther experiments in the manufacture of green teas have resulted in further successes; but as these have already been chronicled in the columns of the *Madras Times*, I need not here further allude to them.

* * *

Our local shikarries have not done very much in the way of shooting lately; but two visitors from Ceylon had very fair sport during a short stay of about three weeks, and succeeded in bagging a couple of tuskers, a few bison, sambur and ibex and a leopard.

P. S.—Since writing the above, there has been an extraordinary change in the weather, which can only be accounted for by some peculiar atmospherical disturbances in your part of the world; and which to have reached us must have been, I imagine, somewhat severe. The land wind has suddenly stopped, and we have had very heavy showers, accompanied by thunder and lightning most unheard of occurrences at this season of the year,—*Madras Times*, Dec 17th.

PLANTING IN WEST BORNEO.

Sir,—The tobacco planters now in Sambas seem to pin their faith to the low alluvial land along the lower reaches of the Sambas Rivor, and none of them seem inclined to give the Sanggauw district another trial, which, I think, is a pity as there can be no comparison between the two soils—that of the lower land consisting of from 6 inches to a foot of humus on the top of a rather stiff subsoil, whereas in Sanggauw you have a rich chocolate colored soil of great depth and of volcanic origin, there being the crater of an extinct volcano close to the Simadrem Estate. Given a fairly dry season, and clearing on land less shut in and at a lower elevation (and there is any quantity of such land in the district) and I cannot but think that a finer quality of tobacco would be produced at only a slightly decreased yield.

There are several contracts held in Sanggauw district, and one gentleman has a very successful pepper clearing near the Sanggauw Kampong, at an elevation of about 500 feet, and pepper and Liberian coffee have been also planted at "Sakong" near the foot of Gunung Baiang at about the same elevation, and I am told both are doing well.

Liberian Coffee grows well in this soil, and crops abundantly, although, when planted by the Sultan, it had little care taken of it, and I have never seen finer pepper of the same age than that growing in many of the native gardens in and about Sanggauw.

The climate also is delightful; and I may here mention that the healthiness of Sambas is one of its greatest recommendations to planters and miners—in fact the death-rate for the whole of Western Borneo is very low.

One thing in connection with the planting enterprise in Dutch Borneo surprises me, and that is that the tobacco experts have confined themselves to Sambas territory in selecting land, while only 100 miles further south in the Pontianak and other districts there are hundreds of thousands of acres of equally good land along the Kapoëas River, and if anything more favorably situated with regard to transport and communication, there being three steamers running regularly between Pontianak and Singapore, a run of about 35 hours, while there are besides several large launches running up and down the Kapoëas river, which is navigable by fair-sized steamers for between 300 and 400 miles from the mouth.

The climate as far as I know, is the same as Sambas. If, as I hope, tobacco planting proves a success

in Sambas, we will see all the land referred to above taken up; and I consider there is a great future for this part of Borneo in planting alone, to say nothing of the mining industry, which for the present attracts more attention than the planting. Next week I will send you a few notes on the mining concessions.—Yours &c.,

KAMBAR.

West Coast, Dutch Borneo, Nov, 1st, 1890.

—"Times of Ceylon."

SEVERAL EXPERIMENTS have this season been made in Virginia in growing teosinte the new southern forage plant. It is said that one grower has exhibited a bunch of teosinte which was very promising. According to a report it was "about 7 feet in height and has some 30 or 40 stalks all from one grain of seed." The producer calls it the greatest fodder plant he ever saw, and alleges that he has fed two milch cows through the summer from less than half an acre; and has still a quantity left.—*Indian Agriculturist*.

AN ENORMOUS TREE.—A correspondent of the *Scotsman* writes:—There are at present ten skilled workmen busily engaged taking out a section of an enormous redwood tree in the Mammoth Forest, California. The section to be taken out will be 9 feet in height, and will be divided into three cuts. The tree, which grows 6,325 feet above sea level, measures 99 feet in circumference and nearly 33 feet in diameter. The saw used in getting out the section is 22 feet long, and requires eight men to handle it. Two months will be needed to complete the work. The section are to be shown at the great World's Fair as Chicago in 1893. Three flat cars will be necessart to transport them, as their total weight will noy be less than 20 tons.

ARTIFICIAL COFFEE BERRIES.—The art of adulteration has made further progress. Many persons buy coffee whole, thinking that by grinding the berries themselves they avoid all risk of adulteration. It is so easy to mix with ground coffee chicory or other less inoffensive ingredients, M. Ludovic Jammes, inspsctor, reports, however, in the last issue of the *Revue d'Hygiene*, that a number of commercial travellers are offering retail grocers coffee berries at a price which yields 60 to 100 per cent more than the usual profit. Good coffee is at present very dear, and when the tradesman expresses his surprise, the commercial travellers, so as to cover their legal responsibility, explain that the berries are artificially manufactured, and to avoid detection should be mixed with real coffee. M. Jammes gives, however, minute details to facilitate the detection of this fraud. The slit in the false berry is nsither so long nor so deep as in the real berry. The colour is well imitated, but the false berry does not feel so smooth; it is also much harder, cannot be so readily broken with the teeth, and is often hollow inside. A real coffee berry can be easily broken by introducing the nail in the slit, while the false coffee will resist very hard pressures. The false coffee has a somewhat faint and nauseating taste. It seems to be composed of vegetable glancs and the flour of some cereal. A paste is made with soms such mixture, placed in a mould, and torrefied. The fraud is therefore absolute; the berry does not contain even the smallest percentage of coffee. It is to be hoped that thsse revelations will put an end to this fraudulent trade, otherwise the French will soon lose the reputation they have so justly won of being the best coffee-makers in the world.—*Lancet*.

A HOLIDAY TRIP TO LABUGAMA LAKE :

THE SOURCE OF THE COLOMBO WATER SUPPLY.

WITH NOTES ON THE VEGETATION AND PLANTING OPERATIONS OF THE NEIGHBOURHOOD.

It is to be regretted that the beautiful scene whence the capital of Ceylon derives its supply of mountain-born water (of a purity unexcelled) is not more facile of access. The Lake which has been formed by damming up the Wakoya (the "crooked stream," as the Dikoya is the "long river") is nearly 28½ miles from Colombo. Over 19½ of those are along the Ratnapura road, to about 1½ mile beyond Hanwella, and to this point the mail coach is available. But there are no horse carriages to be hired at Hanwella, only bullock hackeries to do the 8½ miles of road which were made specially for the purposes of the waterworks. This road turns off at right angles from the high road at Wakoya, 1.54 mile beyond Hanwella. If, as in our case, a party of four can be made up, we can testify to the comfort of the waggon and the excellence of the horses which Messrs. A. Pate & Son can supply. Starting from Colombo on the morning of the 2nd at about half-past 6, we reached Hanwella at 9, and we could have got to Labugama by half-past 10, and returned the same day to Colombo, had we not formed other plans. We must warn any inclined to make the trip, that, although they may find accommodation at Labugama, in a Government building which is used as a resthouse, when not required for purely Government purposes, they had better take provisions with them from Colombo, if they do not follow our example and breakfast at the very nice and commodious resthouse at Hanwella. Even so, information ought to be sent in advance to the resthouse-keeper. With such an arrangement, visitors to the Lake could return to a late tiffin at Hanwella, and then back to Colombo. If they arrange, as we did, to dine and sleep at Hanwella, the enjoyment of the trip will not be marred by fatigue,—the more especially if our example be further followed in floating down the Kelani ("pleasant") river by boat. The resthouse-keeper could get a boat ready; and if there was any difficulty we have no doubt that other Europeans would benefit as we did by the courtesy of Mr. Ameresekere, a most intelligent Sinhalese gentleman, who is a planter and contractor for cutting, carrying and storing timber at Hanwella from the Government forest reserves, of which one block near Labugama extends to an area of 5,000 acres. I may as well mention here that although "wa" is by the Railway Department classed highest amongst firewoods, Mr. Ameresekere agrees with Col. Clarke that this tree is too valuable as a cabinet wood to be used for the furnace, for which purpose he gives the preference to "mendora," the calorific qualities of which are increased by the resin which permeates the fibres of the wood.

We should have got to Hanwella at ½ past 8, but for the fact that our driver, instead of taking the short cut, via Urugodawatta to Ambatale, took us the old route by Grand Pass and then along the road parallel with the Kelani, which crosses the canal near the Bridge of Boats. We were, in the end, glad that this route was chosen, as we thus had the opportunity of appreciating the magnitude of the raft and boat traffic on the river, in bamboos, timber trees, fire wood, coconuts (which fruits in the husk we saw floated down on rafts), bricks, tiles, &c., of which there are well stocked depots along the sides of the canal and road. We could not help noticing, as competing even with salt fish in appeals to our olfactory nerves, the odour of timber in course of conversion after being seasoned in water. The sourness

of the timber smell was a striking contrast to the strong and occasionally semi-putrid odour of the fish. The value to Colombo of the cheap water carriage for fuel, timber and building materials generally, afforded by the Ke'ani, is far greater than many of us imagine. The bricks and tiles are manufactured mainly at Pannebakkery (*Anglice*, the Pan Bakery), where excellent clay for the purpose abounds under a surface stratum, more or less thick, of red mould. Here the Government had an establishment for the manufacture of bricks and tiles, so long ago as 1837; and one of the first incidents of my career in Ceylon was a visit to this place, then under the charge of a Corporal Ross of the 78th Highlanders, who had been left behind when his Regiment was removed from Ceylon. My recollection is still vivid of the huge elephants being compelled to use their broad feet in puddling the clay, their constant efforts being to step into the hollows previously made while the object of the driver was to compel them to put down their feet where the soft and adhesive clay was thickest, against which they occasionally entered protesting growls. The huge bulk of the animals' bodies and the resemblance of their long thick legs to cast iron columns made a strong impression on my mind which time has not effaced. All the way from Pannebakkery to Hanwella, good quality tenacious clay unmixed with siliceous particles, is found at intervals, on which diggers were at work. We were puzzled to see masses of puddled clay near the cottages on the roadside all the way to Hanwella until enlightened by Mr. Gibson at Labugama on an important point in engineering, of which I am ashamed to say I was previously ignorant. It appears that clay subjected only to a process of puddling and then used in building a bund is valueless, because liable to be washed away. The moist mass requires to be "weathered": reduced to dry particles. These are again moistened before being utilized, and thenceforward the mass, having dried and hardened, is as impervious as rock. One of the circumstances which added largely to the cost of the bund of the Labugama Lake, was the fact that the puddled clay used in its construction had to be transported all the way from Hanwella by carts, all attempts to find suitable material nearer at hand having failed,—sharp, sandy particles intermixed rendering the clays unsuitable. Before reaching Pannebakkery, we were interested in identifying, a little up the western bank of the river from the Bridge of Boats, the site of Orta Seda, or Sedawatta, where formerly there were botanical gardens, in which mulberry trees for the feeding of silkworms were grown. And this reminds me of the wrong spelling of Embulwatta, a village about 3½ miles on the Colombo side of Hanwella. The place has undoubtedly derived its name from the gigantic scarlet-blossomed cotton trees, conspicuous on the road and which serve to mark the divisions of korales. The name, therefore, ought to be written and printed Imbulwatta. Passing the outlet of the Mulleriyawa tank, before reaching Kaduwela, we regretted that the time at our disposal did not permit of a visit to one of the few important irrigation works in the Western Province and one which is within easy reach of the capital. There is a nice resthouse at Kaduwela, prettily situated on a rise in the river bank and commanding a view of a great rock which juts out into the river from its eastern bank and of one of the largest sandbanks in the river, on parts of which vegetation, including bamboo, has commenced to grow. There is a ferry from Kaduwela across to Malwana, a classical scene in the history of Ceylon, a visit to which was the main object of our down-river return

trip, and the incidents of which visit will be noticed subsequently. Meantime I would remark, that, as Kaduwela is only about ten miles from Colombo, a trip thither is calculated to be interesting and enjoyable to those who appreciate river scenery and rich tropical verdure, and who take an intelligent interest in the history of European connection with Ceylon: Portuguese, Dutch and British, as connected with the opposite remains of Malwana. The tree vegetation is richly luxuriant in the fertile alluvial soil deposited on the banks of the river, and the grass meadows which occasionally stretch away on each side are calculated to remind the traveller of English hay and clover fields, while the gradual transition from the flat country to the lower ranges of hills adds special interest to the journey. The prevalence of inconvenient but fertilizing floods in the Kelani valley, is indicated by long rows of guide-posts along the sides of the road, by which mail coaches, carriages, carts and foot-passengers are enabled to steer their way, when the waters are out, as a consequence of heavy and sudden rain-storms on the Peak ranges, from which to the sea the course of the river is not much more than sixty miles. The lower portion is lake-like in breadth and fulness; but at about eight or ten miles from the mouth frequent and sometimes formidable sandbanks commence, by which the stream is compressed into narrow channels. The rapidity and force of the stream is, of course, in proportion to the narrowness of the orifice; and while rafts, and especially boats, float easily downstream, the difficulty of the navigation upwards may be judged of by the fact that while five hours on the water amply sufficed for our course of about 20 miles from Hanwella to the Bridge of Boats, 2½ days would be required for the poling upwards. In the case of large and heavily-laden boats (and we were interested to see that besides rice the cargo of one such boat consisted mainly of Japan-made* shooks of tea boxes) the difficulty must be much greater, of which indeed we had proof, in the desperate exertions and wild, plaintive cries of the polemen as they painfully urged their boats against the rushing water. Some of the cargo boats had masts, but we saw no sails actually used. The north-east wind was, probably, far too gusty for safe sailing. The usual voyage upward of boats carrying rice and other supplies for the Kelani Valley tea estates from the Bridge of Boats to Yatiyantota is ten days, and occasionally a fortnight is occupied in the transit. This is slow work, but probably neither car nor railway carriage could compete with that on the river in cheapness. The contrast between the hard labour of the upward-voyaging boatmen on the river and their lounging, lazy countrymen in the villages on shore was striking. But no doubt the latter work hard in spurts, while the boatmen have compensation for the hard work up in the easy floating down. One conclusion forced on us by an examination of the great river for twenty miles of its course was the non-feasibility of dredging and keeping a navigable course open up this stream, at any but a prohibitory cost. The deposits of sand and silt are in some cases enormous, and we could see evidence of great erosion of the banks and shifting of soil from one side to the other. There can be no question that the felling of forest and the cultivation of tea estates along the upper portion of the river have tended to increase the impediments to its

navigation by the quantity of silt washed down. And insanitation—temporary only, let us hope—has followed. On asking our good friend Mr. Ameresekere as to the health of Hanwella, he stated that previously to the advent of the lowcountry tea enterprise the place was eminently salubrious, but that the change for the worse in the last five years had been marked. It is to be deplored that the advance of enterprise and material civilization, which cannot and must not be stayed, should involve such consequences,—in the inconveniences of which the planters and their coolies fully share,—and we can only hope for a speedy amelioration of climate or the discovery of a potent enemy to the organisms connected with what we call "malaria."

The once important Fort of Hanwella, situated on what, up to the cession of the Kandyan Provinces in 1815, was the borderland between "the Maritime Provinces" and "the Kingdom of Kandy," is interesting from the natural beauty of its situation and the associations, ancient and modern, connected with it. Malwana, in the Dutch period was burnt and its small garrison of invalids massacred, the destruction thus effected, and which led to war between the Dutch and Kandyans, accounting for the few vestiges remaining of the fort and the palatial country-houses of the Portuguese governors. Hanwella, although the Kandyans, in 1803 took possession of the fort and village, was not long in their hands. After three days' occupation, the Kandyan forces were ousted and driven back with great slaughter by troops from Colombo, under the command of Lieut. Mercer of H. M. 61st Regiment. The British troops seem, on this occasion, to have been aided by an auxiliary body of loyal Sinhalese collected by Mudaliyar Solomon Dias Bandaranayake. After the massacre of the British troops in Kandy, the elated traitor-king marched his army against Hanwella. But the small fort was held by a soldier of a different stamp to the wretched Davie. Capt. Pollock, with his small force, not only held his own, but became the aggressor, repulsing the enemy, who made a precipitate retreat, after great loss of men, arms and ammunition, and the abandonment of the royal standards. Very different and altogether pacific are the recent associations connected with the place in the successive visits to it, in 1870, 1876, and 1882, of members of the British royal family, in the persons of the Duke of Edinburgh, the Prince of Wales, and finally the two young Princes, Victor and George of Wales. All the royal visitors planted trees—jak, nuga, bo, mango, &c., four at least of which are flourishing, inside circles of laterite and cement. As records of the visits and the tree planting, there are inscriptions on three stone seats which are so placed on the rampart which faces the river, as to command beautiful views across and up and down the stream. The river takes a bend below the ferry, but upwards there is a long reach, the fine vista being closed by a grand background of the Adam's Peak mountains. The view of these, as dawn was breaking and the clear and increasing light revealed their features, before the sun had produced any curtain of haze, was exceedingly striking, contrasted as the blue of the distant mountains was with the silvery waters of the stream and the rich verdure of the vegetation in the foreground. The crisp temperature here on the morning of January 3rd, following a night of special coolness, almost made us fancy ourselves back in the mountains which are "round about" Nuwara Eliya, although the elevation above sea-level is only 40 feet. At 2½ miles from Hanwella, indeed, en route to the mountain Lake where

* Made in Japan, out of timber from the forests of that island kingdom, by means of American machinery, and used for the packing of Ceylon tea,—surely a romantic incident in the free commerce of nations!

amidst the ranges over which Labugankanda (height nearly 1,500 feet) presides, we had only attained an elevation of 75 feet, the rise in the following six miles being to 306 feet, the level of the "top-water" of Labugama Lake. But we must dispose of Hanwella, famous, amongst much else, for a fairly successful experiment in teak cultivation. We can remember the grand old trees which were so injudiciously sold and cut down some thirty years ago. There is still a fine grove of these valuable trees, coppice and original growth, the light-coloured foliage of which contrasts strikingly with the prevailing greens, many of them dark, like the jak, of the indigenous and ordinary trees. Amidst the teak grove and outside the fort (the resthouse stands within its bounds) is the large and well stocked timber depot, the timber in which, we understood, was entirely reserved for Government purposes, none being here available for sale to the public. We were interested to learn that a considerable quantity of teak seed gathered from the older trees at Hanwella, had been sent to Batticaloa, in the neighbourhood of which a fairly successful experiment in teak-growing had previously been made. It is to be hoped that the officers of the Forest Department may succeed in naturalizing *Tectona grandis* amongst our forest resources, for few trees surpass it in value. We should think that any quantity of seed can be obtained from the now grandly grown trees in the teak forest, which was formed on the west coast of the Madras Presidency by the Marquis of Tweeddale and the value of which, as time advances, has been computed at millions sterling. The experience obtained on the Anamallays, as to suitable soil and climate, cannot but be of great value to Ceylon. Amidst all the tree vegetation around Hanwella, bird-life is abundant; and we here enjoyed a woodland concert of mingled and melodious sound, unknown equally to dwellers in towns and the occupants of bungalows at extreme altitudes in the mountains. I am bound to admit, however, that the first herald-sound of approaching daylight, if not the last as "the gloaming" gave place tonight, consisted of raucous utterances of the ubiquitous and ever-in-evidence crows,—so unfavourably prominent with their fellow scavengers the pariah dogs in Sinhalese sannass: "May he who violates the terms of this gift, be born next in the form of a dog or a crow." The association is somewhat unjust to the crow on the score of addiction to water baths, for which the crow is famous. On the score of voice there is little choice between the two. Hanwella has, it seems, superseded the proper Sinhalese name of the place, Gurubewila, just as Welgama is now the common name of the place which the Portuguese and Dutch knew as Malwana. And here a fitting pause can be made before describing our journey in the hills amidst the solitude of which slumber the mirror-like waters of Labugama Lake, and the voyage down the river named after Kelani, the site of the ancient Buddhist shrine, a place so "pleasant," that Hindu legend represents the sun as pausing in admiration, as he comes over it in his diurnal course.

The road constructed by the Public Works Department specially for the purposes of the Waterworks, and which extends to a distance of 8½ miles from Wakoya to the northern end of the Lake at Labugama, cost, including a sum of over R11,000 for land, a total of R175,000, or very nearly R20,000 per mile. The estimate in this case was exceeded by R100,000. At its commencement the track runs through valuable paddy lands and native gardens, whilst the upper portion had to be cut through the lower hill ranges, the moun-

tain streams requiring bridges strongly founded and with openings large enough to allow free passage to the exceptional floods to which this region is specially liable. To such bridges and the sides of other openings, all the way to Colombo, the main pipe is to be seen attached, resting on rollers to allow the movement, slight though it be, produced by expansion and contraction from changes of temperature. During the period in which the work of Lake clearing and bund construction was carried on, flood water has been known to rise up to 17 feet over the level of the road; and it was affecting to learn how Mr. Burnett, suffering from lung disease of a serious nature as he was, rode and boated and waded through the waters of such a flood, in his anxiety to save the works from threatened destruction. That was the last and fatal blow to a constitution weakened not only by physical disease but by anxiety and repeated disappointments connected with the "service reservoir" at Colombo, which, however, he lived to see, with the rest of the great and beneficial scheme he had carried out, a perfect success and one of the greatest triumphs of modern hydraulic engineering: and that too, at a comparatively moderate cost. Visiting Labugama, as we did, on an intensely hot day (the walk up the zigzag path to the Engineer's bungalow about 2 p. m. was an experience easier to recollect than to endure), we could scarcely realize that Labugama forms part of the very rainy region which surrounds the Peak and extends from the sacred mountain as a centre along its flanking ranges and through the river valleys between them. The average annual rainfall, established by ten years' observations at Labugama, is, in round numbers, 160 inches, the deposit in 1890 having exceeded this average by 5 inches. The extremes have been between 187 inches in 1882 and 138 in 1888. The years 1882 with 187 inches and 1883 with 185½ must have been terribly trying to the Engineers and the force of labourers engaged on the construction of the bund (just commenced), for work had to proceed continuously, and in digging exceptionally deep for a solid foundation all the expedients of scientific experience had to be resorted to, in order to avert the destructive effects of flood waters. With such a rainfall as we have indicated, continuous for a large portion of the year (the lowest average monthly rainfall is 4.42 inches for January), it might be supposed that the Lake (176 acres in area) would receive practically the whole of the rain falling over the "catchment area" of nearly 2,400 acres, in which there are no human abodes save the resthouse to which we have referred with the residence of the Engineer in charge and lines for a few coolies, all at the northern end. But the absorption of rainfall by the soil and vegetation have been on the scale thus indicated:—

In 1887, out of a rainfall of 174.89 inches, the loss from absorption was 42.55 inches, or very nearly one-fourth of the rainfall, the exact percentage being 24.32.

In 1888, the year of lowest rainfall recorded, out of 138 inches of rainfall, the loss was 31.29 inches, or 22½ per cent of the rainfall.

In 1889, with a rainfall of 159.28, the loss was 31.33, or 19½ per cent.

If such are the proportions of soil and vegetation absorption in one of the wettest portions of the island, readers can understand the much greater influence of this process in the dry and arid regions where the irrigation tanks are situated. Streams of limited size and originating in the lower and hotter "foot-hills" on the northern and eastern sides of our mountain

system cease to be perennial, and no wonder, when two, and we believe three, years of drought occur in succession. The tanks are then dependent entirely on rainfall; and considering the dry condition of the soil and the thirsty state of vegetation, we can understand why, for the re-filling of such a tank as Kalawewa, rain-storms of 10 to 20 inches in a few days are desiderated rather than the same quantity of rain distributed over a month. In the latter case the arid soil and the drooping vegetation would gradually absorb every drop of moisture that fell, leaving none to even partially supply the tank. But not only must the loss from absorption be greater in the dry regions, say 35 per cent. at least of the rainfall at Kalawewa, against 22 to 25 at Labugama, but the further loss from evaporation, which is astonishingly great in the cases of the Colombo and Labugama Lakes, must be enormous in regard to the streams and irrigation reservoirs in the hot, dry regions where the shade temperature goes up to 100°, and months succeed months, sometimes, when the heavens are as brass and the earth as iron. In Mr. Blanford's book on the climates of India and Ceylon, we have been surprised to find how few and uncertain the data quoted by him for evaporation are. Extended and careful observations by the Survey Department in connection with the Colombo Lake and by the Engineer in charge in the case of the Labugama Lake, on a system—in this latter case, inaugurated by the late Mr. Burnett—are likely, as Mr. Burnett pointed out in his most interesting final report, to give results of unique value to hydraulic science. Readers will be scarcely prepared to learn that the average daily evaporation from the Colombo Lake, with a mean temperature of a little over 80°, and an annual rainfall of 88 inches, is equal to 0.217 of an inch (the total area being 416 acres) or 2,045,589 gallons; the maximum evaporation on a dry day in February being 0.480 inch, or 4,524,804 gallons. Such, however, are the results of observations taken by Mr. Wackrill of the Survey Department. The decimal given for a dry day in February, as it is noted, is very close on half-an-inch. We understood from Mr. Gibson, the experienced and intelligent Engineer in charge of the Labugama Lake, that he takes the most frequent and careful observations of the effects of evaporation on the mountain reservoir of which he is in charge, the extreme effect in one day being, we understood, $\frac{3}{8}$ of an inch. This is consistent enough, the mean temperature of Labugama being about the same as that of Colombo, but the atmosphere being so much the more charged with moisture in proportion to a rainfall of nearly twice the volume of that at Colombo. I cannot, in this connection, refrain from quoting the following paragraphs from the late Mr. Burnett's exceedingly able, honest and interesting report:—

The supply to the town at 3,000,000 gallons in twenty-four hours with strainer washing and scouring of wells, flushing, &c., absorbs about 33 to 34 in. of the rainfall.

The proper maintenance and working of the Reservoir, therefore, require the constant care and attention of a skilled and thoroughly reliable European officer at Labugama every day, and frequently at night, as the floods must be met and dealt with by the sluices when and as they occur; and it has been, and will be, only by the best and constant care, both days and nights when required, of the officer in charge in carrying out his instructions that the purity and safety of the water supply, which has now become a vital necessity to the people of Colombo, can be insured.

In the course of his work and inspection this officer is required to take, not only a daily record

of the rainfall and level of the reservoir, but such constant observations both of rainfall and reservoir levels and opening and closing of sluices, as will enable a complete calculation to be made of the rainfall and the measure of its resulting flow of water, and the receipt into, and discharge from the reservoir of, this water. It is only on this knowledge that the volumes and duration of floods, and their proportions of yield of water to the rainfall, can be ascertained, and that the measures to meet them can be arranged.

The observations thus made enable both the total yield of the year's rainfall to be ascertained and the details of individual storms and floods, and give most important scientific information of, I believe, almost unique value as to the yield of rainfall in water discharge and the loss by absorption in the ground and by vegetation and evaporation in tropical mountain valleys. It is extremely rare in such conditions that the entire results of rainfall and discharge can be measured into a reservoir, as at Labugama, from such an area as a drainage of nearly 2,400 acres, and they should be of great value in the consideration of all works and matters connected with the discharge of the streams of the mountain and hill districts of this Island as well as elsewhere where similar conditions exist. These returns, both of the total annual results and particulars of exceptional floods, should form a part of the annual report of the Engineer.

As the road to Labugama pierces the outlying hills of our mountain zone it crosses the beds of several streams, the multitude of large boulders in which show the evidences of exceptional floods. The Wakoya is not the largest of the streams. It is excelled by the Kalatawa, the waters of which, however, could not be utilized for the formation of the Lake, owing to the lower level of this river. The road to Labugama has helped to open up the country around to the tea enterprise, and strikingly contrasted with the flat paddy fields near Wakoya were the tea fields on some hill slopes that for steepness could compare with some of the cultivated precipices in Haputale, which the railway will skirt as it approaches, over the narrow ridge along which will lie its final course, "the Pass" by which Uva is entered. "Mohideen's tea estate" (inscription on a board by the road side) looked so ship-shape and clean that we were curious to know about the exceptional "Moorman" who was so good a planter. The answer was "Mohideen's estate is looked after by Mr. Ross Wright." "All right," was our natural response. Young coconut palms, planted amidst tea, or as a separate cultivation, looked flourishing, but scepticism was expressed as to the trees' bearing well so far from the sea. The distance from the sea in a direct line being not more than twenty miles, the question arises as to the limit, in distance from the saline influences of the ocean, of profitable coconut cultivation. The best zone for the palm is usually defined as two miles from the sea, but coconut cultivation in many parts goes much further inland, extending in the case of the valley of the Kelani in unbroken groves along the banks of the river, from its mouth to Hanwella and still further towards Ratnapura. Many of the fine and flourishing coconut plantations beyond Mirigama must be more than twenty miles from the sea. In southern India the destruction of coffee by borer was traced to the fact that the cultivation had taken place on "bamboo-land,"—*Bambusa arundinacea* being, no doubt, the species in that case. Along the road to Labugama and in the Kelani Valley generally, the prevalence of the small bamboo of which tea baskets are made in such large numbers at Kalutara, and which is used so generally for fences in Colombo and elsewhere, seems to have no deterring influence on intending cultivators,—a considerable proportion, indeed, of the Kelani Valley tea estates being opened on land, the main vegetation of which

was the *Bata* bamboo. The elegant areka palm is at home in this region and the drive is altogether a pretty one. The approach to Labugama is indicated by signs of lessened traffic in the shape of a green grass covering over the grey gneiss "metal," which latter might seem superfluous if the size of the spare pipes lying alongside the road at intervals did not remind us of the heavy weights the road had to bear and many have yet to bear, in case of damage to the water supply source by exceptional floods. Those who constructed the road for the purposes of the Waterworks could scarcely have anticipated, even in their wildest dreams, the convenience it will prove, if, as is believed, an elephant kraal is arranged at Labugama in honour of the approaching visit of the heir to the imperial throne of Russia. The completion of this road will enable the Governor and his guests—the Tsarevitch and his suite and others,—to drive us interruptedly over the 23½ miles from Queen's House to the margin of the Lake. Then the boat will be ready for the mile of Lake, and the horses which will be waiting at the southern end of the water will carry their riders by a well-cleared path, over the distance of 1½ mile to the intended scene of the "kraal," into which the now freely roaming and peacefully feeding monarchs of our forests are to be driven for human delectation—for the gratification of that hunting instinct which clings so tenaciously to our nature, even in those highest in rank and most advanced in civilization. The resthouse and Mr. Gibson's bungalow are likely to be utilized for the lodging of royal ties and vice royalties, while there will be, of course, the usual temporary "Kraal Town" formed of cadjans, bamboos and similar materials. The kraal, if held, has every chance of being successful, for there are three herds of elephants, with which Mr. Gibson has established relations as amicable as those which now exist between the British lion and the Russian bear, and the benefit of his intimate knowledge of the haunts and habits of his friends of trunk raising and trumpeting fame cannot but be of great value to the leaders of the forthcoming "Keddah," as they call a "Corral" in India. The four-foot path formed round the margin of the Lake is, for the present and with reference to the approaching kraal, closed to the public, and we saw a few coolies going over its course with reference, we understood, to clearing it of all obstruction. To a Prince amongst whose future dominions the Caspian Sea is but one of many inland Lakes, the artificial lakelet of one mile long by about a quarter broad, in the Labugama vally, may seem but "a little one." But seldom in his travels can the Tsarevitch behold a scene more lovely, more intensely brooded over, normally, by the genii of silence and solitude—silence and solitude which will of course give place to sounds of genial festivity, when the representative of British royalty entertains in wild-wood hospitality the heir of a monarch who, in a martial sense and the sense of owning a vast portion of the earth's surface, is amongst the most puissant of "Great Powers." But it seemed to us, on the occasion of our visit, almost desecration to break the silence of hill and forest and fluid, all sleeping around us as we glided in the hours before gloaming over the mirror-like surfaces of the impounded waters, not of the Wakoya alone, but of many other minor streams, distinguishable by the little "bays" and the better grown groups of forest trees at their inlets into the Lake. We were interested to learn, however, that submerged by the waters over which we floated were the site of a former village and a few rice fields. A small top of coconut palms on the shore of the Lake had been levelled by elephants for the sake of the grateful food yielded by the tender tops of the

trees. As we approached the northern end where the waters of the Wakoya lose themselves lovingly in the bosom of the Lake, memory awoke associations which led me to exclaim: "Why, here is a bit of the Trossachs, and there" (as we skirted a beautiful islet, seven acres in area) "is Ellen's Isle!" Mr. Gibson replied "That is just what Mr. John Ferguson said, when he visited the Lake;" and then our good friend expatiated on the delight which Sir William Gregory expressed with the Lake and its framework of juggle clothed hills. Sir William having cultivated a special taste for the beautiful, his judgment is of special value. He has seen all that Italy has to show, including what no one who has seen it can ever forget, the scene from Fiesole, outside Florence, bathed in the glories of a summer sunset; but when I once ventured the opinion that we had scenery and sky effects in the mountains of Ceylon, which compared favourably with the beauties even of Italy, his response was: "Compare with Italy! Why, Ceylon has a beauty of its own with which that of Italy cannot be compared. Even in climate portions of Ceylon far surpass Italy." That was the testimony of a competent authority who had travelled extensively and observed keenly, with an eye open to the beautiful in nature, and I can fancy the author of "Lake Gregory" finding consolation in the fact that in the exquisitely lovely solitudes which surround the mountain mere of Labugama, no exigencies of a racecourse, as at Nuwara Eliya, will intervene, to convert what might have been a full and beautiful body of water into what is largely a series of ugly marshes. But lest I should further mar the tranquillizing and peaceful influences of the silent and solemn beauty which reigns over the waters of Labugama and the hills and forests which guard it and are mirrored in its bosom let me here make another pause, I cannot help recalling the terms of an epitaph I saw in Northern India: "Be still; she sleeps!" The being who sleeps in this case is the spirit-creation of a poet, who described her as

"Lady of the Mere,
Lone sitting by the shores of old Romance."

The circumstances and surroundings of the Colombo Water Supply Reservoir at Labugama, are of a specially favourable nature. The catchment area of nearly 2,400 acres is covered with dense jungle or forest and the streams which flow into the Lake from hills varying in height from 500 to 1,500 feet above sea-level, run over boulder beds, so that the very minimum of earthy matter is carried into the reservoir, while twigs and branches are intercepted at the mouths of the Wakoya and the minor streams. The sluice arrangements, too, for letting out, at the bottom of the reservoir, flood waters and such solid matters as may have subsided, are very efficient, and Mr. Burnett pointed out, in his final and most able report, how they could be made still more so. The usual depth of water at the bund end of the Lake is 60 feet, and Colombo is supplied from the top portion, not lower down than 36 feet in any case and as a general rule from not more than 12 feet below the surface. Added to this condition in favour of the purity of the water, it is passed slowly twice through 560 feet of copper gauze strainers of 900 meshes to the square inch. With such precautions and the keeping a margin of from 30 to 50 feet round the Lake free of forest so that a grass sward forms over it, there is no occasion for filtering beds at Labugama. Indeed Mr. Burnett showed, that, with doubled sluices and other expedients, the enormous quantities of flood and waste water which are now discharged into

the bed of the stream could be utilized as a further supply for Colombo. And, although, by the help of the service tank, with a capacity of 8,500,000 gallons at Colombo, three millions of gallons are now supplied instead of the two millions originally estimated, it seems probable that, looking at the rate at which the population is increasing, (2 per cent per annum at least,) the duplicating of the existing 20 inch pipe may, ere long, become necessary. It is just possible that Negombo, which is now dependent on wells at a considerable distance from the town, might, in addition to Colombo, be supplied from a second pipe? Mr. Burnett expressed the hope that the forest over the catchment area, in which there are no abodes save those we have mentioned and no cultivation of the soil, should be preserved in perpetuity. But as the larger timber trees within the reserve come to maturity, there is no reason we can see why they should not be dealt with by the Forest Department, the vacancies being filled up by planting seedlings or by natural reproduction. Meantime it would seem that there is scope for the planting of handsome and useful trees round the Lake, outside the grass margin, of course. The springing up from the waters, too, of a few of our indigenous freshwater fishes, during our visit, suggested the idea that here are most favourable conditions for breeding the gouami of Mauritius, the large golden carp of Java, and the best fishes of Southern India as described by Mr. Thomas. Apart from the economic value of the fish, we suppose their presence would tend to purify the water of the organic matter on which the fishes would feed. We need not tell our readers how greatly the margin of greensward adds to the beauty of the Lake, while the numerous boulders which are scattered over the surface of this margin give a fresh picturesqueness to the scene. At one place on the shore of the Lake, not far from the remains of the coconut top which the elephants made short work of when the human owners of the palms had been removed, there is further evidence of former life and action, in the shape of mounds of earth thrown out in digging a plumbago pit. The construction of the bund was a work of no slight difficulty from the depth which had to be reached before solid rock without fissures was found. The length of the embankment at the top is 120 yards; the length of the foundation trench 160 yards; and the greatest height of the embankment 72 feet; the greatest depth of the foundation trench 72 feet, and the greatest height from the bottom of the foundation trench to the top of the embankment 109 feet. The contrast of the bright green of the grass on the long outside slope of the bund and the dark weathered appearance of the blocks of gneiss of which the facing wall is composed and also the fragments blasted out of the spillwater channel, is very striking. Equally striking was the contrast between the surrounding expanses of wild jungle and the roses, hibiscus plants, bougainvilleas, crotons and other shrubs, which Mr. Gibson has succeeded in growing around his and his family's ruly solitary abode. The owner of a tea plantation at least two miles distant talks of the Water Works Engineer as his "neighbour, next door." We were glad to find that the family had not suffered from fever, the Engineer himself being a picture of robust health, notwithstanding the performance of duties which involve constant exposure to the weather, by night as well as by day.—The total capacity of the reservoir (176 acres area, and 360 feet above sea level, or 260 feet above the level of the water in the service tank on the summit of Maligakanda at Colombo) is no less than 1,373,000,000 of gallons, equal to 25½

inches depth of rain on the drainage. As we have already stated, the Colombo supply is drawn at depths below the surface of 12, 24 or 36 feet, and the capacity to the lowest level of supply is 1,233,000,000 gallons, equal to 6,000,000 gallons for 200 days. It will thus be seen that if no serious accident happens to the great pipe, against which all possible precautions are taken, there is no fear of the continuance of an ample flow of water to Colombo. The main pipe is 25 miles and 15½ yards in length from the straining well at the outlet towers in the Labugama Lake to the Maligakanda reservoir at Colombo. I now again quote some interesting details from Mr. Burnett's report:—

The top level of Labugama reservoir is 360 ft., and the water-level in the gauging tank is 102 ft. above sea; the fall is therefore 258 ft., giving a head or loss for friction of 10½ ft. per mile. The pipe thus delivers 3,000,000 gallons in 24 hours as measured into the Service reservoir.

The level of the pipe where it leaves the straining tanks at Labugama is 303½ ft. above sea. In three miles from Labugama it falls 233½ ft. to the level of 70 feet. In three miles further it falls to the level of 30 feet, and crosses the Hanwella flat, 19 miles from Colombo, at the height of only 20 to 25 ft. above sea level. For 16 miles out of the remaining length the level of the pipe varies from 5, 10, and 15 to 20 and 25 feet above sea level, rising at intervals for short distances to 30, 60, and 70 ft. For 19 miles the pipe is thus subject to a pressure of 300 to 355 ft., or about 130 to 150 lb. per square inch when a valve is closed. Great care is therefore required in working the valves to prevent shock on the pipe, which would lead to certain breakage, and special valves are placed every half mile or so for this purpose, so that every half mile length can be isolated for repairs when required—even then, special care and training is necessary to avoid danger in dealing with the heavy pressure on the long length of pipe.

The extremely flat contour of the section for long lengths required special arrangements in creating artificial summits for the escape of the air disengaged from the water in motion, with the necessary air escape valves, in order to prevent the flow of water being reduced or stopped from the pipe becoming charged with air. These air valves are often required in duplicate, and are placed from one-eighth to one-fourth mile apart where artificial summits were made, and on every natural summit along the line of section. Cleansing valves have been placed at every depression or hollow for scouring and emptying the pipe. Altogether there are on the main pipe 48 special stop valves, 20 in. diameter; 44 special stop valves, 8 in. diameter; 61 cleansing valves, 6 in. diameter; 106 air valves with stop valves, 4 in. diameter. These all require inspection, cleaning, oiling, and other attention from time to time to maintain them in good working order.

The main pipe is laid either in or alongside the public road from Colombo to Hanwella. For this distance the country is subject to floods two or three times a year, for several days together, and these floods rise to a maximum, as in 1872 and 1883, of 12 and 17 ft. respectively, above the road and pipe.

The road is in many places embanked, and generally the permanent water-level of the country is only about 4 to 5 ft., even in the driest times, below the surface. It therefore was necessary to keep the main pipe above the permanent water-level and as high as possible in crossing streams in reference to the flood and to the free drainage and escape of water from the land. This necessity required numerous and wide openings over drainage outlets and streams. There are thus 56 crossings in all; of these, 42 vary from 6 to 24 ft. openings and 14 vary from 48 to 196 ft. in length.

The foundations of these bridges are below the ordinary water-level, and 60 of the piers are founded below sea and permanent water-level. The ground consists of beds, of sand, gravel, clay, and peat and soft deposit, alternating, and to avoid deep foundation, such as iron cylinders, the piers were made solid blocks of brickwork with as wide a base as possible, so that they could be

forced down by weighting to a bearing should any settlement take place. In only five instances has this occurred, and has thus been met without risk and in only one instance with stoppage to the supply by the main pipe. All are now sound.

The two highest localities in the town were Elie House, where the ground is 100 ft. above the sea, and Maligakanda, where the top of the hill was 70 to 5 ft. above the sea. It was therefore impossible to obtain the usual working pressure for the town distribution piping of 150 to 200 ft., and this was therefore reduced to the lowest safe working limit of only 10 ft. per mile of distribution.

The Elie House site had the advantage of 25 ft. greater elevation, but to deliver the water from Labugama there, instead of Maligakanda, added about a mile in length to the main pipe, while after being brought there the greater bulk of all the water had to be conveyed back again about three miles to the middle of the town, whereas at Maligakanda it was ready to hand. Besides the additional cost of these four miles of large piping about £200,000, the greater distance the water had to be conveyed from Elie House required 30 feet higher elevation in a reservoir there than at Maligakanda to give the same general pressure over the town.

The water had to be delivered, at such times as the full demand exists, at the levels equivalent to 80 ft. in the Fort and Wolfendahl, 70 ft. at Fishers' Hill, and at least 40 ft. at Pashetal in the north and Wellawatta in the south. These requirements have been since proved correct by the frequent complaints of want of water and want of pressure previous to the recent completion and use of the service reservoir, and created the necessity of raising the service reservoir to give the level of 100 ft. to the water at Maligakanda or 130 ft. at Elie House; in either case an elevation of 30 ft. above the ground level.

The cost of the reservoir would therefore be the same at either place, and the Maligakanda site was adopted, as it saved the four miles of large pipes and gave a much more convenient centre for working the distribution. As it is, the northern main from the reservoir is five and a half miles long and the southern pipe four miles.

By the original design this reservoir was excavated from 10 to 15 ft. into the ground, and the water level was raised 30 feet above the surface with massive walls of cement concrete. The top was covered with a double ventilating roof of thin concrete arches, and the floor was also lined with 12 in. of cement concrete. The concrete for the whole of the work was put liquid into the site, the walls being faced with 10-in. concrete blocks on both sides. The inside dimensions of the work were 190 ft. and 191 ft. 4 in.; depth of water, 40 ft.; the height of the walls from foundation to top of parapet, at upper roof, 49 ft.; and thickness of walls varying from 5 ft. 9 in. at top water level to 19 ft. 9 in. at the bottom, the roof parapet being from 3 to 2 ft. thick. The water capacity of the reservoir was to be 8,500,000 gallons.

Then follows the history of the service reservoir, until the addition of an earthen embankment and division into sections preserved the concrete wall from expansion and contraction, from changes of temperature so great occasionally, we believe, as a difference of some 70° in the 24 hours, while percolation through the cement and concrete which Mr. Burnett, (mistakenly, we believe) held to be imperious, was prevented by an internal skin of waterproof and elastic asphalt. Our readers will be interested to learn that the weight of the masonry of the Maligakanda reservoir is no less than 40,000 tons; of the earthwork 39,000 tons; of the water 38,000, or 117,000 tons in all, resting on the paterite foundation. The total length of piping of all sizes is no less than 85½ miles; public stand pipes in Colombo 664; houses with separate services laid 1,414; trade supplies 30; garden supplies 43. As regards separate services for houses, it must not be forgotten that in many cases there are excellent wells attached to a good

many houses, such as those on the sea-side of the road at Kollupitiya. Brackets, as recommended by Mr. Burnett, are now being attached to some of the standpipes, and it is to be hoped that the present reckless waste of water at these standpipes where many of the people bathe as well as draw water in a most careless manner, may be checked, if not entirely prevented. The consumption of water per head of the population at present averages 19 gallons per head per diem. The use of the service reservoir, containing 8,350,000 gallons, with a depth of 39 feet, the inside dimensions being 190 feet by 191 feet 4 inches, has added 40 per cent. to the water available by day to the town, with an increase of 40 feet pressure. If roads are to be thoroughly watered, drains properly flushed, public baths provided, and the Colombo Lake kept full of water, even when evaporation takes away half an inch per diem from its surface, a new pipe from Labugama to Colombo must soon be laid. The difficulty is that already, in consequence of the necessity of meeting interest and sinking fund for the repayment of the portion of Water Works Loans allotted to the Municipality, the assessment of property in the town has reached 11 per cent. on the annual value. But with its grand harbour and other advantages, the population of our chief city is rapidly increasing, and wealth and the value of urban property must increase in proportion. The cost of bringing pure mountain water from the beautiful Labugama Lake within reach of the inhabitants of Colombo has been not far short of £350,000. But even so, the cost is comparatively moderate and the boon in a sanitary and general sense is really priceless. The cost for each gallon of water sold in Colombo, before the Waterworks came into play, was 1 cent; it is now the merest fraction of a fraction of a cent. For a consumption of 19 gallons per diem, or about 7,000 gallons per annum, per head of the population the average cost per annum for each person is only 65 cents, the water being as pure as any in the world; while the supply in olden days was frequently brackish, unwholesome and insufficient. Let the inhabitants of Colombo, therefore, while grateful for the benefits of one of the best water supplies in the world, remember with respect the name of the engineer who, bearing up bravely against anxiety, obsequy and the inroads of fatal disease, just survived to see the great work he had initiated and carried on to a successful conclusion, so thorough a success as it now is. A memorial stone in honour of Mr. Burnett ought to be erected on the bund of the beautiful Lake of pure mountain water at Labugama.

Before saying farewell to the lovely Lake of Labugama, and its romantic surroundings of hill and forest and greensward I must refer to a few unextended notes. The elephants, besides levelling a score of coconut palms on the border of the Lake, which belonged to the submerged village, also killed a cajú tree by denuding it of bark. Recalling reminiscences of "The Lady of the Lake," we asked Mr. Gibson if he had ever seen deer take to the water at Labugama. The answer was in the affirmative: sambur and red deer and that exquisitely formed miniature deer, the meminna, had all been observed swimming. With reference to the climate and soil, too we were told of a rain storm of 9½ inches in 4 hours, which had produced no appreciable wash.

Having thus noticed the main incidents of our pleasant trip to the Labugama lake and some of the main facts connected with the transmission to and distribution in Colombo, of its waters, by gravitation (we were told of a pressure of 107 lb. to the square inch?), we reserve for a final

notice the record of our boating trip down the Kelani river to the Bridge of Boats.

Before we start downwards from Hanwella, on our nicely platformed double-canoe, comfortably roofed, and prettily ornamented with the tender leaves of the coconut palm, with bunches of king coconuts and strings of kitul seeds, another of our party will recall some reminiscences of what was long the border post between the maritime possessions of successive European powers and the mountain kingdom of Kandy:—

“Hanwella is not, so far as I know, mentioned by the Portuguese writers; but they and the Dutch refer to the place under its alternative name of ‘Gurubewula’ (? ‘the great hilly eminence’), which is spelt ‘Grubsbe’ in Ribeiro’s map; ‘Grouabely’ in the map in Spilbergen; ‘Grouably’ in De l’Isle’s map in Le Grand; ‘Gourbeville,’ ‘Goerbevele’ and ‘Goerbeville’ in Valentyn; ‘Orwevel’ by Daalmans; and ‘Horrenwebel’ by Herport. The name ‘Hanwella’ does not undergo such transformations, the worst one being ‘Anguellen’ in Daalmans. The fullest description of Hanwella in the Dutch period is given by Heydt, who accompanies his description with views of the fort from the east and the west (drawn in 1736) and a ground-plan. The fort was built of squared-stones, and had two whole bastions facing landwards, two half-bastions facing east and west, and a horseshoe facing the river, while round it was a dry ditch. It was capable of mounting 32 cannon, but only half that number were actually mounted. The garrison consisted of only 30 to 50 men, who were sufficient, says Heydt, to withstand 50,000 or 60,000 natives, as the latter possessed no large field artillery. The fort was intended to guard the high road between Colombo and the Kandyan frontier, and also the waterway of the river. Inside the fort in Heydt’s time were a number of fine tamarind trees. The gateway was in the eastern side of the horseshoe. By the horseshoe on the edge of the river bank was a little summer-house. On the south western bastion was a belfry. The officer in command did not reside inside the fort but in a house outside. While Malwana was to the Portuguese a pleasure retreat and sanatorium, to the Dutch Hanwella was a place of punishment for mutinous and disorderly soldiers, and was considered a penal settlement. A European student who was amongst those sent to this place left his opinion of it in some lines which Heydt quotes as follows:—

Is dit het Schoene Land? leit Adam hier begraven?
Is dit het Paradeys vaer Gottes Hand geplant?
Kan hier ein ehrllyk Mensch syn Dorst nog Hoenger
laaven.

En leven nog in vveld? ’t gaat boven myn Verstand.
En Patt en Schlangen-Nest, voll Berg en tiepe
Daalen,

Blud-Suygers sonder Taalen Schagers die het Gold
Uyt Sacck en Beirszen haalen, en wat nog hier is all
Soot men oock vvielt betaalen, Krsigt meus maar bey
Gefall.

Is dit het Paradeys, soo ists van Gott vervloekt,
Die meent verlost te syn, der Beed, Vast, en ver-
soekt.

This may be freely translated as follows:—
Is this the lovely land? does Adam’s corse here buried
lie?

Is this the Paradise of old planted by God’s own hand,
Can any honest man his thirst or hunger satisfy,
And yet remain in health? That’s more than I can
understand.

A nest of toads and snakes, and filled with hills and
valleys deep,
Bloodsuckers numberless, and taverners who filch the
coin

From out one’s purse; and what one here considers
all in all,

I speak the truth, one only gets as chance may so befall.
Is this the Paradise, then ’t is by God accurst, I say,
Who wishes to be freed therefrom must fast, beseech,
and pray.”

Taking early tea before we started from Hanwella, we carried our breakfast with us in the boat, the *al fresco* meal being enjoyable, after we had feasted our eyes and hearts on the beauties of the river which has its origin on the Adam’s Peak ranges, and which along its whole course is bordered with varied and luxuriant verdure. The morning air was deliciously cool and as the sun became powerful; the heat was tempered by the north-east breezes, except on the few occasions when sharp bends in the course of the river placed masses of trees in front of us which interrupted the movement of the wind. The succession of long reaches, curves and frequent sandbanks gave interest to the early portion of our journey, and from first to last the river banks were densely lined with indigenous trees and coconut palms, if the distinction is permissible. Prominent as an edging to the water was *Hibiscus tiliaceus* with its large heart-shaped leaves and yellow blossoms, the latter closely resembling those of the *suriya* (*Thespesia populnea*), with *pandanus*, large lilies, and numerous flowering creepers. We were interested in identifying (occasionally appealing to the boatmen for native names) the various trees on the banks, amongst which the rich purple-red foliage of the *hal* was striking, as well as the scarlet tints of the leaves of *Lagerstromia regina*, the splendid flowers of this tree having given place to seed spikes. But next to the bending coconut palms, the prevalent vegetation was that of the graceful yellow stemmed feathery bambu, a plant which combines utility with beauty in an eminent degree. The framework of rafts is generally composed of bambu, and we saw some of these putting forth young shoots as they floated on the water. At night the bambus are the favourite haunts of thousands of fireflies which at intervals, as if by intelligent direction or arrangement, hide and then flash out their brilliant phosphorescent light amidst the branches. Generally the bambus were in detached clumps, but occasionally they were in long rows, forming a series of the most exquisite gothic arches, as the bending branches of separate groups met above and crossed against the sky. Occasionally, at the multitudinous ferries and bathing places, we got a glimpse inland, the expanse of an emerald green rice field relieving the monotony of the luxuriant tree vegetation. Scenes of ferrying, navigating by boats and rafts, fishing and bathing, with the flights of kingfishers, waterhens, and sandpipers imparted life to the river. But the very richness of tropical vegetation has its disadvantages, as from a river such as the Kelani, we see but little of what makes a voyage up the Rhine, for instance, so interesting: towns and ruins, vineyards and orchards. Successive landings would be necessary, even to see spots with which interesting associations are connected; Kelani Buddhist temple for instance, the history of which, as a site at any rate, is said to go back some twenty centuries or more. With a strange idea of morality, an ancient legend records that, as retribution, not for the sin of a Buddhist priest who was discovered in an intrigue with the Queen, but that of the monarch in putting the “holy” man to death, the waves of the sea encroached on the land until 640 villages (470 of which were principally inhabited by divers for pearls) were overwhelmed, the distance between Kelani and

the sea-coast being reduced by about 25 miles. The probability seems to be that some geological catastrophe is shadowed forth in the legend. At present the belief is that Ceylon is gradually being upraised in about the proportion that the mountain tops are lowered by disintegration from tropical heat and rainfall. One of the associations connected with the Kelani is that Bhuvaneka Bahu VII., King of Cotta, who about the middle of the sixteenth century allied himself with the Portuguese, was accidentally shot by a gentleman of that nation on the banks of the river. Half a century ago the Kelani Valley in the neighbourhood of Hanwella was a favourite resort of elephant hunters, and I have a vivid recollection of poor young Walleit, of the Roads Department, son of Major Walleit, being killed by one of those animals, and the immediate vengeance taken, at considerable risk to their own lives, by Capt. Payne Galway and other friends of the victim.

But the main object of our trip down the river was to visit MALWANA, the very name of which is redolent of flowers and sweetness. We were subsequently glad that the boatmen, instead of landing us in the mouth of the fosse (the *wana*, or artificial water channel) of the ancient fort, took us further down. We were thus compelled to make a long circuit, through villages, bazaars and fields, which gave us new impressions of what purely native life and conditions are. We did not traverse roads other than the native paths which, in all probability, are unaltered, save in being worn by the feet of succeeding generations, since the days when the Lusitanian Doms had here their palatial country residences, in connection with the fort on the river bank, the contour of which we were able to trace amidst the jungle which has overgrown alike moats and walls and what looked like a corner battery, looking up the river. Proceeding along the jungle paths we were surprised to find that they led us into quite a populous village with a well supplied and lively bazaar. Two well-built mosques and the appearance of well-to-do "Moormen" in the bazaars showed the predominance of the Muhammadan element in this busy and beautiful place. Amongst our party was the author of "Ingē Vā;" and by the medium of a peculiar dialect of Tamil, sometimes hard to understand, a leading Moorman boutique-keeper gave us, through our companion of Dravidian tongue tendencies, a good deal of information as to the site and traditions of Malwana. "It has that name," he said, "but the people now all call it Wēlgama." In taking a circuit to the fort we passed through exceedingly fertile, rich-soiled fields of grass, and grain, with patches of vegetables and groves of fruit trees. The crossing of the Malwana-ela by trees laid from side to side with a very shaky bambu hand-rail tried the nerves of some of us; but when an hour and a half had been spent in interesting explorations, we all felt that we should not have missed this glimpse into rural and village life on the banks of the "Pleasant" river and so near Colombo, on any account. And this although no inscriptions, ancient or modern, rewarded our search. We heard of and examined fine slabs of stone in the verandah of a mosque and that of a superior Moorish house, but there was no vestige of lettering on them, and they had been taken not from the European fort we had come to see, but from the more conspicuous ruins of a native one on a height lower down, the river of the existence of which we had no previous idea. An intelligent Moorman, who acted as our guide, told us it was known as "HADI-DAMALA," and that tradition connected it with a Tamil Rajah who once reigned here, It

is surely curious that the Portuguese and Dutch writers who have described Malwana take no notice of the more ancient fort which probably was fairly intact in the Portuguese period. If any reader is in possession of information regarding the alleged Tamil fort or can point us to any references to it in the literature of Ceylon, we shall feel indebted for the courtesy. Near the Tamil fort and the Moorish residence already referred to, were some evidently very aged trees, jaks and bilimbis especially,—of unusual size and gnarled to a degree. There was one lady in our party, and she was invited into the Muhammadam abode, placed on a chair and intently stared at by the women and children, the one disappointment being that she could not speak Tamil. Before leaving this interesting place we ascended a great boulder which juts out into the river and commands an extensive view, including the vast sandbank already mentioned as lying in the Kelani, between Kaduwela and Malwana. The historical references to this fertile and really beautiful place we leave our companion who is specially well read in such lore to summarize:—

"Malwana was chosen by the Portuguese more as a country-seat for the Governors of Colombo and a sanatorium for the troops than as a military post. Sá e Menezes says:—

"The Governors held their court in Malwana [Malwana], three leagues from Colombo, in sumptuous Palaces, which they called Rosapani: here three times in each year came to visit them the principal Zingalas of the Island, who brought with them large presents, as a sign of their friendship and allegiance." Ribeiro says:—

Malwana, was situated on the bank of the river, about three leagues from Colombo; moreover, it covers a small area with a square redoubt, without any flank. In it resided a Captain, Ensign and Sergeant, and the soldiers who went there from the hospital became convalescent and returned to their camps. It had a church, a chaplain, a storehouse for provision and ammunition.

To this Le Grand adds:—

"Malwana never was reckoned a fortress; it is only a country seat at which the Captains-General usually resided: they had a handsome palace there called *Rosa-pani*; and as the air was believed to be purer there than anywhere else in the whole land, those who were convalescent were sent there to recover their strength."

The Captain-General of Colombo, according to Ribeiro, assumed the title of 'King of Malwana.' In the curious map in Spilbergen is entered 'Malleuano,' and in the itinerary in the same work the name is given as 'Malevano.' Baldaus does not mention Malwana; but he gives the place in his map, which also has 'Iassepane.' Heydt in his map of the Colombo disawani gives 'Maluvane' as a fort, but puts 'Rassepanne' a long way off westwards. Fraser's great map gives 'Rassapane' a little north-east of Malwana. The Portuguese 'palaces' seem to have disappeared soon after the Dutch conquest; for when Dr. Daalmans (who calls the place 'Malluanen') accompanied Governor Pijl thither in 1687 they were entertained in a hut covered with white cloth. "In 1736 a detachment of troops, 82 strong, sent by the Dutch to put down a revolt among the Chaliyas of the Siyane Korale, was driven from Attanagalla by a large body of lowcountry Sinhalese and Kandyans, with a loss of two field-pieces beside ammunition and baggage, and forced to retire to Malwana. The small fort that had been thrown up here was, however, attacked by the Disawa of the Four and Seven Korales at the head of some thousands of men, and was utterly demolished, the guard of lascareens perishing in the flames. This

act gave rise to a formal war between the Dutch and the Kandjans. In 1881, when the last census was taken, Malwana contained 63 houses and 342 persons. Rasapane does not now exist, apparently; at least it is not mentioned in the last census report. The name may mean 'sweet drink,' 'sweet plain,' or 'rose plain.'

By the time we had again embarked after our visit to the melodious named Malwana, we were quite ready for breakfast, of which we partook as we glided gradually into deeper and broader water. It was a pleasant incident in our voyage that soon after we came in sight of the grand railway lattice bridge, the 2 o'clock train from Colombo to Kandy rattled over it. I was reminded of the period, now a quarter of a century ago, when the first train (a holiday trial one) which crossed the original bridge was seen by me, also from the river. How much has railway communication done since then for the island, which water carriage and road traffic could never have accomplished, in furthering the progress of prosperity and enabling the country to bear and overcome adversity.

P. S.—I find still one note of information obtained at Labugama unused. Mr. Gibson told us that on occasions of the annual, or rather periodical, migration of butterflies, he has seen the lake surface perfectly white with the moving masses of insects, while a number of "large swallows" were actively preying on them. The butterfly-eating bird was probably the alpine swift, *Cypselus melba*; or perhaps the Indian swift, *Cypselus affinis*, the *Wahelaniya* of the Sinhalese.

Here ends the record of our pleasant and interesting "Holiday Trip to Labugama Lake" and the return voyage down the Kelani from Hanwella to Malwana, and finally to the Bridge of Boats, the recollections of which vie in interest with what poetry has imagined in descriptions of Fairy Land. The Dutch student who scoffed at the earthly Paradise on the banks of the Kelani was a miserable misanthrope!

A NEW SOURCE OF VANILLA.

Vanillin is the odoriferous principle of vanilla, which from a previous paper our readers know to be the fruit of a plant called *Vanilla aromatica*. Vanillin exists in the vanilla pod to the extent of about 2 per cent. These pods used to be very expensive, but new sources of vanillin are being discovered, and it seems likely that the vanilla industry will soon be extinct. Vanillin, which is the only substance for which the vanilla pod is valuable, has been found in asparagus, raw beet sugar, and assafetida; it likewise results from the oxidation of olive wood. On a large scale it is prepared from coniferin, a compound which occurs in the sap of the cambium of pine-trees. The latest source of vanillin has been discovered by Herr Schneegans in the seeds of *Rosa canina*. These are extracted with ether; part of the ether is separated by distillation, and the residue is agitated with sodium bisulphite solution saturated with sulphurous anhydride. Dilute sulphuric acid is then added, and finally, after much washing and drying, a brown oil is obtained, which in a few days becomes a mass of crystals. Possibly the vanilla pod will find a new commercial rival in these *Rosa canina* seeds.—*Grocer*.

CABBAGE FOR EVER.

The London *Daily News* has the following amusing ekit at the expense of the vegetarians:—

The Vegetarian Congress has dispersed to the four winds of heaven, leaving upon the minds of some who

take life seriously a sense of humiliation. All the other Congresses have left behind them a pleasant impression, for they have given the race some ground for hope that it is getting on somehow—making, in spite of all its blunders, for righteousness. But if we are to believe the Vegetarian Congress, we have not yet learned how to live. It makes short work even of the last shred of definition of himself to which man has clung—an animal that cooks its food. He cooks, certainly, but it is not food. Four or five millenniums have passed since the pyramid of Cheops first looked down on the Nile, and the Neanderthal man became dust myriads of years ago, and yet we do not know what is good for breakfast. Instead of doing our best to unravel that problem, we have been frying one another about theological propositions. When the great problem is at length started, we find that the new doctors of the law differ as widely concerning our perishable bodies as the old doctors concerning our immortal souls. "What the Vegetarians want is to know what the right and proper foods are." Such is the surprisingly innocent, naive observation made at the Congress by a vegetarian of the Nut-Eating Sect, Mr. Manning. In course of time there will be as many rival sects of Vegetarians as there are rival sects of theologians. Here are the Nut-Eaters, with Dr. Densmore at their head, proclaiming that grain food is as perilous to the body as beef and mutton. Starch is the heretical element, so to speak, in grain food. But then comes Miss May Yates, an ornament of Vegetarian Orthodoxy, and Miss Yates announces that outside whole meal there is no salvation. These are the two Schools, or Churches of the Vegetarian faith—the nut-eaters and the grain-eaters. But there are minor denominations, which borrow from either side the doctrines that seem to them most reasonable. There is even a mystic sect in process of evolution. Thus Mr. Jeffreys described, amidst rapt silence, to his audience in the Memorial Hall, how when he wanted his thoughts to concentrate themselves upon the physical world he "took cereals," but "fruit" when he communed with the unseen. The President, Mr. A. F. Hills, is an out-and-out Mystic; "pulse," quoth he, for muscle; "cereals" for brain, "fruit" for the soul, and nuts for the mighty spirit of man. Dr. Densmore however nearly concedes the anti-vegetarian doctrine when he permits a diet of "eggs, milk, or cheese." If these be not animal substances what are they? The English have conquered the world on beef and bitter beer. Perhaps they might have done it as well on pulso. We cannot tell; but we do know what they have done on the other diet. Then there is this disquieting thought: At the British Association, Mr. Ravenstein argued that in two centuries the earth would be full; but that is not the question at issue—what we want to know is how the supply of nuts can be kept up for the consumption of this rapidly increasing human race. The practical conclusion is, that while the Vegetarians are trying to agree among themselves, we had better go on with our beef and mutton—but in moderation. The solid basis of truth in the Vegetarian doctrine—which we are glad to say is doing immense good in the world—is that English people eat far more flesh meat than is good for them.

RUSSIA AS AN OUTLET FOR INDIAN TEA.

To the Editor of the HOME AND COLONIAL MAIL.

SIR,—In the letter which you kindly inserted in your issue of Oct. 24th I promised to return to this rather interesting subject.

Since that date our Ceylon competitors—always in the forefront of the battle—have clenched the matter, and sent out Mr. Rogivue (whom I alluded to in my previous letter, and who has since been over here to report progress) to commence a campaign in Russia. They have liberally subventioned him, and invited him—if he should find more money necessary, in order successfully to prosecute the enterprise—to apply to them again later on, and that he need not fear lack of support.

I had intended suggesting co-operation on the part of the Indian planting community with Mr. Rogivue's

enterprise, with a view to bringing more money to bear upon what will undoubtedly be an uphill and costly game. From enquiries, however, which I made, both of Mr. Rogivue himself and of other Ceylon men, I found that such co-operation would not be very easily arranged.

Meantime, it cannot but be that the Ceylon Planters' action will "break the ice" for their Indian "brethren" as well as for themselves, and that the introduction of Ceylon tea into Russia, if successful, will be but a stepping-stone for Indian to follow on.

Now, at the first blush, it will no doubt occur to your readers—especially to your planting readers in the distant jungles—that the Indian industry should at once raise a fund and proceed to follow in the lines of the Ceylon men. I do not however, meantime, advocate such a step, for reasons which I will endeavour to state as briefly as I am able.

1. Owing to the action already taken by Ceylon (which will break down the Russian prejudice in favour of China teas), it is less necessary now that India should act than it was.

2. In view of the recent heavy calls made upon the Indian community (1) in starting the New York scheme (*The Associated Planters, Limited*) and (2) in introducing Indian tea into France, both at the Paris Exhibition and subsequently, I fear that it would be extremely difficult to induce our tea circle, for the present at least, again to subscribe money for this purpose.

3. For reasons which will be obvious for those of your readers who are intimately acquainted with the inner workings of the wholesale (especially the export) distributive and dealing trades, I have, after a good deal of reflection, come to the conclusion that it is inexpedient to take, hastily, any action which might tend to interfere aggressively with the operations of the large export tea houses, especially those carrying on business between London and Moscow, and that it would be better at first to endeavour rather to gain their co-operation and good-will, so that our teas may be brought a little more prominently than hitherto before the Russian consumer.

As already indicated, almost all the conditions are, comparatively speaking, in our favour, and "time" also "is on our side," hence there is no need for any hasty, and possibly ill-considered, action.

Two things, however, I would suggest:—

1. That steps be taken by the growers, either through the Tea Association or by means of a committee, to get into communication with the principal Russian tea merchants in London, with a view to ascertaining if any special steps can be suggested for facilitating the introduction of our tea into Russia.

2. That growers, either by means of written communication or by a personal deputation, approach the Russian Government either through our Foreign Office or otherwise, with a view to pressing the Russian finance authorities—in the interests alike of the Russian people, and of the revenue, to consider the expediency of a reduction in the heavy duty now levied on all sea borne tea, whether imported from or through Odessa.

There is every reason to believe that such representations, if properly put forward, would receive fair consideration from the Czar, at any rate, since the well-being of the people (closely connected with which is the supply of cheap necessities of life) is supposed to occupy his mind especially at this time, and seeing also that the Russian Empire is not itself a tea-producing country.

Apologising again for the length of my letter, but trusting, however, that it may be the means of directing attention to the important question of opening up an Indian tea trade in a tea-drinking country of 100,000,000 inhabitants. I am, &c.,

G. SETON.

14, St. Mary Axe, Dec. 17th.

THE DIVIDENDS OF INDIAN TEA COMPANIES.

About this time of the year the directors of the many Indian Tea Companies announce the ad interim dividends that they may feel justified in declaring. Although, of course, such announcements do not furnish sufficient data to estimate the results of the year's working, they must be accepted as supplying no slight indication of the prospects which the directors consider to lie before them. Accordingly we may fairly deduce from the statements published, so far as we have seen them in the English papers, the conclusion that no very promising prospect is anticipated of the working of Indian tea gardens during the current year.

For we observe that the interim dividends declared by the directors of the several Companies—so far as they have yet been heard of—in no case exceed 3 per cent, the majority of instances notified not having passed the limit of 2½ per cent. We may fairly contrast such dividends with those which the majority of the Companies working tea estates in Ceylon have thought it justifiable to declare. The contrast is in nearly all cases very striking. We must, of course, exclude from such a comparison those among the Companies working in this island which—established as coffee growing Companies—have had forced upon them the conversion of the estates they were possessed of into tea gardens. In the case of these it was not to be expected that they would be able to compete in the matter of declared dividends with the Companies more lately formed which have taken over properties already well advanced with the growth of tea. It is only with these latter that a fair general comparison with the gardens of India can, as the rule, be instituted. For it must be recollected that no such hampering process of change in cultivation as we have above pointed out has ever been a necessity to the Indian tea planter. In this case he has either had fresh and unbroken soil to work upon, or he derives his profit from tea gardens of a mature age in a high degree of cultivation. If we go back some twenty-five years or so, before Ceylon had entered as a competitor in any degree with India in the production of tea, it will be found that at such a date tea-growing in India was among the most paying of the industries of that Empire. The cause of the falling-off in this respect at the present day is not far to seek. Indian tea at that time purchased in Calcutta was charged as high for the better sorts as 4s 6d per lb. We have only to contrast such a price with that obtainable now for the finer sorts of Ceylon tea, to see how injuriously the competition of recent years must have affected the profits of the Indian tea planter.

Had this competition been carried on under conditions in all respects similar to those which prevail in the tea-growing districts of India, Ceylon might not have been able to outstrip her neighbour as she has done; but the circumstances of our supply of labour, of our excellent system of communication by rail, by road, by river and canal, with the short distance of most estates from the port of shipment, of our climate which permits of plucking throughout the year, and one or two other minor advantages, have aided us here most materially. Therefore it is that while we find tea cultivation in Assam and other Indian districts to be in the present day, in the case of many Companies, but a barely paying industry, the same cultivation in Ceylon, even at the low prices—relatively to those of a past era—now obtainable, is one of the most satisfactory of any taken up locally. Had we been able, now that our own planting pursuit has

DURING their visit to Assam the locusts did not damage the tea when in hard leaf, but stripped a considerable amount of young tea a year old.—*M. Mail*, Jan. 7th.

passed the stage of initiatory effort and become a well-developed and settled industry, to obtain the prices which the planters of India secured but some twenty years back, the profits which could have been realized by us would have been simply enormous.

Turning from our English files, we find that the *Indian Planters' Gazette* contains tables showing the results of working, &c, for the whole season 1889, by which is meant up to end of June 1890, we suppose, of 26 Companies registered in London. These certainly shew a different result to our deduction from the interim dividends. The totals and averages are thus shewn:—

Capital paid up	£2,951,886
Total area of cultivation	64,953 acres
Do, mature do.	54,769 "
Proportion of young cultivation	15.68 per cent
Yield (total crop)—per mature acre	422 lb.
Outturn (<i>Account Sales weight</i>)	23,100,052 lb.
Loss in Taring	...	[From nil to 2.37 per cent].	
Capital value—per acre of total cultivation	£45 9s 0d per acre,

The largest total area of cultivation is 9,185 acres, of which 7,521 mature, in the case of the Assam Company. The highest yield per mature acre was 809 lb. in the case of the Dejuo Tea Company Limited; the lowest being 255. The results per lb. for the season are thus given:—

		s.	d.
Total cost*	average per lb.	0	8.42
Surplus Commission to managers	"	0	0.23
Do. Profit for shareholders	"	0	2.45
Gross proceeds	"	0	11.15
Shareholders' profit—per mature acre	...	£4	6s 1d
Do do per cent on total cost*	...	29	06
Do do do capital	...	8	53

Dividend paid do do do	{	*4=Nil
	{	22=8.83
	{	8=Nil
Reserve Fund do do do	{	18=9.69

* Old non-dividend paying Companies.

The highest shareholders' profit per mature acre was £13 12s 2d. Four Companies, as shewn above, gave no dividend; one gave 18 per cent; another 15; one 14; one 11½; 7 gave 10; one 9; one 8; 6 gave 6; one 5½; one 5 and one 2½. Leaving out the 4 old Companies, the general result of an average dividend of 8.83 per cent seems good, but there must be a large number of indifferently paying Companies outside the list.

Of course in our review of the differing aspects in which the results to the tea cultivation of Ceylon and India may be considered, we must take largely into account the fact that in very many instances of exceptionally large dividends accruing to the pursuit of that cultivation locally, the lands on which it is so successfully carried on were obtained under conditions which caused them to have been parted with for what was but little more than a nominal consideration. The collapse of the coffee-planting enterprise forced numbers of estates into the market, so greatly reducing their then purchasing value. This enabled the fortunes of the present to be largely built up upon the ruin of the past. Cases of this kind have been much rarer in India, and it is largely because of this that we contend that it would be unfair to accept instances of exceptionally high dividends declared with respect to the Ceylon industry as the standard for comparison with those of the Indian Companies. But when every allowance is made for these and the other conditions that we have mentioned, it remains evident that tea planting in Ceylon has distanced in its remunerativeness that of the neighbouring continent.

Much of our relative superiority as to this remunerativeness may be assigned to the qualities inherent in our teas, which the taste of the home consumer has appreciated, and our brother planters in India have to contend against this superiority as well the local advantages possessed by us which have enabled us to produce at a lower cost.

SALE OF FOREST LAND IN HEWAHETA.

The block of forest land which formed a part of the Mooloya Estate and was advertised for sale today by Messrs. J. AWARD & Co. was purchased by Mr. J. G. Wardrop (for Mr. R. J. d'Esterre) for R7,200, or about R46 per acre for 157 acres.

SALE OF HYNDFORD TEA ESTATE.

The Hyndford property near Nawalapitiya including Wallukelle and extending over 730 acres of which 212 are planted with tea, has just been sold by Mr. Evan Byrde as Fiscal and has been purchased for Mr. David Reid (who had taken the place of Messrs. Dent Brothers as Secondary Mortgagee) for R32,755 which we presume is the amount of the primary claim held by Mr. James Robertson, P. W. D. The estate is to be carried on by the Ceylon Tea Plantations Co., the leaf being prepared at the Mariawatte Factory,—in the interests of Mr. Rossiter and others concerned. Hyndford ought to become a valuable property under regular, careful cultivation.

CACAO THIEVES IN MATALE.

THEFT OF CACAO FROM THE YATTAWATTE ESTATE.

Mr. J. R. Martin, superintendent of Yattawatte charged one Baronchi, a lowcountry Sinhalese man with the theft of a certain quantity of cacao—ripe and unripe fruits—of the Forastero and Caracas varieties. About the 30th December Mr. Martin was informed of a man with a bag of cacao seen going from the estate. He therefore desired the headman of that village to make search and also gave him five men to assist him. On the morning of the 31st the accused with the cacao was brought to him: the cacao was about 20 lb and valued at about ten rupees. Mr. Martin did not question the accused as to how he got the cacao, as he understood from the headman that he had told him before. Having received information that a large quantity of unripe cacao had been stripped from the trees in the cacao field nearest to the accused's village, Mr. Martin visited the spot and found that a large number of unripe pods had been picked recently, also a quantity of recently shelled pods. There are no bearing cacao trees in the vicinity except a few on an estate belonging to a Parsee gentleman. At the request of the koral the arachchi of Udasgiriya, the village in which the accused lived searched the house of the accused and found the cacao seeds placed in a hollow scooped in a heap of paddy in the course of germination, and put them into a bag. The accused told the arachchi that he got the cacao from one Peris Appu of Moragolla. Peris Appu who was called as a witness said that he owned about three or four hundred cacao trees, and that he never sells the produce in the village but sends them to Matale or Aluwihara and that he never gave the accused cacao seeds or pods.

Mr. FRASER, the laird of Wariapola, was called by the Court and said that he had had experience of cacao in Matale district for sixteen years, and that having examined the cacao produced before the Court he found that most of them were immature and that over 75 per cent were unripe.

The accused stated that it was true that the cacao was in his house as he purchased it at different rates from different parties whose names he did not know,

The following is the judgment:—"I find the accused guilty under the section of the ordinance under which he is charged. His story of having purchased the cacao seeds from Peris Appu is obviously false. He made that statement to the arachchi in the hope that he may be able to get Peris Appu to support him in that statement. But Mr. Martin has forestalled him in this. Mr. Martin sent for Peris Appu and he appeared in Court today. He has given evidence which clearly shows that he never gave or sold any cacao to this accused. The only hope accused had of accounting for the urupe cacao in his possession was to have said that he got it from a man whose cultivator the accused was and who had some bearing cacao trees. He could see upon no other, because there is, it appears, no person in Yattawatta or Udagiriya who could give him any cacao, for that product has not been cultivated yet by the people of those villages. Finding however that Peris Appu would not give the evidence which the accused hoped he would give, the accused in his statement gives Peris Appu up and takes refuge under an alleged purchase from unknown sellers. Obviously therefore his defence was false, he knew it to be false. His conduct with reference to the cacao he had in possession strongly proves his guilt. He had concealed the cacao in the middle of a layer of paddy seeds which had been kept to germinate.

"Theft of cacao, just at this particular time, is a very predominant evil, and it is rarely that such thefts can be detected. The offence is committed under cover of night or at a time when the watchmen are not about. I have no doubt upon my mind of the guilt of the accused. I feel bound to do all I can to protect owners of estates from the deprivations of village thieves who not only steal these garden products but do so in the very heartless way in which they set to work. The crop is not only stolen but the trees are ruined and hindered from bearing.

"I find the accused guilty and sentence him to be kept at rigorous imprisonment for a term of 6 months and to receive 15 lashes.

(Signed) J. H. EATON, P.M."

THEFT OF CACAO FROM WARIAPOLA ESTATE.

B. N. Abbas, conductor of Wariapola, charged one Letohimen of Elwala with the theft of five cacao pods, worth one rupee and twenty-five cents the produce of Wariapola estate, the property of Mr. R. S. Fraser. It appears that the accused was a paid-off cooly of the estate, and since he was paid off he has been living near Wariapola estate. On the 31st December he and another boy about 12 years old were seen near a jak tree on the estate. A watcher ran up to him and found five cacao pods in his possession; they were bundled in a cloth. He brought the cacao and both of them to the complainant. In defence the accused stated that he did not pluck the cacao pods, but plucked and ate jak fruits from the estate.

The judgment is as follows:—"It is quite clear that the accused did steal the five cacao pods he is charged with having stolen. His statement amounts to admission of a theft of jak fruits, but I think the evidence makes it clear he stole the cacao too. This is the fourth case of cacao-stealing that I have been trying today. As the season for cacao to ripen is setting in, the thieves who practically live by theft of agricultural products are seen moving about under cover of approaching darkness to enrich themselves at the expense of the proprietors of estates.

"I find the accused guilty and sentence him to undergo rigorous imprisonment for a term of three months.

(Signed) J. H. EATON, P. M."

The cases were tried on the 5th January 1891.

PLANTING NOTES FOR 1891:—

CACAO; COFFEE; TEA.

I. CACAO.—This is really a very paying product where the climate is suitable. The more attention and manure you give it, the more it will respond; but you must protect it from marauding and chilling winds and attend well to shade. Cacao thieving in the Galagedara district is becoming intolerable. The best way to counteract the thieving is to offer large rewards,

and make it worth the while of some of the thieves to use their experience in thieving ways on behalf of the cacao planter. This causes a flutter in the thieving circles, and benefits the growers. One planter admits losing 50 per cent of his produce! I wonder what the proprietor of that estate would say. He would not grudge a good deal of money spent on rewards for thieves or reliable watchers in preference to losing one-half of his produce. The men who are robbed are:—1st. The easy-going phlegmatic office man, whose name is anything but a terror to evil-doers, and whose fields draw the most of the thieves to the advantage of his more feared neighbours.

2nd.—The unpopular man who works through conductors and English-speaking middlemen, and thus keeps the respectable villager at arm's length and utterly drives away the influential headmen whose power is great and can be made use of.

3rd.—The man whose ignorance of the vernacular and the customs of the natives prohibits him from gaining secret or stealthy knowledge so as to be beforehand with the thieves.

The man who is not robbed is the counterpart of the above, i. e. popular, energetic, physically and mentally powerful, foared by all yet approachable by all, just and wise in dealings with the native, thoroughly conversant with native language and ways. This sort of man will be avoided by thieves, and sought after by the better sort of villagers.

A thief will say of such a one:—"Don't rob that master, he is kind, is friendly with the headman, unmerciful when he catches us, and relentless in hunting us down. Let us go over to —. Why, he never ascertains if the watchmen are ever watching. We can soon terrify a few Tamils even if they should be there. These Tamils are only brave when their master goes with them."

II. COFFEE.—The general opinion as to this product, even the Coorg variety, is, that so many plagues are lying in wait and cacao is such a sure thing in the end; therefore plant coffee and make use of it only as a help and "lift" to the more tardy cacao which will eventually take its place. It is argued that though Coorg coffee is precocious and apt to overbear in early youth, and thus it is advisable to strip off the crops in the earlier years; yet should one sacrifice say 3 cwt. an acre to trust to an uncertain future? I say, yes. I would recommend stripping the crop entirely off the first year; and the next two years the crop before the berries turn ripe and dry it in the husk; and then you have an established Coorg coffee field which will pay better than cacao. Prune delicately and top high; in fact do everything opposite to forcing the bush. One V. A. mentioned that the crop off the ends of the primaries had been stripped to relieve those primaries. Had he taken the crop off the inside of the primaries next to the stem it would have been more sensible, but he was taking off the fruit he wished to relieve without relieving the branch from the cause of injury, viz.: heavy clusters of fruit at the head of the branch robbing the end of the branch of sap and vigour. Side branches of shade trees should not be cut but the general tree pruned or thinned. I saw at Matala the other day that they had cut up the side branches of fine shade trees and thus reduced objects of beauty and utility to ugly rook-resters or crow-perches. An umbrella held on a twenty feet pole will not give much shadow—and this argument is ten-fold increased when you remember that the shelter of shade is more valuable than the shade of shelter. Of course with leaf disease and green bug one has to go cautiously and avoid monoculture if possible.

III. TEA.—This is a great industry and has rapidly developed in a manner almost startling. The old painful drudgery of standing behind coolies' backs is disappearing. The new method of paying coolies by the amount of leaf, and arranging the totals in the check-roll so that the kanganyas can still benefit by the coolies' work fairly, is reducing work to general inspection and careful calculation. Men (male coolies) are becoming less and less desired on a tea estate, and this alone should work a

wonderful reform among the ryots of Southern India, among whom female children have long been very much at a discount. It will recommend itself to oriental ideas, which incline largely to the idea that "women must work and men must sleep," and not "men must work and women must weep." A good plucking girl has thus acquired a new value besides that of personal feminine charms, and the ugliest daughter amongst them, if she plucks well, will soon be adorned with jewelry and sought after by the lads.

As there is such a small difference between the finest and commonest teas, it is found that fairly coarse plucking pays because the factory figures are known, and when once the average is settled say at 10d with coarse plucking, and a margin is left as profit—the more leaf the more money. Now comes in manure. That horrible yet universal saying, "If you once start manuring you must keep it up," is really doing harm. With the past experience of our climate and its susceptibility to blights surely we should "make hay while the sun shines," and manure heavily and pluck heavily and bank the profits. The old gingerly finicking way,—aiming at appearance and tidiness and pretty teas,—that is all going out. Low pruning and topping two leaves above the fish-leaf from any point in the bush, not merely from level but from any sprouting point, thus drawing the hush at all its sprouting points and not allowing side branches to grow up to satisfy the leaf requirements of the plant. No—there must be no satisfaction allowed; the bush must be continually worried and plucked, always leaving first round two whole leaves above fish leaf; then one whole leaf above fish leaf—this to go on for six months. Then half a leaf above fish leaf for another six months. Then down to the fish leaf; and if you have manure you can run a second year and have the labour free for remunerative works. You must have manure, and it must be artificial manure. Cattle manure is all right for cacao or any fruit-bearing trees. We want to stimulate the leaf-producing powers, not the reproductive powers.

The moment the difference between the best teas (commercial) and the common teas becomes sufficiently marked in price and thus sufficiently attractive, then it will pay to pluck fine. Gow, Wilson, & Stanton's Sales Lists have encouraged an unhealthy competition, misleading to proprietors at home and injurious to their interests. Proprietors should say to their Managers: "Give me a margin of profit, the higher it is, the greater percentage you will get"; and if the man is worth his salt he will take the best method you may depend on it.

That was a very milk-and-water production regarding COAST ADVANCES emanating from the august Association. It has a decided touch of the "Old Masters" about it, and should be respected on account of its venerable character. But it does not help us a cent. Proprietors and firms have to act and put pressure on their superintendents to secure themselves for the pressure of flushing months in the legitimate market in India. But as for myself, if I want labour and find labour to be had in the local market and am allowed to pay a good price for it, and am urgently in immediate need of it, I shall avail myself of such labour being in the market and deal with such labour for my proprietors' interests. But if I want to establish a force which, as in the old days, I could increase and decrease without robbing, or being robbed by, my neighbours, but by internal arrangements, I gradually encourage a free circulation of my coolies between their scattered homes in the arid plains of India and the clustering well-packed "lines" of a Ceylon estate, and have my labour and advance account so in hand that tunds need be neither given nor taken. It is for proprietors and firms to stop the competition in the local market of paid superintendents who are pressed by irregular and unequal calls for labour and the fluctuations of weather and special flushing periods. Places where there is much carrying of tea chests or rice, or even leaf, will suffer greatly by reason of want of labour, as compared with places favourably situated. Places where other pro-

ducts are cultivated, and heavy works such as holing for new clearings or for manure are carried out, these places suffer as compared with those where the only manual works are plucking, pruning and weeding. Are you then to lay down rules and issue them under the authority of the P. A. rules which cannot be applied universally? The more planters encourage the local market the more they are damaging a valuable labour supply; so the instinct of self-preservation will right the abuse so eloquently complained of by Mr. Young, so long as the proprietors and agency firms are kept awake to the danger.

It is high time the inventive genius which has developed in Ceylon so largely should apply itself to a cheap, light, effective PACKING cover for our tea. The delicate care bestowed on Ceylon packages is cruelly abused by dockers' hobnails and iron shovels; and the expensive dry air obtained by refiring and a carefully constructed factory is ruthlessly allowed to evaporate amidst the damp and smoke of a London warehouse. Then our teas are subjected to all the hurry and waste of a system of sale originally intended for sleepy China, and a comparatively small Indian trade. I believe that if a really suitable package were invented admitting ready inspection and quick and effective re-closing, and a thorough re-organization of the system of public sales made, then our teas which are the most carefully prepared in the world will get more justice and be better appreciated by the trade and the public, and thus give us more margin of profit. Strange to say the Ceylon system has elucidated the fact that an acreage over say 300 acres under tea is worked more profitably in private hands than through Companies. It used to be said that tea, with its outlay in machinery, suited the broader basis of a company with its greater division of risk, but the division of profit composed of fractional margins depends more on the excellence of the man in immediate charge than on any adopted system; and these divisions of profit are apt to be swallowed up by the various charges and the numerous necessary officials of a company.

It is admitted on all sides, that the force energy displayed by Ceylon in advertizing herself has revolutionized the tea trade and benefited India immensely. We want reform in the handling of tea by the Customs, and we want reform in the public sale-rooms. Then if blights are averted the future of the island is now sure. We grow the *drink of the universe*, the relish of the rich, the solace of the poor, a drink wholesome and harmless, and within the reach of all

SUCCESS TO CEYLON FOR 1891.

"1873."

COCONUT BUTTER.

In reply to an inquiry the following reply was sent on the subject of making butter from coconuts:—"My experiments were on a very small scale. The coconuts were scraped out with a *Karni* in the usual way, a small quantity of water added and rubbed in a mortar. The milk-like fluid was then strained through cloth and churned in a bottle. The churn used was a disc of wood of about the same diameter as the hottle, cut with a wavy edge and with holes through it, this was forced up and down by means of an upright handle. The churning was over very quickly, and the fat globules on being formed were skimmed off and washed in salt and water. The kernel which had been strained off was put into a small cheese press, and the fluid squeezed out added to the "butter-milk" and again churned, a further small quantity of butter being obtained. The cake of scrapings still retained its flavour and would be fit for various purposes. The butter was almost tasteless while fresh, but after being kept a day (in the cold weather) had a strong taste of coconut. It had the appearance and consistency of butter but was very white."

The writer continued by stating that the authorities at Kew had been asked by the Society if they could

afford information as to the manner in which coconut butter is deodorised in Germany, but they had stated that the subject had not come before them, and suggested that the information might be obtained through the Government of India; the subject being of considerable interest to India.

Mr. B. O. Basu of the Agricultural Department of Bengal, very kindly communicated the results of his experiments in the following letter:—

"I took four nuts of average size, neither very big nor very small, and had the kernel reduced to a coarse pulp with a native instrument called *Karni*. The nuts were not fully ripe; the kernel was fully formed, but was yet a little soft. After the kernel had been made into pulp, the latter was squeezed in a thick piece of cloth to express the 'milk.' A little water had to be added to the pulp to make the milk run out freely. The whole of the milk could not, however, be expressed, as I had no proper appliances to do the work. The 'milk' was measured and found to be 3 *paos* or roughly 24 oz. of which quantity 1 *pao* may be taken as water added to the pulp in the act of expressing the milk.

"Immediately after the milk had been expressed, it was churned in a soda-water bottle. I intended to use the English churn which I have recently procured from England, but the quantity of milk was too small to be put into a churn. I should mention here, that in the experiment with coconut milk which I made in the last cold weather, I had no need to add any ice or cold water, but in the present experiment which was made sometime about the end of last April, the weather was hot, the consequence being that the butter refused to 'come.' I then added a little iced water to the 'milk' in the soda-water bottle, and the butter grains immediately appeared. The whole operation did not take more than 15 minutes, and could be finished in half the time if cold water was added in the beginning. All that I had now to do was to wash the butter in cold water, and gather it into a lump. The butter weighed just a little over 1½ chittaks or 3 oz., that is 12½ per cent. on the milk. This I considered encouraging; but my surprise and disappointment were great when on opening the vessel in which I had put in the butter, I found that it had all melted and was floating on the top of the water. In the cold weather the butter kept pretty firm day and night; but in the hot weather it would be impossible to keep it solid, unless it was put in iced water. Under the circumstances, I believe it is useless trying to make coconut butter in a hot climate like ours."

In a subsequent letter Mr. Basu conjectured that the butter fats of the coconut might be of two or more kinds, with different melting points, and in that case those that melt at a low temperature might be removed and the balance would remain solid.

In connexion with the subject the following from the Journal of the Society of Chemical Industry is of interest:—

The following is an extract from the last report of the United States Consul at Mannheim on the subject of the manufacture of Coconut Butter in Germany:—

"German Chemists discovered in the coconut a fatty substitute for butter. This discovery was made by a Dr. Schlunk, practical Chemist at Ludwigshafen-on-the-Rhine. Shortly after the discovery was made a firm was established in this City under the name 'P. Müller and Söhne,' which sunk a large amount of capital in an enterprise, having for its object the production of the new article, to which they gave the name of 'Coconut butter.' The results achieved have more than justified their expectations. The firm is not able to meet the constant demands made upon it. Although in existence only one year, it employs 25 workmen, who got from 25 to 75 cents, a day, has a 40 horse-power engine, and produces daily 3,000 kilos of butter, which retails at from 55 to 65 pfennings, or from 13 to 15½ cents. per pound, or 25 to 30 cents. per kilogramme.

"The nuts are obtained from almost all lands lying in the tropics, especially from the South Sea and Coral Islands, Arabia, the Coast Countries of Africa, and South America. Natives in countries where the nuts

grow have for a long time used the milk of these nuts instead of food oils. It contains 60 to 70 per cent. of fat, and 23 to 25 per cent. of organic substances, of which 9 to 10 per cent. is of albumen. Liebig and Fresenius had already discovered the value of the Coconut oil, or fat, but did not succeed in its production as a substitute for butter. The new butter is of a clear, whitish colour, melts at from 26° to 28° C., and contains 0.0008 per cent. water, 0.066 per cent. mineral stuffs, and 99.9932 per cent. fat.

"It hardens at 19° C. It is better adapted, however, for the kitchen than for the dining-room, that is, for cooking purposes, than for the uses to which butter is put on our tables. It is neither disagreeable to the taste nor smell. In a country where real butter runs all the way from 25 to 35 cents, per pound, and Coconut butter costs but 15 cents., a great future must open up before the latter. At present it is chiefly used in hospitals and other state institutions, but is also rapidly finding its way into houses or homes where people are too poor to buy butter. The working classes are rapidly taking to it instead of the oleomargarines, against which so much had been said in the papers during the last two or three years.

"The new butter is said to be singularly free from acids and other disturbing elements so often found in butter, especially that from milk taken from cows diseased with tuberculosis. Here it is estimated that fully 10 per cent. of the milk-giving cows are so troubled. This absence of acids and other matter renders its digestion much easier, hence the preference already shown for the new article by hospitals and such institutions. There are those who do not hesitate to declare this new substitute as healthier, and infinitely preferable to the too often bad butter brought on the markets, and not to be named in the same breath with oleomargarines made too often from the diseased fat of horse and sheep flesh.

"When it is remembered that Germany has already some 50 factories making oleomargarines and other artificial butters, and that some 180,000 *centners* are produced annually, it will be readily seen that regular butter will have hard work to hold its own in a hundred uses against its new rivals, and especially so since the oleomargarines and artificial butters of all kinds are placed under severe, careful, and watchful State Inspectors. It is hoped, however, that no losses, but gains rather, will arise; for besides the profits resulting from the new substitutes more meat and milk, as such, will come on the markets, and consequently into use.

"If, with Köning, we assume that the principal nutriment albumen, fats, and carbon hydrates are paid for in the ratio of 5 : 3 : 1, *i.e.*, a kilog. of albumen costs five times, and a kilog. of fat three times, as much as a kilog. of carbon hydrate, we arrive by comparison of the nutritiousness of milk with other articles of diet, at the following results:—If we pay for 1 kilog. of milk, 15 pfennigs; for a mark we get 21.33 per cent. of nutriment; for 1 kilog. lard (bacon), 172 pfennigs, 16.03 per cent.; for 1 kilog. fatty cheese, 162 pfennigs, 14.32 per cent.; for 1 kilog. pork, 131 pfennigs, 14.01 per cent.; for 1 kilog. veal, 112 pfennigs, 10.33 per cent.; for 1 kilog. beef, 128 pfennigs, 9.11 per cent.; for 1 kilog. eggs, 200 pfennigs, 4.97 per cent.

Now, if these facts are once known, milk as an article of diet will be more in demand, and the quantities no longer needed to make butter will find their way into the families where formerly pure butter was unknown, but where its substitute, coconut butter, has taken fast hold."—*Board of Trade Journal.*

ECHOES OF SCIENCE.

Geologists have proved that the diamond mines of South Africa are situated in vents or chimneys, varying from about 70ft. to 1,500ft. in diameter, and descending vertically through the schists which form the ordinary strata of the district. These vents are filled up with fragments of silicated and magnesium rocks, in which the diamonds are scattered, and

before the diggings began each was capped by a hillock, or "kopje." They are 17 in number, and run in a straight line for about 120 miles.

The question of their origin has recently been discussed by M. Dambree, a well-known French geologist, at a meeting of the Académie des Sciences, Paris. They have, of course, been opened by an eruptive force from the interior of the earth's crust, but they differ from the usual volcanic cracks or fissures. M. Dambree attributes them to the outburst of imprisoned gases, and has made a number of experiments at the Laboratoire Centrale des Poudres et Salpêtres, in Paris, to prove his theory. Explosions of dynamite and gun-cotton were made in a steel cylinder or mortar, and the escaping gases made to perforate masses of rock. Limestone, gypsum, slate, granite, porcelain, glass, crystal, and steel were all fractured and bored in this manner. It follows from his experiments that gases at a high velocity, say exceeding 1,300 metres a second, and especially when aided by heat, are powerful agents of geological erosion. They are able to bore regular vents or chimneys in rocks, if there is a crack or fissure to concentrate their energy in one spot. The diamond vents of South Africa are, in his view, the effect of compressed gases exploding from the interior of the earth at certain points along a line of fissure; and the striæ or grooves observed on the sides of the vent are another proof of this explanation.

Professor Liversidge, F. R. S., of the University of Sydney, has found that certain fungoid growths have the power of removing gold from water containing it in suspension or in solution. Bottles of distilled water containing finely divided gold which had been reduced from a weak solution of the chloride by phosphorus dissolved in ether were allowed to stand for some years, and it was observed that while some of them cleared, others retained the ruby or purple colour characteristic of gold thus reduced. Examination showed that the clear bottles had a purple-blue growth in them, which, under a microscope, appeared as a mass of matted filaments. When dried over a spirit lamp, these filaments exchanged their purple tinge for the metallic lustre and colour of gold. A similar change took place when the growth was rubbed in a mortar.

In some cases the mould or fungus was white and blue-black. The white growths had a blue-black nucleus, and floated on the water. They had an oval shape, and were about $\frac{1}{16}$ in. in length. Ether or alcohol is food for such growths, and phosphorus is favourable to their growth. There was little or no fungoid when other solvents were used for the phosphorus; for instance carbon bisulphide, chloroform, or turpentine.

Professor Liversidge finds that the mould from cheese or banana skins, as well as bread and other organic bodies, will, when placed in water containing gold, either in suspension or solution, remove it, they acquiring, at the same time, the characteristic blue colour.

A French chemist, M. Aimé Girard, has shown that the potato called "Richter imparator" is well-fitted for the production of alcohol by distillation on a commercial scale. At one operation 78,000 kilogrammes of potatoes were treated, and 10 litres of alcohol, absolutely pure, were obtained from every 100 kilogrammes of the tuber. Another distillation gave 14 litres for the same quantity of roots. The "draff" which resulted was readily eaten by cattle.—*Globe*.

THE CHAMPION SWEDE CROP.—Lord Wantage has this year grown on his Home Farm at Ardington, Berks, an enormous crop of Sutton's Champion and Sutton's Crimson King Swedes, weighing just upon 40 tons per acre. The individual roots were of excellent shape and quality and were awarded the Champion Prize given by Messrs. Proctor and Rylands, competed for by farmers in the counties of Hereford, Salop, Stafford, Warwick, Worcester, Gloucester, Berks, Hants, Surrey, Oxford, Bucks, Herts, Bedford, Northampton and Huntingdon. Some of these roots will be exhibited on Messrs Sutton & Sons' Stand at the Smithfield Club Cattle Show next month, and will be well worthy a visit.

PINE-APPLE FIBRE.—From Mr. E. W. Dana, Lakewood, N. J., U.S.A., referring to an article on Pine-Apple fibre which was published in the Society's Journal and reproduced in the *Scientific American*, and asking if the writer could furnish him with further particulars as he is greatly interested in the subject. A small sample of the fibre was sent to Mr. Dana, and he was informed that there is early prospect of the Mauritius aloe fibre machine being tried on pine-apple leaf in India, when the results will be published in the Proceedings.—*Agricultural and Horticultural Society of India*.

OUR WEALTH OF LIVE STOCK.—Some interesting calculations of the value of the live stock held by British and Irish farmers, prepared by Mr. R. E. Turnbull, are published in the Journal of the Newcastle Farmers' Club. They are evidently founded, as far as the number of animals is concerned, upon the official statistics collected in June of each year. The following table shows the estimated value of the live stock in 1887 and 1889, and the increase in each case within the two years:—

Description of Live Stock.	Value of Farmers' Live Stock in the United Kingdom.		Increase in total value per cent.
	Total value in 1887.	Total value in 1889.	
Cattle	£100,018,452	£120,702,141	20.7
Sheep	38,417,735	50,826,357	32.3
Pigs	6,511,675	6,835,263	5.0
Horses	35,778,875	45,807,720	28.0

Mr. Turnbull concludes that the total value of the live stock of this country, including poultry and goats, was last year £227,771,481, or at the rate of £4 15s per acre, whilst in 1887 it was only £183,806,737, or £3 16s 9d per acre. The increase within the two years has thus been £43,694,744 or 18s 3d per acre.—*Bell's Weekly Messenger*.

PRODUCTION OF GUTTA PERCHA.—The probabilities of a future scarcity of gutta percha has been a subject of concern to the French government, which accordingly sent a scientist (M. Serullas) to the Malay peninsula and the adjacent islands to investigate and report on the matter. The results of some of his labors have recently been made public. M. Serullas states that until some substitute is discovered gutta percha is absolutely indispensable to submarine telegraphy, for other gums cannot be used for the purpose with any practical results, as they do not possess the proper qualities. While good sonandra trees (from which this gum is taken) are to be found only in the Malaysian Archipelago and the Malacca peninsula, bad species grow all along the equatorial lands. Many efforts have been made to use the gutta percha produced from the inferior trees, but they have all failed. It has been found that submarine cables laid in the same waters lasted same according to the quality of the gutta percha used in the covering. The cause of the scarcity of genuine gutta percha is explained by M. Serullas by the fact that the Malaysian natives began by cutting all the trees as soon as they found them in a producing condition. Then, after having thus prevented the production and multiplication of the species, they attacked the youngest trees. Later on they felled trees giving an inferior gutta percha and mixed the gums, which were sold to Chinese merchants, who adulterated and weakened them still more. The extent of that blind destruction is shown by the following figures. In 1845 only 9,000 kilograms (the kilogram is equal to 2 1/5 pounds) of gutta percha were exported to Europe; in 1857 240,000 kilograms were exported. In 1879 the amount sent from Sumatra reached 135,000 kilograms, and from Borneo 1,900,000 kilograms. It was calculated that in order to obtain that amount the natives must have cut more than 5,000,000 trees. In view of this situation France, England and Holland in 1881 sent scientific missions abroad to study the question, and to explore the producing regions of Malacca and Malay Islands. It was discovered that it was next to impossible to find adult trees, and that the situation was nearly desperate. England caused bills to be passed prohibiting the cutting of gutta percha trees, and Holland ordered plantations of them to be made, but the latter only produced species of inferior quality.—*Bradstreet's*.

Correspondence.

To the Editor.

SULPHATE OF COPPER WITH LIME
FOR COFFEE LEAF-DISEASE.

Bonn, Dec. 13th, 1890.

DEAR SIR,—Herewith I beg to inform you that I sent on 27th Sept. 1 kg. sulphate of copper (Kupfervitriol) to my Tientsin estate in Bogawantalawa to try it against leaf-disease, and I send today 1 kg. more for further trial. For the last two years there has been a similar leaf-disease in the vines here, and the sulphate of copper (Kupfervitriol) proves a good remedy against it. I saw last September one part of vines sprinkled with this remedy and next to it one part without. On the first part the leaves were of a fine green colour and the vines healthy; on the other part the leaves were mostly yellow and drooping and the grapes tasted not so good as on the sprinkled part. The vine-owners in most places are now forced by the magistrate to use this remedy.

The composition of the remedy is:

1 kilogram dry sulphate of copper (Kupfervitriol)

1 do do fresh lime (Kalk)

100 liters water.

The 1 kg. sulphate of copper is to be dissolved alone in about 10 liters water.

„ 1 „ fresh lime is also dissolved alone in water, and then these two solutions poured together and the required water up to the 100 liters is poured in.

The lime must be fresh, without sand. The sulphate of copper must be completely decomposed: otherwise the leaves will suffer. The complete decomposition is obtained, if the composition has subsided and litmus paper sprinkled with the composition is not coloured red, otherwise the composition must get more lime-water.

The trees must be sprinkled during dry weather, but not if the young shoots or blossom are coming out. In rainy weather the composition is washed off and must be renewed.

The sprinkling can be made twice or three times in the year: the trees will not suffer, and it is good that the falling leaves be dug in. Sound trees will not suffer by this sprinkling: sound vines here are sprinkled with this remedy to preserve them against infection.

Mr. Bremer on my Tientsin estate in Bogawantalawa can give more particulars, and as soon as I have notice from him that the remedy is successful I shall send to Tientsin a sprinkling-squirtle to operate on the bark, by which one man can sprinkle in one day about $1\frac{1}{2}$ acre with 400 liters of the composition.

This remedy should be tried by all planters who have leaf disease in coffee, and I believe it will be of interest for the Ceylon planters if you notice this in your paper.—Yours truly, H. SIXTUS.

[We should be glad to hear from Mr. Bremer the results of actual experiment with this somewhat potent application if it is not properly reduced by water. We believe it to be quite possible that it may thoroughly clear the bushes to which it is applied of the fungus, just as a mixture of sulphur and lime did. But we fear that in the one case as in the other, the result will be only temporary, and that while the spores exist in unlimited numbers, they will again attack the fresh leafage, the mycelium feeding on the life-blood of the plants elaborated in the leaf cells. The only real hope for the revival of coffee in Ceylon, we fear, is the gradual wearing out and final disappearance of

the pest. Of that "consummation so devoutly to be wished," we fear there is as yet no decisive sign?—Ed. T. A.]

TEA PACKING IN PATENT PAPER LINING;

London, Dec. 19th.

DEAR SIR,—You will probably be interested to hear the result of the sale of the consignment of Elkadua tea sent home packed in the new patent paper lining.

The break in question consisted of 32 chests, 16 of which were packed in the new lining and 16 in the ordinary lead. They were put up at public auction last Tuesday, and both commanded identically the same bid. You will see by the brokers' circulars that the paper is very favourably reported upon. On arrival of the tea I went to Arthur Street Warehouse and had the packages opened before me, and in no case was there one single tear or damage of any kind. The superintendent appeared much pleased at the facilities for bulking and sampling purposes afforded by this new style of packing as compared with lead; for whereas with this latter cutting is necessary the paper is so fastened at the top and bottom of the chest that the insertion of a man's finger is all that is required to undo it without any tearing whatever.

As you may remember I tried a small break in 20lb boxes some months ago which was put up at public auction with precisely similar results as the present lot; but before bringing the matter definitely before the public I was anxious to see how the paper would succeed in the larger packages. This has now been done, and as already shown I think the result must be considered so far as one can see an entire success. It now remains for planters generally to take the matter up. They will naturally ask what they are to gain by the innovation. My answer is simple. To pack a 100 lb. chest with the ordinary lead lining costs say £2 or at the moderate rate of exchange of 1s 6d 3s 0d, while his cost of lining the same size chest with the patent paper would be f.o.b. London nett 1s 4 $\frac{1}{2}$ d

or a saving on each chest of 1s 7 $\frac{1}{2}$ d exclusive of saving in freight &c. Surely this is good enough for most planters: it is for me. Prejudice ever has been and ever will be rife, when suggestions are made to leave the beaten track, and often prejudice proves itself in the right, and in the present instance I confess I have not been without many a question as to ultimate success—not so much as doubting the paper itself, but as to how the trade would take it. In talking to an influential grocer with a large business one day on this point, his reply was "If the tea is all right sir, we don't look much to the packing," and so I say while prejudice may be to some extent wholesome, it may at the same time perhaps be carried too far. In conclusion I can only say, that in bringing this new packing before the planters and merchants in Ceylon, I am calling their attention to an article which I have thoroughly tested myself and which I think they will find, if they try, that it will achieve the point arrived at, which is to reduce materially the price of one of the most expensive items in the cost of our tea, and that this will be done thoroughly, consistent with maintaining the quality of the tea itself.

Mr. Ambrose of Elkadua will I feel sure be pleased to afford any information as to packing &c., and consignments of the paper can be made

direct from this office or subsequently can be obtained from our Agents in Colombo.—Yours faithfully,
J. M. MAITLAND KIRWAN.

P.S.—Since writing the foregoing, I have given instructions to de-patch of a consignment of the paper to the Colombo Agents, where it can now be had.
J. M. M. K.

CACAO CULTIVATION IN CEYLON.

SIR.—In looking over the report of the Lanka Co. I notice that their cacao estate gave a profit during the 1st year of about 25 per cent on the amount this property stands at in their books.

What does your correspondent "Eldorado" think of this?

I do not know what return on capital is considered to constitute an Eldorado, but I fancy 25 per cent would be considered by most of the shareholders in the Company
ELDORADO ENOUGH.

SIR.—Evidently our estimable friend "Eldorado" is not interested in the Lanka Co., or he would not attempt to traverse my suppositions as to the feelings of shareholders. I have nothing to add to my previous letter on this point and nothing to retract. But does he in all seriousness expect a cacao estate not yet in full bearing to pay 25 per cent on its cost calculating this with compound interest at 8 per cent? It would appear indeed that there was a time when some such fantastic dreams floated before his heated imagination. How I wish, dear "Eldorado," that we had for-gathered in those happy days of your:

"When all your geese were swans, lad,
And every lass a queen!"

We should not have been long. I'll go bail in un-earthing some confiding capitalist, and this is how we would have put it, *n'est ce pas mon ami?*—"In other producing countries" (there is a judicious vagueness about the phrase which lingers on my palate; if he had remarked that the yield in Trinidad, say, was less than we stated, we would have fixed him with Venezuela or the Celebes Islands).—"In other producing countries" the average crop is not less than 6 cwt. per acre with a primitive cultivation. In Ceylon, where tropical agriculture has been thoroughly studied and developed to a point of perfection unknown elsewhere, we shall be well within the mark in placing our production at 10 cwt., which, cured as it will be with the latest inventions of our XIXth century civilization, may be relied on to fetch 100s per cwt. all round. We have, then, a gross return of £50 per acre, or allowing £5 an acre for a liberal and scientific cultivation, a net return of £45 per acre showing an income from the 500 acres prop-erty we have in view of £22,500 per annum.

"To a well-informed man like you, sir, it is unnecessary to point out that the variety of cacao chiefly grown in Ceylon is exactly the same as that in "other producing countries" and that it is entirely planted in the finest virgin soil, no old coffee land whatever having been rushed into this product so that the yield of "other producing countries" gives us an accurate basis of comparison in every way, and we have only increased it from 6 to 10 cwt. on account of the well-known advantages which our island possesses.

"There are those who will tell you that a considerable proportion of the land appearing in the Ceylon Directory as under cacao ought never to have been planted, that practically the whole crop comes from a much smaller average, and that planters in their dislike of a "primitive" cultivation made the most fatal mistakes in the early days of the enterprise—do not, my dear sir, give any credence to these malicious statements.

"In conclusion, Mr. Moneybags, we cannot too strongly urge on you the necessity of appointing two thoroughly experienced managers one for the London office and one for the estate. We believe we are in a position to name to you two parties who would be prepared for the nominal salary of £2,000 a year each to undertake the onerous duties of those posts, and we are confident that whatever your position might be at the end of a few years, they at least would find it

ELDORADO ENOUGH."

J. S.—Joking apart, if your correspondent started

with some such grand ideas as the above I do not wonder that he has been disappointed, and he has my sincere sympathy. I believe however and shall continue to do to till convinced by stronger argument than he has yet advanced or by the inexorable logic and fact that a well-chosen, carefully cultivated cacao plantation in Ceylon offers as good an opportunity for remunerative investment as any other product in the island. Because mistakes have been made, which we all know is the case, is no reason why mud should be thrown at the whole enterprise.
E. E.

CACAO CULTIVATION.

DEAR SIR,—Some weeks ago, one of your correspondents, who seemed to be disappointed with the results of the past few years, quoted figures from your Directory showing that the average yield of cacao was only 1½ cwt per acre in bearing. Another correspondent, more fortunate, gave his returns as 2 or 3 cwt. per acre, but no higher figures have been quoted.

As the total exported includes, of course, all the cacao stolen from estates and sold through native traders, actual return to proprietors must be very low indeed. At a moderate computation the quantity stolen may be reckoned at ten per cent; many individual estates losing very much more.—Yours faithfully,
POWDER AND SHOT.

WIRE SHOOTS.

Dec. 20th.

DEAR SIR,—"Shoot" 's letter of 10th inst. asking if "a wire shoot can be worked at a gradient of one foot in seven from point to point with a road tracer" has been drawn to my attention, and my opinion is that a shoot can be made to work at such a gradient.

If the land between the two points is of a similar gradient, in my opinion it would be necessary to have intermediate supports to carry the wire to prevent it from bagging. If the shoot is not a very long one and wanted to cross a ravine or gully, intermediate supports would not be required.

On large tea estates where transport of leaf and fuel from a higher to a lower elevation is an expensive item, wire shoots will by-and-by, I have no doubt, become as common as spouting which was found so useful in the coffee days.

These shoots can be made to tap the different fields of the estate *en route* by a simple arrangement of stunts at the various receiving houses or turnings, so that bags of leaf and billets of wood will be seen flying through the air like miniature trains zigzag fashion from the top of the estates to the factories at the bottom. Where estates are not very steep, and as managers acquire a thorough knowledge of regulating the loads, they will, later on, where the gradients are easy, find it perfectly safe to slip the small pulley with pocket brake and cord they carry for the purpose on to the shoot, and without any exertion descend from any one point to any other of the estate along the line of wire, at the rate of 10 or 12 miles an hour.

With so many able engineering firms in the country, I have no doubt that when the demand arises for the wire shoots to do as I have tried to describe, they will be made and guaranteed to work satisfactorily.
—Yours truly,
OLD HAND.

ON FORKING TEA LAND:—NO. 1.

DEAR SIR,—I see no difficulty in reconciling the deep-hoeing system of Assam with the danger of the same operation on Ceylon upcountry estates. All organisms adapt themselves to their environments so long as these minister more or less to their requirements. In proportion as these are favorable the plant (in the case we are considering) flourishes, or, in their entire absence, dies. If the humus and other plant food be equally distributed through the soil, however

sparse, down to two or three feet, the feeding rootlets will follow it in the same degree. On nearly flat land, as I believe is the case in India, the rain moisture tends to sink in rather than flow off, and this mechanical action having been always in force has carried the solubles with it to a depth below the surface; hence the necessity for "deep hoeing" to reach the feeding ground of the plant. But where, as on our hill-sides, the true soil is all on the surface, getting thinner and thinner every year as the rain rushes rapidly off, the feeding rootlets confine themselves to those few inches; and if you destroy them all round the tree at the same time that you prune the top, only a climate like Ceylon would prevent such drastic treatment, killing the plant outright. There are roots which find their way down to great depths, as may be seen in any deep cutting; but these are generally single feelers, or explorers after food and moisture, and only develop a network of feeding-roots at their ends when they find it. This, I think, is their function; but on old coffee land in Ceylon the surface only for a few inches down is absolutely filled with fibrous roots. I have no doubt there are fields of tea in Ceylon which can be as deep-hoed as in Assam, but not on our steep hill sides without the utmost care. In this respect each field must be treated as we find it.

But our great sheet-anchor is climate. I remember years ago turning my back upon Dimbula (where just before the great coffee boom I could have bought several estates cheap) frightened at the shallowness of the soil compared to my own Uva. I lived long enough to see those estates bear large crops of coffee, and they are flourishing still. Even where all surface soil is gone, given healthy trees established and roots well covered, the climate alone will give 200 lb. an acre. But you will find all the feeding roots at the surface, and where is the cause for surprise that if these be all destroyed the tree suks? Top-dressing would be enough if we could keep it from being washed off, and in suitable places I have seen very good results from this with no digging at all.—Yours, R. W. J.

[In the portion of Dimbula we are acquainted with, the soil is deep. We have seen the hoeing process in full operation on the hill-sides of Darjiling, which are as steep as the Ceylon mountains. In a description of work on a tea garden on the northern spurs of the Himalayas, too, we find such passages as the following:—

"Right and left the trim round bushes run in exact order, the rich brown earth turned up between them.

"Many of the coolies seem to think clothes superfluous luxuries; for they are attired in a single coat and their own long bare legs. How distinctly one can see the sinews work under the smooth brown skins, as they raise the heavy hoe high in air and then come down with a thud, detaching a heavy clod of earth from a neighbouring tea bush.

"Presently the sahib has registered the names, sounded the depth of the digging here and there, chatted with the Jemadar, and then turned leisurely homewards—leaving behind him the spruce tea bushes, the bending supple figures, all enclosed in ranges of grey-green misty hills, topped by the unmelting snows."

—Ed. T. A.]

FORKING TEA :—NO. II.

Dec. 22nd.

DEAR SIR,—I have been very much interested in the letters about forking tea. I have little personal experience in forking, but I have a wider experience in regard to the forking carried on on neighbouring estates. I have always been against the system of forking as carried out in Ceylon; and I did not suppose that so many men of experience were of the same way of thinking. I only forked 20 acres about 5 years ago, and it threw the tea back for a couple of years. The 20-acre field was a light soil, and deep forking properly carried out is beneficial only on clayey soils. A neighbour of mine has had very marked success in forking, but the soil on his estate is largely composed of clay and he simply loosens the clods without turning them over.

The system of digging in India is quite different from that carried out in Ceylon. In India the digging is done with boes, and in Ceylon it is mostly carried out with forks 18 inches long in the prongs, and I am of opinion that the leverage applied by forks with such long prongs shakes the bushes to their very foundations. I opine that forks with prongs only 9 inches long would show quite different results, and a light digging applied with such forks in October would conserve the rains of November and December which come in heavy plumps and 75 per cent of which is lost by running off the soil.—Yours faithfully,
J. F. R.

CACOA CULTIVATION IN CEYLON.

Kandy, Dec. 29th.

DAR SIR,—A correspondent in your Supplement of 23rd wants to know what "Eldorado" thinks of the report of the Lanka Company concerning cacao.

1st. The return of crop is under 2 cwt. per acre which in face of the fact that in other producing countries the average return with a primitive cultivation is 6 cwt., is a poor return, although above the average of this Island.

2nd. In your Directory of 1883-1884, Yattawatte estate is put down as having 435 acres of cacao in cultivation. In the last report there are only 371 acres, or a decrease of nearly 15 per cent even if no new land since then has been opened in favoured spots.

3rd. The 25 per cent profit which your correspondent takes to be the result of the Lanka Company's report, is by no means the correct one from a financial point of view which has to be worked out allowing 8 per cent compound interest per annum on capital invested. Had your correspondent the figures to make such an account he would find that he has no reason to be sanguine nor to add "enough" to EL DORADO.

COCONUT CULTIVATION BEYOND THE DEDURUOYA.

Rajakadalawa, Chilaw, Dec. 31st.

DEAR SIR,—In your account of the coconut industry of Chilaw, there is an error which in justice to another should be pointed out. The first coconut plantation opened up north of the Deduruoya river in this district was at Sittamadag and is owned by our genial unofficial Police Magistrate and leader of the Chilaw bar, Mr. Thos. Cooke. So this gentleman is the "pionser."—Yours faithfully,

GEORGE D. MILLER.

CEYLON TEA EXPORTS IN 1891.

Strathellie Tea Co., (Ltd.), Nawalapitiya, Jan. 1st, 1891.

DEAR SIR,—I am today reminded of my promise to send you my computation of probable total exports of tea from Ceylon during Commercial Season, which is now made concurrent with the Calendar year.

My figures for the Fiscal Year ran, you will remember, to 52,000,000 lb. Taking 25,000 acres as giving their first returns and a reasonable increase from say 30,000 acres (mostly in the younger districts and Uva) I arrive at 54,000,000 as the figures of probable exports, thus:—

70,000 acres at 340 lb. per acre =	23,800,000 lb.
45,000 " 300 " "	13,500 000 "

PATENT LEAD-PAPER.

Gartmore Estate, Maskeliya, Jan. 2nd.

DEAR SIR,—Allow me as representing the owners of “Clark’s Patent” lead paper to reply to your editorial on the subject of Lead Lining for Tea Chests, appearing in your issue of 30th ulto.*

The reports that you say have reached you regarding the satisfactory results of shipments of tea made in “Clark’s Patent” lead paper are correct, and I would ask you still further to suspend your judgment until I am enabled to find out who has been using worthless imitations. This paper lead has been protected by the Ceylon Patent No. 323 of 1889, and the application of it as a lining for tea chests &c. by the United Kingdom Patent No. 9,099 of 1889. I have a list of the shipments of tea made in chests lined with this material, and in no single instance has any fault been found with it, but, on the contrary as the enclosed list of testimonials will show you (from utter strangers to the patentee and from leading brokers in London).

All the “Clark’s Patent” lead paper hitherto used has been prepared in the island, and from Messrs. W. and R. Johnston’s Tea Lead ordinarily used for packing tea—none of it having been under 4 oz. weight. If your London correspondent’s statement as to the perforations he noticed in one sample shown him, is correct, I shall feel obliged if he will furnish me with further particulars regarding the parcel of tea in which it was used. In his previous letter, however, I think, he made no mention of the lead having been lined with paper, or I should have taken notice of the matter at the time.

It must not be accepted as a fact, what your London correspondent only gives as an opinion of a London tea taster. His statement is ambiguous; but if he infer that the sample of tea referred to was packed in Clark’s Patent Paper Lead, I challenge the correctness of his opinion. I should be glad to know more about it, the name of the estate, and the vessel it was shipped by.

Your London Correspondent after condemning all paper lead linings for tea chests proceeds to describe a “new discovery” as follows:—“The working of it is of quite a distinct character from that of all the so called lead paper, hitherto tried. There are manifestly, from their feel, of paper coated only with lead, while this is equally manifestly of lead, only lined with paper. There is therefore a very sufficient and capable distinction to be drawn between their respective characteristics.” The above is a very fair description of “Clark’s Patent” Lead Lining! In the specification of the Patent the description runs:—“a lining of paper, cloth, calico, or similar material, or one or other of the combined &c., &c., to the lead used in packing tea.” From the above you will see that your correspondent has had worthless imitations brought to his notice. Clark’s Patent paper lead is manifestly dearer than the ordinary lead, being made from it, but it can be prepared at very little extra expense, and the advantages of it are beyond doubt. The lining is considerably strengthened, and not so liable to be damaged when packing the tea, or afterwards in bulking or sampling

in the bonded warehouse at home. It further preserves the tea, and also prevents the actual contact of the tea with the lead which is considered by many medical men injurious to health. So convinced am I that the lining is a success, and a real gain over the trifling cost, that not a single package has left my factory not lined with it. Two sample boxes packed and kept in store for a year were, a short time ago, sent to Messrs. Gow, Wilson & Stanton for their report &c. They reported that it arrived “in excellent condition” and sold for 1s 5d. and 1s 4d. per lb. respectively. The parcel of Gartmore tea which sold for 10s 6d. per lb. in London, the other day, was similarly packed.

A shipment of the lead paper has been received from England, by the agents of Clark’s Patent, the Colombo Commercial Company, Limited; but it has been so badly prepared, and packed, that it has been withdrawn from sale. Suitable paper, of the correct width and any length, can be procured from the Colombo Commercial Company, Limited, and authority to use it or lead of sufficient thickness and good quality,—Yours faithfully,

T. C. ANDERSON.

SULPHATE OF COPPER FOR COFFEE AS RECOMMENDED BY MISS ORMEROD.

SIR,—Can you or any of your readers inform me through your columns, where this can be purchased in Ceylon and what its cost about is?

Also how it ought to be applied to coffee suffering from green bug and what season is the best—in sunny, cloudy or rainy weather; also if it should be applied just before the attack is renewed or only after it has made its re-appearance—i.e. is it simply a deterrent or a potent extinguisher?—Yours faithfully,
O.

P.S.—There are fine fields of coffee in Haputale, and every effort should be made to preserve them—who shall say if they will not eventually prove the nucleus for a renewal of the coffee enterprise in the hill districts of Ceylon. I could instance at the present moment one case of a field of over 100 acres bearing at the rate of cwt. 8 (eight) per acre. How will this compare with profits from tea at its best, say with Mariawatte 100 acres?

[This Uva correspondent will find some of the information he wants in Mr. Sixtus’s letter on page 573. Certainly, every effort should be made to fight the enemies of the good coffee remaining in the country. Let our correspondent work out the profit-reckoning between coffee and tea in bumper crops and send us the result.—Ed. T. A.]

TEA LEAD VS. PAPER LINING:

January 10th:

DEAR SIR,—Mr. Maitland Kirwan in his letter advocating the use of, or a trial given to, his “patent” paper, starts on the supposition that the ordinary lead used, costs on the estate R2 per chest or 3s stg. as against his paper costing 1s 4½d in London, or a saving of 1s 7½d per chest.

My last purchase of lead was one box at R13.50 per cwt. in Colombo. 5 oz. lead which is now generally used in preference to 4 oz. lead, gives 28 sheets to the cwt., or at above price costs 48 cents per sheet. It requires a little under 1½ sheet to line a full chest 24 by 19 by 19 (outside measurement), so that the lining with 5 oz. lead costs in Colombo 72 cents. In England I have no doubt, 5 oz. lead can be had under 15s per cwt. f.o.b.

* See page 541.—Ed. T. A.

but taking it at that price, the lining would cost 9½d per chest, as against Mr. Maitland Kirwan's paper at 1s 4½d. This is not good enough for Ceylon planters. However, it may suit the inventor.

Your proposal to have a Committee of the Planters' Association to enquire into inventions and new processes in the manufacture of tea, &c. is an excellent one, and I trust it will be adopted. The Committee should first of all agitate for a reduction of the cost of Patents. At present it is prohibitory.—Yours faithfully,
PLANTER.

COFFEE LEAF-DISEASE AND SUGGESTED REMEDIES.

Bombay, January 7th.

DEAR SIR,—I have read in your paper of November 16th a letter from Messrs. W. and A. Gilbey under the heading of "Enemies of Coffee and Remedies,"* recommending solution of sulphate of copper as the best means of destroying the pests which beset the trees.

The remedy suggested is certainly an effective one, but the method of applying the solution is so expensive and difficult that few would resort to it on coffee estates which are hilly and steep.

If 30 gallons of this solution are necessary on an acre of vines, it would, at the rate of 2 gallons per tree, necessitate about 2,400 gallons on an acre of coffee. Application of the solution by means of a force pump would cause a deal of wastage, for in order to saturate a whole tree efficiently 2 gallons of the solution would not count for much.

What is necessary is a simple and inexpensive remedy that would lay hold of these pests and exterminate them. To find this out I have been trying different modes of destroying them, viz.: 1 by solution of gum arabic, 2 rice starch, 3 pipe clay, 4 black clay, 5 Mooltan clay and 6 red clay. Each of the last four substances was by itself mixed with water and made into a paste. A paste of each of these four was also separately prepared with solution of gum arabic and rice starch, making in all 10 sorts of pastes. To test the adhesive properties of these pastes, I applied each of them (with the finger), on leaves of different sorts, gathered in a flower garden, and while watching the process I found that each leaf after about three hours of application began to curl up, and cracks became visible half-an-hour later in the surface of the paste applied which fell off in pieces on mere touch, leaving no trace of it on the leaves, which resumed their former shape immediately after. The result arrived at in all the ten cases being the same, I would recommend the last of the ingredients, i.e., red clay, which can be had in large quantities from every coffee estate without any outlay. The clay should first of all be rid of all sand and gravel which it is generally found mixed with, and then made into a paste of thin consistency say that of oil paint ready for application, and applied on the back of the leaves gently with the finger, taking care not to rub it hard.

I may state that the experiments I tried were on healthy leaves, and not on those attacked with the bug or other disease, as I could not procure any of such; but I believe the paste, if it is applied to leaves attacked by the bug &c., would fall off sooner by the movements of the insects which they would be forced to exercise. To prevent this early falling-off of the paste, country soap soaked in water to form a paste of some consistency, and mixed with equal part of red clay paste, would answer well, and adhere to the leaves for about 6 hours. An application of simple soap paste

minus the red clay would also give the same results, but for the sake of economy I would recommend a mixture of both soap and clay paste.

Red clay should be prepared for paste by soaking it in double its quantity or more of water in a large tub, and let it remain for a time without stirring. It is to be well stirred with hand afterwards, and filtered through thin cloth, and allowed to settle, which being accomplished the water is to be gently drained off and the residue will be the paste required.

The country soap I have alluded to is imported into Colombo from Negapatam and can be had in the bazaar. Large tubs and galvanized iron buckets are the only expensive items necessary for the purpose, the rest being manual labour which any efficient estate manager would be able to furnish himself cheaply.

I have forwarded through a friend, who left here for Colombo on the 2nd instant, two packets to be handed over to you, one containing samples of the different sorts of clay and soap, as well as soap and clay pastes; the other two leaves, one anointed with soap paste, the other with soap paste and clay combined. These packets should have reached you by about the 6th inst., and the adhesiveness of the paste on each of the leaves must have been observed by you.

If these applications do not prove of sufficient efficacy to destroy the bug, &c., I would recommend a strong solution of alum (which is cheaper and not dangerous to handle as compared with sulphate of copper), to be added to any one of the two pastes I have above described. What the strength of the solution of alum should be I am not in a position to state, and leave it to the experience of those better able to form an idea on the subject. Alum could be procured in Bombay at about R4 a cwt.—Yours &c.,
K. H.

[This letter, the experiments recorded and the substances of which specimens have been sent are interesting, but surely our correspondent cannot be serious in writing of the application of clay, starch, soap, &c., by hand! The expense would be prohibitory. The difficulty in regard to scale insects, and especially in dealing with the coffee fungus, does not arise from inability to kill the pests actually on bushes. The problem to be solved is the extermination of the insect eggs and the fungus spores. The soap and the clays can be seen at our office.—ED. T. A.]

CACAO CULTIVATION IN CEYLON.

Kandy, Jan. 14th.

DEAR SIR,—Your jocular correspondent "Eldorado Enough" asks in your issue of 8th,* "But does he ["Eldorado"] in all seriousness expect a cacao estate, not yet in full bearing, to pay 25 per cent on its cost, calculating this with compound interest at 8 per cent?"

Let me put my answer on a firm basis, for he seems disposed to pierce it with his wit. Being given an estate of upwards of ten years old, of which 15 per cent has gone out, I do expect it to give 25 per cent on the actual capital which has to be rapidly amortized, considering the great many blanks there are in the lottery called "cacao cultivation."

Would the facetious "E. E.," if the coffee enterprise, starting under the same conditions as he surmises that I based my calculations upon, had obtained the results he mentions—would he, I ask,—have had the audacity to suggest his receiving £2,000st. as the family physician of Mr. Monsybags?

No cultivation, except rubber, has offered such disastrous results in this island as

* See page 461.—ED. T. A.

* See page 574.—ED. T. A.

that of cacao: after six most promising years during which the trees flourished under all conditions, a sudden mysterious scourge as bad if not worse as the coffee disease has devastated the most flourishing plantations, destroying one-third of the trees and leaving the balance in such a lingering condition that the very small average production in place of rapidly increasing has remained stagnant and has been reduced last year by 3,000 cwt.

If the crop comes from a much smaller acreage as the humorous "E. E." asserts, the amount of land which the scourge has laid bare is increased, which does not better the aspect of the cultivation.

Ingenious "E. E." has forestalled my intention, but leaving Trinidad and the Celebes apart, does he know that the crop of the Puerto Cabello* District in Venezuela, chiefly sold in France and Spain, comes up to the average I mentioned (6 cwt.) as also the one of the Catholic Republic of Ecuador, the export of which has varied from 310,000 to 340,000 cwt. a year for the last decade, besides the local consumption which is very general amongst the one million inhabitants of Spanish descent.

The pleasant "E. E." speaks of the "fatal mistakes in the early days of the enterprise." If he would clearly point these out to his ignorant brethren they might get up a subscription perhaps equal to the snug sinecure of £2,000 for which he hankers.

"Ne faut-il pas essayer pour réussir?"

If exposing blunders is synonymous to throwing mud, I prefer doing this than to bolster up a languishing industry to make it appear an

ELDORADO.

[Does our present correspondent not allow that Ceylon planters of cacao having discovered the proper management of shade, are in a better way now than some years ago? We were recommended the other day to visit Gonambil as an example of the great improvement effected in cacao plantations.—Ed. T. A.]

TEA LEAD vs. PAPER LINING.

January 16th.

SIR,—I do not want to find more fault with "Planter" than I can help, because he has done us a service in commencing the ventilation of this subject. His quotation of Colombo price of lead however at £13 50 per cwt. is not quite fair. I paid last month £300 for a ton, and see that another firm charged £310 for the same lead mentioned by "Planter." This would make 83s per chest instead of 72c. A committee of enquiry into inventions would be of great service.

B. L.

TEA IN ASSAM.—At the close of last year the number of tea gardens borne on the District registers in Assam was 868. The number of gardens opened during the year was eight, and three were removed from the registers, of which one was closed and two amalgamated. The area of land held by tea planters is said to have increased from 955,499 to 1,000,665 acres. This increase, appears to have been largely due to revised figures of area having been submitted by some gardens, and it is impossible to tell what the real extension of tea planting amounted to.—*M. Mail*, Jan. 6th.

*The apostle of Tropical Agriculture "Peppercorn" who occasionally imparts instruction to the Ceylon planters, recently wrote under a misapprehension that the earthing of cacao was easily detected in the market and considered a fraud. It will surprise him to learn that this highest priced cacao is always unmistakably earthen. In France and Spain I know the earthen kind generally to be preferred by manufacturers. In Bordeaux the price ranges from 175 to 190 frs. per 50 kilos of the Puerto-Cabello cacao at the public sales. (£7 to £7 12s. per cwt.)—E.

HYDROCHLORATE OF COCAINE.—The Madras Government is not at present prepared to institute any experiments in the manufacture of this article as suggested by Dr. Macnamara.

COCONUTS AND CINNAMON.—Kadirapa, Jan. 3rd.—There has been no rain since the 12th of last month, and a nasty dry wind is blowing, inducing colds, fevers, rheumatism and aches generally. This state of things and a bud with blossom just appearing, makes peeling of cinnamon difficult. Some estates have already stopped work and the others will soon have to follow. The rainfall for 1890 is 53.46 inches, being 31 inches less than the average for the previous four years. This does not look well for cinnamon and coconut crops next year, and both I fear are bound to be much below the average.

THE PROFITS ON CATTLE SPICE.—The profits from the manufacture of cattle food, as shown in the prospectus of a well known Cattle Spice and Poultry Food Company, are almost on as liberal a scale as those drawn from patent medicines. A business which manufactures a ton of stuff for £6 6s 4d, and sells it for £27 9s 2d, is the sort of thing everybody would like to be in. But, apparently, the opportunity is not to be given to many to share in the profits, for, though £60,000 of the capital of the company is nominally offered to the public, more than half of it is to be applied for by the directors and their friends.—*Financial News*. [The above we reproduce for reasons which will be obvious to the reader. Such profits are extortionate.—S. D. & Co.]

UTILIZING THE POWER IN WATER MAINS.—The *New York Engineering Record* says:—"J. Gibson, of Ayr, Scotland, proposes to utilize the power in waterpipes under pressure by forming a by-pass or junction with the water main, through which the whole or any part of the water in the main may pass. In this by-pass is placed a spiral motor, the spindle of which projects through the elbow of the by-pass, so that it can be connected to a machine, to be driven without any loss of water. It is proposed to place suitable stop-valves in the supply-pipe and by-pass in order to regulate the quantity of water passing through the by-pass, and also to permit of repairs to the motor being made."—*Bradstreet's*.

BINNY'S COFFEE WORKS.—There is no localised centre of industry so busy at the present than the well known and long established Coffee Curling Works of Messrs. Binny and Co., situated close to the Cantonment Railway Station. Operations are in full swing just now, and the inside of the buildings afford a pleasant and practical illustration of successful work carried out in a systematic and well conducted manner. Coffee from all parts of the Mysore Province—and outside too—is pouring in, and the various provisions of drying, peeling, sizing, sorting, garbling and packing for the home market are carried out with a precision and arrangement, entailing an order and supervision, which reflects much credit on the establishment. Many years' experience in these matters have led to the introduction of many improvements in the machinery and the internal arrangements of labour which have resulted in the curing from Binny's Works being classed among the best seen in the London Market, and Mysore coffee has during the past seasons maintained selling figures which must be very encouraging to all concerned. The coffee works give employment during the season to over one thousand hands, and from the liberal treatment accorded to the operations, we believe, that while it is sometimes difficult to get labour in the open market the coffee works never experience a dearth of hands.—*Bangalore Spectator*.

LORD DERBY ON TECHNICAL
EDUCATION.

The annual meeting and distribution of awards of the Liverpool School of Science and Technology took place on September 25th in St. George's Hall, under the presidency of the Mayor (Mr. Thomas Hughes). There was a large attendance.

The Chairman mentioned that Lord Derby had given further evidence of his interest in the school by giving £200 to provide two more special prizes.

Lord Derby, who handed the awards to the successful students previously, delivered an address on technical education. He said—Gentlemen,—You have asked me to attend this meeting and to deliver the prizes earned within the year. That is a duty which I undertake with pleasure, because, having watched from the beginning this School of Science, and I may add, having been one of the earliest contributors to it, I am satisfied it has done good and useful work in the past, and that it is capable of doing much more if only adequate support be afforded. It has lived as yet less than 30 years since its foundation, in 1861. Its progress has been steady and not slow. From 28 students in 1865 the numbers have steadily increased to 905 at the present date. In all since the opening it has been attended by 12 916 students, and the total cost has been £26,700, being an average of £920 yearly. I am told that our students have been mostly, though not exclusively, taken from the artisan class. Of the practical results of the school we have no cause to be ashamed. It is never possible to state them in an entirely satisfactory way, because the exceptional success of an individual here and there proves less in favour of the training which he has received than a high average of attainment which does not so easily admit of evidence in a statistical form. I am told that very many of our students are employed in all parts of the world as marine and civil engineers and builders; that the winners of the prize which you have been kind enough to call by my name are nearly all in responsible and important positions. One is a manager of the Mersey Forge. One is an expert in the Patent Office. One is an architect and surveyor to the Board of Works in London, and others are in various capacities which I do not state to you in detail, because the list would be too long. The school has suffered, like most institutions, from "that eternal want of pence which vexes public men." I am told that its space is utterly inadequate, and that increased accommodation is urgently required. But there is some comfort, on the other hand, to be found in the prospect that when the Technical Instruction Act is in operation, as it is expected to be, the corporation will come to its assistance, and meet what is no doubt an increasing and urgent popular demand. (Hear, hear.) Of the practical utility of a school of this kind you have heard enough, and it is needless to prove what nobody doubts. The necessity of technical instruction, if our workmen are to hold their own against foreign rivals, is a common place of the platform; but we must not forget that there are other objects to be served, less pressing—some would say less practical—yet in their ultimate results surely not less important. You will not expect from me, who can claim no relation to science, except that of a respectful admirer and in some very humble degree a student, a disquisition on the use and value of scientific training; but some facts are clear, and need no special gift of observation to detect them. Ours will be remembered as pre-eminently the age of science, I might say throughout the civilised world, but more especially in England. In literature our age has done well, but we can scarcely, perhaps

claim to rival the generation that gave us Shakespeare and Bacon. In politics we cannot judge the work of our time. We are too near it, and we have not seen the end; but the changes of our day, many and important as they are, can scarcely be set alongside the Reformation of the 16th century, or the civil wars and revolutions of the 17th. I speak here not as judging any of these movements, but only as weighing their relative magnitude and importance. In regard of wars and of conquests, happily we have little in the last 50 years to look back upon. But the triumphs of applied science in our day are the veriest commonplace. To dwell upon them would be absurd, and in such matters one success leads to another. More than that, spread as civilisation is over the whole earth, there is no fear of such a reaction of barbarism and ignorance as that which followed the decadence of the Roman Empire. Whoever wishes to see an admirable summary, at once concise and comprehensive, of scientific progress in the last half century will find it in a little volume by Sir John Lubbock, published this year, which has no fault except the rare one of too great brevity. In this one respect I think we may praise ourselves without fear of seeming ridiculous to the next generation. Our successors may excel us as writers, as politicians, as soldiers; they may surpass even the industrial energies of the present time, but it is not likely—it is scarcely possible—that in the region of science, the 20th century should witness advances greater than, or as great as those of the 19th. (Hear, hear.) The general experience of the world hitherto has been that brilliant but brief epochs of advance have been followed by long intervals of stagnation, and sometimes even of retrogression. Retrogression is not likely, as I said just now, but stagnation is quite possible. There is one phrase much employed when people talk on these subjects, which, to my mind, contains a fallacy. I mean the common phrase of popularising science. Now, to popularise science is simply impossible. You may give everybody an opportunity of learning, but not everybody will or can take advantage of it. You may popularise the results of science, but that is quite a different matter. As an old saying runs, there is no royal road to mathematics. Anybody could cram up, with the help of an average memory and of easily-acquired handbooks, a summary of what has been done in astronomy, in chemistry or other science, but when that result is accomplished he will be very little nearer to any real gain which science could bring to him. It is only labour and perseverance, added to natural capacity that can give a scientific mind. Fortunately, not everybody is required to have it. I have no doubt a man may be a good workman, a good clerk, a good man of business, and discharge all the duties of life in a satisfactory way, although he believes that the sun goes round the earth and that the moon and stars are lighted up at night to enable mankind to see their way. We cannot all be what the hideous slang of the day describes as "scientists," any more than we can all be poets; but I think the answer was a good one which was given long ago to the objection, "You want to make your pupil Jack of all trades, and master of none." "No," was the reply, "I want him to be Jack of all trades, and master of one." Nobody is required, nor, indeed, is it usually possible to make a serious study of more than one profession; but, just as it is good to have a taste for books, though we may not wish to become authors, and to have a love of pictures, though we may never intend to paint, so it is desirable to have a

sympathetic insight into studies alien from our own. Time is not wasted in that way, for there are very few people a good deal of whose time does not run to waste, and when they talk of want of time, it is really, nine times out of ten want of energy that they mean. No doubt, much labour is monotonous and wearisome, but those who have tried the experiment will tell you that, given a reasonable degree of bodily health and mental activity, the best repose from monotonous labour is to be found in change of occupation, not in absolute apathy and vacancy (Hear, hear.) and there is one reason why, in my judgment, some tincture of scientific knowledge is desirable for every educated person. The result may not be great, but the process is valuable. An entire absence of the scientific spirit is no doubt compatible with brilliant talent and high distinction. You do not find fault for a deficiency of that kind in a novelist a poet, or a writer of light literature, but it is a deficiency notwithstanding. If you ask me what I mean by a scientific spirit, I think I know, but I must confess that it is more easily described in vague and general terms than precisely defined. I mean by it, in the first place, a habit of accuracy and exactness in matters of fact. It matters very little to an orator that his facts should be carefully verified—sometimes he is wise in abstaining from the attempt but a calculation or an experiment must inevitably fail if there is a want of accuracy anywhere. In the next place, I mean that temper of mind which seeks for conclusions, but does not jump at them; which is equally opposed to the stupid incredulity of ignorance, refusing to accept any idea which is not familiar; to the reverential credulity, which accepts as true any statement coming down from old or high authority; and to the careless indifference which, so long as a theory looks and sounds well, and especially if it flatters some previously existing feeling or prejudice, does not care on what foundation of reality that theory rests. (Cheers.) Ours is an age when the half-educated are a power in the world; when more men than ever before reason and speculate on difficult matters, and when, consequently, there is all round us and on all subjects a quite bewildering amount of loose talk and inconclusive argument. (Hear, hear.) More than that there are fashions in opinion, and you constantly hear it said, "Oh, yes, that was the way people reasoned 20 years ago, but it is quite out of date now." Well, such fluctuations must exist in what are called practical affairs, but that is all the more reason why it is good to have to do with theories that cannot go out of fashion, and with trains that are absolutely incapable of being affected by the ebb and flow of what is called public opinion. Else we should be apt to rest in the conclusion that nothing is true and nothing false, and that the best thing to do is simply to accept the current ideas of the day, which, indeed, from the point of view of personal interest, very likely for most people is the best thing. That the world is governed by laws which we did not make and cannot abolish—laws which will operate whether we recognise or ignore them, and which it is our wisdom therefore to study that we may obey, and in obeying utilise them—that is what I take to be the outcome of scientific teaching (cheers), and if anybody thinks that a useless or an unimportant or unnecessary lesson I do not agree with him. (Hear, hear.) Something else science, rightly understood, will teach us to know—what it is that we can hope to know and to understand; and to recognise how little that is, and how much lies, and probably always will lie, beyond the reach of our faculties. One word only I will add—that, having known

men of many professions, I should say, as far as my observation goes, the happiest lives are those which have been devoted to science. Every step is interesting, and the success of those who do succeed is lasting. What general, what orator, what statesman, what man of letters can hope to leave a memory like that of Darwin? An invalid in health, a man who seldom stirred from home, a man until his later years very little known to the outer world, but who, from his quiet study, revolutionised the thought of Europe, and will be remembered as long as Newton and Bacon. If fame be ever worth working for—I do not say it is—that kind of fame is surely, of all, the most durable and the most desirable. (Cheers.) Well, I have perhaps digressed from our proper subject, for it is not likely that we have a future Darwin in this room, but it is no exaggeration to say that, as a rule, no man who has taken to science as the work of his life regrets the choice, while men who have done important work in other lines feel like Renan, who, at the height of his literary eminence, tells us in his autobiography that he has often regretted that science, rather than historical research, had not been the object of his early pursuit. Nothing remains for me now except to offer to this school of science my sincere good wishes for its future prosperity, and to you, the successful students who are attending here to receive your prizes, my congratulations on the good beginning which you have made, and my hope that neither early success nor possible temporary failure may induce you to desist from those steady, unobtrusive, unceasing exertions without which the great prizes of life can never be attained. (Cheers.)—*Pioneer*. [There is so much that is good in Lord Derby's address that it is the more to be regretted that he should have held up for admiration two men like Darwin and Renan, the first of whom did not think Christianity worthy of the same examination which he instituted regarding the phenomena of the physical world, while the other, most unnecessarily introduced, has devoted his life to destroying the faith which is the light and the hope of the human race, and will remain so when Renan is forgotten.—Ed. T. A.]

THE COCONUT trade of Tahiti is a growing one. Notwithstanding the destruction of many of the palms by the storm which raged over all the islands of the Pacific last season, and the blight which attacked the fruit there is an immense excess of production over last year's crop with a ready market for the fruit, either fresh or as dried copra.—*Mildura Cultivator*.

THE BENGAL IRON AND STEEL COMPANY are proving what success can be gained by private enterprise in developing the mineral resources of the country. When they took over the concern from the Government of India there were two blast-furnaces on the old-fashioned "open-top" plan. A third and larger blast furnace of better design and with all the recent improvements which can be thought of is now being erected. When this new furnace is completed it is intended to remodel the old ones. The Company are also putting up two new blowing engines and in other respects making the blast-furnace portion of the works equal to meeting modern requirements. The foundry is being extended with a view to the manufacture of cast-iron pipes suitable for waterworks, which are now being so widely carried out in many cities. The management are showing such energy and enterprise that the Government must congratulate themselves on having practically entrusted to the Company the task of developing the native iron industry of India.—*Pioneer*.

IS SULPHUR TO BE FOUND IN CEYLON!

The above query is put to us by a correspondent who tells us he has searched the Import and Export tables given in our Directory for any mention of sulphur in vain. He further adds that as he finds brimstone to have a place in those tables, he conjectures that our import of sulphur is generically included under that heading. If this be not the case, he says, he is at a loss to conceive whence the supply for the local demand for the article is obtained, and he asks us if we can inform him whether there is any local production of it from which this apparently obvious demand can be met.

The only instance known to us personally of sulphur being found in Ceylon is that of the well-known hot wells at Bubula on the Badulla-Batticaloa road. These springs are distinctly sulphurous, the yellow crystals forming in abundance around their edges; but we have never heard whether these are collected, or, if they be, whether they have been so dealt with as to form an article of trade or commerce? Now it is certain that in one form or another sulphur enters largely into the daily uses of civilization. It is one of the main components also of gunpowder, and we fancy, though we do not feel certain on the point—that we have read that in earlier times, before the introduction on a large scale of this explosive from Europe, the natives used to manufacture the coarse powder they employed for themselves. If this was the case, there is every probability that the sulphur required for the preparation was obtained from local sources. Even in regard to India, we learn from our own compilation of "Gold, Gems" &c., that the sources of sulphur are limited in extent and only sufficient to meet local demands. "They are chiefly connected with the occurrence of hot springs." Whether therefore the sulphur now required locally be imported under the head of "brimstone" or not, it is certain that, to some extent at all events, sulphur in its natural state is to be found in Ceylon. As we have said, but one locality is at present known to us where it may be found; but even this solitary instance is a sufficient ground for the assumption that it might be found more widely diffused. Geologists tell us that wherever igneous rocks are to be found, wherever there exists traces of a past volcanic action, sulphur is sure to be more or less present. If this be the case, it is certainly singular that hot mineral springs are not to be found more commonly in Ceylon than is generally known. The knowledge possessed on the subject of local deposits of sulphur seems to be extremely restricted; Tennent scarcely refers to it, and yet the consumption of sulphur in any modern community must be large. Whence then is the supply for our local demand for it met? We have cited proof of its existence in Ceylon, and it might well be that some discussion of the matter would tend towards the creation of an industry concerned with its collection and preparation. Does the residuum found in our salt-collecting pans ever show traces of sulphur? We have always understood that it is more or less present among the impurities of rock salt, but are unaware if it be a constituent in that obtained by the evaporation of sea water. Probably some local scientist would be able to throw light on this part of the subject. The chief source of European supply we believe to be from mines worked in the neighbourhood of Mount Etna in Sicily, an active volcano certain to bring the article to the surface. But it must exist in many other places, and the only question is whether in such localities it is at so great a depth as to

commercially unworkable. The springs at Bubula before referred to at all events bring it in considerable quantities to the upper levels, and those springs are scarcely likely to be the solitary instance to be found in Ceylon.

IRRIGATION AND ARTESIAN WELLS.

The following is a communication from one who has spent some years in the N. C. Province which, since its formation by Sir William Gregory, has shared very largely in the Irrigation vote.

"After the recent experience of the comparative failure of several large Irrigation works lately restored, any sensible man interested in the welfare of the colony, should protest against the Government undertaking any further expensive works, the success of which depends entirely on rainfall, which, it need hardly be said, often proves to be precarious and disappointing. It is admitted that all the stupendous tanks in the Island were once in splendid working order and had under each of them a teeming population quite happy and contented with their lot. The question is how these tanks fell into disuse, and eventually into dis-repair. Undoubtedly a drought continuing for a series of years was the cause of their ruin and desolation. People who once thought their position happy had to migrate to other parts of the Island where they were provided with an unfailing water-supply; and this was how certain tanks were abandoned, neglected and desolated. Who will now guarantee that, in the case of the tanks recently restored by Government, a like failure and abandonment will not occur. To provide against such a contingency is the imperative duty of a paternal Government; and the only feasible means of effecting this seems to me to be by boring artesian wells to serve as feeders to these tanks. A cheap apparatus for boring purposes can now be had for R3,000, and the cost of sinking a well will be very inconsiderable when compared with the enormous expenditure incurred in the restoration of "giant" tanks. In view of these circumstances, it is to be hoped that the Government will make a start in this direction without delay. An experiment may be made in the case of one of the tanks in the Northern or North-Central Provinces. There is, I believe, a vote of R9,000, allowed in the Supply Bill for 1891, for experiments with regard to Artesian wells.—"Jaina Patriot."

A PEPPER SHIPMENT.

In the Probate, Divorce, and Admiralty Division, before the Right Hon. the President, Edward Boustead & Co. and Edward Park & Sons v. the Owners of the ship "August" was an important case heard on Saturday, involving points of interest to traders and merchants, more particularly to dealers in Eastern produce. Mr. J. G. Barnes, Q.C., and Mr. F. W. Hollams appeared for the plaintiffs; Sir Walter Phillimore, Dr. Baikes, and Mr. Arthur Pritchard represented the defendants. The statement of claim, which was delivered on February 12th, 1890, set forth that the plaintiffs had suffered damage by breach of the contracts set forth in five bills of lading of goods shipped by or on behalf of the plaintiffs, at Singapore, on board the defendants' sailing-vessel the "August," and consigned to London. The bills of lading were dated May 14th, 1889, and were respectively signed by the master of the said vessel as the agent for the defendants. The non-delivery of 1,091 bags of peppercorn part of the cargo shipped in the said vessel, and included in the said bills of lading, was the breach complained of. Alternatively, the plaintiffs alleged that they had suffered damage by the defendants, their servants and agents, wrongfully depriving the plaintiffs of certain goods, to wit, 1,094 bags of pepper delivered to the defendants by or on behalf of the plaintiffs, to be carried in the defendants' vessel the "August," from

Singapore to London. The particulars of the damage were as follows:—1,094 bags of pepper, weighing 70 46 tons, at 6d per lb. arrived value 3,945/ 15s. The plaintiffs claimed (1) 3,945/ 15s and interest; (2) alternatively damages. The defence and counterclaim were substantially to the following effect:—The defendants alleged that the plaintiffs were not the owners of the pepper or the holders of bills of lading in respect thereof, and that they were not entitled to maintain this action. The defendants denied that there had been any breach of the contract contained in the bills of lading. They alleged that by the said bills of lading the pepper was to be delivered to the plaintiffs, only unless prevented by certain excepted perils, and that the delivery to the plaintiffs was, in fact, prevented by the said excepted perils. With respect to the alternative claim, the defendants denied that they wrongfully deprived the plaintiffs of the pepper or of any portion thereof, and that even if it was the property of the plaintiffs, it was lawfully and necessarily sold in the interests of, and on behalf of, the plaintiffs, and that the defendants had always been ready and willing to account for the proceeds of sale of the said pepper to the lawful owners thereof, on being paid the money due to them (the defendants) in respect of the freight of the said pepper and other charges in connection with the same. The defendants had paid into court in this action, in respect of the said pepper, on account of the sale thereof, an amount which they stated to be far in excess of any balance due to the plaintiffs. The defendants further pleaded in the alternative that the contract for carriage of the goods was entered into by the master of the defendants' ship as the agent of the charterer of that ship, and that she, being a German vessel and entitled to fly the German flag, was also entitled to all the privileges of a German ship; that the defendants and charterers of the said vessel were German subjects, resident in Germany, and that the master was a subject of that country; that the charter-party was a German contract, and that the contracts contained in the bills of lading were made and entered into subject to German law; that, by that law, the sale of the goods, under the circumstances, at the place where and at the time when they were sold, was lawful and right, and that the defendants incurred no liability by reason of the said sale; that the defendants are, by German law, entitled to receive from the plaintiffs or owners of the said goods or holders of the bills of lading the freight agreed upon and specified, and that the defendants should be entitled to set off the said freight and other charges incurred by them or their agents on and about the said goods against the proceeds of sale of the same in their hands, and that the plaintiffs are only entitled to the excess, if any, of the realised value of the said goods (if such goods, or any part of them, belonged, in fact, to the plaintiffs) over and above the amount of such freight, together with the charges upon the said goods. The defendants further alleged that they had always been ready and willing to pay over any such excess in value, and that the amount in court was far greater than such excess; and, by way of a counterclaim, the defendants asked that they should be paid for the carriage of the said goods or any part thereof belonging to the plaintiffs; also for charges incurred and disbursements made by them on account of the plaintiffs in respect of the goods; and they claimed to receive from the plaintiffs their due contribution to general average charges on account of the said goods or such portion thereof as belonged to the plaintiffs. In the alternative, the defendants claimed freight and charges on the goods in accordance with the laws of the German Empire, by which, they said, the contract was governed. The defendants further said that, subsequently to the institution of these proceedings, they had ascertained that the amount paid by them into court was 217/ 4s 8d in excess of all possible claims by the plaintiffs, and they asked repayment of that sum from the plaintiffs, who had received the whole of the sum of 1645/ paid into court by the defendants. Portions of the damaged cargo were discharged, were surveyed by merchants called in for the purpose, and, upon their

recommendation, were sold at Cape Town, as damaged goods, at public auction, for the benefit of whom it might concern. With regard to the pepper, it was contended that, being of the kind known in the trade as Kongpoot pepper, it was almost impervious to damage by sea-water, that the sale was quite unnecessary, and that after immersion in salt water, if it were allowed to dry, by exposure to the air or sun, it would be practically as good as before its immersion. Some considerable portion of the pepper sold at these public sales in Cape Town was, in fact, reshipped to England by the mail steamer "Garth Castle" and "Tartar," the first of such shipments taking place within eight days or so of the first, and on the very day of the second public sale of cargo ex "August." On arrival here it was sold by Messrs. Lewis & Peat of Mincing-lane, and fetched, at public sale, prices for the most part only about a farthing or three-eighths of a penny per pound below full market prices ruling for sound pepper of a similar kind. Of the 240 bags sold ex "Garth Castle," 159 bags were classified by the dock samplers as "sound," while of the remainder of that shipment fifty-one bags were catalogued as first class, twenty-three as second class, six as third class, and one as fourth class damaged. Of the 101 bags ex "Tartar," eighty-three were sold as "sound," sixteen as first class, and two as second class damaged. These were sold by the same brokers on November 13th and fetched 5½d., and 5½d., and 5d. per lb. for the three descriptions respectively, the market having fallen between the sale of the previous shipment and the above date. Buyers would be aware that the pepper had been reshipped from the Cape of Good Hope, where no pepper was grown. They would, consequently, suppose that some reason had existed to cause its transshipment, and would bid slightly lower prices in consequence.

Mr. Thomas Cuthbertson, of the firm of Edward Boustead & Co., London, and Boustead & Co., Singapore, was the first witness for the plaintiffs. He stated that he had carried on business at Singapore for a number of years. His firm made the contract for this pepper, cost, freight, and insurance, to Messrs. Edward Pink & Sons, their co-plaintiffs in this action. It was not the same as what is known as Singapore pepper, which was prepared by smoke and heat, and would on that account more readily damage by water. This Kongpoot pepper was sun-cured, and could thus be more easily decorticated and ground into white pepper. Inside the outer husk was a skin which was almost impermeable. The skin, even if the sea-water were to penetrate the husk, would effectually prevent damage to the kernel which was inside it. The sole use for this kind of Kongpoot pepper was for ground white pepper. The "August" brought back about 638 bags of the shipment.

Mr. Thomas Pink said he happened to see samples of the pepper ex "Tartar" and "Garth Castle" not knowing at that time that they had been drawn from the lot shipped in the "August." The samples were perfectly "sound" except those which represented the bags classified as "damaged." He would have bought some of the lots, but that he expected the "August's" shipment to reach his firm about that time or soon after. The pepper would do quite well for making into white pepper, as the outer husk would be removed by the process called "pearling," and the kernel would be ground into white pepper, this being the particular use for Kongpoot pepper.

Mr. William Lee Darling, foreman sampler at the London and St. Katharine Docks, who sampled and classified 101 bags of the pepper ex "Tartar," and Mr. Stockwell, formerly foreman in a similar capacity at the East India Dock, who sampled and classified the 240 bags ex "Garth Castle," were called to speak to the correctness of the classifications, as was also Mr. William James Barker, inspector of cargoes at the latter dock. Mr. Andrew D'vitt, a member of the firm of Lewis & Peat, brokers of Mincing-lane, was also called by the plaintiffs. This witness, in cross-examination by Dr. Raikes, admitted that, in his opinion, sea-water would affect this class of pepper a little, making

it slightly grey in colour. This would, however, hardly apply to "first class damaged." If pepper were re-packed it would be classified as third class. Mr. Cuthbertson having been recalled, stated, in answer to Dr. Raikes, that he might have ordered the sale of pepper at Singapore on account of sea damage when acting surveyor of cargo. He did, not however, remember having done so.

The plaintiffs' case having closed, Mr. Otto Mübry, a member of a firm of merchants at Singapore, and now on a visit to this country, was called, and examined by Dr. Raikes, on behalf of the defendants. He had been engaged in the Eastern produce trade for about seventeen years. The "August" was chartered by his firm, and was put up as a general ship, and he remembered her loading. Boustead & Co. loaded the pepper, which was consigned to Edward Boustead & Co., London. The captain had instructions as to what firms he was to apply to in case the "August" should be obliged to put into any ports during the voyage. On August 15th, 1889, witness received a cablegram from Thomson, Watson & Co., Cape Town, the charterers' representatives at that port. The contents of the telegram were communicated, through witness's clerks, to the shippers, who were asked whether they had any instructions regarding the cargo. On August 27 the witness received a second cablegram, which stated that part of the cargo was seriously damaged, and that the surveyors had ordered the same to be sold without delay. This news was also communicated at once to the shippers. On November 4 witness got another cablegram, stating that the expenses of the "August" at the Cape amounted to 2,600*l.* and suggesting that the shippers should be asked to advance that sum, or a portion of it, to avoid a bottomry bond having to be resorted to. Witness sent round a circular to the shippers, who, however, declined to contribute anything towards the expenses. Witness thereupon cabled to Thomson, Watson, & Co., "Shippers decline." In witness's opinion such pepper as that shipped in the "August" is liable to damage by sea-water, but, perhaps, not so much as other goods. He had known cases of sea-damage to pepper, and remembered instances in which pepper had been recommended to be sold.

Sir Robert Phillimore having replied upon the arguments put forward on behalf of the defendants, the President said he would deliver his decision upon this point of the case at an early date; but, in any event, he would like to have translations of those decisions of the German Courts upon which reliance had been placed by the expert.—*London Grocer.*

PLANTING NOTES IN CEYLON FOR 1890.

The year that has just closed has been in most districts an exceptionally favourable one for flushing, and from all I have seen of 7 years old tea, with ordinary cultivation, I think a maximum yield has been secured. If 1891 is an equally mild and genial one, it strikes me, we are safe to see 56 million lb. shipped for the year. Coolies have generally been plentiful, and, with the exception of the wave of influenza, healthy. With so much really light work on tea estates there is not likely to be any great labour difficulty. With the judicious use of *real* Coast advances coolies will be forthcoming for all our needs. I have found more difficulty in regulating my labour force so that there shall be no short time than in actually securing the number required. With high cultivation in the shape of manuring this difficulty would be readily overcome, as tea over 6 years old in old coffee land with good soil and one-third manured yearly is safe to yield 100 lb. per acre per annum. The greater portion of the younger districts show growth equal to an average yield without manure of 500 lb. per acre off all 7 years old tea. Uva generally gives excellent promise, the higher fields showing as fine a growth and style of bush as I have seen anywhere, and much of the lower fields in Haputale that were so doubtful some time ago will in my opinion be excellent tea yet. All that is necessary here is more care in planting and

shading, than what is required at higher and more moist elevations, and patience to wait an extra year or two for results. Good mana and guinea grass land, planted in tea, continues to yield very satisfactorily.

The planting out of timber trees on waste land and along roads has been extensively carried out during the year. For easy and rapid growth, with almost no liability to die off, the grevillea takes the palm, while it appears to do little or no damage to the tea and adds a large quantity of fallen leaves annually to the soil. It would be interesting to know what these fallen leaves contain and give back again in fertilizing matter to the soil. *Cudrela toona* (red variety) and *sapu* are excellent for medium elevations, but the latter is fatal to tea if planted amongst it.

TEA AND TOBACCO IN MATALE.

We have got excellent tea crops in Matale—20 per cent over estimates in some cases, and I personally am pleased with the result of the year's working, and yet it has been one of the driest seasons for many years. Dry seasons are however becoming monotonous, and I will welcome a change. It has not been very successful so far, and this season in particular has been very unfavorable for it.

The Tobacco Company Directors hope to do well in tea, cacao and coconuts, and I wish them every success.

THE SCHOOL OF AGRICULTURE.

The school opened, in 1890 with the full complement of students, classes and cases being well represented. Mr. Jayawardene, who succeeded Mr. Lewis as headmaster continued to instruct the boys in practical work, as he had been doing since the foundation of the school; Messrs. de Silva and Rodrigo (acting for Mr. J. S. de Saran) being the other assistants. Under the supervision of the practical instructor a variety of crops were raised on the grounds attached to the school, such as paddy, cotton, dhall, Indian, corn, arrowroot, sugarcane, yams, beans, and other vegetables. The object of such cultivation is mainly to demonstrate to the students the best methods of growing these crops so that they may help to introduce or extend their cultivation in the rural districts, in place of less nutritious food products. The headmaster has also done much towards showing the boys the best methods of housing and feeding cattle kept for dairy purposes, while he has no doubt proved that the milk trade is not to be despised when properly set about, with a view to profit. The superintendent has endeavoured to make their agricultural studies as interesting as possible to the boys by the formation of classes in elementary geology, zoology, entomology, veterinary, and field surveying in so far as these services bear on agriculture, and it is satisfactory to note how much the students appreciate the instruction in these branches, and strive to excel in a knowledge of them. The boys taken generally were a very satisfactory lot last year, and among them were some of special ability, notably J. A. Kodippily among the seniors and E. Johannes among the juniors. The agricultural instructors in various parts of the island have reached the number of thirteen; of these seven are paid by Government and six privately. It is gratifying to find that the managers of the Prince of Wales's College have introduced agriculture into their curriculum, and that a large number of students attend the class. The Buddhist community have also started agricultural teaching in their school at Hatton. In both cases passed students of the school of agriculture have been chosen as instructors. Such private and voluntary efforts are most praiseworthy, and the benefits arising from them must be very great. It is satisfactory to find that a good few of the old boys of the school have started cultivation on their own account—some on a tolerably extensive scale. To make the work still further attractive excursions to Botanical Gardens, plantations, manufactories and other places of interest are periodically made. The school also has its own reading-room, museum discussion society and magazine. Looked at from an unprejudiced point of view, and with an intimate

knowledge of the results of agricultural teaching at the school, it cannot be doubted that the institution has fulfilled the object for which it was founded, and that its influence is slowly permeating the classes it was intended to reach. Granted that officialdom seconded the efforts of agricultural officers (and so far it is a matter of congratulation that much valuable help has been derived from that source) and that the rulers of the people persist in their endeavour to ameliorate the condition of the native agriculturist, and the work initiated by Mr. H. W. Green, late Director of Public Instruction, will be a source of much material benefit and happiness to the poor cultivators in Ceylon.

OUR FOREST DEPARTMENT.

The policy of the department has been to subordinate all other work as much as possible to the work of selecting and demarcating our future forest reserves. The Survey Department was busy during last year surveying blocks of forest selected by the forest officers. In the Western Province, in the neighbourhood of Mirigama some three or four thousand acres of forest have been surveyed for Railway Forest Reserves and the work is not yet finished. Two large forests of about 3,000 acres and 2,000 acres have been surveyed in the Kalutara district. For the Colombo district two forests of about 1,500 and 1,000 acres respectively are being "settled" by Mr. Mantell. There are one or two other small forests ready for settlement.

The other provinces in which reserved forests have been selected and are either proclaimed or are in process of settlement are the Central, the Southern, the North-Western and Saharagama.

The difficulty now is the appointment of a suitable Forest Settlement officer: different officers have been appointed from time to time but the work done by them has been as a rule very unsatisfactory. So far Mr. Mantell appears to have been the only one who understood the duties and took a real interest in them. It is the intention of Government, we believe, to appoint some civil servant as permanent Forest Settlement officer for the island. A R7,200 man will be appointed and he will get R10 per day commuted travelling allowance so that the appointment will be a good one. But one Forest Settlement Officer will not be enough. He could only "settle" 6 to 12 forests a year and at that rate a generation will pass before the Forest Department has its full extent of reserved forests. It would be very much better if Government were to appoint the different Chief Surveyors as Forest Settlement officers, each for his own province. They are far and away the best public officers outside the Forest Department for the work.

A good deal of timber and firewood was supplied to public departments during last year. In the Western Province however it has been found that the extent of forest land and the supplies of timber in private hands is so great that it is not worth the while of the Forest Department to compete with local traders. For the next few years the department will only supply public departments in the Western Province with timber that cannot be obtained from tenders or that may be urgently required. This however, applies only to locally felled timber. The Central Timber Depot in Colombo will be kept up and will be stocked with satinwood, halmilla, milla, palu and other woods from other provinces. At present the Central Depot is located on the Harbour Works Yard in Galle Buck, but the Forest Department is to take over from the Colonial Storekeeper in the course of the present year the land called "Beira" which juts into the lake between the Pettah and Fort railway stations. This will be a splendid site for a depot, and it is proposed to improve it by reclamation from the lake and by the construction of a railway siding, timber sheds, saw mills, &c.

During the past year timber depôts were opened at Kelaniya on the banks of the Kelaniganga, and Kalutara on the banks of the Kaluganga and at Alutgama on the banks of the Bentota river. The work of stocking them will be commenced this year.

The work of checking the transit of timber on the Kelaniganga, the Kaluganga and the Bentota rivers was fully organized last year. Two superintendents and 10 river watchers were appointed. The illicit removal of timber is now almost stopped.

The felling of ebony has, we believe, been restricted throughout the island owing to the low price.

LONDON AND COLOMBO PRICES OF CEYLON TEA.

The average prices for our Ceylon tea in the London and local markets has been well maintained, as may be judged from the following:—

CEYLON TEA IN MINCING LANE.

Average rate realized	1885	1/2d
Do	do	1886	..	1/1d
Do	do	1887	..	1/1d*
Do	do	1888	..	1 1/4d
Do	do	1889	..	1 1/2d
Do	do	1890	..	1 1/2d

LONDON AND COLOMBO TEA PRICES.

The weekly averages for London and Colombo sales are in the first two columns as follows, (in the third column we add the ruling quotation for Standard Fair Pekoe Souchong):—

A TUSK OF IVORY.

MR. HERBERT WARD, IN "SCRIBNER'S MAGAZINE."

Silent, and almost motionless, quite hidden in the darkness, stood the huge form of an old bull elephant, one of whose tusks had been damaged in his youth and had become totally decayed. His head was bent forward in order to rest his one monster tusk upon the ground, his trunk, loosely coiled between his fore-legs, was also resting on the ground, and his great ragged ears flapped spasmodically in vain endeavours to shake off the myriads of mosquitoes that persistently hovered around his head. Suddenly the forest was lit up by a most vivid flash of lightning, followed an instant afterwards by a crashing peal of thunder. The elephant raised his head with a startled jerk, his huge limbs shaking with fear. Almost before the rumbling, echoes of the thunder had died away, the rain, that had been threatening for so many hours, fell in torrents. Flashes of lightning succeeded each other so rapidly that the attendant peals of thunder were converted into one continuous roar, and the violence of the wind soon increased to a veritable tornado—a tropical hurricane. Trees were blown down and uprooted on all sides of the terrified elephant, who remained for some time motionless with fear, but, as the tempest continued, the monster became suddenly panic-stricken, and charged madly through the dense forest, stumbling and falling over the trunks of uprooted trees in his endeavours to gain some open patch where there would be no danger of being crushed by the falling timber. The lurid flashes of lightning revealed the frightened animal with coiled trunk and head bent low, blindly smashing a way through the dense woods. Suddenly, in the midst of a mad rush, the elephant sank to the ground with a sharp squeal of pain. The poor brute had severed the vines that supported one of the traps that had been arranged the previous day, and a heavily weighted spear was plunged between his shoulders. For some moments the wounded animal remained motionless, then the great body rolled slowly from side to side in vain endeavour to free himself from the spear, but the weapon was barbed and the points had penetrated too deeply to be shaken off. After many efforts the animal at last got on his legs again and staggered a short distance through the forest until, growing rapidly weaker from loss of blood, he stopped to rest and leaned the weight of his body against a large ant-hill, breathing heavily and groaning deeply in agony. Here he remained, exhausted, until daybreak, his hide covered with patches of mud and deep red smears of blood. Gradually the rain ceased, and the wind died away. With the first glimpse of dawn in the village, there was creaking from the small square cane doors of the huts, as they were removed one by one, and dark, manly figures, with long spears in their hands, stepped forth and stretched themselves, after their night's sleep.

After hastily arranging their scanty loin-cloths of beaten bark, the men all started into the dark woods to see if any elephant had been wounded by the traps. The party entered the forest in single file, but soon divided into small companies and set off in different directions. Ioko took an entirely different route from the others, and when about two miles from the village he halted suddenly, snapped his fingers, and placed his hand over his open mouth saying to himself in a low tone: "Look at this elephant track! See what a path is here!" He followed the trail for some time, until within view of the trap he had set the previous day, when his excitement became intense, for he found the spear was gone, and the grass and leaves beneath the snare were covered with blood. Without hesita-

tion, he followed the blood-stained tracks, until he approached the great ant-hill, near which he stopped a moment to extract a thorn from his foot. He was startled by a deep groan, and, cautiously stepping forward, he saw his prey leaning its unwieldy form against the mound. "Lo-o-o! It is the evil one, Litoi Linene!" (Big Ears) gasped Ioko to himself excitedly. Silently watching the animal, to decide in his own mind upon the best mode of spearing him in a vital part, he firmly gripped his heavy spear, the shaft of which was fully eight feet long, and stepped softly forward until within reach of the left shoulder of the unconscious animal. With steady nerve he poised his weapon, and with a mighty plunge drove the keen-bladed spear deep into the elephant's heart, and sprang away among the trees. With a shrill, trumpeting cry of pain, Litoi Linene staggered to his feet, swayed forward quivered, and fell to the ground lifeless. Ioko after waiting a few moments to satisfy himself that the animal was dead, calmly stepped fourth and raised a cry that echoed through the woods, and which soon brought several of his companions to the spot. Without any further sign of excitement he quietly busied himself in cutting his barbed spear from the carcass. He then examined the one large tusk and the decayed stump of its fellow, remarking to his companions, who were now arriving: "Now the evil spirit is dead, Litoi Linene will lead no more devilish elephants to our plantations."

In a very short time the scene became indescribable. Excited men with sharp knives commenced cutting lumps of meat from the still warm carcass, and throwing them to the eager women and children, who crowded around the baskets, quarrelling like wild animals over the possession of each piece of flesh that was thrown among them. The savages' hearts were filled with joy at the prospect of a huge feast. That night, under cover of the darkness, Ioko, all alone, buried the one heavy tusk of Litoi Linene in a swamp far from the village, so that only he himself knew of the place of concealment. He hid the tusk according to the tribal custom, for in the Aruwimi districts the people of neighbouring villages are seldom good friends, and they all have a habit of attacking each other at odd times in order to capture men, women, and children for cannibal purposes. As tusks of ivory have an acknowledged value, equal to that of a human being, it is customary for the members of each village to conceal in the forests as many tusks as they can obtain, so that they may be in a position to redeem, if permitted, any of their companions who may be unfortunate enough to fall into the hands of their hostile neighbours.—*Public Opinion.*

RETURNS FROM THE INDIAN MINES.

As the present year of grace approaches its close investors are naturally on the *qui vive* for information upon which to base their divided calculations—where there is any possibility of such a happy termination of the twelvemonth's operations. It will not be out of place, therefore, if we give some particulars with reference to the production of gold from the three leading Indian mines. We do so with the greatest pleasure as the properties are yielding well up to the expectations we have often expressed, even when the gold mining industry of Southern India was at such a low ebb that Mysore shareholders flung away their holdings at 3s. or 4s. each; and intelligent and enterprising men like the late Sir William Abbott; to say nothing of the Messrs. Taylor, Sir Charles Tennant, and other believers in the value of the Mysore Goldfield, were regarded by many people as misguided and sanguine visionaries,

Last year, as was shown in an article which appeared in the *Financial News* on October 18 last, the Mysore Company paid dividends of 75 per cent. from actual mining operations, and 50 per cent. from the sale of a portion of the property to the Champion Reef Company, and there is every reason to expect that this year, without any assistance from a subsidiary venture, the Mysore dividends will reach the very satisfactory figure of 100 per cent. The Nundydroog Company has already paid nearly 14 per cent. on account of the present year, and will probably pay double that payment when the full accounts of the year come to be dealt with; and the third property of the trio, Ooregum, although unable to declare a dividend until the House of Lords decides whether or not the issue of the Preference shares was *ultra vires*, has unquestionably placed the Company in possession of a handsome balance of profit for division when it can be legally done. The trio are thus doing so well that we think those who hold shares in the undertakings would act very unwisely in parting with their holdings at anything like the prices now ruling. For these mines at all events, the days of doubt and uncertainty have passed, and their success cannot but be an incentive to greater exertions on the part of the managers of the other Indian properties, and to renewed confidence on the part of those whose hopes have been so long deferred. However, our present purpose is to analyse the returns of the three really successful properties.

It is worthy of note, in the first place, that last month's yield of gold from the Mysore Mine—5,250 oz.—was the best on record, showing that as the property is opened out in depth and in width its productiveness steadily increases. We should be exceedingly sorry to under-estimate by one iota the services which Captain Plummer rendered to the Mysore Company, and, indeed, to the district generally; but at the same time it would be equally unjust to dispute the fact that his successor occupying a difficult position in following such an expert, has well deserved the golden opinions which his management has won. Some months ago the influenza and its after effects caused a falling-off in the returns, and it was concluded by some pessimists that with Captain Plummer the glory of Mysore had departed. That this conclusion was an inaccurate one is now manifest. In the following table the crushings month by month since the end of 1888 are given, from which the shareholders will see at a glance what progress has been made:—

	1890.		1889.	
	Tons.	Oz.	Tons.	Oz.
January ...	3,271	5,003	2,066	2,376
February ...	3,000	5,884	2,023	3,038
March ...	3,200	5,884	2,459	3,249
April ...	3,661	4,571	2,600	3,249
May ...	3,385	4,263	2,672	3,872
June ...	3,491	4,461	2,866	4,275
July ...	3,207	4,174	2,947	4,527
August ...	3,133	4,118	2,900	4,739
September...	3,100	4,258	2,942	4,879
October ...	3,009	5,014	3,030	4,424
November...	3,100	5,250	3,040	5,157
December ...	—	—	3,021	4,829
	35,564	52,865	32,566	49,234

The average yield during the past eleven months has been just under $1\frac{1}{2}$ oz. of gold to the ton of quartz, comparing with a trifle over that percentage for the whole of last year. Last month's average was, however, very nearly 1 oz. 14 dwt. per ton, showing a distinct improvement on the aggregate percentages which we have just mentioned. For the eleven months of the current year it will be seen that the gold produced has exceeded by 3,631 oz. the total production of last year, when, as we have

said, 75 per cent. was paid to the shareholders out of the working profits.

Turning, in the next place, to the Ooregum Mine, the table given below shows that the monthly crushings have augmented in a very satisfactory manner, the eleven months' production exhibiting an increase of nearly 50 per cent. over the whole of last year:—

	1890.		1889.	
	Tons.	Oz.	Tons.	Oz.
January ...	825	1,784	454	839
February ...	957	2,032	482	927
March ...	1,055	2,075	508	1,032
April ...	966	2,049	555	1,225
May ...	1,004	2,107	626	1,353
June ...	1,010	2,127	691	1,427
July ...	1,022	2,161	714	1,467
August ...	1,110	2,306	745	1,506
September ...	1,173	2,491	729	1,563
October ...	1,247	2,646	756	1,620
November ...	1,297	2,725	772	1,662
December ...	—	—	777	1,683

11016 24,503 7,639 16,434
The percentage of the gold produced has been practically the same this year as last—2 oz. 2 dwt. to the ton of quartz, and that was almost precisely the result of last month's crushing. The average is an exceedingly good one, especially in view of the steady increase in the amount of mineral crushed, and the Nundydroog returns are, relatively, even more satisfactory, as will be observed from the subjoined table:—

	1890.		1889.	
	Tons.	Oz.	Tons.	Oz.
January ...	670	1,139	370	581
February...	700	1,321	280	394
March ...	650	117	300	514
April ...	650	986	300	485
May ...	700	1,085	300	520
June ...	750	1,400	300	498
July ...	800	1,488	300	497
August ...	900	1,418	310	491
September ...	875	1,421	339	324
October ...	900	1,478	320	363
November ...	925	1,475	312	700
December ...	—	—	350	751

8,520 14,223 ... 3,781 6,118

Here we see that the yield of the precious metal for the past eleven months has exceeded by 8,110 oz., or about 130 per cent., the total production for the whole of last year; and whereas the percentage last year was a little over 1 oz. 12 dwt. of gold per ton of quartz, the percentage this year has been about 1 oz. 13½ dwt.—also a very satisfactory average. Results such as these cannot fail to be gratifying to those who are interested in the Companies. They show that the Champion Reef of the Colar district is highly auriferous, and that with systematic and competent management, such as these mines undoubtedly have, permanently valuable returns are tolerably certain, and they suggest also that, whatever may be the fate of the lag-behinds among the Indian properties, the Mysore trio promise to give a very good account of themselves for some time to come.—*Financial News*, Dec. 15th.

COFFEE PLANTING.

TO THE EDITOR OF THE "MADRAS TIMES."
Sir,—If you will allow me the space, I should be glad, as a novice in Coffee Planting, to obtain opinions from some of your readers. Men of experience, will I hope, not consider me on certain details unduly sceptical, I would, in the first place, ask why forest land, independent of good lays, is invariably preferred to grass lands in the hollows of valleys. The best permanent soil is to be found in such positions in India

as elsewhere, probably. Forest land in this country requires manure for coffee, yet apparently for a quicker start men prefer steep slopes. The land after clearing must from its position and in a climate of great heat and heavy rains, quickly deteriorate. On the other hand, levels can be forked without loss of soil, the process alone without manure being a continuous improvement.

Drainage of course is necessary, as with nearly all other cultivation.

Moreover the hill sides seem most difficult to protect from winds, necessitating what would appear a severe and wasteful topping. From the consequent excessive growth of wood and succours in so small a limit, pruning has to be rigorously attended to. An art that even few English gardeners understand.

The next question is as to the best distance to plant. Irrespective of the size of a healthy bush, it may be asked why 6 into 6 is advocated with a plant having such immense and exhaustive lateral roots. The only answer I could ever obtain was, that by covering the ground, weeding is saved. This seems a doubtful argument with labour at 5 annas the day; crop at £100 the ton. Again with the casual labour of India compared with the skilled of Europe it is reasonable to expect satisfactory profits from such large plantations, as appears to be the correct idea? To properly cultivate 100 acres of fruit trees, 1,200, even 1,500 in some cases, to the acre, is no casual work. Some able men succeed, but it is safer to ask the cause of ninety-nine failures, than to be told, as is too often the case, of one success.

If men of experience could have begun with what they know now, would they or not have sought out the sheltered hollows of valleys, planting their coffee in small fields with ample space between each bush, say at 9 into 9 and topping at 6 feet, where grass lands would admit manure on the spot and irrigation available? What secures good crops in coffee, the writer knows not; but it is certain that in Europe fruit trees best succeed by regular surface digging and top manuring, thereby enticing the lateral roots towards the surface. It is stated that there is no gain from topping high, as the lower branches die; but is this really so if the bush is well nourished and has sufficient room for light and air?

Shade is now advocated. Is it an advantage where irrigation is available, or is it only a help in the event of showers failing to give sufficient moisture to lateral roots when the blossom is out? L. C.

TEA IN AMBAGAMUWA giving 450 lb. all round per acre at five years old, and planted on patana and scrub land, must be considered very good, and shut the mouths of critics who speak of the district never bearing more than 300 lb. all over. One of the largest places in lower Ambagamuwa has, we hear, exceeded the estimate by over 10,000 lb. of tea giving 400 lb. an acre for young and old fields all over.

DARJEELING.—Simply delightful weather here for those who are left in the "Holy Spot," and barring a few cases of mild chilblains, I know of nobody who is either sick or sorry after the Christmas festivities. The tea drier controversy in your columns, I confess, is a little over my head, but I certainly think Mr. Davidson has the best of it. I know as a fact, that one of his driers in this district was tinkered at by an amateur *ka walleh*, of course with a view to improving it, and equally of course, with the result of very much lessening its drying capabilities. *Verb. sap. sat.* I have heard great things of the Blackman air propeller, as used in this district on one garden, which almost always tops the list in the London market, and hope to be able to tell your readers all about it when the next manufacturing season comes round. So far as I can hear and see, cold weather work in this neighbourhood is well in hand, and I have heard nothing in the way of complaints as to labour being in any way short.—*Indian Planters' Gazette.*

ECHOES OF SCIENCE.

MM. Fremy and Verneuil have presented another paper to the Académie des Sciences, Paris, on an improved method of manufacturing rubies. Instead of employing pure alumina, they now use chromated alumina, alkalis with carbonate of potash, which does not impair the purity of the crystals, while facilitating their formation and embracing the beauty of their colour. Other improvements have been introduced, especially in lengthening the time of the reaction to a week or more, thus engendering hard, rhombohedral crystals of a large size. A gas furnace is used in place of, a coke one, and thus a constant temperature of 1,300 deg. C. can be maintained for weeks. Large crucibles, giving more than three kilogrammes of rubies at one operation, are now adopted. MM. Appert, the well-known glass-blowers, have allowed the investigators to make use of their furnaces, and they have thus been able to prepare rubies which are in part sapphires or crystals, red on one side and blue on the other a phenomenon sometimes found in nature. The same charge will also produce crystals entirely red, and others wholly blue, perhaps owing to a difference in the oxidation of the chromium.

Can these crystals, which are large as natural stones be used for jewellery and in clockwork? Practice alone can answer this question, but M. Taub has submitted them to a lapidary, who found their hardness comparable to that of the ordinary ruby. The experiments may now be considered to have reached the industrial stage.

On the right bank of the River Lunain (Seine-et-Marne) there are beds of sand which, according to a recent discovery, served to polish the flint weapons of the Neolithic men in that part of France. M. Armand Vire has found no less than ten *ateliers* of the new stone age in this district. Most of these primeval work shops are situated on the hills along the rivers, and not in the valley itself. Probably it was safer in those days to work under cover of the forest than beside the stream, although the polishing sand had to be transported with some labour.

Gutta percha derives its name from the Malayan words, *gutta* a gum, and *percha* a cloth, and was introduced to the civilised world in 1842, by Dr. Montgomery, a Scotch surgeon. The first specimens were brought to London from Singapore by José Almeida, and the properties of the gum were announced by Hancock, Wheatstone, and Faraday. The last two physicists recognised its fitness as an insulator of wires conveying electricity, and it was so employed in the first submarine cable, laid by Mr. C. V. Walker, in the Channel, and subsequently in that laid between Dover and Calais in 1851, and in the Transatlantic cables.

The only gutta percha suitable for insulating cables is obtained from the species *Isonandra*, inhabiting the Malay Archipelago, and during the last forty years the trees have nearly been exterminated by the natives recklessly cutting down the second growth. The original variety, the *Isonandra Gutta* of Hooker is now only found on the Chasseriau Estate in the old forest of Boukett Tunah (Hill of Tin), situated in the middle of Singapore. Other representatives of the species are also becoming scarce, and the gums of the African *Bussia Parkii*, the Guianan *Mimusops Balata*, and the *Payena Leerii* are very inferior substitutes. Fortunately the Dutch have taken up the culture of the plant in Java with success; but it would be well if serious attention were turned to its propagation in Singapore, its native habitat. Gutta percha farming is likely to be profitable.

A tree recently discovered in, tee Sequoia National Park was 41½ feet in diameter, 250 feet high, and had 6,126 annual rings of growth.

The motto the Brazilians had stamped upon their new 20 rs. bronze coin is "Vintem popundo, vintem ganho,"—a cent saved is a cent earned.—*American Grocer.*

THE PREVENTION OF LEAF DISEASE IN COFFEE.

TO THE EDITOR OF THE "MADRAS TIMES."

Sir,—Some of your planting readers might be disposed to try whether the immersion of coffee seed in hot water previous to sowing would have the effect of preventing partly, or altogether, leaf disease. The idea was suggested to me by reading part of an article, of which the enclosed* is an extract in the *London Standard*, and I also enclose an extract † from Stephen's Book of the Farm, shewing how seed was pickled to prevent smut in barley, wheat and oats.

Some weeks ago, I steeped 2 lots of coffee seed in hot water of 120 and 130 degrees Fahrenheit, respectively, for 5 minutes, after soaking it in cold water for 15 hours previously. It was quite soft and was sown immediately. It has come up strong and vigorous, and I am making nurseries with the seedlings. Next year, if I am spared, I shall steep some in still hotter water, say 135 degrees, as the cold moisture in the seed after soaking in cold water cools the water considerably.

S. E. Wynaad, 19th July 1-90.

T. M.

ENCLOSURES.

* Extract from *Standard* of November 6th, 1888,
HOME AND FOREIGN AGRICULTURE.

Farmers who have not finished sowing their wheat may with advantage study the results of some important experiments in the prevention of bunt and smut carried out by Mr. Jansen, of Copenhagen, and recorded in the new number of the Royal Agricultural Society's Journal. Mr. Jansen has found by repeated trials that both the fungoid diseases referred to can be prevented by immersing the seeds of wheat, barley or oats in water of the temperature of 127 to 135 degrees, Fahrenheit. In the case of wheat and oats immersion for 5 minutes, without previous soaking suffices, but the husk of barley adheres so tightly that it is necessary to soak the grain in cold water for about 12 hours, and afterwards to place it in hot water for 5 minutes.

It is important to observe that a temperature of 135 degrees is the extreme allowable with safety. This prevention is recommended for wheat instead of the ordinary plan of dressing the seed with sulphate of copper or other chemical preparation, because we are told the latter treatment is injurious to the grain and the crop grown from it.

Sulphate of copper in the quantities generally used, Mr. Jansen says, destroys not only the fungus but from 3 to 10 per cent of the seed corn; whereas water, at the temperature mentioned above is harmless to the grain, though destructive to the fungus, nor is this all, for the experimenter finds that the vitality of the plants not killed is impaired by sulphate of copper so that their average weight in autumn is diminished. This year he found that the yield of wheat in plots sown with best disinfected seed was 30 per cent. more in grain and 23 per cent. more in straw than that of plots sown with grain dressed with the chemical preparation.

† Extract from Stephens' Book of the Farm, Vol. 1. Para 2307.

Seed wheat should be pickled, that is subjected to preparation in a certain kind of liquor, before it is sown, in order to insure it against the attack of a fungoid disease in the ensuing summer called smut, which renders the crop comparatively worthless. Some farmers affect to despise this precaution, as originating in an unfounded reliance on an imaginary specific; but the existence of smut, and its baneful effect upon the wheat crop, are no imaginary evils; and when experience has proved, in numberless instances, that steeped grain prevents the appearance of this serious disease, the small trouble which pickling imposes may surely be undertaken rather than place the entire crop in jeopardy. Why pickling the seed should have the effect of preventing the smut in the crop is a question more easily asked than answered: and it is perhaps because it has never received a satisfactory answer that pickling is disregarded by some farmers. No valid objection can be stated against the practice,

for the palpable fact stands obvious to conviction, that one field sown with pickled wheat, and otherwise managed in the usual way, will escape the smut, while the adjoining one managed in exactly a similar manner, but sown with wheat in its ordinary state, will be almost destroyed with the disease.

I have seen such a case tested by two neighbouring farmers, the Messrs. Fenton, late tenants of Nevay and Eassie, in Forfarshire. It is true that on some farms, wheat sown in its usual state, escapes the disease, which I have heard the late Mr. Oliver, Lochend, near Edinburgh, state was the case on his farm; and it is also true that pickling does not entirely prevent the occurrence of the disease on other farms; but such cases do not prove that every farm must also be free of smut, indeed no one, beforehand, can aver that any farm shall be so, and while so much uncertainty exists, the safer practice will be to pickle the seed, the expense being a mere trifle.

It is now an ascertained fact that vaccination will not insure immunity from small pox, yet it certainly very much modifies its attack, when it does occur, and precisely so is the case with pickling wheat.

[There is no harm in trying experiments, but the misery of it is that plants, the most healthy and robust as they spring from the ground, get at once infected, if leaf disease is in the locality or country.—Ed. T. A.]

THE FOCHOWA native paper states that the tea trade in Formosa this year, has been very brisk, and that the Douglas Company had three steamers carrying the tea.—*China Mail*.

SULPHUROUS ACID is now being used to act upon starch under pressure and at a high temperature. The product, after neutralisation, is Schumann's universal gum, which is soluble and extremely adhesive, and closely resembles gum arabic, which is now very scarce and dear.—*India-Rubber and Gutta-Percha Journal*, Dec. 8th.

NEW ZEALAND FLAX.—Says the *New Zealand Herald*:—"The import of New Zealand flax into the United States under the McKinley tariff should give this industry a fillip, and lead to its more extensive introduction for manufacturing purposes into the Great Republic. Captain Webb (of Arnold, Cheney and Co.) states that the duty formerly charged was 25 dollars, or £5 per ton which was a pretty heavy impost.

A NEW INDUSTRY has sprung up in Germany with young leaves of the strawberry. These are taken, carefully dried and used instead of Chinese tea. They are said to give a decoction nearly approaching that of tea in flavor, and having the same refreshing influence. In many parts of England the leaves of the raspberry, hedge bramble and of the sage are commonly taken as a substitute for tea. The Chinese use the common sage very largely in flavoring tea for their own use.—*Mildura Cultivator*.

A BOTANICAL DISCOVERY.—A very important discovery is reported from Goa, writes a correspondent. For what can be gathered from a pamphlet issued by Mr. B. F. da Costa, a gentleman well-known in Portuguese scientific circles, he claims to have discovered in the milk of *Nivol-Cantem* (*Euphorbia nerlifolia*) an admirable substitute for gutta-percha. The plant is abundant, and grows wild in the Concan districts, generally used for hedges. Mr. da Costa in describing its qualities, says that it is insoluble in water, it softens under heat, and hardens in the cold. It receives and retains a given moulded shape, can be cast into very thin sheets, and is capable of receiving the minutest impressions on its surface. It is liable to become sticky, if exposed to the sun. In its dried state, it is of a chocolate colour. In fact, it has all the properties of gutta-percha.—*Pioneer*, January 2nd.

COMPARATIVE CONSUMPTION OF TEA FROM DIFFERENT SOURCES IN BRITAIN.

The figures afforded by Messrs. Gow, Wilson & Stanton are strikingly illustrative of the extraordinary revolution which the tea trade in Britain has undergone between 1878 and 1890. In the former year Indian tea had commenced to be a formidable competitor with China, the proportions consumed by British tea drinkers having been 23 per cent of Indian to 77 of China. Ceylon did not shew even 1 per cent until 1884, when the proportions had become:—China 63 per cent; Indian 36 and Ceylon 1. In 1887, Indian with 45 per cent and Ceylon with 6 per cent, became, for the first time, unitedly in advance of China: 51 per cent against 49. In 1889 Indian by itself took first place with 52 per cent, and retained this position in 1890. Meantime Ceylon had risen, by leaps and bounds to 18 per cent, while China had receded to 30 per cent, in the market in which she was once supreme. In the next few years the competition will be mainly between the mature giant of India and the young giant of Ceylon, the aged genius who presides over the product of the flowery land sinking gradually, we feel pretty certain, into decrepitude and decay. While India is now, after passing the limit of 100,000,000 lb., making but slight annual advances, Ceylon is increasing her output at a rate which in less than a decade is likely to see her exports, which were inappreciable in 1883, up to the round 100,000,000 of pounds, with India probably at 140,000,000 and China a vanishing quantity of perhaps 10,000,000. The figures for deliveries, (for export and consumption), in the season ended May 1890, were:—

Indian tea	101,000,000 lb.
Ceylon „	32,000,000 „
Java „	3,280,000 „
China „	87,652,000 „

More than one-third of the latter was for export.—The import of Indian tea in October 1890 was so high as 15,237,000 lb., with deliveries equal to 9,822,000. Of Ceylon the highest import was 5,142,000 in July, the highest figure for deliveries being 3,960,000 in September. But in May 1889 the deliveries had exceeded 5 millions by 19,890 lb. The rapid rate, indeed, at which Ceylon is gaining on India and distancing China, is the special feature of the really revolutionary returns which reveal the recent history of the tea trade. In looking at the figures for import of Ceylon tea into Britain, we must not forget that our exports direct to Australia now exceed 2½ millions of pounds, while to other colonies and foreign countries we send more than a further half million. The actual distribution of our 1890 crop was:—

To Britain	42,828,743 lb.
„ Australia	2,562,861 „
„ other countries..	561,865 „

NOTES ON PRODUCE AND FINANCE.

(From the *H. and C. Mail*, Dec. 26th.)

REGULATION OF THE SUPPLIES.—We understand that at a meeting of Indian Tea Brokers, held this week, it was resolved that endeavours should be made to regulate the quantity of Indian tea offered at auction in January to 35,000 packages per week, and in February to 30,000 packages, after which a further meeting is to be held to consider the matter.

INDIAN TEA IN FRANCE.—We learn that the Indian Tea Districts' Association have submitted to the Trade and Treaties Committee of the Board of Trade a special report upon the desirability of obtaining a reduction in the rate of duty levied upon tea entering France. A simultaneous effort will be made through

the London Chamber of Commerce to get the industry better terms in connection with the revision of the French Customs Tariff.

INDIAN AND CEYLON TEA IN AMERICA.—They are selling inferior Ohina tea, some of it re-shipped from London in the United States as “English Breakfast Tea,” and obtaining a high price for it. Americans who have been in England lately know something about the merits of Indian and Ceylon Tea; and on their return these visitors to Europe express their opinion rather freely upon the Ohina and Japan tea offered them at many American hotels. This should help the sale of Indian and Ceylon teas in America.

PRICES OF PRODUCE.—The prices of produce, compared with these in the previous year, do not show general depression, and with the steady increase of consumption the outlook seems more favourable than was lately the case. In the tea, coffee, and sugar there are no special causes of complaint, and importers and brokers are inclined to take a hopeful view of the outlook.

CLEARING TEA.—The Commissioners of Customs have appointed a committee with instructions to report upon the mode in which the accounts are kept in connection with the various bonded warehouses particularly those in which tea is stored.

DAVIDSON'S SIROCCO.

Mr. Davidson has drawn our attention to a long letter in which he meets criticisms on his down-draught sirocco. We cannot find room for the letter entire, but we make extracts as follows:—

When your paper reached me in Belfast on the former occasion, I at once telegraphed to my agents, to, if possible, ascertain where the machine was to which “Darjeeling-ite” referred, and for them promptly to send my engineer, Mr. Maguire, to the place to put matters to right.

After some delay this was ascertained, and Mr. Maguire visited the garden. On examining the machine he found fitted upon the outlet of the fan, a pipe for conveying the exhaust air to the leaf withering loft, and not only was this pipe in itself much too small to let the necessary amount of air escape (unless the fan were driven at about double or treble the speed I arranged it for) but the air passage through it was further blocked by the pipe having several angles in it, and its end was entirely closed, but holes were made along it to let the air out in small jets, in accordance with Darjeelingite's special ideas for withering his leaf.

Of course Mr. Maguire insisted on this pipe being removed, as I did not arrange for the machine being worked as a compound leaf wither and tea drier, and he very properly declined to make any test until it was taken off, eventually it was removed, and the trial of the machine's capabilities as a drier proceeded with. The details of the trial were most minutely entered up and tabulated in one of my usual report forms and signed by the Manager of the garden. This report shows 164 lb. of tea dried in the hour with 124 lb. wood fuel, and as it bears the Manager's signature, it would be casting a serious imputation upon him, were I in any way to doubt its being a “really fair trial” (as your other correspondent, “A Manager, &c.” asks me to do) or to impute inaccuracy to what he signed.

My estimate was that the machine could dry about 100 lb of tea per hour with about 130 lb of ordinarily good wood fuel.

Now, sir, have I, or have I not, proved my case “up to the hilt” as against Darjeelingites original accusations that the machine could only dry half that amount of tea per hour, and would burn five times the amount of wood?

“Darjeeling” I see states, that although “The mechanical arrangements are otherwise good, one fault of the Sirocco is that dry air does not enter the machine but the damp air of the floor,” but surely he scarcely expects the machine to manufacture its own air supply as well as work his pipe contrivance in addition to drying the tea! He, however, says his pipe contrivance “cannot affect the action of the fan,” and certainly if

the fan can cope with such a blockade as he applied on it without being affected thereby, why he may perhaps find it making its own supply of air some day as well!!

Meantime, however, I would advise him to provide the stove with a direct supply of air from outside the house, even although it be at the point of complete saturation (which is seldom if ever the case with the outside atmosphere) as air fully saturated at 65° F. if raised to 120° F. becomes practically dry air—which latter temperature is as low as air ever reaches in the exhaust of the fan. Hence saturated air at 65°, forms practically a dry air supply for an apparatus which discharges its exhaust air at 120° F. What causes many managers to think that it is owing to the dampness of the outside atmosphere on wet days that their driers give lower results than on dry days, is that on wet days the windows and doors of the tea-house are usually closed up, and they go on using the same air that is within the house over and over again with but little fresh air being admitted, and it is not long till this becomes absolutely saturated even at the high temperature it attains to, seeing that a Down-draft Sirocco passes about 300,000 cubic feet of air through it per hour and turns about 200 to 250lb. weight of water into vapour in the same time—so that ere long the machine is actually drawing in hot vapour with very little air in it and drying with superheated vapour instead of hot air to the very serious detriment of the quality of the tea produced. On fine dry days the windows and doors of the tea-house are all wide open, and the vapour gets out, and fresh air gets freely in and the drying goes on so much better in consequence.

My advice to all users of Siroccos is, to either blow the exhaust air out of the factory entirely or else provide a large duct to lead fresh air to the stoves from the outside atmosphere.

From the testimonials adhibited we quote as follows:—

From.—J. N. Campbell Esq., Superintendent of Moray Tea Estate Musketry [!—Ed. T. A.] Ceylon, 22nd August 1890.

“Outturn per hour of dried tea 214 lb. wood fuel per hour 98 lb. This is equal to about 2½ lb. of tea dried per lb. of fuel.”

From.—H. D. Dean, Esq. Superintendent Kintyre Tea Estate, Maskeliya, Ceylon, 6th August 1890.

“I am perfectly convinced that the capabilities of the Down-draft are in no way over-estimated in the advertisements, and have no hesitation in saying that from 180 to 200lb. tea an hour can be easily obtained from the machine.”

MIXED SPICES.

A correspondent asks the nature of mixed spices, a question the reply to which will be of interest to many. Mixed spices are a compound of many different sorts, in order to save the housekeeper time, trouble and expense. She need no longer buy a small quantity of many sorts and experiment in combining them in the right proportion, for this is done for her by the spice dealer. In a popular formula the following eighteen kinds of spice are used: White pepper, shot pepper, allspice, ginger, mustard, coriander seed, celery seed, cloves, long pepper, cardamom seed, cassia buds, cumiu seed, mace, caraway seed, Ceylon cinnamon, bay leaves, Chili pepper, Malabar pepper. The proportions are kept secret by the leading mixers, being regarded private property.—*American Grocer.*

CHINA: PROPOSED IMPROVEMENTS IN TEA GROWING.

Mr. E. Pinches, who lately gave the Shanghai Chamber of Commerce some information as to his proposals with reference to the cultivation of the tea plant in China, writes to the *N.-C. Daily News* as under from Lientsin, where he has been stopping on

his way to Peking. Mr. Pinches says:—

“Briefly my proposals are simply to endeavour to obtain from the Government at Peking a tract of land either at Shanghai, Hankow, Foochow or Formosa, to be handed over to a Chinese Company for a period of not less than 15 years, in which would be established a tea-garden to be worked in the same manner as tea gardens are worked in India. The very latest tea machinery would be introduced, suitable buildings erected and the tea bush cultivated and plucked in the same manner as in India. The introduction of machinery would considerably lessen the cost of the tea and give China a better chance of competing with India. It would also improve the make and appearance of the tea. The reason to my mind why China tea has so fallen off in quality is simply that less attention is now given to the cultivation of the plant than used to be given formerly. The cultivator has received a lower price for his tea year by year. To meet this, instead of working up his cultivation more, so as to get an increased yield from his plant and thus reduce the cost of his tea and also improve its quality, he has spent less on cultivation, thus hoping to reduce the cost of his tea, entirely forgetting that by doing so he is really killing the goose that lays the golden eggs. The Chinese—at any rate in Formosa, the only tea district of which I can speak with confidence—have simply no idea whatever of pruning as understood in India. As a rule the tea bush is backed down once in about six years, branches being left split half-way down in a most barbarous manner. Scientific pruning means really giving the tea bush a new lease of life. After a season's plucking, especially as done in China, there are a certain number of twigs which have a partially dead bark, and which if left alone will next plucking season only give very few leaves, and these of a thin spess character. Cut away this partially dead wood at the end of the plucking season and next year when the sap commences to rise you will have a fine young shoot which will not only give you plenty of leaf but will also be good quality. I have always found the foil round a Chinese tea bush caked so hard that a fork could scarcely penetrate it. If this soil were properly loosened by forking round the bush more moisture would get to the surface roots of the bush, and thus ensure a more rapid rise of sap, which again would of course mean increased quantities of leaf. Again, the Chinese system of plucking is very bad. Chinese wait till in a plot of tea all the bushes have got a lot of leaf on them, and then men, women and children, sometimes the latter only five years of age, are let loose among the tea bushes. Nearly every leaf is ripped off the bush whether it is properly ready or not. Some of the leaves have of course grown too old and others are not properly ready. To get the best quality of leaf you must be constantly going round your tea garden, say once in 7 days or so, only taking the leaf which is perfectly ready and leaving the rest for your next time of going round. Practice alone of course can teach you this. If you allow leaf to grow too long it becomes hard and difficult to manufacture and does not make good tea. On the other hand if you pluck it too young you lose leaf, as if it had been allowed to grow a little longer, it would have weighed more. It seems to me a most extraordinary thing that such an intelligent race as the Chinese undoubtedly are should calmly sit down and allow one of their most important industries to pass away from them without making an effort to prevent it. If figures are true facts, unless the Chinese make some attempt to keep abreast of the times, at the present rate of yearly decrease in the China tea crop, about four or five years should see the end. There are plenty of tea gardens in India which can lay their whole crop down in London at an average cost of 7d per pound, some even less. China at present cannot do this. First let China try what can be done by a better system of cultivation and the introduction of the latest tea machinery, and then, if that is not enough to place her on an equal footing with India, the likeliest must be done away with.”—*China Mail.*

CEYLON TEA IN RUSSIA:

THE JAMES TAYLOR TESTIMONIAL.

Kandy, Jan. 14th.

SIR,—I beg to transmit copy of letter from the Secretary to the Ceylon Association in London, together with the connected correspondence which is of public interest.—I am, &c.,

A. PHILIP,

Secretary to the Planters' Association of Ceylon.

LETTER FROM MR. LEAKE.

4, Mincing Lane, London, E.C., Dec. 24th 1890.

To A. Philip, Esq., Secretary, Planters' Association Kandy, Ceylon.

Dear Sir,—I have the pleasure to acknowledge receipt of your letter of 1st instant, informing me that the available balance of the vote of Rs5,000 towards Mr. Rogivue's mission to Russia is now Rs2,485.56. Of this I take due note.

I enclose a letter addressed to you by Mr. Rogivue together with a translation by him of an article from a Russian newspaper.

I am also sending you by this mail a copy of a letter addressed by our Association here to Lord Knutsford on the subject of the proposed increase of the amount to be contribution by Ceylon for military expenditure.

In respect of this document the Association has been greatly indebted to Sir Arthur Gordon for the care and trouble he has taken in drawing it up.

Wishing the Planters' Association and its officers many happy and useful years,—I remain, yours faithfully,

WM. MARTIN LEAKE.

P. S.—Our lists for the Taylor Testimonial amounts now to £106 7s. The following names have to be added to the list:—

The Colombo Commercial Company, Ltd.	..	£5	5	0	
C. E. G. Hatherell, Esq.	2	10	0
Messrs. Geo. White & Co.	2	2	0
R. A. Cameron, Esq.	1	1	0
Sir G. H. D. Ephinstone, Bart.	1	1	0
J. H. Alexander, Esq.	1	1	0

"THE TEA FUND."

Moscow, 1st/13th December, 1890.

To A. Philip, Esq., Secretary, Ceylon Planters' Association, Kandy.

Sir,—I wrote you last on the 30th August/11th September and have since sent you through Mr. Wm. Martin Leake, London, my general report upon my mission in Russia, dated London, 15th October 1890, which I trust, has reached you in order and has given satisfaction to your Committee.

In London where I was for about three weeks, I was indeed very fortunate in making arrangements with an old and kind friend, Mr. P. G. Speace, who gave me, with capital credit, good advices and introductions, a very helping hand for the establishment of a business here in order to push by the direct trade the Ceylon Tea in Russia. I returned here about a month ago and I am now ready to open on Monday next, 3rd/15th inst., my office and store of the "Ceylon Tea and Produce Agency of Russia," for the sale by retail, wholesale and, or, otherwise, the speciality of "Ceylon tea" exclusively, which, as I have already written you, has never before been brought as pure to the reach of tea consumers in this country.

I am expecting in a day or two from London a first supply of Ceylon tea selected by me especially in London to suit the Russian taste, which, I hope, will sell rapidly, and I trust to have before long to report of having been successful in establishing a good and regular trade for this staple of your island.

A fact worthy of notice—which, I think, will please your Committee as showing that Russian merchants begin to take great interest in Ceylon tea—is that Mr. Popoff, Managing-Director of the large firm of K. N. C. Popoff Bros. & Co., Limited, whom, when I visited him two months ago, would not listen to anything about Ceylon teas, will now very shortly proceed to Ceylon with a Dr. (Professor of Chemistry) to analyse and taste them there,

study everything connected with their planting and manufacture. This, of course, is a very important question and shows a good advance in the work done by me in Russia, as I am certain it will very soon lead to large imports of Ceylon tea into Russia.

Regarding the Reuter's telegram published in the Ceylon papers some time ago, "that the Russian Minister of Commerce proposed to establish a direct trade with Colombo and to introduce Ceylon tea into Russia," I may mention that the other day, on my return to St. Petersburg, wishing to interview the Minister of Finance, His Excellency M. Pichnegratsky, upon this important question, I had the good fortune of an audience with him, and he told me that the question has indeed been brought before, and agitated by, the Government, but that, up to this time, the best means to be adopted to do it, has not yet been found. However, he thinks that my establishment in Russia to sell Ceylon tea will greatly facilitate the matter, and he offered me every kind of protection and assistance in my enterprise. It is certain that the Russian Government will do anything to introduce into the country and protect an article of "first necessity" to the Russian public, which they can procure so much nearer than China and of better and purer quality. They have been stimulated by numerous articles published in the Russian press upon the subject, of which I send you the translation of one, which will perhaps interest your Committee and the public in Ceylon.

My work of "reclaim" for Ceylon tea is, however, far from being completed; I shall have still large expenses to incur for advertisements, publications, etc. and will require all the money available for me in London, voted for the purpose by your Committee; and I hope that the latter will continue to support me, and be, later on, in a position to grant me, if necessary, some further funds to be spent for the continuation of my work.—I remain, dear sir, yours faithfully,

M. ROGIVUE.

[Translation of an article published on the 16/28 October 1890, in the *Moskovsky Wedanosty*, No. 286.]

THE NEW CEYLON TEA MARKET FOR RUSSIA.

A telegram from St. Petersburg on the 1st October 1890 says the following:—"The Minister of Finance and Foreign Affairs had proposed the establishment of direct commercial communication with Ceylon, in order to introduce Ceylon teas in our markets. It is contemplated, with this proposal, to get independent of English tea markets and to prevent the adulteration of teas which is more and more complained about as taking place in China and London."

This appears to us as a word of gold on behalf of Russian interests. Up to the present time, we Russians, on account of our little enterprising spirit, have bought, and are buying, have drunk and are drinking Ceylon and Japan teas (where we have no Russian agents) as *China teas*, through the medium of *English merchants*.

Japan tea differs very little from China tea. The Japanese have already, long ago, taken the greatest care and trouble with the planting and preparation of their tea; let us say more. The Japanese prepare their tea in a much cleaner way than the Chinese, and this may be accounted for by the smaller quantity they produce and also by the "go-ahead" spirit of the Japanese who are, no doubt, more civilized than the Chinese. In Japan there is no primitive dirty hand-work to be seen in the preparation of tea such as we have seen and heard as being done in China. In India and Ceylon the tea manufacture is still on a higher scale, and, as East India is of so near neighbourhood with the Chinese tea hills, it is quite comprehensible that they have taken so much of the Chinese ideas for planting and cultivating tea, the position of the mountains and the climate there being greatly in favor of good cultivation; the result has been therefore, that very fine qualities of tea have made their appearance from the hills of Hindustan. But, let us go further, and we see the tea cultivation in the island of Ceylon, with her peaceful and hardworking Sinabese and the most

Propitious soil, has, in every respect, gained the best ground, and there a plant gives 12 to 15 pounds of tea whilst the same plants in China would give only about 10 pounds, and this only stimulates the energy of the Sinhalese and induces them to venture largely in the planting on their own account.

It is not long ago that Ceylon began to plant tea, and already such enormous and splendid results have been gained, that capitalists have taken seriously the matter in hand.

The teas which are planted and prepared in Ceylon can certainly, with very few exceptions, be advantageously compared with the tea produced in the best Provinces of China, viz., Kin-Tschow and Quen-Fan. The tea from the Provinces Fau-Bohea-Dan and Panan (Asjam-Tan teas are not to be compared) are positively inferior to Ceylon and even Japan teas.

Ceylon tea, however, cannot compete for flavor and aroma with the high grades of China "Monings"; but certainly they are equal to the best Souchongs and Pakings to be seen and so much praised in China.

All these kinds have their first and best grades, and find a large sale in Europe.

England makes an enormous amount of money with her tea business, especially with Russia, where almost all the best sorts—which are here rather scarce and difficult to be found—are imported. Such a second-hand purchasing method is of course very detrimental to us; it only gives help to the foreign country who act as third hands in our tea trade and deprive Russia of a lot of benefit. In view of our unsatisfied requirements in high-class teas, which cannot be bought on the direct markets without the intervention of a third party, the offer of our Ministers to come to our help for direct communication between Russia and the Ceylon market is to be considered as *most valuable and desirable*. At any rate, the teas bought in Ceylon and shipped *via* Odessa, have the great advantage of a much shorter voyage. By its geographical position the island of Ceylon is certainly by half nearer Odessa than Shanghai, and again also nearer than Chantow, the only market where Russians operate. Therefore the development of the tea purchases in Ceylon would not only be very desirable for Russia, but also a very easy possible "factum" to attain. The question is whether our oldest Russian firms, who lead the tea business in Russia, will be enterprising enough and have the energy to develop in the proper manner this, *without doubt*, profitable business.

As a proof of the advantages to be derived from this business, we may point out the rather—so to say—secret way the English houses are speculating upon the Ceylon Tea Market. They conduct this business in such a clean, "robber-like," better said, "smuggling" style and fashion, and selling Indian and Ceylon teas for "Foochow" teas, which, for aroma, taste, flavour and appearance are much the same. Packing also is counterfeited; and with the aid of English agents, the Ceylon packages, cards, labels, etc., are transformed to give them the appearance of Chinese "emballage."

All these deceive the clients and lead them to great errors in accepting quietly Ceylon "Souchongs" for Chinese "Monings."

Would it therefore not be better that we Russians, instead of helping the unfair trade and without allowing ourselves to be cheated and robbed, find the best remedy for buying direct the genuine and desirable merchandise, and thus save the medium of European merchants to whom we pay so enormous profits for "dark" commissions and who are so fond of speculating upon our pockets!

(Sgd.) G. KUDIMOW.

Kandy, 1st December 1890.

To the Secretary, the Ceylon Association in London 4, Mincing Lane, London.

Dear Sir,—I beg to acknowledge receipt of your letter of the 31st of October with enclosure, and also your letter of the 7th ultimo, which shall be duly submitted to the Committee at next meeting.

Meantime, I beg to state that your demand draft for R728.27 has had due protection, the amount being passed to debit of the grant made towards Mr. Rogivne's mission to Russia for the purpose of introducing Ceylon tea.

The cost of the remittance of the £150 on the 15th September was R1,786.17 at exchange of 1/8 13 16ths per rupee plus cost of message R22, and I enclose a memo. showing the different sums advanced up to date leaving an available balance at date, of say R2,485.56.—I am, &c., A. PHILIP, Secretary to the Planters' Association of Ceylon.

CHINA TEA AND RUSSIA:

The *Morning Post* thus concludes an article on Tea:—Though China has been beaten back from the commanding position it formerly occupied in the British tea markets, it must not be inferred that the total tea trade of the Empire has suffered in anything like the same proportion. It has declined, but the decline since 1886 has been only a little over 12 per cent in quantity, and about 7 per cent in value. It would be altogether premature, therefore to assume, as some rashly have, that China is on the point of losing her foreign tea trade. Russia, so eminently conservative in its preference for certain grades of tea, is beginning to take kindly to the Indian leaf, but there are still many countries, such as the United States, where people evince a strong objection to any but the genuine growths of the Flowery Land. Still, when a comparatively small island like Ceylon can raise and export in a single year over forty million pounds of tea it is evident that the Chinese cultivators will have to bestir themselves pretty actively, if they are to hold their own in those markets they still contrive to monopolise.—*L. and C. Express.*

NOTES ON PRODUCE AND FINANCE.

TEA COMPANIES' SHARE LIST.—We are now able to show particulars of fifty of the limited joint stock tea companies with headquarters in England and with a sterling capital. The list (which, however, does not yet contain more than about three quarters of the entire number of companies which exist), shows an aggregate paid up capital of nearly £5,000,000, a debenture capital of £500,000, and reserves of about £200,000 (or about 5 per cent on the capital).

TEA INCREASING IN POPULARITY.—The consumption of tea should be largely on the increase. At a West-end club no less than eighty teas were served on a single Saturday afternoon, and the tea shops of the Aerated Bread and other companies are usually full. Mr. Gladstone is a confirmed tea-drinker, and, unlike other people in this as well as in other things, finds a strong cup before bed-time an excellent sedative.

MINING AND PLANTING.—A company with the title of the Indian Gold Mines Company, Limited, has just been registered in Scotland. The capital is £50,000, divided into 5s shares. The object is to acquire and work gold and silver mines, mineral and mining rights in India and elsewhere, and to grow coffee, tea, or cinchona. The first subscribers who take one share each are:—W. Anderson, Govan Factory, Glasgow; A. Breingan, Bank of Scotland, Helensburgh; P. Hons-ton, c.b., 12, West Clyde Street, Helensburgh; W. A. Smith, merchant, 6, Hanover Street, Glasgow; W. H. Malcolm, writer, 119, St. Vincent Street, Glasgow; John Brown, Brandon Grove, Helensburgh; J. Mitchell, The Mains, Helensburgh.—*H. and C. Mail.*

ALOE FIBRE.—The last advices from Europe, shows a rise on prices, and has had for effect to revive the pretension of the manufacturers and would not be possible today to obtain good qualities under R250 to R260 per ton. Second qualities remain untouched.—*Mauritius Gazette*, Dec. 11th.

THE EXTIRPATION OF DELETERIOUS VEGETABLE GROWTH.

We had a call today (Jany. 20th) from Mr. R. I. Murchison, an Australian colonist, on his way back from India, where he has successfully interested the authorities in a specific he has invented for the destruction of deleterious vegetable growth. It is to be used freely for the extirpation of prickly pear and other troublesome growth in some parts of India. The specific is described by those who have witnessed its effects as quite wonderful for its speedy destruction of deleterious growths (vegetable) of any and every description from the biggest tree to the smallest grass. It has to be very carefully used, however, being a deadly poison, and also that it does not come near plants or trees that are meant to be preserved. The specific is supplied by the maker in the form of a powder, but applied in a liquor form. Mr. Murchison, who goes on by the S. S. "Valetta," expects to send an agent to visit Ceylon shortly, when fuller particulars will be made available and experiments no doubt undertaken.

CEYLON STAPLE EXPORTS AND THEIR DISTRIBUTION.

We call attention to the full and correct tabular statement given as a *Supplement* (page 592 b) today for our Staple Exports and their Distribution for a series of years. It is interesting to note in regard to tea, the increased proportion of our shipments diverted from the United Kingdom in 1890, thus,—

	1889. lb.	1890. lb.
Tea to United Kingdom ...	32,510,747	43,756,912
Do. other ports ...	1,537,333	3,141,642

Total ... 34,048,085 46,901,554

In 1889, the percentage diverted was 4 per cent; in 1890 it was close on 7 per cent of the total exports.

Summing up the exports to the different ports representing the European Continent, we find as follows:—

	1889 lb.	1890 lb.	Increase lb.
Tea for Continent of Europe direct	54,743	92,839	38,096
For Africa and Mauritius ...	30,612	143,048	112,436
For America ...	42,252	204,223	161,971
For Australia	1,120,094	2,559,901	1,439,807
For India ...	289,637	144,631	145,006 (decrease.)

It is gratifying to see the largely increased export in the case of shipments to Australasia and America respectively, and we hope to see still greater progress made in 1891, while Russia should also take a big portion of our staple. The New Year has begun with heavy shipments and also with specially large sales of tea in Colombo, so that with sales rising to half-a-million lb. of tea per week, we can now offer ample encouragement to Russian or other large buyers to establish themselves in Colombo.

In regard to the distribution of our staples, the more notable facts are as follows:—the large share of our coffee taken by Australia which also figures for some cinnamon, coconut oil, coir and plumbago. America is a big customer for plumbago taking nearly as much as the United Kingdom and three times as much citronella oil, also a large quantity of coconut oil, some cinnamon, cocoa, coffee and cinchona bark. The Continent of Europe also takes large supplies of a variety of our products direct.

THE AMSTERDAM CINCHONA MARKET. THE RICHEST AND AVERAGE BARKS.

The total quantity of cinchona bark offered by auction in Amsterdam in 1890 was 3,271,054 kilos., an increase of 58 per cent upon the quantity offered in 1889 (2,073,921 kilos.), and fully 2.25 per cent upon 1888 (1,435,647 kilos.) The following shows the composition of the Java barks, which form practically the whole of the Amsterdam supply:—

	1888. Kilos.	1889. Kilos.	1890. Kilos.
From Government Plantation ..	353,423	369,703	350,576
From Private Plantation ..	1,082,224	1,690,898	2,920,478

The average proportion in sulphate of quinine of the manufacturing barks was in 1888, 4.20 per cent; in 1889, 4.12 per cent; and in 1890, 4 per cent. The richest parcel of the year was offered for sale on June 5th. It consisted of 13 bales Ledger stem bark, in broken quill, from the Government plantations, and analysed 9.42 per cent of quinine sulphate. The Dutch broker who sends us these particulars estimates the total quantity sold by auction in London during the year at about 5,000,000 kilos., averaging 2½ per cent quinine sulphate, and being equal, therefore, to about 3,938,000 oz. The total of bark sold in Amsterdam equalled (according to the published analyses) 121,420 kilos. (about 4,250,000 oz.) sulphate of quinine. If these estimates are correct, the combined auction sale of bark in London and Amsterdam during 1890 have represented 8,183,000 oz. quinine sulphate.—*Chemist and Druggist.*

CINCHONA FROM JAVA.

The exports of cinchona bark from Java during the period from July 1st to October 31st are by far the largest of any corresponding section of the last five years. This is all the more noteworthy as the increase is entirely due to the enhanced production of the private plantations. The Government plantations, in fact have this year only exported about one-fourth of their average July-October shipments. The following are the figures:—

	July 1st to Oct. 31st.	1890	1889	1888.	1887	1886
Govt. plantns.						
Amst. lb.	64,208	231,410	226,235	238,246	168,550	
Private plants.						
Amst. lb.	2,035,890	1,600,888	1,204,732	1,308,133	595,990	
Total ...	2,100,098	1,832,298	1,430,967	1,546,379	764,540	

—*Chemist and Druggist.*

PLANTING NOTES IN 1891.

(Concluded from page 570).

SOILS—FORESTS IN COORG AND IN CEYLON—SOIL POISON —INSECT PESTS AND INSECTICIDES—MANURES—THE GREAT OBJECT OF TEA CULTIVATION.

SOILS.—I will first begin by quoting from an article entitled "Forest Soils in Coorg" from the *Indian Forester* of Dec. 1882, signed "Coorg" (*Tropical Agriculturist*, Vol. II, page 734). The following facts regarding the forest soils in Coorg will be of interest; they somewhat upset the generally received theories as to formation of vegetable soil in forests:—

"Coorg, as will be seen by the map, is a little country occupying a small portion of the Western Ghats, and jutting out a short distance in the Mysore plateau. The western slopes of the Ghats are covered with dense lofty evergreen forests into which jungle fires never penetrate. On the east is a belt of deciduous forest, varying from four to six miles in width, which have been constantly burnt through by jungle fires for time out of mind; and indeed we may infer that this has been going on for centuries. Do not we all know that the natives of India always burn the forests on principle in order to get an

early crop of young grass for their cattle; in fact they consider it a duty they owe to themselves and their neighbors to burn off the forests as completely as possible. Is it likely that this is a habit developed of late years, and not rather one as old as the first settlement of inhabitants in the country? Then that the forest has been much in the same state for the last 500 years is proved by the existence of teak trees of that age which evidently grew in the same conditions from the first as they are doing now. The almost invariable wide centre rings two to three in the first inch seen in these ancient trees, would appear to give direct evidence of the young plant having been constantly burnt down every year, every time sending up a larger shoot until a shoot is produced, large enough and high enough to defy the jungle fire. This is the process to be seen going on under our own eyes. A teak plant grown under other conditions in the forest, would have six or eight rings in the first inch. We may then, I think, infer that these deciduous forests were constantly run over by fire 500 years ago, and have been ever since, and probably were burnt for centuries before that.

"Now what is the result on the soil? In the one case we have the virgin ever-green forest of the Ghauts in which fire never penetrates, constantly giving back to the soil a vast amount of vegetable matter in the shape of leaves, wood, and bark. On the other hand high deciduous forest, the vegetable matter from which has been constantly burnt by jungle fires for centuries. According to preconceived notions there would be a thick layer of the vegetable mould in the former and next to none in the latter. As a matter of fact the very opposite is the case. In the Ghaut forests there is seldom more than an average of 6 inches of vegetable mould—whereas in the deciduous forests there is a thickness of from one foot to 28 inches. It must be distinctly understood here that I am not speaking of scrub jungle but of high and fairly deciduous forest.

"In open scrub jungle the formation of vegetable mould is naturally very much less, and, as might be expected, if the subsoil is examined, it will generally be found to be poor. No doubt there are other circumstances conducing to the poverty of the jungle, and amongst these chiefly the want of rain, and these causes act and re-act on each other.

"The difference in the soil of ever-green forest and deciduous forest is very distinctly marked on the lower western slopes of the Ghauts. Here up to an altitude of 800 to 1,000 feet, the slopes are covered with semi-deciduous forest of *Terminalias* and *Lagerstræmias* mixed with the large thorny bamboo, the greater portions of which are burnt almost annually. In coming down the Ghaut roads the difference in the soil of the road cutting is at once noticed; between the thin greyish layer of the vegetable mould of the ever-green, and the thick black layer of the fire-devastated deciduous forest, I have noticed the same thing on the Carcoor Ghaut from Nilgiris to Calicut. A few days ago in going through a coffee estate on the Ghauts, I passed a place where the soil was a rich deep black resembling what is seen in the Eastern deciduous forests, strongly contrasting with the absence of mould in surrounding portions of the estate. It had been lately dug, and on looking closely, I noticed a number of pieces of charcoal mixed with the soil. On remarking on this I was told the place was the site of a toddy-drawer's house and garden and the rich black mould was evidently partly produced from burnt vegetable matter.

"The fine coffee estate in what is called the 'Bamboo' district in Coorg owe their flourishing condition to the rich black vegetable soil of the deciduous forest: In the first days of coffee planting, every one thought that the soil of the dense Ghaut forests must be over-laying as compared with the deciduous, but the fallacy of this supposition is proved by thousands of acres of abandoned coffee estates on the Ghauts, whereas estates planted fifteen years ago in the "bamboo" are as flourishing as ever and shew no signs of decay. Supplies come up as well as when first the estate was planted, showing that the soil retains its vigour. In the Ghauts it is not so, the exhausted soil refuses to rear the young plant, so

that vacancies cannot be filled up. And it is remarkable that this is not only the case on steep slopes, but also on flat places and hollows where there can be but little wash. I trust those observations will bring out those of other observers on the subject."

You put a footnote:—"On the other hand was it not the case that a large proportion of the bamboo estates in Wynad were killed by borer?" Borer came because men attempted to grow coffee in a dry climate without shade; and in a specially dry year terrible were the ravages of that worm. But that was no fault of the bamboo. You will find it a good rule in selecting land whether high or low—follow the bamboo. This applies in Kalutara and Udugama.

As to the article above quoted the facts are borne out in other parts of India, and are they not borne out in Ceylon? Where are the evergreen forests? Ramboda, Nuwara Eliya, Dimbula, Dikoya, Maskeliya, Nitre Cave, Laggala,—in fact all those forests beyond the reach of chenaing, unswept by forest fires, and deluged with heavy rains. Then you have the deciduous forests of Uva, Dumbara, Matale, and Kurung-gala, and between those extremes is the border land of evergreen forest land converted into scrub by constant chenaing in the past. We have thus 1st evergreen virgin ghaut forest (example Laggala), 2nd evergreen forest converted into mana grass or scrub by chenaing (numberless example.) 3rd—deciduous forest; 4th—cultivated lands (not paddy). But now in applying this to Ceylon we must take the climate of our ocean island into account and we find the surface of most lands stimulated by the heat and moisture so that natural osmotic action is promoted without the help of a forest covering. Much land in Ceylon with its light scrub covering would be dried up and gradually rendered infertile in a dry climate.

Then we have other varieties of soils. There is Matale East where the whole soil is of a rich nature even in steep mountain slopes. Here coffee flourished and tea is now flourishing. Then you have the Ambagamuwa valleys where coffee was a great failure on account of the cold clayey nature of the soil. Then in the lowcountry the three tea districts—Kelani, Kalutara and Udugama—have to be considered. Kelani Valley is a long straggling district composed of steep valleys running up from the river where the soil is not rich, but, along with the steamy forcing heat, forms a good ground for the necessary evergreen growth of tea.

Kalutara also lies along a large river, and though the soil is of a poor description yet it has a firm subsoil which tea likes. Some of the flats in Kalutara are very fine.

Udugama is a district by itself literally and figuratively.

When you leave Galle you come on fine deciduous forests at Kottowe which are the remnants of old original lands preserved by the Dutch, and in a way also preserved by the British. This land proves that the remarks of the Coorg writer quoted above do not apply to lowcountry forests, because when once the original forest is felled, the fierce heat of the Ceylon lowcountry extracts the nitrogen and available manurial elements of land where the soil is not rich, and gradually the land is covered with a poor scrub or that poisonous *kekilla* fern. As you approach Udugama you find all the original forest has many years ago been destroyed except in small pieces here and there. Large expanses are covered with the *kekilla* fern and show where a large cultivation was carried on 80 or 100 years ago by natives who were driven away in the first place by fever and elephants and in later days by the law prohibiting chenaing. The soil in Udugama is poor by reason of the tremendous amount of sand with which it is clogged. The roads and drains are full of white sand. It is also full of what would be considered the very thing for tea—namely iron. The streams run red with the iron ore. But read *Tropical Agriculturist*, vol. II., page 508:—"Soil Poison.—Nearly all soils contain iron; it is this that gives them their reddish colour. But iron has two oxides. One of them, containing the least amount of oxygen, is soluble in soil water,

and is therefore readily taken into the roots of plants. Copperas, or green vitriol, is composed of this low, or protoxide of iron and sulphuric acid. On exposure to air for a time, this low oxide takes in more oxygen, forming what is called sesqui-oxide of iron which is insoluble in water. The subsoil which has never been tined to admit the atmosphere freely, contains the low oxide, and when first turned up, if sown or planted soon, the roots of the crops take in this poisonous soluble compound of iron and are much injured if not killed outright.—*American Agriculturist*

Now may I apply all this to tea cultivation? As far as I have seen the best soils for tea are those that have a stiff subsoil into which the tea-plant roots descend, like the Ghaut evergreen forest tree, and yields a large return of leaf or flush. If there are good manurial qualities in this soil all the better. Then the next best soil is that of Matale or Haputale of high manurial quality and of good consistency combined with favourable climate.

Then the next is that of Kelani Valley and Kaltura, where the subsoil has good consistency, and though the manurial qualities are deficient, yet the climate is steamy and forcing.

After this comes the general run of old coffee lands in the Central Province, where there are pockets and valleys which possess favourable conditions for tea. But in all this will it be said that manure is not wanted? Government must help the planting enterprize and allow manure to be carried at very low rates. You will see in a few years, that a universal revival of manuring (fish or poonac) will arise in the Ceylon tea districts. Let me quote *Tropical Agriculturist*, Vol. II, page 418:—

"It is assumed, but not proven, that electricity nitrifies the azote of the air in the interior of the soil by a union with hydrocarbonaceous matters: or effect a similar end in the interior of plants by their starch sugar, &c. We know however that the azoteous matters in the soil can be nitrified, but that is not an augmentation of richness. * * *

"The extent of vineyards in France is 4½ million acres. One quarter of this area is invaded by the phylloxera, and the new ravages of the insect are estimated at the rate of 200,000 acres annually. Three official remedies are recognised. Sulph. carbonate of potassium and sulphuret of carbon, submersion, and American stocks for grafting on the affected vines. To these must be added a relatively high manuring. It has been found that purely nitrogenous manures, as wool-clippings, ham-parings, dried blood, oil cakes, &c., develop the vine at the expense of the fruit; but farm yard manure, or a composition of potash salts, soluble phosphates, and a proportionate dose of azoteous matters have the opposite effect."

Here now—"develops the vine at the expense of the fruit." That is what tea planters have to attend to. They have to develop the tea bush at the expense of the seed by applying purely nitrogenous manures such as fish, oil-cakes, &c.; while castor planters must use farmyard manure to develop the valuable fruit on which their efforts depend. The *Tropical Agriculturist* is a treasury of richness to the planter who is beyond the reach of libraries. It is a library in itself from whose shelves one may gather much knowledge if he only looks for it.

There were Mr. Carter's experiments which are well worth studying. In reference to those Mr. Hughes says (*T. A.*, Vol. V., page 465):—"In my remarks upon Mr. Carter's experiments I pointed out the probable reason why the results of the application of castor-poonac had proved more satisfactory than those obtained from the use of bone-dust, namely, that, inasmuch as nitrogen was the principle manure ingredient required by the tea plant, it was only reasonable to conclude that the fertilizer which supplied the largest proportion of this valuable constituent in a form suitable for assimilation was the most suitable and economical manure for tea plantations." See the rest of his remarks. He concludes as follows:—"That tea plantations will require manure sooner or later, there can be no doubt whatever, and the poorer the soil and the more forcing the climate (lowcountry planters please attend), the more immediate necessity will there be for its

application, hence the importance that planters should select these manures which are likely to prove practically the most economical."

Mr. Carter recommended manuring at the rate of 24 cwt. of poonac per acre every three or four years. The great object in tea cultivation is to do everything in our power to keep the soil moist and prevent drying up or pulverization of the soil which will check the necessary evergreenness of the tea bush. * Thus forking and digging are inadvisable in ordinary soils, still more in light sandy soils. But in very adhesive soils digging is necessary to enable the soil to retain moisture. You all know how sticky clayey or leamy soils are in wet weather and how hard and metallic they are in dry weather, these soils should be dug, forked, turned over and kept broken. Why? Because you introduce large quantities of air between the lumps, and this prevents the process of evaporation by the sun in dry weather, from drawing every drop from the soil. On the other hand it prevents saturation and stagnation of the surface in wet weather, which tends to rot the fibres of the plant. Thus it is only an adhesive soil that should be forked or dug. Of course with a soil like Udugama where there is a poisonous protoxide of iron present the turning up the soil and admitting air will do good. Mr. Cochran (*Tropical Agriculturist*, Vol. VII, page 563) says: "Protoxide of iron is converted into the harmless or beneficial peroxide by aerating the soil by mechanical working or by liming." *Liming!* surely this is the only case where lime is wanted. Lime is the base of a tea planter. It promotes long inter-nodes of wood and rapid run to flower and seed, because it renders food more quickly available to the plant, and this is useful for fruit-growers. Why is it that on an old coffee estate which has been converted into a tea estate, those fields where crops were heaviest in coffee will not grow tea satisfactorily? Some might say that was because coffee had exhausted those fields. No, the reason is that generally the soils where coffee did not flourish are the soils where tea yields leaf most freely. Of course, this rule does not apply all round, as there are places (Dambullagalla and Naya-bedde) which were mines of wealth in coffee and are mines of wealth in tea. That is because, taking for granted the soils are rich, yet they contain constituents and meet conditions which are favourable to tea growth, namely—they have nitrogenous elements freely available and the subsoil is sufficiently adhesive. Thus you have the necessary vigour which would go to fruit or seed if allowed, but, being checked, allows a full crop of leaf to be taken. But a soil like this must be supplied with lots of nitrogenous manure to make up for this heavy exhaustion of certain elements.

Thus flat land, adhesive yet manurial subsoil (well forked), forcing damp and hot climate is the best for tea.

Flatness saves disturbance of the main roots of the tea which are sensitive of injury. † Adhesiveness of the soil (if forked) with good manurial properties promotes evergreenness and luxuriant foliage.

Damp heat is known everywhere to be a forcing agent in promoting vegetation. I have, perhaps, wearied you by these imperfect notes. But if I have even in a small way, helped to arouse the Ceylon planters to the necessity of manuring, my object will have been attained.

"1873."

THE WYNAED PLANTERS' ASSOCIATION has suggested to kindred bodies that a prize of at least £20,000 should be offered for a practical cure for Hemileia, the cause of coffee leaf disease. The French Government has a standing offer of 300,000 francs for a practical cure of phylloxera.

* In coffee we had to check the evergreenness of the bush to force out fruit buds.

† To prove how sensitive the side roots of tea are it is a fact that young tea plants will not tolerate "trimming" the roots when taken from a nursery; whereas this treatment benefited young coffee plants. In forking adhesive land care must be taken not to go near the plants.

COLD WATER WITHOUT ICE.

The following method of obtaining a constant supply of cool water at all times is described by *The Railroad and Engineering Journal* as being in general use in Hanover, York County, Pa. The town, says the *Journal*, is closely built up and without any system of drainage, so that the water from the wells is unfit to drink. Some years ago these reasons led to the introduction into the town of a supply of very excellent water from a large spring about three miles distant. This water is brought through iron pipes, and when it reaches the consumer in summer is warm, while the water in the wells is cool. For this reason many of the inhabitants drink the well water, and as a consequence, typhoid fever is a prevalent disease in that community. In order to obtain pure cool water, not impregnated with lime, some of the inhabitants of the place have adopted a plan which is so simple and gives such excellent results that it is worthy of general adoption wherever there is a water supply other than wells or springs.

The plan is as follows:—A cylindrical galvanised sheet iron tank, 12in. in diameter and 4 or 5ft. long, is placed in the bottom of a well. This tank is then connected by a galvanised iron pipe with the water supply pipes, and another pipe is carried from the tank to the surface of the ground, or to any convenient point for drawing water, and has a cock at the upper end. The tank is consequently always filled with water from the water supply, and being in the bottom of the well the water is cooled off and acquires the temperature of the well; so that that which is drawn from the tank is as cool as well water, and is without any of the impurities with which the latter is contaminated. The water drawn from the tank in one of the wells in the place named had a temperature of 56deg. when the thermometer in the atmosphere above stood at 76 deg.

This method gives an abundant supply of cool water during the whole summer, and can be adopted in all cities, towns or in the country. If a well is available it can be used; if not, by simply digging a hole in the ground, deep enough so as not to be affected by the surface temperature, and burying the tank, it will answer equally well. This hole might be dug in a cellar or outside the building. If the water has any impurities in suspension, such as mud the tank should be made accessible so that it can be cleaned separately.—*Invention.*

JAMAICA SORREL.

There is one plant that would well repay a more general cultivation than it now receives—at least from a housewife's point of view. That is the Jamaica Sorrel plant. It grows readily from seed, stands transplanting well, bears prolifically, and the fruit when cooked in jelly, or as sauce, so closely resembles cranberries as to almost deceive an expert. It is quite as good and would prove a most excellent substitute for those delicious berries. The plants in this neighbourhood are now just blooming and in two or three weeks will be ready for culinary purposes, and unless injured by cold, will continue bearing till sometime after Christmas. The plant should be cultivated by every family where a delicious jelly, or sauce, is suddenly appreciated.—*Tampa Journal.*

[Ordinary sorrel comes on exhausted ground in Australia and after a time is said to restore fertility. But what is this Jamaica sorrel?—Ed. T. A.]

OLD King Coffee is once more making an effort to raise his head. A Hapuala proprietor tells me that this season he will obtain a better crop than he has had during the past 12 years, and in consequence, he and other planters have ceased planting up more tea. I also hear of an estate in the Rangalla district with good coffee prospects, so good indeed that an abandoned block is to be re-opened with the old staple! I hope anticipations will be realized.—*Cor.*

BARK AND DRUG REPORT.
(From the *Chemist and Druggist.*)

LONDON, Jan. 1st.

ESSENTIAL OILS.—In Citrouella there has been some business today at 7d per oz. for bottles; tin oil is quoted at 47 to 13-16ths per oz.

COCONUT OIL.—Steady of sale, with some business in fine Ceylon, delivered at 28s; and for near at hand 26s 9d to 27s 1s quoted. Cochin oil on the spot is held for 33s 6d to 34s; and for near at hand 32s. c.i.f. terms.

QUININE.—Since our last report this article has been in good request, and prices improved slowly until today, when the market again became noticeably weaker. The transactions reported since the middle of last week include about 100,000 to 120,000 oz. German-bulk quinine (B & S and Brunswick) in second-hands, at from 12d up to 12½d per oz. the latter price being paid yesterday but today it would probably be possible to buy at 12½d per oz. This morning it was announced that Messrs. Howards & Sons had reduced their quotation by 1d per oz. their brand in bulk being reduced to 1s 5d, and in vials to 7d per oz. The announcement of this reduction appears to have created some surprise. For delivery, the transactions which have become public total up to about 5,000 or 60,000 oz second and first hand German bulk (B & S and Brunswick), at 12½d up to 12¾d per oz for near-at-hand to March delivery, and the B & S agents report also a sale (for consumption) of 5,000 oz at 13d per oz, early delivery.

HOW TO CAPTURE PORCUPINE.

Has Mr. Nock, who is so much troubled with porcupine in Hakgala Gardens, ever tried the native dodge (a trench baited) as related by "Tennent"? Here is the passage from his "Ceylon":—

Porcupine.—The Porcupine* is another of the rodentia which has drawn down upon itself the hostility of the planters, from its destruction of the young coco-nut palms, to which it is a pernicious and persevering, but without so crafty, a visitor, that it is with difficulty any trap can be so disguised, or any bait made so alluring, as to lead to its capture. The usual expedient is to place some of its favourite food at the extremity of a trench, so narrow as to prevent the porcupine turning, whilst the direction of his quills effectually bars his retreat. On a newly planted coco-nut top, at Hangwelle, within a few miles of Colombo, I have heard of as many as twenty-seven being thus captured in a single night; but such success is rare. The more ordinary expedient is to smoke them out by burning straw at the apertures of their burrows. The flesh is esteemed a delicacy in Ceylon, and in consistency, colour, and flavour, it very much resembles that of a young pig.

THE FORESTS of "Darkest Africa" strike the imagination; but they are not the greatest on the earth. In the Empire of Russia there are 491,218,000 acres of forest; in Africa, according to Stanley's calculation, there are only 224,000,000 acres.—*Home paper.*

COL. BELL'S MEMO. ON MADRAS IRRIGATION.—Some copies of a memorandum by Col. J. H. Bell, R. E., late of the Madras Public Works Department, on the Irrigation Works of General Sir Arthur T. Cotton, K. C. S. I., R. E., in the Madras Presidency, have been sent out by the former officer now in England for distribution to officers and others in Madras Public Works Department. Colonel Bell in forwarding the copies has informed the Chief Engineer that the memorandum was drawn by him at the special request of Indian Engineer officers. Colonel Bell, we believe, is the only officer who was personally cognisant of the details of all Sir Arthur Cotton's projects, and it is highly desirable that his memorandum should be put into the hands of all Engineering officers. The volumes have been supplied gratis, and have been acknowledged with suitable thanks by Government.—*Indian Engineer.* [Copies ought to be obtained for the Ceylon Irrigation Officers.—Ed. T. A.]

* *Hystrix leucurus, Sylves.*

SAMBAS IN WESTERN BORNEO.

(Translated from the "Indische Mercur" for the "Tropical Agriculturist," by Mr. John Dent-Young.)

SEARCHING FOR GOLD—SAMBAS AND ITS DESCRIPTION—CONNEXION OF NETHERLANDS WITH SAMBAS—THE SULTAN—AGRICULTURAL UNDERTAKINGS.

There was a time when the very name of California caused excitement. Huzza! for California! the cry gold! gold! resounded on every side. Later on Australia was the centre to which all eyes were turned. There again was gold, the attraction which drew vast crowds to that part of the globe. And now whenever we take up a journal, we find gold to be the great exciting cause of the multitude.

Numerous are the associations which are now working gold mines with more or less success in South Africa, and multitudes are presenting requests to the Resident of West Borneo for permission to set on foot scientific examinations of sites for gold mines. No less than thirty-three such applications have been tendered in Sambas alone, whilst in other parts of the Residency 60 concessions have been applied for. Public attention had hardly been turned on Sambas before requests poured in for such concessions. Thanks to the ready co-operation of the Resident and the Sultan, but little formality is necessary in making those requests. Frequently the simple mediation of a friend has been sufficient. As a preliminary, the application is made for permission to institute a scientific search for gold, for the Government insists on this, and it is only after the lapse of three years that the permission is exchanged for a notarial contract. In this way the danger of sinking capital in a bottomless pit is greatly diminished if not altogether avoided. During these three years there is surely time to make such an inspection of the ground as can establish proof of its being able to repay the cost of working or not; if unfavourable, no further loss is incurred, than the outlay for making the inspection, a risk inseparably connected with all such undertakings.

But we are speaking of the district of Sambas as if it was a well-known locality to each and all, whilst some of our readers may be desirous of knowing more about the possession, for which reason we propose to give the following brief sketch of it:—Sambas is under a Sultan dependent on Netherland, situated at the northern extremity of West Borneo; it is bounded on the north by Sarawak, on the east and south by Landak, on the south by Mampawa, and on the west by the sea, or to be more precise it stretches from Tandjong Datu in the north-west to the Duri river which forms the southern boundary, to the north and north-east it is bounded by the mountain chains of Krinabang-Semadju and Kewai, whilst on the south and south-east it is separated from Sanggow and Landak by the Kurum, Bajang, Mint and Pandang mountain ranges. Sambas comprehends the basin of the river of the same name, from its mouth to its confluence with the Sambas Kiri and Kanan.* The Sambas river takes its rise in the above-named southern chain of mountains, and falls into the sea at Pemangkat after traversing the Chinese settlement of Larak, becoming navigable at Ledo. To the north of the Sambas river rises the mountain of Palo, well-known for the iron of superior quality that it used to furnish.

Sambas, the chief town of the State, lies at the confluence of the abovementioned two branches. It presents to the visitor but little beauty for his admiration. It contains however a good place of entertainment, so that anyone wishing to make some stay there will find no difficulty in obtaining a lodging. Sambas is at the same time of easy access. Every month a steamship belonging to the Ned. Ind. Steam Navigation Company leaves Tjandjong (Chanjong) Priok for Pontianak via Biliton. Soon after the arrival of this ship, a steamer belonging to the transport con-

tractor leaves the port according to the terms of the contract for Sintang, whilst one of the ships belonging to the Indian Marine leaves for Sambas via Singkawang. The vessel of the transport contractor leaves Pontianak on the last day of every month for Singapore via Singkawang and returns by the same course.

Should the traveller not wish to go direct from Batavia, he should take his passage on board one of the fine steamships built expressly for this service, the "Ban What Soon" or the "Ban What Hien," the former of these two has plied for years between Biliton and Pontianak, and the latter has for some months taken her course via Sambas. The development of the mining and cultivating operations on the concessions will decide if steam communication can be continued. As the two last-named vessels are bound by no contract, they do not adhere to any particular time, and therefore the transit via Batavia is to be preferred, as well as on account of the necessary formalities which have to be fulfilled. Let us then select this route, go over to Pontianak, and thence make our way to the Sambas river. As we enter its mouth, we see what appears to be a vast lake, as the river for some distance inland is of great breadth. Both sides are bordered by thickly-wooded hills, amongst which the lofty Peribangan rears its head, overtopped in height by the more distant Bukit Pemangkat, whose dark summit and light-green sides are recognized at a great distance. On the right bank towers on high the Kalimbu, a so-called saddle mountain. To the left of us is the Chinese settlement, while in our front, to the north-east the Bukit Raja extends its crown towards the heavens, whilst its foot stretches away like a tongue of land ending in the rocky Kalimbu. But let us make way for the words of the admirable writer on Borneo's West Coast:—"Further eastward a noble panorama opens to the view, endless forests fringed on the seaside with tjemaras (chimar trees) and extending beyond the Kumé and Batong Mountains, which appear like grey masses defined in sharp outline against a cloudless sky, with the Sambas river shiuing through occasional openings like a silver band. Here bright green rice-fields and gardens, next clumps of coconut palms and other fruit trees, lie like islands spread about in this of sea green. In the midst rises the Bukit Pemangkat. Its summit is clothed with heavy timber, its slopes are planted with enau palms, or are terraced for rice cultivation. From all parts flow rivulets; here, rushing wildly over bare crags whence they are led to water the neighbouring rice-fields; there, winding gently amongst magnificent orchids, and picturesquely intertwined, climbing plants which serve to protect man and beast; westward lies the boundless sea before us, always in motion, always full of life. And through the green waters shine huge stones and rocks with which the coast is strewn."

A sandbank in the embouchure of the river, alas! prevents the entrance of ships of greater draught than 12 feet; higher up the Sambas presents no features of importance except to the lover of the picturesque. "Besides the Chinese Settlement at the base of the Pemangkat," thus continues the Heer Veth, "nothing beyond the town is to be met with, as a sign of habitation not a speck of cultivated ground. All is morass and wilderness, amongst which trees of amazing height force their way upwards, and the silence of the forest is seldom disturbed by the traces or presence of animal life. The small river (a branch of the Sambas) presents at its frequent windings most lovely prospects often not less remarkable for their fantastic forms than for their tropical luxuriance. There is the home of the orangutan (Malay—*orany* man, *utan* forest), and of thousands of smaller apes, here the buzzing of myriads of insects unites with the song or divers noises of birds, whilst dangerous crocodiles lurk for their prey amongst the water-plants on the banks."

The country between the river Sambas and the already mentioned river Duri is intersected by numerous small streams, most of them having their sources in the Mandor districts.

Amongst these and further inland the Chinese Settlements are spread about, the inhabitants of

* Kiri and Kanan are the Malay words for right and left.

which are occupied in the cultivation of rice near the coast. This district is considered the most productive in the western division; still further, inland, the dwellings of the Chinese who are employed in mining operations are met with. This is the scene where the sanguinary drama of the Mandhor insurrection was enacted, which originated in the obstinate resistance of the Chinese "Kongsis" against the steady extension of the Netherlands authority.

The connexion of Netherlands with Sambas is of ancient date. The first treaty with this State was concluded by the East India Company in 1609, and stipulated chiefly that the Company would defend the Sultan against all foreign enemies, particularly against the Spaniards and Portuguese. The Sultan on his side engaging to exclude all other European nations from intercourse with his country, and to concede the exclusive right to free trade with his State to the Netherlands, with the right to build a fort for the protection of their persons and possessions, and ensuring them the monopoly of the diamond trade from which even the native traders were excluded. In 1816,* after the restitution of our Eastern possessions by England a new agreement was made with the Sultan, by which he recognized the sovereignty of Netherlands, and ceded all the revenues of his Sultanate and of its tributary states to the Government, in return for which he was to be paid a fixed income, the amount of which depended on the full tax levied on the Chinese and on the Dayaks. In 1819 this arrangement underwent further changes, containing amongst other stipulations a clause by which the Government was placed altogether in the power of the Netherlands. After further amplifications and renewals, the present existing Charter was established in 1848 with the following principal clauses:—The State of Sambas forms an integral portion of Netherlands India, and is immediately under the authority of the King of the Netherlands, locally represented by the Governor-General, and accepts his State as a fief from the supreme government and exercises authority in concert with officials appointed by the Government. The successor to the throne according to adat (ancient custom) is elected, the election being subject to the approval of the Governor-General; all the revenues including the poll-tax paid by the Chinese, rents, customs and public property of all kinds belong to Government, the Sultan receives an allowance of R12,000 guildens a year (12 guildens being equal to £1 at par). In the interior of the State the Sultan is bound to provide reasonable maintenance for all the members of the princely family, the village contribution of labor shall be at the disposal of Government for the public service; the Sultan is to appoint the native chiefs in accordance with custom, and in consultation with the chief Netherlands official, he is to maintain law and justice; afford all help to the law courts and to the police, and decide minor matters of police and justice. Europeans, Chinese and foreign Easterns are subject to the legal authority of the Government.

The Sultan will do all that is possible to suppress "head cutting"† the slavetrade, piracy on the sea and coast; he will do all he can to abolish the pawning system, and will give all practicable aid to encourage trade, navigation and all useful branches of industry;

* Which had been held since 1811.—*Note by Translator.*

† Potong-kapala, a time-honored institution amongst the Dayaks, is a kind of duel in which two men at a time engage in a fight with heavy swords, sharp as razors, the delicate attention of each is confined to the endeavour to chop off the head of his opponent; other wounds are not allowed to count, so the entertainment goes on until one of the players loses his head and the game at the same time. Until "the grinding tyranny of the Dutch" interfered these exhibitions afforded great amusement to crowds on all State occasions; in the case of the combatants it used to be considered, that the more the merrier, and a successful stroke of the gollock or razor-like sword was "mighty pleasant to behold."—*Note by Translator.*

and to render the utmost help in case of shipwreck, and to shipwrecked persons; he will not enter into any compact with foreign princes or people, or permit them to establish themselves in his State, but will give intimation to the Netherlands authorities immediately on the occurrence of any attempt at so doing. He binds himself on oath in writing to fidelity to the King of the Netherlands; and lastly, he acknowledges a debt on his State to Netherland of f48,080, and will submit to all such measures which the Government may deem necessary for the recovery thereof. As may be seen from the foregoing, Sambas is a well-regulated State, in which the security of person and property is as well guarded as in any European country. The present Resident, Heer J. van Nieuwkuijk, lately replaced by the Heer Tromp, both most excellent men, and the present Sultan Mohamed Tsafudin, Knight of the Netherlands Lion, an enlightened man, do their utmost to promote the welfare of the country.

As we have already mentioned, there are many persons desirous of establishing themselves in Sambas for the purpose of cultivating the ground as well as for working gold mines. Up to the present time the latter pursuit has been exclusively in the hands of the Chinese, whose appliances are of the most primitive nature, yet they are the people in whose footsteps Europeans are about to tread. Applications for concessions have for some time past been pouring in. Thirty-three mining concessions have already been granted, but of these only three have passed into formal contracts. The others remain still, only permits to examine the ground in order to ascertain its adaptability for the proposed purpose. This examination, as we have already said, lasts only for three years, at the end of which period it must be changed for a notarial deed, or be given up. As soon as a contract has been signed, the rent becomes payable, at an annual rate of 10 cents per bouw and 2½ per cent on the gross produce. So that those who enter into the contracts naturally limit the extent of the concession to the land which has been found absolutely necessary.

We have just said that hitherto the gold was collected principally by Chinese who obtained it chiefly by washing, being ignorant of any other mode of working the quartz reefs. These gold washings are situated on the slopes of hills or in their immediate neighbourhood, and are connected with a flow of water which is essentially necessary for the work. When a site has been selected, every effort is made to turn a sufficient supply of water into it, no trouble or expense being spared in the construction of an efficient watercourse.

The nature of the gold deposit, whether mixt with sand, incorporated with quartz or in veins, necessitates the adoption of different processes for its collection. The Dayak goes to work in the most simple manner. When the burung (bird in Malay) Soho has indicated to him where the gold lies, he washes away the earth in a wooden trough until nothing remains but the particles of gold. The Malay goes a step further; he digs a pit, and gathers all the gravel and earth, and washes it out, whilst the Chinaman goes to work in different ways, according to the formation of the site. If the gold stratum lies above the level of the water, and if the water supply is sufficient, as is the case near Pagong in Montrado, all the surface earth is dug away, and the stratum of gravel or silt thus exposed is carefully washed in broad wooden *kotaks* (troughs) arranged in steps, then removed into small tubs and rised, and from the residue the particles of iron ore are removed by means of a magnet.

Where the gold containing silt lies below water level a sufficient number of channels are dug, which are kept dry by means of a (*tali-ayar*) water-rope acting like a chain pump. As soon as the sought-for stratum is reached, it is removed gradually into troughs, and washed until the gold is separated. Should the gold lie in veins, the stratum through which the veins run is broken into pieces with sledge hammers, until the depth of water puts a stop to the process, the ore is then picked out and reduced to

powder in wooden mortars, and then washed. It need hardly be pointed out that in this last method there is much gold lost: in the first place, the sorting of the ore is done by the eye; secondly, the appliances are of the roughest kind and very inefficient; thirdly, it is only practicable to a very little depth.

The European engineers will manage matters better. A large quantity of machinery has already been introduced. That the gold strata are frequently rich is evidenced by the amount of gold produced with very defective appliances and most clumsy methods by the Chinese, who obtain as much as yields about 200,000 guildens (or guilders) a year. With the method described they get 0·012 per cent of gold from the quartz.

If the above data are not exaggerated, colossal results may be looked for; even if the proportion of gold should turn out to be only one-third of what it is said to be, the mines will be well worth the trouble and expense of working, and with good management will yield considerable profits.

AGRICULTURAL UNDERTAKINGS.

Thus far we have confined our observations exclusively to mining enterprise; we now propose to consider the question of the application that have been made with reference to the extension of cultivation in these regions.

The number of persons desirous of obtaining land for agricultural purposes is also great. The newspapers from India give us the names of those who from time to time continue to swell the list of proposed agriculturists, and so it will go on until all the western division shall be parceled out.

In Sambas alone 55 concessions have been granted, of which 25 have been confirmed by contract entered into. That more contracts have not been made is explained by the fact that within a year after the completion of the contract, the rent becomes due for 10,000 bouws, 2,000 guildens is the sum that has to be paid as rent, for the second year 4,000, for the third year 6,000, for the fourth year 8,000, and for the fifth year 10,000, without any regard to the fitness of the land for the proposed cultivation or to the circumstance of its being uncultivated. [The contractor has to pay the stipulated rent whether he cultivates or not.—*Note by Translator.*]

Of the twenty-five concessionists who have passed over this difficulty, many of them are members of a Syndicate at Singapore, the name of which does not appear in connexion with the undertaking. The contracts are in favor of the person who enters into them. Amongst these there are several who have begun to work on their own account.

The produce of the cultivation thus begun is up to the present time not very satisfactory. The reason for this is to be sought, not so much in the constitution of the soil, as in the great difficulties which the planters have to overcome. In proof of this, may be mentioned that two persons who are members of the Syndicate have produced tobacco of excellent quality, which was received in town with high approval, but that an outlay of 80,000 guildens was made before the result was obtained.

Another concessionary established a tobacco enterprise on a large scale, which according to Heer K. (*Bat. Nieuwsblad*, 15th July 1890), promises very well, but he had his full share of troubles. In the first place he could not obtain sufficient labor. The Chinese coolies displayed gross ignorance as cultivators, as well as unwillingness, and when at last help came from Singapore, it was found to be of little use. Shoemakers, tailors and clerks were sent, but no people who knew anything of planting. These were soon found to be very difficult to manage, and were continually deserting. To trust exclusively to Dayak laborers, seemed to him to offer as little hope of success. He has therefore endeavoured to engage a better class of Chinese work people.

But all this does not disprove the assertion that Sambas has very certainly a good future, if these difficulties can be removed out of the way. More than once has the soil of this region been examined, and

the conclusion has always been arrived at, that it must be regarded as in every respect most favourable for cultivation. The soil has been found well adapted for the planting of sugarcane, tobacco, coffee, rice, pepper and many other products, whilst there is a great variety of good timber ready to hand, which will amply repay the cost of felling and transport.

We furnish the above as explanatory of the map which accompanies this number.

As will be seen by the map, Sambas is very favourably situated. It should be remembered that the divisions there marked indicate chiefly the lots where permission has been awarded for mining inspections, or for which requests have been tendered for concessions for cultivation. Only one contract has been entered on to the south, 20 miles from Sambas, when Heer P. van Dijk has commenced operations. Further south, near Mentrado, Mr. Gordon has brought a tract of land under cultivation on similar terms, and a little further north Mr. Liddolow has in like manner commenced operations near Benkajang; whilst twenty-five cultivators have contracted.

Too much importance should not be attached to the absence of the names of many of the concessionists; in a latter map of concessions, for it is more than probable that many of those whose names now appear on the map, may withdraw from the undertakings. Our readers are not to consider this article as written for the purpose of urging the cultivation of Sambas, or for encouraging the enterprise. Our only object is to convey a correct idea of the present condition of the country, and nothing more. It is certain that great expectations are entertained regarding Sambas. It is said even that applications have been made to the Sultan for the formation of a railway, but we are not in possession of any particulars.

CULTIVATION OF FIBROUS PLANTS IN CEYLON.

Our correspondent, W. A. D. S., mentions in his last letter the fact that the stem of the *Bandakai* yields a good fibre. We think that fact is well known, but what is necessary to turn it to useful account is the quantity and cost of the fibre produced by the plant. In other words, the information wanted is the economic value of the plant for the production of fibre. Capital is a scarce commodity in Ceylon, especially amongst those people who are most in need of new industrial resources. Such persons are not likely to be attracted to risk their slender means in experiments with plants of which they know only vague and indefinite possibilities. They want some fair prospect of gain, based upon ascertained results, not on mere chances. In countries where there is a large amount of unemployed capital seeking investment, the case is different, but even there it is not easy to induce people to make experiments otherwise than upon definite estimates of profit. In this country the only chance of obtaining a satisfactory trial of a new product rests with the School of Agriculture, or other similar institutions possessing means of experimenting independently of a remunerative result. It is quite possible that the *Bandakai* plant might yield fibre profitably, but our correspondent, W. A. D. S., does not give any data for estimating the economic value of the plant for its fibre, and therefore leaves the matter practically just where he found it.

The same may be said of the Sunflower plant as of *Bandakai*, namely, that it yields a strong and serviceable fibre, as well as an abundant crop of nutritious seed, but the fact that both these plants are extensively cultivated for their fruit, and not for the fibre they are well known to contain, tends to show that the fruit is a more valuable product than the fibre. We think the School of Agriculture would do a good service by testing the value of both these plants for the fibre they yield. The result of their experiments would be valuable, if not conclusive as to the question whether either would pay for fibre cultivation in Ceylon. In the meantime, we could not advise the expend-

ture of capital on either by anyone who could not afford to risk a loss by the venture.

The Niyanda fibre is superior to either of those just mentioned. It is of great strength and flexibility, and is of beautiful texture. It is not cultivated anywhere, so far as we are aware, but grows wild in some parts of the Island, and is largely employed by natives, who collect it and prepare the fibre for mats and other useful articles. Whether it would repay regular cultivation is, however, just what we should have expected our practical friend, W. A. D. S., would tell us. In the absence of the necessary data by which to estimate the chance of successful cultivation, it must be relegated to the same category as the two plants first mentioned. Over them, however, it has the advantage of being already in considerable use, and of therefore possessing a certain economic value.

Hitherto, notwithstanding the large number of fibre producing plants that grow freely in this island, and the high value of the fibre some of them produce, the attempts that have hitherto been made to produce fibre, as a commercial enterprise, have resulted unfavourably, except in regard to Coir and Kitool fibre, which we number amongst our regular exports.

Aloes, plantains, and other plants have been repeatedly and extensively tried, without success. Cotton promises to do well, and possibly some other of the numerous plants that are profitably cultivated elsewhere may hereafter be cultivated successfully in Ceylon, but the difficulty as regards nearly all of them, is to free the fibre from the pulp in which it is formed. This is not peculiar to the plants of Ceylon, but is common to nearly all. The separation and cleansing of the fibre is therefore in almost all cases the chief part of the work, and the essential feature of success in regard to the profitable production of fibre.

It is possible that the forcing climate of this island may cause the fibres that are formed in the tissues of the plants that produce them to adhere more closely to those tissues than in countries where growth is periodically interrupted by winter or other change of season. Be that as it may, the art of separating and cleansing the fibres of Ceylon-grown plants has not hitherto been successfully acquired, and until that cardinal difficulty is overcome, the cultivation of fibrous plants is not likely to be remunerative.

Considering the importance of the subject, as shown by the magnitude of the jute industry in India, the extensive coir manufactures of this Island, and other similar industries, it is one to which the School of Agriculture might give particular attention, especially as the students possess the advantage of a chemical laboratory and a fair elementary knowledge of the science of chemistry, which may be expected to suggest or to supply solvents suitable to aid in the process of separating the fibres from the pulp in which they are formed.

It may be here remarked that the failure of sugar as a profitable product, in all those parts of Ceylon where the cane has been cultivated, is due to the forcing climate and its influence in promoting an uninterrupted growth. The ripening process, in which the saccharine is formed, is unduly delayed for want of an effective check to the flow of sap. The experience of the past attempts to cultivate sugar profitably in Ceylon suggest that any future trial should be made in parts of the Island where there is a definite growing season and a marked period of comparative stagnation of growth. Possibly, the same may apply to the cultivation of those plants in which the fibre is formed in the substance of the tissues. Here again, the School of Agriculture could do good service by making trials in some of the numerous stations where they carry on their useful and practical operations in different parts of the Island.—Local "Indereudent."

PLANTING IN GUATEMALA.

Sarsaparilla.—Among the products which find shipment from the Atlantic coast, of which the town of Livingston is the port, sarsaparilla should be mentioned. The exports of this article during 1887 were 51,311 lb.

This product was in such demand at one time, and commanded such good prices, that the natives gave up almost every other kind of employment and devoted themselves entirely to its production. During the past two years, however, the price has receded by one-half, and the demand has largely fallen off. It grows readily from cuttings of the indigenous vine, and, as the natural supply is giving out on account of careless digging, it is possible that the cultivation could be made profitable, even at the present low prices.

Drug Cultivation.—The Government is offering a good many inducements to agriculturists to take up the cultivation of economic plants, including many varieties of drugs. Anyone desirous of cultivating sarsaparilla, rubber, or cacao, and not having land for the purpose, can, on requisition, be put in possession of a suitable lot. The following rewards are offered to agriculturists who at the end of eight years can show healthy plantations of cinchona (calisaya or succirubra):—15*l.* for 1,000 plants eight years old to the first cultivator, 7*l.* to the second, 3*l.* 10*s.* to the third, and 1*l.* 10*s.* to all others. A premium of 4*l.* for a term of three years is given for every 150 lb. of indigo grown and made in the country, and at the end of ten years after commencing the cultivation a reward of 11*l.* 10*s.* for every thousand gum trees planted out, of five years old.

Cochineal.—The industry of cochineal-raising has almost entirely disappeared from this country. For thirty years cochineal was the principal article of export, but now what little is grown is used for native consumption.

Coca.—A quantity of coca seed was imported from Peru in 1883, for distribution among the people in a suitable zone for its growth; but the result was unsatisfactory, from the bad quality of the seed, and fresh means are being taken to extend the cultivation of this plant.

Pepper and Cinnamon.—Pepper and cinnamon are grown in the department of Alta Verapaz; good seed has been imported from Ceylon, and planting is extending in the fertile district, while good results have also been obtained in the department of Escuintla, where a few plantations have been made.

Vanilla, Cinchona, &c.—The vanilla plant grows wild on the mountains all over the country. The quantity of the vanilla is good, but though it figures as an export it is not cultivated for that purpose. Peruvian bark has proved a failure, and the cost of introducing the tree has been practically lost. Indigo works are subsiding in the country; a few still exist in the east, but though means are taken to encourage them, only 93*l.* of indigo was exported in 1888.—*Chemist and Druggist*.

EUCALYPTUS GLOBULUS.

Of all the 150 varieties of eucalyptus, the common blue gum is the most useful and the most important tree for Southern California. It does not thrive in Florida; the cold spells of winter cut it down or stunt its growth; but on the Pacific Coast, from Eureka to Tia Juana, a distance of 800 miles it is a stately, mighty advance agent of our new civilization. Twenty years ago our plains were absolutely treeless—desert-like, parched and brown, lifeless almost—a picture of despair. Then the first boxes of seedlings were imported from Australia and sold at the public auction in San Francisco, at \$5 a tree.

Today the precious little giants sell for one cent a tree. Rsmi Nadeau, a recently departed genius deeply regretted by his friends, was one of the first men to appreciate the value of the eucalyptus as a fuel tree. He conceived and executed the gigantic project of planting 1,200 acres of sandy land at Florence to blue gums. Over one million trees in one plantation! Today is a stately forest of mighty trees, towering tall and straight 150 feet, a monument to the enterprise of our bygone friend. Every third year the trees are cut down, yielding 60 cords of 4 foot wood to the acre, worth \$6 to \$7 a cord standing, or \$7 to \$8 cut and corded; the net income is therefore \$420 for

the three years or \$140 an acre per year. And every time these are cut, a new forest springs up from the old stumps, and there is no expense to be incurred after the first year for either plowing, cultivating or irrigating, for deep down into hidden water courses in the earth does the blue gum send down its thirsty roots, even thirty feet where the water is so far below the surface; and it makes its giant growth in the poorest sandy wastes of our river washes, drawing its sustenance from the atmosphere through its wealth of evergreen leaves. What a perfume, what a tonic is inhaled by the beautiful foliage of the eucalyptus when night brings rest and coolness to our plains. Fevers lose their terror and malaria departs with a creeping horror, where the rustling, whispering groves of stately eucalyptus waft fragrance over the home. Pour boiling water over the blue gum leaves and drink the powerful tonic. It is equal to quinine to dispel the terrors of sickness. The contagious atmosphere of the sick room today is cleaned by sprinkling on the floor of an essential oil "Eucalyptole," extracted by the science of the chemist from the resinous leaves of *eucalyptus globulus* or *eucalyptus amygdalina*. Years ago winds swept over our treeless, uncultivated plains. The "Northerners" were a terror to the farmer and orchardist. Today miles of eucalyptus surround our fields, line our avenues and encircle our orchards. They act as powerful wind-breaks, protect the tender buds of our fruit trees from the March winds, and yield an abundance of fuel, where of yore the shiftless Mexican vainly hunted for dried manure or brea to light his smoky fire. Stranger, imagine the beauty of our avenues of blue gums twenty or a hundred years from now, when the trees average over 200 feet in length, over 15 feet in diameter, as they do today in their native land, Australia. Our southern plains will rival then the wonders of the Yosemite in their big trees. The question of fuel and timber supply is becoming more serious, more important from year to year on the Pacific Coast, as the giant redwood yields to the greedy axe of the all-absorbing lumber trusts.

If you own any lots or acres that are idle or unproductive, plant them in blue gum. A town lot 50 x 150 feet will grow 200 trees 6 feet apart, and every tree when 5 years old, is worth \$1.50 for fuel in a city. Your lot thus yields \$300 in five years or \$60 a year, and fifty acres in blue gums will yield you an annual income of \$7,000. The mayor of Los Angeles is planting 150 acres of blue gums this season; they will yield him a handsome revenue a few years hence. The mighty forest will be an object of beauty to behold and a source of perpetual income to his heirs. Let the good work proceed of planting the beautiful blue gum in forests for fuel, around orchards and fields, for wind breaks and for ornament in sightly avenues, affording shade and shelter along our streets.—*Rural Californian*.

THE COST OF GROUND PEPPER AND THE ADULTERATION ACTS.

At the public sales this week light shelly Penang Black Pepper has been sold at the price of 4½¢. per lb., the lowest point that has been touched for a long time past. According to the test analysis published in the catalogue (as is now usual for Penang Black Pepper, under the recent arrival contract form), this parcel weighed 3lb. 7½ oz. per gallon, and contained 4.53 per cent. of dust, &c. The following are the regulations in the arrival contract form which regulate this analysis:—

"(1) The following to be the standards of quality:— Class A, Heavy, weighing 4lb. 13 oz. per gallon measure; B, Fair, weighing 4lb. 5 oz. per gallon measure; C, Fair Merehautable, weighing 3lb. 13 oz. per gallon measure; D, Light, weighing 3lb. 5 oz. per gallon measure=Dust 3 per cent.

"(2) The term dust to include stalks, stones, clay, and other foreign matter.

"(3) For the purpose of ascertaining the proportion of dust, 5 per cent. of each mark shall, in the first

instance, be sifted through a No. 9½ sieve, in galvanised iron with round holes (one of which is held by the General Produce Brokers' Association). Of the sifted Pepper fifty pounds of each mark shall be hand-picked free from stalks, stones, clay, and other foreign matter, and the percentage of impurities so found shall be added to the percentage of dust as ascertained by sifting. These operations to be performed by one of the customary docks or wharves.

"(4) Should the Pepper be found to contain more than 3 per cent. of dust, any excess up to 2 per cent. shall be treated as valueless, and allowed to the buyer. Should the additional 2 per cent. be exceeded, the buyer shall have the option of taking the Pepper with allowance for any dust in excess of 3 per cent., or of invoicing back the parcel to the seller at the fair market value of the day of the quality contracted for, plus a fine of not less than 2 per cent., and not more than 10 per cent., the value and fine to be fixed by arbitration in the usual manner. Any fraction below half per cent. to be neglected, any greater fraction to carry the next higher integral.

"(5) For the purpose of ascertaining the weight of a parcel, the average sample taken by the Dock Company or Wharfingers shall first be freed from dust and other impurities, and then filled into a gallon measure, shaken down as closely as possible without pressure, and struck off and weighed, the average of three fillings to be taken for 25 tons or less. This operation to be performed by the selling Brokers, who shall state the separate weights of the three tests on the out-turn accounts.

"(6) In the event of seller or buyer being dissatisfied with the return of the weighing by the selling Brokers, either of them shall have the option, within a week from the date of the first selling Broker's return, of calling for a fresh average sample to be drawn, and the matter shall be referred to arbitration. The arbitrators to test both the landing and re-drawn samples, and the testings to be averaged, and the result to be considered final. Should the Pepper have been re-shipped before a fresh sample is asked for, the first weighing shall be taken as final.

"(7) Should the Pepper be found to weigh less than the minimum of the class named, the buyer shall take the same with an allowance of one quarter per cent. on the sale price for the first ounce or fraction of an ounce, and a further one-half per cent. for the second ounce or fraction over an ounce, but should the deficiency in weight exceed two ounces, the Pepper to be invoiced back to the seller at the fair market value of the day, of the quality contracted for plus a fine of not less than 2 per cent., and not more than 10 per cent., the value and fine to be fixed by arbitration in the usual manner.

"(8) Samples to be drawn of not less than 28lb for parcels of 25 tons or less. In case a second sample be required, half of the total quantity drawn to be returned to the bulk."

No machine has yet been invented which will entirely remove earth or sandy matter from Pepper, and, in fact, practical experience shows that in some cases screening or brushing machines, by the forcible pressure used in this process, do harm instead of good, by breaking up pellets of earthy or clayey matter that a sieve would to a great extent remove unbroken. The only plan that the trade can adopt, therefore, to avoid risk of prosecution under the Adulteration Act, is to buy whole Pepper as free from dust and dirt as possible, and the analyses published with each parcel of Penang Black enable them to a great degree to do this. It appears, however, that the test analyses carried out by the London docks and wharves do not mean that all the dusty matter consists of sand and earth.

Penang Black Pepper is more largely used for grinding than other descriptions and heavy Acheen can now be bought at 5d. per lb., and West Coast Peang, which is heavier Pepper, at 5½d. to 5¾d. per lb., according to weight per gallon and percentage of dust. In the best cases the percentage of the latter would be 2 to 2½ per cent. The cost of grinding, including barrels, and loss in weight in grinding

and between warrant weights and re-weights, would add $\frac{1}{2}$ d. to $\frac{3}{4}$ d. per lb. for expenses, without any profit to the wholesale dealer. The usual charge for grinding and barrels is $\frac{3}{4}$ d. per lb., and there is a considerable loss between warrant and delivery weights, and a further loss of weight in grinding. In our opinion, Penang Pepper with 2 per cent. to 3 per cent. of dust is the lowest quality which it is desirable to grind, if the public are to have pure Pepper. The first cost without profit to the dealer of this quality just now is about $5\frac{1}{2}$ d. to $6\frac{1}{2}$ d. per lb., ground and packed in 10wt barrels. The finer qualities of Black Pepper, such as Tollicherry, Alleppy, and Malabar are selling whole on the Market at $6\frac{1}{2}$ l. to $6\frac{3}{4}$ d. per lb. If barrels are separately charged for (which is not, however, usual in the Spice trade), a corresponding reduction could be made in the quoted price.

It is well for the retail trade to have those undoubted facts clearly in view, for, with the infinitesimal difference the sale of doubtful Pepper could possibly make to them in the course of the year, the risk of a prosecution, and possible conviction, for selling adulterated goods, is obviously not worth running: even if they desired to take such a risk, which is not the case by any means. Indeed, in the "poivre" and other cases, the retailers undoubtedly bought in entire ignorance of the adulteration. Nor would a guarantee from the wholesale grinders or dealers that the Pepper was pure be much satisfaction to a self-respecting man if he found that adulterated Pepper had been sold to him, under the proper price for a genuine article.

It is true that, instead of selling Ground Pepper at $\frac{3}{4}$ d. to $\frac{5}{8}$ d. per lb. above the cost of the whole corn, which is the lowest legitimate margin, Ground Pepper is habitually sold at about $1\frac{1}{2}$ d. per lb. below the first cost of the whole, or apparently about $1\frac{1}{2}$ d. under its proper relative value. When buyers purchase Ground Pepper at prices apparently below those that are practicable, it would be a good plan if they asked for samples of the Whole Pepper used, and insisted on being supplied at the same time with an equivalent parcel of whole Pepper, at say, $\frac{3}{4}$ d. under the ground price. Such quotations are explained by the parcel consisting wholly, or in great part, of the husks given by the process of decortication of Black Pepper. These are produced when the outer shell of Black Pepper is mechanically removed in order to make White Pepper from the Black Pepper corns. How far the sale of ground husks as Ground Black Pepper, is legal, without a declaration to that effect, has not been settled nor has it been decided whether the public analysts would pass husks as Pepper. The husks in any case must contain a very much greater percentage of the dirt that was originally in the parcels, and the buyers would thus run more risk with them than with parcels ground from the whole Pepper as imported. In the meantime the retail grocers may feel perfectly certain that if they are offered ground Black Pepper, at present market values, under 6d. to $6\frac{1}{2}$ d. per lb., that it is either sold at a loss, or that dirty whole Pepper has been used, or that husks have been mixed with it, or that it consists of husks altogether. In the present state of the law there seems no objection to the admixture of husks, so long as the buyer knows the fact.

It is satisfactory to find that the action taken some time back has stopped the admixture and adulteration of White Pepper with the so-called "Long" Pepper. The price of the latter has fallen to about 25s. per cwt., at which under, its own name, the Spice in question has a legitimate sale and use. When used for adulteration the value was run up to 70s.

A good deal of almost open adulteration, is still carried on by mixing ground Rice, worth say $1\frac{1}{2}$ d. per lb., with White Pepper. This admixture if carried to any great extent can be detected by the dirty, greyish tint, and also by the weight of the sample, ground Rice being heavier than pure Pepper. A strong magnifying glass or weak microscope at once shows this adulteration, as the Rice grains look like bits of quartz or camphor in the Pepper. A further test is to pour boiling water on two samples, one the suspected one, and one of real ground White Pepper. The difference in the aroma of a sample adulterated

with Rice Flour can at once be detected, and the latter also often goes into a starchy pulp or into a more solid mass.—*Produce Markets' Review.*

ECHOES OF SCIENCE.

Whether or not a plant draws the nitrogen it requires to form its tissues directly from the atmosphere, is a question which has been much debated. Herren Hellriegel and Wilfarth, two German chemists, have already shown that seeds sown in calcined soil produce only puny plants, having little nitrogen in their substance, but if they are watered with a few drops which have drained from a vegetable mould they begin to prosper, and secrete nitrogen which apparently can only come from the atmosphere. The water supplies it appears, the microbe necessary to abstract the nitrogen from the air. M. M. Schloesing and Laurent, two skilful French chemists, have now put the question beyond all reasonable doubt by a memoir read before the Académie des Sciences, Paris.

They have found by careful experiments on plants grown in a confined atmosphere, that these abstracted nitrogen from the air around them to the extent of 30 cubic centimetres, and analysis of the plants practically rendered this quantity back again. M. Laurent has also succeeded in cultivating the microbe which fixes the nitrogen and defused the conditions of its existence. The most unexpected fact brought out is that this proto-organism flourishes above all in a medium deprived of nitrogen in combination; nitrates in particular appear to hinder its development.—*Globe.*

NOTES ON POPULAR SCIENCE.

By DR. J. E. TAYLOR, F.L.S., F.G.S., &c.,
EDITOR OF "SCIENCE GOSSIP."

There is only one agent we are acquainted with which will in a great degree replace the energy produced by the consumption of coal—ELECTRICITY. At present we generate it chiefly from coal, although it can of course be produced by chemical action. But there are certain great mechanical forces in the world, generated by solar energy now, just as coal originally was. The first of these is the wind. Few people have formed an idea of its enormous and as yet unused energy, except in the case of our ancient and picturesque windmill. But the windmill is an archaeological suggestion of a future rescue. Imagine a head of wind a mile across and a hundred feet in height—the latter a mere trifle. Then multiply this by the force moving over the path it takes. There are millions of horse-power represented thereby. Irregular in its action though the wind is proverbially said to be, our storage batteries (as yet but in the infancy of their development) can accumulate much of this now almost wasted energy. The latter can be stored and drawn upon at pleasure. Further, think of the as yet almost unused energy represented by streams, especially tidal rivers. One of our chief electrical engineers has shown that the phenomenally high tide of the Severn, coming and going twice a day, represents more energy than all the cotton mills in Lancashire and Yorkshire. The Americans have already commercially and scientifically formulated a scheme for utilising Niagara. Some day, perhaps, somebody will formulate a method for enlisting the energy of the tides all over the world in the service of man. The energy represented by the vast consumption of coal every year in every part of the globe is a mere trifle compared with the energy of moving wind, flowing streams, descending waterfalls and cataracts, and the always certain ebbing and flowing tides. A French engineer is already making propositions to supply electric power to Paris by utilising the ebbing and flowing tides of the coast; and he is constructing, at Havre, two large basins, into one of which the sea at flood-tide will flow over a dam, whilst during ebb it will flow out of the

other dam into the sea again. There is a similar antiquated dam on a very small scale at Woodbridge, in Suffolk, only it turns a mill-wheel instead of working a dynamo.

A new and ingenious milking machine is being tried at the Duke of Portland's dairy farm. It is a simple contrivance, being merely an iron pipe and a hand-pump. Connected with the pipe is a length of indiarubber tubing. The latter has teat-cups for clasping the cow's teats in such a manner as to be air-tight. When the cups are applied to the "cows," the pump can be worked by a lad, the air exhausted, and the milk drawn from the animal, all four teats giving out at the same time. The cow is thus milked dry in about eight minutes, and is said to behave herself decently during the operation.—*Australasian*.

JAPAN is about to enter the field as a producer of indigo. The soil and climate of parts of the island are stated to be favorable to the cultivation of the shrub.—*American Grocer*.

TWENTY or thirty Europeans and about two thousand Africans are working on the Congo railway to Stanley Pool. It is thought that the railroad will suppress the slave trade better than the army.—*Ibid*.

Rev. Dr. E. E. Hale, in the *Commonwealth*, suggests that cheap sugar may drive out the taste for whiskey. It supplies the hydro-carbon needed to take the place of whiskey. He says that the Spaniards are addicted to the use, almost every hour, of sugar and water as a beverage.—*Ibid*.

OUR EXPORTS.—As much as 892,934 lb. of tea, 661 cwt. coffee, 111 cwt. cocoa, 12,446 lb. cinchona bark, 3,353 cwt. coconut oil, 1,601 cwt. plumbago, 14,720 lb. cardamoms and no cinnamon (nor "chips") sum up the week's exports in Ceylon products. We suppose there must be some further additions to be made before 1890 season is closed: we ask because Messrs. Forbes & Walker in their circular the other day gave 46,310,295 lb. as the total export of tea for 1890, whereas the Chamber today only make up 45,943,469 lb.

RINGING TREES.—Hartig gives the following account of his experiments in ringing the bark from trees. Trees from which a ring of bark has been taken are affected differently, according to the kind of tree, and the thickness of the trunks. Some die rapidly, while others remain alive a long time. The author has already expressed his opinion that most likely root-structure has considerable influence on plants submitted to this operation, and any prognostications as to the probable effects must be guided by the fusions or inoculations which may have taken place between the roots of the tree under treatment and those of the untouched trees around. If the roots, after the cessation of nourishment, and of growth, and the formation of new rootlets, soon lose the faculty of absorbing water and mineral substances (Pine, Spruce Fir, &c.) from the soil, the death of the plant must be the direct consequence of the operation, unless there are underground unions with the roots of neighbouring trees by which life is sustained until the dead part of the trunk becomes impermeable to water. But if the roots do not entirely lose the power of absorbing water even in their oldest parts—as in the case of Maples, Lime trees, &c.—the trees continue to thrive without underground union so long as the denuded trunk is in a fit state to allow of the passage of water. The following interesting example will therefore be easily understood. A Spruce Fir tree a hundred years old, divided at a height of about twenty-three feet from the ground into two almost equal trunks. In 1871 a complete ring of bark was removed from one of these trunks. The tree was cut down in the winter of 1888—9; the two crowns were quite green, those of the ring side being rather less abundantly provided with leaves. The roots of the injured side had ceased to grow but in spite of that, the ringed branch continued to grow for seventeen years, nourished by the roots of the uninjured side.—*Annales Agronomiques*, Nov. 25, 1890, p. 526.—*Gardener's Chronicle*.

SAVE ALL THE WOOD ASHES made on the farm and buy more from the neighbours. They will make an excellent fertilizer for onions, and are beneficial to all fruit trees, no matter on what soil they may be growing. Coal ashes, also, are said to be valuable, not only for walks, but to mix with hard, stiff soils, to which they give a softer and more porous nature.—*Indian Agriculturist*.

A CANADIAN DAIRYMAN describes a plan by which he gives his calves fresh new milk, and yet manages to have a good supply of butter from his milk. The idea is simple enough, and well worth consideration. The plan adopted is as follows: At milking time two large vessels are put outside the byre door, one marked "dairy" and the other "calves." One half of the milk given by each cow, viz., that first drawn, is put into the vessel marked "calves," and the other half, viz., that last drawn, is put into the vessel marked "dairy." This latter half is found, on being tested, to contain from two thirds to three-fourths of the cream. The calves have the advantage of being fed with milk warm from the cow; at the same time they are reared at a moderate cost, as their allowance of milk does not contain much cream.—*Indian Agriculturist*.

THE MAGAZINE
OF
THE SCHOOL OF AGRICULTURE,
COLOMBO.

Added as a Supplement monthly to the "TROPICAL AGRICULTURIST."

The following pages include the contents of the *Magazine of the School of Agriculture* for February :—

AGRICULTURE AND ENTERPRISE.

It cannot be questioned that there is a great lack of enterprise in the south of Ceylon,—of whatever class, and more especially among the natives. There are undoubtedly cases that can be brought forward to disprove this general statement, but these are few and exceptional. Of late we have seen a number of Ceylonese leaving the Island to try their fortunes in other lands, impelled by the success of a few pioneers to imitate their example, till quite a little colony of young men has been formed in the Straits Settlements; but there is little doubt that one of the chief incentives to this action is the charm of novelty in leaving this country and journeying over the seas to visit new lands and new peoples.

Taking agriculture in its widest sense, we find very few of the Burghers of Ceylon as cultivators of the soil. It does not take long to count those who are engaged in the cultivation of tea, coffee, cocoa, coconuts, and cinnamon. Many who have gone in for these industries have proved themselves successful planters, while some have held up their heads well above the crowd. There have also been stray cases of those who have tried sheep farming, cattle and horse breeding, and tanning among the Ceylonese with more or less success: but how few compared with the hundreds that crowd the legal and medical professions, merely because these professions show beaten tracts, and because these hundreds have not the enterprise to strike out a new path for themselves.

Some time ago a native young man came to us full of the idea of starting off to America, after having read a plausible advertisement in a newspaper, with the idea of cultivating land. Of course it did not take long to dispel from his mind the gorgeous prospects he had conjured up there, from our own knowledge of the import of such advertisements; and we strongly advised him if he had any special desire for anything like colonization under difficulties, he might begin on a moderate scale by applying to the Ceylon Government for a grant of land in some neglected region of the Island, on the promise of bringing it under cultivation of paddy, cotton, dhall, Indian corn, arrowroot or the like. But with this suggestion his enthusiasm died away. Why this should have been the case it is difficult to explain, except by supposing that it was the charm of novelty more than the determination to work for one's living that was the dominating influence in this special case, and thus accounting for the fact of a youth, who had never left the shores of his Island home, conceiving the idea of travelling thousands of miles to cultivate land under, what would be to him, insuperable difficulties, rather than of carrying on similar work under more favourable circumstances in his own country for his own and his kinsmen's benefit.

There are parts of this Island in a sadly depressed state, not so much because they are incapable of supporting a population, but because all that might be done to help nature to yield her stores of food has not been done. It is not to be thought that we look upon such cultivation as an easy matter, and it must be acknowledged that it is no light task to work up lands that have been allowed (no doubt owing to objections against soil, rainfall, climate and situation) to lie neglected. Yet there is an experiment to be attempted, and an honest effort to be made, that have not yet been done. There must be some who, having come under the influence of agricultural instruction in Ceylon, have a taste for

and a fair idea of opening out and cultivating land, but who want encouragement to give them enterprise. The religious zeal that fires the Salvationist to form schemes for colonization and cultivation is not theirs. Official encouragement and aid is what is necessary to start them. Certain terms should be laid down with grants of land—not of course as grand or visionary as those of the American newspaper advertisements—and the plea (an honest though a common one) of a want of capital, might be met.

If in this way a few bands of young men of an adventurous turn of mind can be got to open up the neglected areas of Ceylon, there is no reason why, with steady perseverance and a knowledge of their work, they should not succeed in bringing relief to the indigenous population by introducing new methods of cultivation and new food products to their notice, but also in benefiting themselves.

OCCASIONAL NOTES.

We referred some time ago to the case of Mr. Jayasinghe, a student who passed out in 1888, who was engaged in opening out a very large tract of land in the South with the object of sugar-cane cultivation. Of last year's batch of boys, three or four have already started cultivation on their own lands. Mr. Abey Suriya, who since he left in December last, has been planting arecanuts, dhall, sugar-cane and Indian corn, writes that he is at present occupied in clearing an area of two hundred and seventy acres. Mr. Jayawardene has invested in some land in the Polgahawela district which he intends to lay under coconuts and cocoa. Mr. Manchanayake is working hard at paddy cultivation, according to improved methods, in his native district of Cotta, where he also intends to cultivate vegetables on a large scale. Messrs. Cooray are co-operating with a relative in working a tea estate in the Kalutara district. This is all most encouraging, and the news comes as a pleasant surprize to us since we penned the lines regarding the want of enterprise in the natives of Ceylon. We heartily wish all these old boys the full measure of success which their pluck and perseverance will deserve. With their start in life as independent agriculturists, and the late appointments as Agricultural Instructors, both Government and private, our stock of passed men waiting for 'something to turn up' is all but exhausted.

The notes which our Agricultural Instructors were wont to send us pretty regularly in the early days of the Magazine, seldom or never reach us now. This is unfortunate both for ourselves and them: for while such notes must be of interest in a circulating medium of agricultural knowledge and news, there are ways in which we may be able to help these correspondents through the Magazine or privately. By means of regular reports (which otherwise we seldom if ever see or hear) communicated to our monthly, we shall (having no alternative of personally visiting, encouraging, and advising) be always kept informed of the state of affairs agricultural at each station, and be best able to deal with

special matters, when it is thought necessary to refer to us.

The idea of publishing current crop and weather reports, brought forward by the Hon. J. J. Grinlinton in the Legislative Council the other day, is a very happy one, which, moreover, has been carried out to great advantage out of Ceylon. Early information regarding matters of such a nature as brooks no delay when interference is demanded, is very necessary. Timely notice often arrests incalculable damage or loss.

Mr. Mendis has been appointed Agricultural teacher at Prince of Wales' College, Moratuwa, where he has a large number of students, who are also being instructed in practical work. We hear that the boys evince a great interest in their agricultural studies, and take very kindly to outdoor work. It is contemplated, we believe, to start dairy work before long at the College. Our best wishes are with the Principal, Mr. Goonewardene, and the Messrs. De Soysa, the patrons of the school, that their efforts on behalf of the inhabitants of Moratuwa may be fraught with success.

Two other appointments have been made lately, viz., that of Mr. Goonewardene to Kolonna Korale, Rakwana, as a privately paid Agricultural Instructor, and of Mr. Gunesckere as teacher of agriculture in the Buddhist School at Hattton. These private appointments, coming as they do after much adverse criticism and ridicule of the instruction imparted to the students at the School of Agriculture, must be a source of great encouragement to the teachers and promoter of that institution; while at the same time it is an indication that there are those amongst us who recognise the need of improvement and reform in native agriculture, and are taking active measures to bring about so desirable a result.

There is at last some prospect, however remote, of a geological survey of the island being made. The officers of the Survey Department have been instructed to collect geological specimens from all parts of the country, and forward them with their notes to the Colombo Museum, as a first step towards a geological survey. But who is to identify and arrange the specimens at the Museum? Evidently a special officer will have to be appointed, for to judge from the present collection of rocks and minerals at the Museum, there is no one qualified for the work among the officers of that institution. The specimens now there are miserably poor in number; some have evidently not yet been identified; and what is worst of all, a good few are wrongly labelled. Even mica, which every tyro knows, is named talc; while the labels 'lemonite,' 'orthoalase,' 'granulite' go to show that someone requires a few lessons in spelling. However, let us hope that before long our students of geology will have a collection at the Museum that will help them and not mislead them in their studies.

It is a great matter that the School of Agriculture has been chosen for the office of the Central Committee of the Imperial Institute in Ceylon,

Specimens of natural products from all parts of the Island will find a temporary home in the school, the students of which, from contact with so representative a collection as is sure to be formed, and one, moreover, which will deal largely with agricultural products, should derive incalculable benefit. It is to be hoped that it will be found practicable to have the specimens on view after they are finally classified and arranged.

Paddy growers in lower Ambagamuwa are more fortunate than the majority of their brethren. A hundred bushels an acre are not an uncommon crop there, while a cultivator who is fortunate enough to have a rest-house for cattle overlooking his fields, is reported to take in four hundred bushels off an area of three acres. Transplanting is practised in this region, but the improved plough has not yet found its way among the agriculturists. Perhaps with the appointment of Mr. Gunsekere as agricultural teacher at the Buddhist school at Hatton, there is a prospect of the new plough being introduced to the neighbouring cultivators.

A beautiful specimen of the *Acherontia Satanas*, the Sinhalese representative of the English Death's-head moth (*A. atropos*) has been received for the School Museum. The beautiful moth belongs to the family *Sphingidæ* or hawk-moths of the Lepidoptera order. The distinguishing character of this insect is a skull-like mark on its back, and from this circumstance and the squeaking sound it emits when disturbed, it is said to be regarded with much superstitious dread by the country people of England and other parts of Europe.

The caterpillar of this moth measure sometimes nearly five inches in length and is of considerable thickness. It is beautifully marked, and on the last joint of the body there is a process curving over the joint like a tail.

The following is taken from the Rev. W. W. Gill's "Life in the Southern Isles" to show the very peculiar use to which a species of the hawk-moth is put to in the Islands of the South:—"A large handsome moth called the *iriano*, or sphinx moth (*Charocampa erotus*) is common in the Harvey Islands. . . . The silky proboscis, exquisitely coiled up, sometimes attains the length of five inches. At dusk in the warm season these insects are very numerous, coming out of their hiding places and entering the dwellings of the natives, attracted by the light inside. In ancient times a certain method of secretly wreaking vengeance upon a foe was, on a dry night to catch two or three *irianos*, and after carefully unwinding their probosces, tie on narrow strips of stout native cloth lighted at one end. This cloth only smoulders, and like touchwood never goes out. The affrighted moths would then be set at liberty as near as possible to the dwelling of the intended victim. The *irianos* dragging through the air these strips of smouldering cloth would make for the highly-combustible thatch. In a few seconds the house would be in a blaze."

INDIGENOUS FOOD PRODUCTS: CULTIVATED AND WILD.

BY W. A. DE SILVA.

Cucurbitaceae.

42. *Trichosanthes Cucumerina*, L. Sin. Dummella.

Is a wild plant growing in the uncultivated places of the warmer parts of the Island. It generally abounds in low jungles. *T. Cucumerina* is a prostrate creeper with a thin green wiry stem and alternate green, cordate leaves. The fruits are oval, having a smooth green surface with white streaks, and are about half the size of an egg.

The fruits borne on some plants have a pleasant taste, somewhat resembling that of cucumber, but in others it acquires a very bitter taste. It is ordinarily believed that if the fruit be eaten just as it is plucked, it has no unpleasant taste, but when kept for a while, even a few seconds, it acquires its bitterness; others more superstitious believe that so long as the name of the plant is not pronounced the fruit keeps well, but the instant the name is uttered it develops its unpleasantness! From observations made I find that some plants growing in jungles have naturally the bitter principle, whilst others growing in open grounds are devoid of it. In both cases it is increased by keeping the fruit after being plucked.

The importance of this plant is not much as a food product, but it is in great demand among the natives as a medicine. It has well-marked characteristics of a febrifuge, and is largely and successfully used in cases of fever.

43. *Cucumis Pubescens*, Wild Sin. Gonkekeri.

This plant is common in the low-country of Ceylon and grows wild in waste lands and on heaps of rubbish and roadsides. It is a creeper with thin tendrils. The stem is green and thin, and the whole plant is very hairy. The flowers are monoecious, and are borne in the leaf axils, the staminate flowers being very small with yellow corollas. Several pistillate flowers spring from the same axils, and hence it is not uncommon to find two to five of them in the same place, somewhat in the form of clusters. The full-grown fruits are about the size of the eggs of a house lizard, and are rounded in shape, green when not quite mature and attaining a scarlet colour when ripe. Before ripening, the small fruits possess a taste similar to cucumber, and are eaten by children; whilst in a ripe state they possess a bitter taste, but not altogether unpleasant.

44. *Cephalandra Indica*, Naud. Sin. Kowakka.

Is a plant common throughout the Island, and largely met with in higher elevations. It grows in waste places, and is a creeper with a thin green stem and cordate leaves much resembling the above-described variety. The leaf possesses a darker green colour and is not much covered with hairs. The fruit of this plant is considered to be poisonous, though much eaten by crows. The leaves are eaten especially in the upcountry in the form of dry curries, made with coconut and the usual curry stuffs.

45. *Zeheneria Umbellata*, Arn. Sin. Kavadu-kekeri.

This plant is generally found growing in wild places, but is rarely met with in cultivated grounds. It resembles much the *C. Pubescens* in its general characters, though the leaves of these plants look more succulent and a little larger in size. The fruits are larger resembling those of *T. Cucumerina*, but have not the bitter principle of that plant. They are eaten when obtainable.

The above-described varieties cannot strictly be reckoned as food products, as they are not much used as food.

Rubiaceae.

46. *Sarcocephalus Cordatus*, Miq. Sin. Bakmi.

Is a tree common in the warmer parts of the Island. It thrives generally in moist places, such as the banks of streams or ponds, and grows very high with many branches. The leaves are large, coarse, and rounded in shape with prominent nerves branching from the midrib to the margin almost at equal distances, but the general venation of the leaf is reticulated. The leaves and the epidermis of the soft parts of the stem are covered with coarse hairs. The inflorescence of this plant is somewhat characteristic, the flowers being borne in a glomerulous capitulum, of the shape of a spherical ball. When the small flowers which have whitish yellow corollas open themselves, they give a most charming appearance to the tree. The compound fruits which are formed by these flowers also take a rounded shape. They are about the size of ordinary tomatoes. The fruits are covered with a dark brown epidermis with small black indentations, and consist of a yellowish fleshy mass which is hard and astringent when immature, and soft, and of a sweetish acid taste when ripe. The fruits are much eaten, and in some places they are sold in markets. A single tree bears a very large quantity of these fruits in a season.

The wood of this tree is of some value as timber, and the bark and young leaves are used medicinally in cuts, bruises, sores, boils and dislocations.

WATER-LIFTS. III.

BY ABA.

The Double Mhote is an adaptation of the whim used in England for raising water and rubbish from mines, and in Australia for raising water for stock &c. It is said that the first machine of the kind was erected in India in the year 1869 from a model obtained from Australia. Since that time it has been much improved, and the following description of the action of the machine as it now exists on the Saidapet Farm is taken from the "Farm Manual," compiled by Mr. C. Benson, M.B.A.C., the former Superintendent of the Farm;—

"The water is raised by two leather buckets, similar to those in ordinary use in other parts of the Presidency; to each of these buckets is attached a rope which is fastened to a drum; one of these is coiled and the other uncoiled, as one bucket ascends and the other descends; the drum is fixed on a rotating spindle, to which is

fixed at right angles the draught bar to which the bullock is attached; the diameter and thickness of the drum varies with the depth of the well; as a general rule, for all ordinary lifts the diameter of the drum may be equal to about one-fifth the number of feet that the water must be raised; the drum is placed about 6 feet above the ground in order to allow the rope to pass over the head of the draught bullock; the spindle upon which the drum is placed is kept in its upright position by means of two beams, into which it is fixed, which cross each other at the middle, and are supported at the ends on posts placed opposite each other on the outer side of the bullock path. The bullock walks under the draught bar attached to a curved yoke, which turns on a swivel. In raising water the bullock travels round the upright spindle, thus turning the drum and winding one rope and unwinding the other. If the diameter of the drum is as suggested, $1\frac{1}{2}$ circuits around the path will raise each bucket to the requisite height; the bullock is turned round, facing the opposite direction, while each bucket is being discharged, no longer time is required to do this than is needed for the bucket to discharge its contents."

There is a model of the Double Mhote in the School Museum also sent from Madras by my friend, Mr. C. K. Menon, of the Saidapet Farm.

In my previous article on water-lifts I described the Single Mhote which is in use throughout India. To compare the two machines it will be seen that the "double" will raise about 30 per cent more of water than the "single" at a saving of about 50 per cent of the cost of lifting. But the Double Mhote has not yet come into general use, owing probably to the poverty of the ryot. The erection of the Single Mhote is within the power of every ryot almost, while the double requires the services of carpenters, and the outlay of a sum of money not within the reach of many a one.

NOTES FROM INDIA.

[Being translated extracts from letters by a Sinhalese Gentleman.]

The ryots of India are a more industrious lot than our Ceylon goiyas. At present there is a drought, such as we are having in Ceylon, prevailing in Southern India, but while the Indian ryots are irrigating their fields by means of wells, our goiyas are crying over their withering crops without adopting any remedy to save them. The practice of irrigation by wells is well worth a trial on the part of the Sinhalese cultivator. The Indian ryots irrigate even their coconuts, plantains, &c., when they suffer from want of moisture.

The paddy cultivators in India systematically adopt "transplanting" with paddy, and there is no doubt that this method produces superior results to that of ordinary broadcast sowing. As I travelled by rail I observed hundreds of acres of transplanted paddy. Why shouldn't the Ceylon goiyas do in more for transplanting?

The peasant women of India are decidedly more devoted to agricultural work than our country-women.

Another thing that struck me from contrasting the natives of Ceylon with the natives of India is, how prone our people—both men and women—are to imitate foreign customs and foreign dress. This no doubt acts directly and indirectly as a great drawback to their agricultural pursuits.

In some of the waste lands I observed that the Indians plant *Casuarinas* (whip-trees), quick growing trees, the wood of which is sold as fuel to the Railway Companies. Here is a hint for the Ceylonese.

Madras, January 1891.

The Castor-oil plant is cultivated to a large extent in India. In some parts I saw gardens of twenty to thirty acres under this plant. It grows easily here, and the Indian ryots obtain good profits by its cultivation. A cwt. of castor-oil fetches from R13 to R18. The ryots prepare their land for castor-oil by ploughing; no manure is used, and the seed is sown broadcast.

Bombay, 7th January.

AGRICULTURAL SALT.

Prof. Thompson of Aspatia College appears as a vigorous advocate of salt for agricultural purposes. In an article on Agricultural Salt he enumerates a large number of references made to salt in connection with agriculture. In Luke chapter xiv, it is written, "Salt is good, but if the salt has lost its savour, wherewith shall it be seasoned? It is neither fit for the land, nor yet for the dung-hill; but men cast it out." Cato who died B. C. 150., says:—"When you lay up your straw, that which is most nutritious is to be laid under cover; sprinkle salt over it, then serve it for hay. If your sheep are scabby, take some lees of oil and water, in which lupines have been boiled and the dregs of good wine, mix them all together; when you have shorn your sheep anoint them all over, suffer them to sweat for two or three days, then wash them in the sea; if you are not near the sea make salt water and wash them with it. If you do this your sheep will not be scabby, they will have more fine wool, and the ticks will not molest them."

Virgil also bears undoubted testimony to the successful use of salt for cattle.

In 1638, Lord Bacon expressly mentions the benefits derived from watering various vegetables with a solution of salt and water. Sir Hugh Platt, in 1653, states "that it is salt which makes all seeds to flourish and grow, and that no dung which is laid on barren grounds would in any way enrich the same if it were not the salt in it."

In 1742 Professor Hoffman observes "that small pieces of fossil or rock salt were given to animals to keep away internal corruption and disease."

Dr. Brownrigg, in 1748, says:—"Salt is dispersed all over nature, it fertilises the soil, it arises in vegetables, and from them is conveyed into animals; so that it may well be esteemed the universal condiment of nature, friendly and beneficial to all creatures endowed with life, whether it be vegetable or animal. When properly used as a manure, it affords ample nourishment to corn and other vegetables, and renders kingdoms rich and fertile."

In 1817, Lord Kenyon, Sir Thomas Bernard, Bart., and Mr. Curwen (Workington Hall) bore testimony to its value as an admirable manure, and for cattle.

So that since the date of the New Testament the beneficial effect of salt on the land, the dung-hill and for sheep and cattle have been noticed in some parts of the world at least. Its value in cattle treatment is still recognised very generally, and the Ceylon Cattle Commissioners have strongly recommended its use in cases of murrain. In the agriculture of the country, however, it is little used. From the great solubility of common salt, it must be expected owing to the very great rainfall in many parts of Ceylon, especially in districts where the soil is overporous, that the greater part of the sodium chloride in the soil must be washed off in a tolerably limited period—the land thus "losing its savour." This washed-out condition of soils, as Mr. Thompson points out, will greatly facilitate the development of minute organisms, which, if not checked, attach and destroy our cultivated crops. It is difficult to think of a plant that has not some insect which affects it, for a great variety of inferior insects are nourished and live by their ravages on the vegetable world. For the destruction of a large number of lowlife forms there is nothing, says Mr. Thompson, so effective or so cheap as a judicious and plentiful application of crude crushed rock-salt. It is pointed out that wet seasons have always been known to generate and develop parasitic diseases in animals; and it may be noticed that insects injurious to plant life are favoured by the dampness and humidity resulting from such weather. It is therefore recommended that there should be a timely dressing of the lea lands and stubble with salt, previous to ploughing or turning up the soil, and before the ova of the future insects have had time to hatch and bring forth the larvæ or grubs, in which stage they are most destructive, so that a great many evils to plant and animal life may be averted. All lea and stubble lands Mr. Thompson suggests, should be dressed with 10 or 15 cwt. of crushed rock salt to the acre, previous to ploughing. This advice is especially applicable to cultivated land in tropical countries where insect life is so abundant.

Miss Ormerod, in her report issued last June, recommends the use of guano and salt for wheat infested with the maggot of the wheat bulb fly (*Hylemyia Coarctata*), because, she says, "Wheat having the power of imbibing salt until the plant tastes strongly of it, this application would be likely to be very detrimental to the young maggots feeding on the stems."

All this testimony goes to prove the value of salt in agriculture, and that it is very desirable that salt for agricultural purposes be placed more within the reach of cultivators in Ceylon.

COCA LEAVES (ERYTHROXYLON COCA).

By W. A. DE SILVA.

Owing to the medicinal principle (cocaine) found in the leaves of this plant, it is being cultivated at the present day in many parts of the world. In Ceylon there are some species of *Erythroxylon*, viz., the *E. Monogynum* and *E.*

Lucidum, which grow wild. Both these species are considered to possess certain medicinal properties, the former possessing properties very similar to that of coca, in as much that the leaves have the property of appeasing hunger.

The *Erythroxylo* Coca, or the plant from which cocaine is obtained, is a bush about four feet high with a small light green leaf. The flower is white and the fruit a red berry. Herndon mentions, that in cultivating this plant, the seeds are sown in beds at the expiration of the rainy season. Arbors of palm trees are built over the young shoots to protect them from the sun, and they are watered, if it continues dry, for a week or so. The tree is transplanted a year and a half after planting, and gives its first crop in one year from that time, and a crop every four months after.

The bush if not destroyed by ants, will give crops for many years. Sometimes, but rarely, the leaves wither and the crop fails. The leaves should be dried when gathered, as quickly as possible. A hundred plants of coca are estimated to yield 20 lb. of leaves at a plucking.

The coca plant is likely to thrive in Ceylon, as the specimens growing in the Henaratgoda Tropical Gardens tend to prove.

About the properties of these leaves, Mr. H. F. Fish in a paper on the subject in the *Technologist*, mentions that when supplied with an abundance of coca leaves, the Indian sometimes performs prodigies of labour and can go without food for several days; without it he is miserable and will not work. It is said to be a powerful stimulant to the nervous system, and like strong tea or coffee takes away sleep, but unlike tobacco and some other stimulants, no one has known it to be injured in health.

It is said that by taking a sufficient quantity of coca a man is capable of dispensing with food for 5 days without any material inconvenience, even though he be engaged in rapid travelling on foot the whole time. This leaf is highly valued by the inhabitants of Chili, Peru, and Bolivia, not only as a medicine, but also as an article of food, and serves with them as a substitute for the tea, coffee, betel, tobacco and opium used by other nations.

It has been established by experiments carried on by Dr. Mantegauza, as reported in the paper mentioned before, that the leaves of coca, chewed or taken in weak infusions, have a stimulating effect on the nerves of the stomach, and thereby greatly facilitate digestion. In a large dose coca increases the animal heat and augments the frequency of the pulse and consequently respiration. A medium dose, three or four drachms, excited the nervous system in such a manner that muscular exertion is borne with great ease, but afterwards produces a calming effect. Used in larger doses it causes delirium hallucination, and finally congestion of the brain.

GENERAL ITEMS.

The School of Agriculture opened on the 16th January. Out of a large number of applicants, some fourteen resident pupils have been chosen, besides four day scholars.

The harvesting of the paddy crop (*Sudu wi*) at the school was the first practical operation which claimed the attention of the students.

It is reported from Anuradhapura that the kurakkan crop has been much damaged by caterpillars.

A complete set of bones of a Ceylon bullock has been presented to the School Museum by Mr. Manchanayake, an old boy. This comes as a very opportune gift, which will be of great value to the Elementary Veterinary class—there being no complete skeleton of a bull or buffalo in any of the Museums in Colombo.

Mr. Menon, of the Agricultural College, Saidipet, has been writing to the *Ceylon Independent* recommending irrigation by wells for paddy cultivation in the dry parts of Ceylon. The letter has given rise to some discussion; some favouring, others throwing discredit on, the suggestion. Mr. Menon was for a time connected with the Colombo School of Agriculture, where he proved himself an able teacher, deeply learned in the science and art of agriculture.

Professor McConnel of Oxford, author of *The Agricultural Note-book*, has published a pamphlet on agricultural education. "My experience," says the Professor, "is that agricultural education of the proper sort enables a man to farm better and make more money than he would without it; if it does not do these things, then it is a mistake altogether, and the present movement had better stop where it is, and go no farther." In the Professor's view there are only four institutions in Great Britain which realise what he believes to be the best system of agricultural education. These four places are the Edinburgh University; the Normal School of Science, South Kensington; the Glasgow Technical College; and the University College of North Wales. The Professor has been brought to task for not including Aspatria College in Cumberland, which, while it has gained many distinctions of late at public examinations, is an institution which charges a very low scale of fees. It will be observed that Cirencester College, which was the 'fashionable resort' of agricultural students for a long time, is quite out of the reckoning.

Fourteen agricultural students, who successfully passed their examinations at the Nagpore School of Agriculture, have obtained posts as revenue inspectors.

Bamboo is considered, according to a Bangalore paper, the best material for making charcoal for blacksmith work, and is in large demand all over Mysore. It is said to give out more heat than the best coke and to require less blast. This bamboo charcoal fetches twice the price of the best charcoal of any other fuel. The method of charring bamboo is rather different from that used for harder woods—the stacks being carefully covered with green leaves and plastered with wet clay. While the burning is going on, care is taken to exclude air as much as possible without extinguishing the fire.

Says the *Indian Agriculturist*:—Lupins have been found very useful as binders and regenerators of sandy soils. *Lupinus luteus*, the scented yellow variety, is predominantly in use in

Middle Europe as a green manure to improve sandy soils; it is the best of all yet tested, and will do even for coast drifts. Lupin seeds are very fattening when used as an addition to ordinary fodder, and are in this respect quite equal to oil cake, while the hay is said to be not inferior to that of clover, and more bulky. Plants native to California, says the editor of the *I. A.*, ought to succeed fairly in Ceylon.

Dr. William Fream, B. Sc., has been appointed Steven lecturer in the University of Edinburgh for three years. Dr. Fream devotes his first year to the Science of Entomology in its bearings on agriculture.

Would we had such men in Ceylon as Mr. Lumsden, of Garmond, in Aberdeenshire, who has bequeathed £10,000 for the prevention of cruelty to animals.

Mr. Chaplin, the Minister of Agriculture in Great Britain, hopes to bring forward proposals which will entail some addition to the present grant for agricultural education.

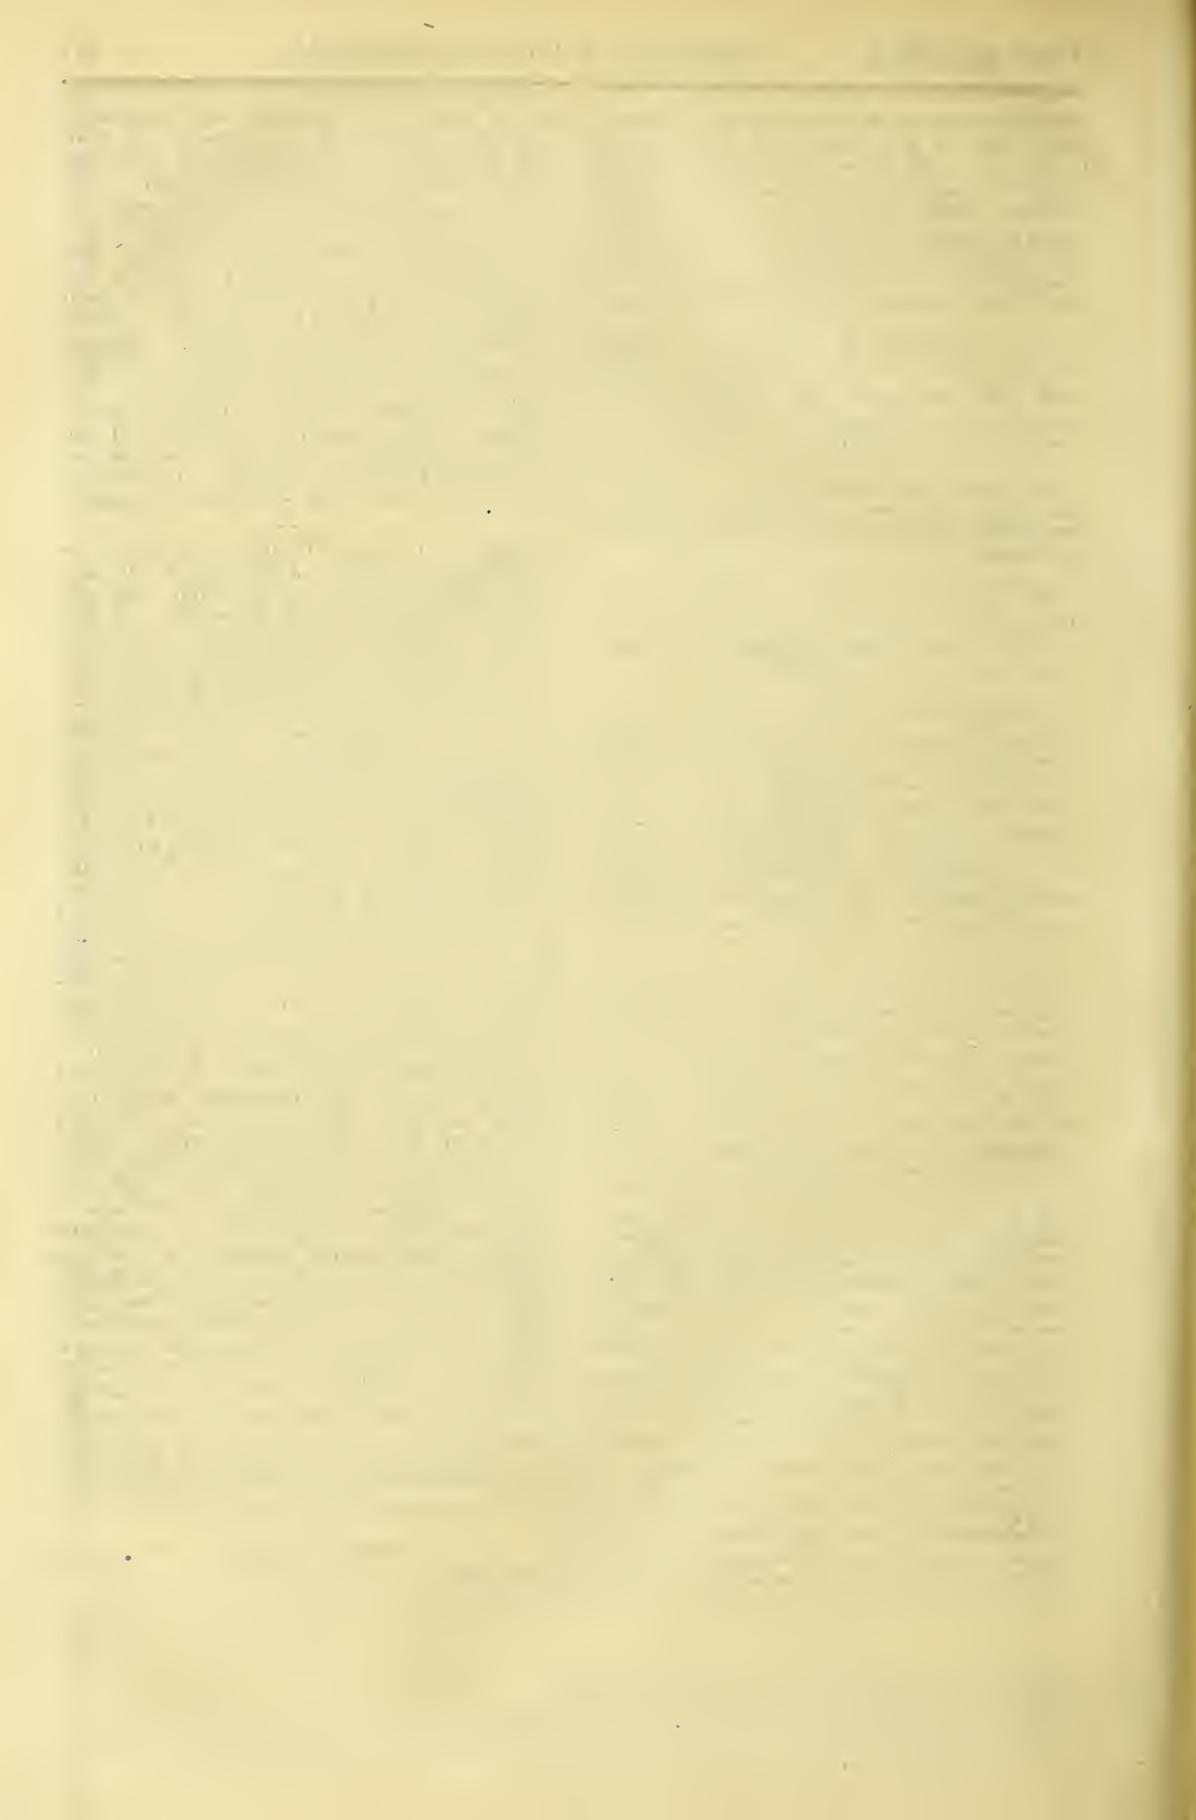

A correspondent writing to the *N. B. Agriculturist* states that a section of an enormous tree is being taken out in the Mammoth Forest, California, the section being 9 feet high. The tree which grows 6,325 feet above sea level, measure 99 feet in circumference, and nearly 33 feet in diameter. The saw used in getting out the section is 22 feet long, and requires 8 men to handle it. Two months will be required to complete the work, and the weight of the section is expected to be not less than 20 tons.

A bulletin of the Maryland Experimental Station places great stress on the "testimony of plants" in the application of fertilizers. Pale green colour betrays a lack of nitrogen, or a red brown shade in the green of the leaves indicates that the slowness of their development, in spite of rain and sunshine, is a result of insufficient nourishment. A bright and deep green colour in almost all crops is evidence that nitrogen is not specially deficient, but no proof that more might not be used to advantage. Luxuriant growth and good crops of corn, cabbage, potatoes and grass shows a good natural supply of potash. If small grains produce well with the kernels, plump and heavy, phosphates cannot be especially needed. Simple experiments which any farmer can make for himself will show whether the soil is need of manures, and to what element of plant food it especially responds. On this branch of the subject—what plant food to buy and what quantity—Prof. Wagner's conclusions are substantially as follows:—Phosphoric acid and potash should be used liberally, and with reference to the needs of the soil rather than the demands of the crops. These food constituents should be applied in excess of the needs of the plants. In this there is no danger of

waste of potash and phosphoric acid, substances which the soil binds up and preserves for later crops in case the one immediately following demands them only partially or not at all. Consequently, as to these two, they may safely be applied till present in sufficient surplus; that is till a further application is without effect. The greatest profit results in holding the soil in this degree of food surplus as to phosphoric acid and potash. With nitrogen it is quite different; this is not found to be retained by the soil, and although temporarily held it is freely moveable. Any residue from the wants of a crop to which it has been applied, is in danger, especially during the winter months, of being washed into the sub-soil and lost. Hence nitrogen should be measured out as accurately as possible according to the needs of the plant for which it is particularly applied.

Copper in Cereals.—Writing to the *Lancet* on this subject, Mr. Wm. Johnstone, Ph. D., &c., says:—"This question has very lately been prominently brought under my observation, and that in a novel and unexpected manner, necessitating the examination of a large number of samples of wheat and barley, which resulted in 15 per cent. of the samples being found to contain copper in more or less quantity, particularly in the Scotch barley. The existence of copper in cereals, therefore, becomes a serious question, especially to manufacturers of infants' food, as they are liable at any moment to have proceedings instituted against them under the Sale of Food and Drugs Act. It was due to legal proceedings being threatened against a manufacturer of infants' food which caused the matter to be placed in my hands. The plaintiff's analyst certified that the food contained lead, which had caused serious illness to an infant; but upon closer investigation by myself, it proved to be copper, and it was present there as a natural constituent of one of the cereals used in the preparation of that particular infants' food. Granting that cereals do possess the remarkable property of taking up copper from the soils in which they are grown, provided that soil contains copper, the question immediately arises, What is the maximum amount of copper which barley or wheat is capable of taking up? Few soils in this country contain copper to any appreciable extent. I am therefore inclined to attribute the presence of copper in Scotch barley and English wheat to the prevalent practice of dressing the grain and also the ground with sulphate of copper, so as to protect it from the ravages of vermin after the grain is sown. The possible existence of copper in cereals may also account for some of those mysterious and unaccountable cases of illness which occur from time to time in families, and is therefore well worth the attention of medical practitioners, and also that of the manufacturers of infants' food."

E. T. H. received with thanks: will appear in our next.

THE TROPICAL AGRICULTURIST MONTHLY.

Vol. X.

COLOMBO, MARCH 2ND, 1891.

[No 9.]

THE CULTIVATION, MANUFACTURE AND CHEMISTRY OF TEA.

SOME very valuable information on these heads will be found in the report of Mr. Bramber which is given in the proceedings of the Horticultural Society of India on page 616. As a preliminary to his detailed and exhaustive analyses of the tea bush, soils, manures, &c., the chemist employed by the Horticultural Society and the planters has commenced visiting the various tea districts, and the report we are to extract contains a record of the impressions produced by the first of those visits. With reference to recent discussions on forking, it will be seen that Mr. Bramber attaches much importance to frequent and deep hoeing of the soil so that air and moisture may be admitted for the decomposition of micaceous and other rocks containing potash. Very close planting is objected to because of the obstacle to hoeing presented by the interlaced roots, such interlacing also rendering the bushes more liable to attacks of blight. All planters will agree that when plants are diseased, whether suffering from insect or fungus pests, the prunings ought, as Mr. Bramber suggests to be burned and the ashes (with all ashes from the factory and lines), carefully applied as manure. But we submit that the prunings from healthy plants can be better utilized if buried unburnt. Our experience is that neither decomposing prunings nor rotting tree-stumps do any harm to, but rather benefit, tea bushes, with one notable exception in the case of a very beautiful but very fatal *symptocos*. On the decaying tuberous roots of this special tree, a poisonous fungus forms, which, when it comes in contact with the roots of the tea bushes, is speedily and inevitably fatal, gaps arising from the destruction of three or four to a dozen tea bushes, being scattered over estates, where stumps

of this upas-like tree have been left to decay in the ground, instead of being carefully removed and burnt, as they ought to be. What Mr. Bramber says about plants left to grow in old nurseries is in accordance with all experience, and what is said of the loss of nitrogen by the periodical firing of grass lands is worthy of attention. Whether for improved pasturage or cultivation with tea or other plants, our patanas would be enormously benefited by the application of nitrogenous manures. The pity is that such substances are so costly, the disturbed condition of the American sources of supply tending to make them still more so. Droppings in caves haunted by bats and swiftlets would be valuable, but we believe the Sinhalese rice cultivators appreciate and use this matter largely. The question is whether grass lands might not be enormously improved by the growing and burial in them of several successive crops of leguminous plants, such as the lupins, common peas, &c. Clover might also be tried, as its roots go far down into and improve the soil, in which it will grow. Mr. Bramber's notice of the heat produced in tea leaves by the friction of the roller, and the subsequent rapid cooling down from evaporation in the "fermenting" process, are suggestive of important and beneficial results, likely to be attained from further research in this direction. We shall look with keen interest for further reports of the comprehensive experiments which Mr. Bramber is to institute.

SALE OF VALUABLE ESTATE PROPERTY.

The estate of Holyrood West in Dimbula, consisting of 546 acres of which 350 are planted with tea and 150 acres still in good coffee, has just been sold by Mr. G. S. Duff to the Ceylon Plantations Tea Company for £15,000 sterling. The Company is to be congratulated on acquiring so valuable a property which apart from its intrinsic value, has a railway station at each end of the estate—Watagoda and Talawakele. Mr. Talbot has now in charge for this Company a series of as valuable properties as have ever been owned by a plantation Association in Ceylon.

OPERATIONS FOR GEMMING IN CEYLON.

The capital which was conditionally underwritten should the preliminary work by the Syndicate prove satisfactory was, to the best of my remembrance, £250,000, or even £300,000. All hope of the underwriters carrying out such an engagement must now, it is certain, be abandoned. This class of speculators have, as you have before been informed by me, been so fearfully hard hit during the last six months, that there is scarcely a penny of available capital among all its members. Fully alive to this fact, Mr. Saunders tells me he and those working with him have quite given up all idea of ultimately proceeding on so grandiose a scale. At length, and for the first time, Mr. Saunders has informed me that Mr. Barrington Brown's report was a hopeful one. That report stated in effect that, while the conditions as regards gemming in Ceylon prevented him from giving full assurance as to ultimate success, he felt the conviction that its undertaking on a considerable scale had a hopeful future before it. He has, since the sending in of that report, furnished estimates for the machinery, &c. necessary for preliminary working on a moderate scale, but the Syndicate, in view of the total impossibility of obtaining any public subscription at present, has determined upon itself commencing work with the £6,000 of its capital as yet uncalled up: in pursuance of that intention, a practical miner is to leave England for Ceylon within the next few weeks, and he will take with him steam pumping machinery adequate for clearing water from mines of a depth of 100 to 150 feet, and will begin operations as soon as that machinery can be erected. This, as I understand, has already been purchased here and is to be shortly shipped for Ceylon. At the same time, one of the plumbago properties owned by the Syndicate is to be simultaneously worked, and should satisfactory results be obtained from both industries, subsidiary companies may be started with a capital of £50,000 each; or failing any prospect of starting these successfully, additional capital for extension of the work will be subscribed by the members of the Syndicate themselves.

THE CEYLON (AMERICAN) PLANTERS' TEA COMPANY.

A specimen of one of the paper packages used by this Company for packing their teas has reached us. It is of a very pretty design and intended to hold one pound of tea. The printing is executed in several colours and looks very attractive. The trade mark of the Company (an elephant surrounded by branches of tea) is printed in white on a red ground in the centre on four sides of the box, together with the following inscriptions in suitable type and positions:—

"The Ceylon Planters' Tea Company trading under the auspices of the Planters' Association of Ceylon. The Ceylon Planters' Tea Company, New York City, trading under the auspices of the Planters' Association of Ceylon.

"Buddh-Tea of Ceylon, formerly Buddha, altered at the request of the Buddhist Defence Committee of Ceylon.

"INFORMATION:—This Company has been formed by the British tea planters of Ceylon to open up and control the American trade in the teas of Ceylon. They are interested in having their teas sold pure, understood and properly used. They will not allow it to be mixed or tampered with in any way, and this package contains one full pound of Ceylon tea, guaranteed strictly pure and unadulterated. Our brands all come from the same bush and differ only in the age of the leaf. They are sorted by sifting and the smaller the leaf the finer the flavour. Buds finest of all.

"GRADES AND PRICES.—Bhud (tea-leaf buds) 1 dollar and 25 cents a pound; this brand has the finest flavour. Tiffin (small leaves) 90 cents a pound; this brand has fine flavour. Bungaloe (large leaves) 65 cents a pound; this brand has good flavour.

"Till you have a local supply we pay freight or expressage. The three are alike, except in age of leaf. All come from the same bush, and the leaves are plucked together. The smaller the leaves the finer the flavour; and yet some prefer Tiffin to Bhud.

"How to MAKE PERFECT TEA.—Use an earthen pot and have it hot to begin with. Use fresh water that has just come to full boiling and has not been boiling so long as a minute. Make tea at table, not in the kitchen. Pour the boiling water into the pot, put the tea in on top of the water, and in from two to seven minutes pour into cups or another tea pot. Do not let the tea stand on the leaves much longer than seven minutes. Use half or a third as much of this tea as of China or Japan tea. How to make it better than usual but not perfect:—Steep it after the old American fashion and use half or a third as much as of China or Japan tea."

Ceylon tea in these packages will no doubt find favour with the American public soon.

SALE OF ESTATES.

Harmony estate in the Pussellawa district, hitherto belonging to Mr. J. Russell Grant, has been purchased by the proprietors of Nayanane for R45,000. It consists of 204 acres of which 115 are in tea.

Rogart and Lang's Land estates in the Kalutara district—proprietors Messrs. F. D. Mitchell and Donald Mackay—have been sold to Mr. Booth, the proprietor of Glendon estate in the same district, for £3,500 sterling. They comprise 779 acres, of which 238 are in tea with some Liberian coffee and cardamoms.

CACAO STEALING ON MAKULUSSE ESTATE, BEREDOWELA.

One Ramasamy kangani of Makulusse estate in Beredowela charged a man by the name of Ukkua Kattadia with theft and having the urripe fruit of a cacao tree in his possession, without being able satisfactorily to account for the same the property of Makulusse estate, whose manager is Mr. Tennant of Beredowela. It appears that the complainant noticing a pod that had been very recently pulled off near a tree below the store, took another two coolies along with him and went running along the path which led to the boundary of the estate on the Beredowela village side. He then saw a man with a bag on his shoulder going towards the village. One ran up and caught his head; he then dropped the bag, which contained thirty-five pods worth about R5. When the accused was asked where he got the pods found in the bag he said that while he seized the thief who was carrying it dropped it and ran away.

JUDGMENT.—This is a very clear case, and the defence is as audacious as it is novel. The accused is a very old man about 55 or 56, and I therefore will not sentence him to receive lashes, but he richly deserves them. I cannot help thinking that the accused was not the only thief who had been robbing the Makulusse estate. However, his attempt to go scot-free by throwing the theft on others has entirely failed. I find him guilty and sentence him to undergo rigorous imprisonment for a term of six months. (Signed) J. H. EATON, P. M.

THEFT OF CACAO FROM SUDUGANGA ESTATE.

The superintendent of Suduganga estate, Mr. L. Falkner, charged one Kalimuttu with stealing 22 pods of cacao valued R262½, the property of Mr. Hutton. It transpired in evidence that the watcher hearing a rustle amongst the cacao, went with another man to the spot and saw some six or seven men pick-

ing cacao. Seeing them the thieves ran towards a jungle, while one with his handkerchief bundled with cacao pods was seized about a chain's distance from the jungle. He was immediately brought to the head kangani and from thence to the superintendent. On being questioned he said that he stole the cacao upon the instigation of some other men.

JUDGMENT.—The son of the accused only confess the case of the prosecution: "a party of about six men came to his father last night and took him away saying that the kangani of Saduganga estate wanted him. His father (the accused) did not return home last night, but this morning that had heard his father had been taken to the estate." That story (if true) tallies with the case for the prosecution. The accused was seen at midnight running away with a party of six or seven men in the direction of a jungle into which five of them escaped and the accused was caught within a chain's distance from the jungle carrying a parcel of about nineteen cacao pods, sixteen of which were unripe. He is taken promptly to Mr. Falkner, the superintendent, and he there makes a clean breast of his guilt. He says he was inveigled into this theft by six others and that he alone was captured. That fact does not exculpate his guilt; it only aggravates it, for it shows that he is willing to unite with gang-robbers and help them in their depredations. I cannot under the existing state of law find him guilty under the 2nd section of the Ordinance No. 22 of 1886.—If I thought I could, I should feel certainly called upon in this case to do all I could to suppress the theft of prædial products by inflicting the only punishment which I think is likely to have a deterrent effect upon the village thieves, who live and thrive by thefts on European estates in the neighbourhood, viz., by imposing lashes on the offenders. The possession of the unripe fruit of the coffee or cacao tree, &c. by any person who is unable to give a satisfactory account of his possession thereof is constituted an offence by sec. 2 of Ordinance No. 22 of 1886, and shall on conviction be liable to the punishments provided for the theft of prædial products under section 368 of the Penal Code, and if the case fall within the power of the Police Magistrate to try, he the Magistrate may add lashes not exceeding 20 to the punishment he is authorized by section 368 to inflict. I may be mistaken in my construction of the section of the Ordinance No. 22 of 1886 I have quoted, but I feel strongly that the power of a Magistrate to inflict lashes is limited to a case where a man is found in the direction of a jungle into which five of them escaped; and the accused was caught within a chain's distance from that jungle carrying a parcel of 19 cacao pods all tied up in a handkerchief. He is taken promptly to Mr. Falkner, the superintendent, and he there makes a clean breast of his guilt. He says he was inveigled into this theft by 6 or 7 others and that he alone had the misfortune to be caught. This fact, instead of extenuating his guilt only aggravates it, for it shows that without any hesitancy or fear of consequences he could readily unite with gang-robbers and help them in their depredations. The value of the cacao found on his person may be very small, but the unchecked prevalence of a crime for which I think only lashes will be a deterrent, demands that I should inflict as severe a penalty as is competent for me to impose. I find the accused guilty and sentence him to undergo rigorous imprisonment for a term of six months.

(Signed) J. H. EATON, P. M.

THEFT OF DRIED CACAO SEED FROM CRYSTAL HILL ESTATE.

Mr. A. G. K. Borron charged one Barakare Gedare Suddara with the theft and removing of about four measures of dried cacao seed worth Rs. 50. From the evidence it appears that in consequence of the theft of cacao on the estate Mr. Borron put a villager on the watch. This watcher saw the accused going towards the caddies with a bag of cacao for sale. The accused was brought to the store to Mr. Borron, and on being asked from where he got the cacao said

that a cooly gave it him. He was asked to point out the man, but pointed one who denied ever having given cacao to the accused.

JUDGMENT.—I find the accused guilty and sentence him to undergo rigorous imprisonment for a period of four months.—(Signed) J. H. EATON, P. M.

THE NEW GUINEA CO. AS PLANTERS.

From the Far East news comes that the S. S. "Ysabel," owned by the New Guinea Company, has arrived at Finchhaven, landing there the Plenipotentiary of the Kaiser Wilhelm Plantagen Gesellschaft (Hamburg), Mr. Kindt. The company intends to cultivate cocoa and coffee, and Mr. Kindt therefore had bought at Ceylon the necessary material, of which about 18,000 young cocoa plants have arrived at Finchhaven in good condition. The cultivation of coffee will be commenced later on. Herr Kindt is accompanied by four Malayan artisans, viz., two carpenters and two smiths, as well as by eighteen Malayan coolies.—*L. and C. Express*, Jan. 2nd.

RAINFALL IN LAXAPANA, MASKELIYA.

Mr. Goo. Greig is good enough to send us a carefully compiled, coloured diagram of rainfall which we shall notice fully hereafter, meantime giving his explanation:—"I enclose a very carefully kept record of the rainfall on this estate during the past 15 years. No doubt it will interest you as you so frequently refer to the heavy falls of rain that take place on Theberton, which in air line cannot be more than 3 miles from this, while we here are much more under the shadow of the great Peak than Theberton is. The falling-off in the last four years to an average of 121.21 against 157.35 on the previous 11 years is rather remarkable—the short-fall having taken place in the south-west months chiefly. At the same time there has been no falling off in the south-west monsoon—rather the reverse in 1890, along its main track between this and Yatiyantota.

MANA GRASS EXPERIMENTS; COLOMBO COMMERCIAL CO., LD.; COFFEE IN UVA; PATENT TEA-ROLLING MACHINE; ASSETS REALIZATION CO.

London, Jan. 9th.

My last letter described to you an interview had by me with one of the partners in the firm of Messrs. Curtis & Harvey on the subject of its proposed utilization of mana grass from Ceylon. It seemed to me to be singular that that firm should have ever conceived the idea of using a charcoal burned from this grass in the manufacture of gunpowder. As the result to my further inquiry made this week, we now know that Messrs. Curtis & Harvey had long experienced a difficulty in obtaining a supply of suitable material. The willow trees which long furnished the best-adapted form of supply, and which in past times fringed the banks of our English streams in such wild luxuriance, have gradually become thinned off that their number has become so wholly inadequate to the modern demand for the main base of gunpowder manufacture. The firm, therefore, had given general instructions to the patent agents to be on the look-out for anything novel coming under their notice which they might think offer a chance of being suitable. Messrs. Jensen, the patent agents of Chancery Lane, heard of the experiments proceeding with the mana grass on behalf of the Stanley-Wrighton Syndicate, and took a specimen of it to Messrs. Curtis & Harvey, who thought that they saw in it a possible alternative material, and consequently gave the order for a ton to be sent to them from Ceylon for the purpose of experimenting with it.

Calling at the offices of the Colombo Commercial Company this week to see if the report now about due could be obtained, it was told me that it would not be ready before the end of the present month, but that it might be expected to be of a not unsatisfactory character. The Uva and Spring Valley Companies, as you know, share the offices of the abovementioned Company, and Mr. Roberts told me that the directors of these had determined upon paying an interim dividend of three per cent in both cases, payment of this being due on the 12th of this month.

Conversing with the last-mentioned gentleman, the subject was introduced of the success reported in our last received *Overland Observer* of some of the land in Ceylon lately planted out with coffee plants from Mysore. Mr. Roberts, in reply to my questioning, said that although their coffee in Uva was doing pretty well, the results were nothing magnificent, the trees still suffering much from their insect pests. He further said he did not think it unlikely that new blood introduced, and planted well away from old infected coffee, might do well. "At all events," he remarked, "it is quite certain that no idea is at the present time entertained of rooting up coffee on our Uva estates for the purpose of planting tea. "I can't tell you, he continued," whether our directors may think it worth their while to replace exhausted trees with others obtained from India, for I have never heard the subject discussed. Mr. Brown is out in Ceylon now, and he will doubtless be able to judge whether the experiments reported by the *Observer* have had such a measure of success as to induce him to make such an alteration on our estates as you have suggested. It occurs to me personally, that, although the course mentioned might be successful on a new clearing away from proximate bad influences, it might not prove to be so in the case of isolated plants put down among coffee trees which have been infected and infested for years past.

The mention of Mr. Brown's name reminds me that it has been told to me this week that one of his patent tea-rolling machines is to be put up and worked for exhibition in some public part of the city very shortly, and this form of advertisement being now very popular and very successful, it may be expected that orders for these useful machines will be greatly stimulated. But we hear that such stimulation is not as yet much needed, for Messrs. Abernethy of Aberdeen, the manufacturers of the machines, have orders booked very much in advance of their power of immediate production. A modification introduced by Mr. Brown since his earlier machines were made is said to have given particularly valuable results. In the first instance the lid of the rolling casing was fixed. This is now made to revolve, and—as far as I can understand—at a speed differentiating with that of the rollers. This, combined with the use of brass liners instead of wood and a slightly increased spacing, is said to have completely stopped any tendency to throw the leaf out, while at the same time it keeps the tea under treatment far cooler than under the first arrangement adopted. —London Cor.

CINCHONA IN THE DUTCH MARKET.

Amsterdam, Jan. 7th.

CINCHONA BARK.—At the sales to be held in Amsterdam on January 22nd, 2,332 bales and 238 cases (about 215 tons) will be offered, divided as follows:—Java bark, from Government plantations, 252 bales, 39 cases, about 23 tons; from private plantations, 2,000 bales 199 cases, about 192 tons,

of which are: *Druggist's Bark*: *Succirubra* quills 172 cases, broken quills and chips 113 bales, 13 cases; root 60 bales; *C. Schuhkraft* quills, 6 cases *Lancifolia* quills, 4 cases; broken quills and chips, 5 cases. *Manufacturing Bark*: *Ledgeriana*, broken quills and chips, 1,430 bales, 22 cases; root, 360 bales; Hybrids, quills, 11 cases; broken quills and chips, 281 cases; root, 88 bales. Total, 2,332 bales, 238 cases.

The January sales are comparatively small ones, because several parcels destined for that auction could not be warehoused timely enough, owing to our canals being closed by ice. Most probably the next sales—on February 25th—will be so much the larger—say at least 4,000 packages.—*Chemist and Druggist*, Jan. 10th.

WIND POWER.

DEEP WELL PUMPS.—It is remarkable to find water close to the surface in the alluvial soil in Vere in sufficient quantities to give a continual flow from pumps worked by windmills. It appears to me that, though there is not sufficient water at a depth of 30 feet for the purpose of irrigation, an increasing quantity would probably be found at lower depths and even enough to supply the large quantity necessary for irrigation. A series of tube wells driven at intervals with deep-well pumps attached might bring up a flow large enough for irrigation. The immense value of irrigation is evident to anyone who sees the parched look of the canes this year after the continuous drought, and knows what the land will produce with good seasons. At any rate the experiment of a deep well pump would be worth making.

[The above from the *Jamaica Botanical Bulletin* shews that wind power is commonly employed in the western island to raise water. Why is it not more utilized here? A wind-mill has been a success at Galle.—Ed. T. A.]

ANALYSIS OF TEA SOILS, MANURES, &c.

The following letter was received from Mr. Bamber after his first visit to the Tea Districts:—

"Having returned from a visit of inspection of some of the tea gardens in the Doocars, I now give you an outline of my observations and inquiries.

"The chief gardens visited were Sissobare, Matilli, Ohulea and Hope with others in the neighbourhood, and I have to thank the managers of the various gardens for their kindness and hospitality, and also for their willingness to afford me any information and assistance I required.

"The soil of the district varies a good deal, that of the higher land being of a redder colour and slightly heavier than that of the lower with land, which is generally of a light open texture, varying considerably in depth, and with a subsoil full of boulders and pebbles. Both soils have, however, been formed by the decomposition of the older rocks, and contain a large amount of micaceous sand, the decomposition of which, if it was not so slow, would yield a sufficient quantity of potash for the use of the tea plant. This however could be hastened by deeper and more frequent hoeing, which would enable the air to act more freely upon it, rendering it soluble and therefore in a condition in which the plant could make use of it.

"Although the soil of the lower lands is so open drainage is found to be absolutely necessary for the healthy growth of the plant, owing to the flatness of the country. If this is not done, the heavy rainfall causes the soil to become waterlogged, which stops root growth, and the plant naturally sickens and yields a smaller quantity of leaf.

"In the older gardens, the plants (a mixture of China and hybrid) have been found to be planted too closely, being in some instances only 2' to 3' apart, and this has caused a slower growth, owing to the small amount of feeding and breathing room allowed for each plant; it also appears to make them more subject to blight, as these bushes suffer more than those planted at wider intervals. Another disadvantage of this close planting is that the surface roots interlace with each other, so that deep cultivation is impossible without injury to the plants and therefore the air does not penetrate so deeply into the soil.

"I have suggested the burning of all prunings, especially all blighted leaves and large wood, as it is probable that hoeing in the former, unburnt, is one of the chief causes of the continuance of the disease, and if every manager would see that this is thoroughly done every pruning season, the serious ravages of this disease should be considerably lessened. The larger branches, also, if allowed to slowly decompose in the soil, form a suitable home for many insects and fungi, which may injure the growing plants. That decomposing would have an injurious effect on the plant is plainly seen where bushes are placed near a dead stump.* As a rule, they flourish for a time until their roots reach those of the decaying stump, when the leaves suddenly wither up and the plant dies. It is also very important that the ash obtained from the prunings should be restered to the plants, otherwise considerable loss to the soil would ensue. Besides it is the best possible manure for the plants, as it contains all the necessary mineral constituents in an easily available condition.

"Another important source of manure is the ash of the wood burnt in the engines; the ash from which is rarely made use of, being usually merely thrown out in heaps and exposed to all weathers, causing a loss of valuable plant food; whereas if it was placed under cover to protect it from the rain until a sufficient quantity for application was collected, a cheap and effective manure would be always available. Its good effect on the tea plant was well marked in one instance where it had been thrown among some bushes growing close to the engine house, these being of a healthy dark green colour, and nearly a foot higher than the surrounding bushes.

"The soil of the new extensions, which had previously been covered with jungle, is more suitable for the tea plant than broken-up grass land, no doubt due to the larger amount of organic and easily soluble mineral matter present in the surface soil in the former, and also to the burning or removal of the grass which causes an annual loss of organic matter and nitrogen, so that probably the application of a nitrogenous manure to this soil would be of great benefit.

"The site of the old nurseries is plainly marked in the old and new gardens, by smaller plants of feeble growth; this is no doubt owing to the large amount of surface soil removed with young plants, and consequently most of the readily available plant food, so that to these places either soil from the jungles near by, or some complete manure, should be applied to restore them to their former condition.

"There was only one point called for attention in the manufactory, which was, that in some cases the leaf was sifted after the first rolling, so as to separate the coarser from the finer leaves, by which means a more even fermentation is secured and a better sample of tea obtained.

"In noting the temperature of leaf during the fermentation I found that there was a gradual lowering for about two-thirds of the time, after which it remained constant at a temperature below that of the surrounding atmosphere. The high temperature of the leaf at first was due to friction in the rolling, and the rapid cooling to evaporation of moisture from the damp cloths covering the leaf. The following were the temperatures noted for fine and coarse leaves, taken at intervals of half-an-hour:—

Fine leaf ..77.9°, 74.3°, 73.7°, 72.6° F.
Coarse leaf ..74.6°, 72.4°, 71.6°, 70.2° F.

* However no definite conclusions can yet be arrived

at as to the best temperature for the fermentation, as probably in the rainy and hot season, a different one would give as good or better results, and further trials will be made at that time when an opportunity occurs for again visiting the districts.—I remain, yours faithfully,
(Sd) M. K. BAMBER.

It is proposed that Mr. Bamber should have an opportunity of seeing the districts of Assam and Cachar &c., before settling down to the analyses of soil. During his tour through these districts he will collect samples of soils and plants to be analysed, and organize all arrangements for manural experiments.—*Agricultural and Horticultural Society of India.*

GROCERIES AND THE AMERICAN TARIFF.

One day last week a reporter of the *Public Ledger* of Philadelphia, dropped into the store of Finley Acker & Co., and was fortunate in meeting the unusually shrewd and level-headed senior member of the firm, who spoke as follows regarding the effect of the tariff on the prices of groceries:—

"Ever since the passage of the bill in nearly all branches of trade the cry has been heard: 'Higher prices! Higher prices!' So general and familiar has become the cry that when a young lady was facetiously asked to pay five cents for a two-cent stamp which she had ordered she gravely paid the amount without a murmur, attributing the advance to the operations of the McKinley bill.* * *

OTHER CAUSES OPERATING.

"Have any other causes operated to advance the prices of goods in your line?" asked the reporter.

"Yes, there is tea. On account of the rapid advance in the price of silver several months ago, teas advanced considerably in price, but are now back again to their former value. Although our trade has been rapidly growing, we think that tea should be used much more freely than it is. When we consider that a pound of tea will make nearly 300 cups, while a pound of coffee makes but 32 cups, we can readily see how economical tea is in comparison with coffee, even if the highest priced tea be used.

"The cost of coffees have still further advanced, but not to an extent sufficient to affect retail prices. We are hoping that in time we will again be able to sell coffee at the very low and popular prices of several years ago.

"While speaking of beverages we must refer to the development of the cocoa trade within the last year or two," continued Mr. Acker. "It has been almost phenomenal. Instead of cocoa being used on rare occasions, or in the sick rooms, it is now in daily consumption in many families. One reason for this is that more enterprise has been shown by cocoa manufacturers in popularizing this nutritious beverage, and demonstrating its cheapness as compared with coffee. One pound of cocoa is said to make from 60 to 80 cups, and when you can buy it at 40c a pound you can readily see how cheap it is. Even if you buy it at \$1 a pound it will still be as cheap as coffee.—*American Grocer.*

"A CEYLON TEA-SELLING COMPANY, LIMITED.

UNDER THE PATRONAGE OF THE CEYLON PLANTERS' ASSOCIATION."

Such is the important decision arrived at by the representatives of the Ceylon Tea planters assembled in the Tea Fund Committee—namely, to take steps for the formation of a Limited Company to undertake the business of selling pure Ceylon teas, in new lands especially. The immediate cause of this movement has been the enquiry through the Imperial Bank of Russia on behalf of constituents as to the financial standing of the Planters' Association of Ceylon—made, evidently under the impression that the Association was a business Company of planters ready to sell their tea direct. There can be no doubt that there is room for such a Company as that now proposed, and that if managed judiciously on business principles, it ought to be specially successful in giving

* See *Proceedings*, March and May, 1887.

CEYLON UPCOUNTRY PLANTING REPORT.

CACAO : LOSS IN WEIGHT ; THE " SUBMERGED TENTH " AND " NATURAL DRIAGE "—WEATHER—COOLIES.

Jan. 26th.

The cacao crop is drawing to a close; and while some have reason to regret that it has not been quite so good as they expected, others have done better and rejoice accordingly. There is no denying that many who went in at the first rush for this product were sadly disappointed. Here and there, all over the planting districts, there still remain evidences of that outburst of enthusiasm in the shape of isolated cacao trees—deplorably ragged looking things which would be enough to scare anyone from renewed efforts. They stand there as warnings and awful examples, and are pointed to as conclusive when a good word is said for a first trial. But about cacao we have learned much and are still learning, and I am of opinion that if, when there was a general run into cacao, the knowledge of its ways and wants had been at all abreast of what we possess today, there would not have been that shrinkage of cultivated area which we deplore, nor the current belief, which is pretty strong amongst us that only in highly favoured spots can this profitable cultivation be carried on.

Cacao is not a hardy thing like tea, but is a plant demanding much patient care; and it may be because this care had to continue unrelaxed for so long a time that we have in our midst those who scout at it, and question its profitable nature. Men who are in possession of good cacao gardens know whether the thing pays or not, and the sort of feeling among them as far as I can discover is that of an inclination of laughing in their sleeve, and satisfaction that cacao should be decried. The more it is proved on paper that the industry cannot pay, the more they like it.

The grower of cacao is, however, not without his bothers. If he has a fair field to fight these bothers in, it only adds a little zest to life; but when he feels that he is running his head against a stone wall, it is different. We can fight the borer, the porcupine, the want of shade, the cutting effects of wind, and to some extent the raid of the Sinhalese rogue; but loss of weight in London is as hard a nut to crack as the problem of the poor, and, like that unfortunate class is always with us. Cacao shipments, however accurately they are weighed on this side, invariably come out short. There is a "submerged tenth" over and above the regular allowances which goes astray in the modern Babylon, and, alas! is never reclaimed. I fancy that all cacao shippers have had, at some time or another a tussle with their home correspondents over loss in weight, and have found that "mickle din and little oo" &c. accurately describes all that was ever gained when time was called. You may enter gaily into the controversy, but you come out with a chastened spirit. One who had gone through this valley of humiliation when I made up my mind to tread its tortuous way gave me this as his painful record:—"I have gone through all the performance of correspondence, and of sheer humanity charge you to desist. You will gain nothing, and the advantages of a cool climate are so completely in the brokers' favour that wisdom dictates a moderate course." Are these the words of wisdom or pusillanimity? Let each judge for himself. I

certainly did not take them as my guide, but went into this loss of weight question with the hope to see the bottom of it.

The first bone that was thrown to me to worry at and break my teeth over, was that fine, elastic, all embracing phrase "natural driage." "Natural driage" is a good general term, with an honest healthy ring about it and can account for much. If a shipment is half-a-cwt. or half-a-dozen cwt. short, all complaints when met in this way are hard to sustain. I knew a shipper of cinchona bark, irritated to exasperation through the loss from "natural driage." But he followed his produce on one occasion to London, saw the weighing done himself, and came out with an increase rather than the usual deficit to his friend's astonishment "Natural driage" is, however, a very subtle kind of thing, and in connection with cacao shipments holds the same place as the term electricity often does in the explanation of natural phenomena—an explanation which does not explain.

To test what there might be in the "natural driage" plea, I had a bushel of cacao carefully weighed just before packing and it turned out 38½ lb; when it was weighed on arrival in London it was 40 lb. My friends there who were at one with me in their desire to understand the shortage in weight, when sending on the result of this test, which nailed the "natural driage" plea to the counter, put the thing in these few pregnant words:—"It will not help you much, in fact nothing will. The brokers and the trade will only recognise the sworn weighers' weights, and in our experience these are never satisfactory to the shippers."

When I got this lengthy I thought of the cynical advice tendered me when I began the enquiry and which I have given above, as the words of true wisdom. Still I have a hankering after this "submerged tenth" of ours, and would gladly see it reclaimed. If necessary I would willingly subscribe my experience for the outfit of any prophet who may arise prepared to tackle the subject, and preach a reform.

The late showers were very welcome and have done a lot of good. Now the weather is taking up and the clear brightness of the N.-E. is with us again. If the cold wind will only be moderate things will be "booming."

The coolie is turning restless and thinking of home. If all were to leave who propose to do so, the labour force would be much reduced. But Ramasami does not always ride when he's saddled.

PEPPERCORN,

HILL-COUNTRY PLANTING REPORT.

The weather is now simply perfect, the wind having ceased and the morning and evening temperature being that of an English summer. There is, of course, tropic heat of an emphatic character during the day. There is not a sign of rain; and the only modification of the clearness of the sky arises from the smoke of burning patanas which is floating about, and this raises a curious question. According to the Coorg Forest Report quoted in the *Observer* the other day from the *Tropical Agriculturist*, the effect of the annual burning of grass growing in forests is to improve the soil by adding to its stock of nitrogen. Mr. Bramber, the Indian tea chemist, on the other hand takes the view generally held that it is the annual burnings which keep grass lands so poor in nitrogen. The premises granted, how are we to reconcile the opposite effects? For, be it remembered, the falling leaves in the forest are burnt equally with the grass.

BARK AND DRUG REPORT.

(From the *Chemist and Druggist*.)

LONDON, Jan. 8th, 1891.

ANNATTO.—Prices are a shade easier as compared with the last auctions, and 33 bags of good seeds from Ceylon sold at 2½d per lb. For a parcel of 50 bags fine seed from Ceylon, an offer of 2d per lb. was refused, 2½d per lb. being named as the price.

COCA LEAVES.—Of 5 belos South American leaves offered none were sold. Thin, dusty, and very broken Truxillo leaves are held for 1s per lb. A parcel of small, thick, dark brown damaged Ceylon leaves was offered at 4d per lb., but there was no demand. New York quotes higher prices—viz., 1s per lb. o. i. f. for light green Truxillo, while Huancoco leaves are reported out of stock.

OILS (ESSENTIAL).—Of 100 cases Citronella, 20 cases (in tins) sold at ¼d per oz. Nine cases cinnamon-leaf oil sold at 1½d per oz.

QUININE.—We have not heard of any business in this article this week, but the market has become very dull, second-hand German bulk being offered today at 1s per oz. At the auctions 5,000 oz. B. & S. second-hand in 100-oz. tins were bought in at 1¼d per oz.

NOTES ON PRODUCE AND FINANCE.

(From the *H. and C. Mail*, Jan. 9th.)

ENGLISH REGISTERED INDIAN TEA COMPANIES.—There are altogether sixty different companies, with capital varying from £11,800 up to £354,000, and with an aggregate paid up capital of nearly £4,800,000. Add to this the mortgage debentures of about £700,000, and we arrive at a total capital expenditure of 5½ millions sterling. The cultivated area of the sixty concerns totals up about 115,000 acres. In addition to this, of course, there are all the Calcutta registered companies, as well as the innumerable private properties; many of which are very large, so that we shall not be far wrong in estimating the entire capital sunk at something near to 10 millions sterling. It is remarkable that with so large a block of stock the property is still so very unmarketable, and that at all times it is alike difficult either to realise or to acquire even a very small number of shares. Time, and also a more extended knowledge of the conditions under which the vast enterprise is carried on, will, no doubt, eventually cause an alteration in this respect. Already, as has before been mentioned in our columns, various efforts of a substantial kind are being made both to induce holders to turn over their stock and to induce investment companies, private investors, and insurance and other bodies to direct their attention to these much neglected securities.

THE GROCER DARE NOT GO BACK TO CHINA TEA.—In connection with a statement made in an article on the Board of Trade returns in yesterday's *Times*, to the effect that a revival of the China trade may be expected, the following from the *Grocer* of last week is interesting. In its reference to Indian tea it says:—The consumption is again on the increase, and the total deliveries for the year 1890 will be over 103,000,000 lb. against 93,000,000 lb. in 1889, or an increase of over 10,000,000 lb. for the year, while in 1889 the increase was 11,750,000 lb. over 1888. The strides that Indian tea is making in public favour are only equalled or excelled by Ceylon growths. The public will have strong and dark-liquoring tea irrespective of flavour, and the grocer finds that only India can supply it. The value that the grocer has been able to get from 8d to 10d per lb. is striking, and he has been obliged to make use of Indian growths freely, to the detriment of poor China. Last year China teas were exceptionally poor, but although they have been better this year, yet the grocer has so cultivated the public taste that he dare not go back to China teas: except in the smallest way.

CHINA TEA PROSPECTS.—Messrs. W. J. and H. Thompson, in their China Tea Circular take a hopeful view of the prospects of China tea. They say:—For the past year we have to note a very satisfactory increase in deliveries, home consumption showing seven millions and export one million in excess

of last year, the total amounting to 231 millions, against 223 millions. The stock on December 31st, 1890, was 11 millions less than at the same time in 1889. The large increase in the home consumption is, no doubt, chiefly owing to the reduction of duty in May last from 6d to 4d per lb., but also to the improved state of trade, which has, to some extent, benefited the large consuming classes. The increase in export from this country was quite unexpected early in the season, owing to the large purchases made in China for Russia; but the supplies of suitable qualities proving inadequate, considerable orders had still to be executed in this market. The figures for export include nearly four millions of Indian and Ceylon teas, which seems growing in favour in Russia as well as in other countries. The quality of the crop from China was again disappointing, but, in consequence of the moderate supply, prices for the finer grades of black-leaf Congou ruied very high, and were mostly taken for export. Shippers from the northern ports have had reason to be satisfied with results; from Foochow, however, the reverse has been the case, except as regards the finest chops, which sold at good profits. The quantity of the lower grades has been comparatively large, had been met with small demand beyond the moderate requirements of the trade for these classes. The total export from China promises to be about 20,000,000 less than last year, and as the deliveries for the last six months have been almost equal to the corresponding period in 1889, and with much reduced stock, the position of China tea must be considered more favourable than for some time past.

CEYLON TEA.

The *Grocer* says:—The total consumption for 1890 is nearly 33,000,000 lb. against just over 30,000,000 in 1889, and 18,500,000 lb. in 1888, thus showing an increase of nearly 8,000,000 lb. for the year, and 19,500,000 lb. for the two years. The supply for the year is about 40,000,000 lb., and the stock has increased some 3,000,000 lb. to, say, 8,500,000 lb., or two and a-half months' stock, which may be considered very moderate and quite necessary recollecting the steady, all-round demand there always is for Ceylon teas. The year's crop of 1891 is now estimated to yield 50,000,000 lb. for the London market, so that consumption will again have to make great strides to keep pace with such an import. Now the question arises, What is this extra supply to take the place of? China Congou for home consumption is already so small that it cannot well be smaller, unless it is to be wiped out altogether. Perhaps these teas will rapidly increase in favour on the Continent, and if so, it would prove a great relief—otherwise we cannot but foresee a fall in prices before the summer, which would prove very disastrous to this deservedly popular British possession. Still, the trade has little to do with this question, as supplies are so evenly regulated that dealers only supply their wants week by week; the sale of Ceylon is also so steady that buyers require to hold stock.

THE EXTENSION OF FRUIT CULTIVATION.—We learn from the *Pall Mall Gazette* that about London, in almost every direction, but especially towards Farningham, in Kent, an added extent of land is being prepared for the growth of fruit. Fields many acres in extent, are wholly arranged for Strawberries. There are scores of acres being planted with Current bushes. For the most part this vast area of fruit is destined for jam-making, an industry very large in London, which the policy of the Government as to sugar at one time placed in jeopardy. An estimate has been published in an official document, that seven of the principal jam-makers and confectioners in London use 34,000 tons of sugar per annum. It has been estimated that the quantity used in Scotland for similar purposes is about 40,000 tons per annum. The soil and climate of parts of Sootland are admirably adapted for Strawberries, and, as far north as Aberdeen they are produced very extensively.—*Gardeners' Chronicle*.

THE RAINFALL OF LAXAPANNA ESTATE,
MASKELIYA.

Laxapanagala, "the mountain of the hundred thousand lamps," is so called because bands of pilgrims to Adam's Peak were and we suppose still are in the habit of congregating at its base and there lighting their lamps at midnight preparatory to the ascent of the mountain of the Sri Pada (sacred footstep), so as to reach the summit before sunrise. It is one of the chief flanking ranges of the central mountain, and nearly 6,700 feet above sea-level, so that it ought to and does intercept a considerable portion of the rainfall of the south-west monsoon. But the estate of Laxapanna is evidently less fully exposed to the monsoon current than is Theberton at a straight line distance of three miles; for while the average rainfall of Theberton (the rainiest position on the Surveyor-General's map) is 217 inches, the average of Laxapanna is only 147 inches. Mr. George Greig, in sending us his very interesting diagram, coloured and conveying to the eye a vivid idea of the rainfall for each month and each year of the past fifteen,—notices the curious reduction, of the average from 157.35 inches in the first 11 years to 121.21 by the results of the last 4. As there seems to have been no failure of the south-west monsoon generally, the question naturally arises whether there has been any change in the locality of the rain-gauge, or any erection of buildings or growth of a grove of trees which might affect the local results? The figures on which the largely differing averages are founded, are as follows:—1876 133.30 inches; 1877, 176.10; 1878, 159.05; 1879, 177.65; 1880, 141.62; 1881, 155.83; 1882, 191.62; 1883, 151.07; 1884, 143.05; 1885, 147.53; 1886, 153.72. These are the years (11) and figures which established, apparently, the rainfall of the estate at an average of 157.35 inches. Then came the remarkable decrease which in four years brought the average of those years down to 121.21 inches, thus:—1887, 118.80 inches; 1888, 133.52; 1889, 125.90; 1890, 106.61. In this the lowest year of all at Laxapanna, the rainfall at Elfindale, down the valley, was considerably more than double the quantity, not less than 249.33 inches. We have little doubt that the record for the neighbouring Theberton will considerably exceed 200 inches, so that the persistent diminution of rainfall at Laxapanna for 4 years, until we get only 106.61 inches in 1890, against 191.42 in 1882, is one of the most puzzling of meteorological phenomena we have met with. We have records of great discrepancies in particular years, but here we have a sunspot period of 11 years giving an average, which might well be relied on as true and permanent, of 157.35 inches; while the average of 4 years succeeding 1886 gave an average of only 121.21. The average for the whole fifteen years was thus brought down to 147.71 inches. We might adduce the explanation of the commencement of a cycle of drought in 1886, but for the continuance of records of normally heavy rain in the neighbourhood. We seem shut up, therefore, to some local cause of changed position of rain-gauge shelter, of buildings or trees, change of the gauge itself, or change in the observer?

The monthly averages are given as follows:—January 2.67 inches, February 2.28; March 5.09; April 10.35; May 17.85; June 27.19. In 1888 the rainfall of this month at Laxapanna was 44

inches, against the enormous deluge of 84 inches at Theberton; July 22.20; August 18.75; September 12.14; October 16.68; November 9.65; December 7.76.

Looking at the rainfall map, it is interesting to notice how the deposit of moisture increases as the monsoon current sweeps from the western shore at Colombo, inland. The average at Colombo is in round figures 89 inches; then a little to the eastward amidst the foot hills is Labugama with 161 inches; at about an equal distance again, and still amongst the lower hills comes Pambagama with 163 inches; finally we come to the rainiest centre in our mountain region and find Theberton, at the elevation where the mass of the rain clouds strike and are cooled down by the mountains, 3,315 feet, with 217 inches. But for some intercepting hill or spur, Laxapanna ought to be well up to a similar figure. Local features, however, divert both wind and rainfall very materially.

GAS DIRECT FROM THE MINES.

Dear Sir,—Having read with interest the letter of Hon. R. Russell on the abatement of the smoke nuisance, and having experienced the difference in Pittsburg, U.S.A., since natural gas was introduced there, I beg leave to submit the following suggestion.

In the United States natural gas is already piped fifty or sixty miles, and it has been proposed to pipe it 250 miles or more to the seaboard. Fetching the crude coal to London by rail involves using a car that often weighs as much or more than its load, the car having to be hauled back empty. The coal then has to be hauled to the house, carried to the cellar, carried up to the fires, and finally, the ashes carried away, and the soot and dirt created in the room cleared up. As a matter of fact, we consume our coal at great loss by first heating it in the grate and then burning the gas it evolves.

As I sit by a glowing, gas fire, I imagine that—

1st. The gas consumed in London is immensely enhanced in cost by the transportation of the raw coal to the gas works in the city.

2nd. That a very cheap heat gas could be produced from coal.

3rd. That gas could be manufactured at the mines (the nearest of which are about 110 miles from London) and piped to the City with great economy and at a great reduction from present rates.

4th. That the towns and dwellers along the route between the mines and London would take a liberal supply also.

There may be some practical difficulties to be overcome, such as forcing or sucking gas long distances, leakage of the pipes, etc., but these do not seem insuperable nor even very great.

The cost of the plant, in pipes, may be large, but the economy would seem to be so great as to recoup that.—Respectfully.

HORACE J. SMITH.

44, Grosvenor Road, London.

—Speaker, Dec. 27th.

INCREASED DEMAND FOR JUTE.

Government encouragement for the production of jute in the lower Mississippi valley has proved a failure. The quantities raised are not sufficient to cover even a small fraction of the annual cotton crop. Even under high cultivation the plants have failed to obtain the luxuriant growth of those raised in India. The difference in the cost of labor in India and this country, together with climate disadvantages, apparently renders it impossible for us to compete in the production of this article.

The plant requires a very strong soil and comparatively little cultivation. The regions in which it is grown were originally swamp lands, which were carefully drained under the direction of the English government. Being carried to Dundee as ballast over fifty years ago, it fortunately came under the inspection of a French weaver, who studied its properties

and succeeded in making the first yard of jute bagging Dundee has ever since been the chief manufacturing centre of articles made from jute. From 207 208 bales imported into Dundee in 1870, there was a rapid increase, until in 1883 the imports amounted to 1,013,109 bales. Within the last seven years new methods of decorticating jute have been invented, and cloths of finer texture can now be made, so that the increased demands have caused the imports to advance even more rapidly than during the preceding thirteen years.

Many substitutes have been tried for jute by southern manufacturers. None of these have as yet been made a success. Cotton bagging has been made for several years. The objections have been the expense and failure to protect the cotton from dirt and moisture. Several of the firms which have tried to manufacture it have either failed or turned their attention to some other field until there are but two left, and these are doing business only on a small scale.

The process of making cheap bagging from the fibres of the cotton plant is still in its infancy. Favorable reports of its development have been received from several sources during the year. This may in time prove a success, but at present the outcome is doubtful.

No material is manufactured at less cost per yard than jute. After cost of production, shipment to Calcutta, insurance charges and ocean freight have been added, it is placed upon the American market at an average price of 3c. per pound, and at this low rate the profits are large. The bagging made from it is exceedingly strong and can endure almost any amount of rough handling. It has frequently happened that when cotton bagging has given out in course of transportation jute bagging has been substituted. Many steamship lines refuse to carry cotton as freight if covered with any substance other than jute.

The increase in the size of the cotton crop is well shown in the increased demand for jute bagging. The mills, although they have been greatly enlarged within the past year, find it impossible to keep up with their orders. Manufacturers have given consumers the benefit of the change in tariff rates. The imports for the last ten years in tons were as follows:—

	Tons,		Tons.
1880	82,471	1885	98,343
1881	68,631	1886	83,054
1882	84,186	1887	88,514
1883	125,318	1888	115,163
1884	64,389	1889	88,665

—Bradstreet's.

LABOUR SUPPLY IN THE STRAITS.

EX-CYLON PLANTERS GIVING EVIDENCE.

LABOUR COMMISSION.—Present, Capt. Cameron, Messrs. Powell, Turner, McGregor and Brown.

Mr. John Anderson recommended a Government agency in Singapore, abolishing independent coolie depôts and brokers. If the Chinese Government could be persuaded to co-operate in the emigration it would do good. There should be fixed rates for brokerage and importation expenses, and over-charges should be made penal. The trade should be encouraged to remain in Singapore as a distributing centre. Direct traffic with North Borneo was not to be encouraged. Oost to Darvel Bay would be \$65, while through Singapore it was about \$95. He thought the direct traffic to Sumatra from China was no cheaper, and in some cases dearer, than through Singapore. He objected to estates being harassed by medical or other Government officers, when if left alone they were getting well enough. Witness had been in the Government service (laughter). The Trafalgar Estate would be better closed than further hampered.

At 1-30, the Commissioners adjourned until Monday, at 11 a. m.

Singapore, Jan. 19th, 1891.

Present:—Capt. Cameron R. E. President, Messrs. J. Turner, A. Macgregor, E. A. Brown (Secretary) and R. P. Gibbs (Assistant Secretary).

Mr. C. E. St. Caulfield, Manager Pulo Obin coffee and pepper estate, had been connected with the estate for nearly three years; in the Straits 9 years and in Ceylon since '58. Free Tamils are employed on Pulo Obin, formerly Javanese were employed there, and over also indentured coolies. The latter were unreliable in their work and regularity, and were more expensive, so their indentures were cancelled and they were employed on higher pay as free coolies. He used to be on Loon Choo estate. Did not see any way to avoid unsatisfactory Contract labour. The headmen bring enough. He considered it unsatisfactory to take a coolie to court at present. A monthly indenture was sufficient. Of course if any inducement the coolie would leave but the contract had no effect in that respect, the only way of keeping the men being by offering them sufficient inducement to stay. The headmen got them from India at their own risk, being paid their charges. They receive no payment until the men actually arrive at the Estate. If they ran away before the charge is repaid the headman was responsible. They had no difficulty in getting sufficient coolies or in keeping them. The arrangements for the Native States, owing to the keen competition, were not satisfactory. When a man ran away there was a great deal of difficulty to get them back again. More protection was needed for the employers and more coolies were wanted. A system of discharge tickets, without which employment could not be obtained would be useful. That would only keep a man till the end of the month; but unless there was a good reason other employers would not take him on. That was the system in Ceylon, where there was a great demand for labour and it answered very well there. It was an understood thing among planters that a labourer was not to be taken on without knowing where he came from. The employers here should combine to fix a maximum rate of wages and work the discharge certificate system, on all estate work throughout the States and the Colony. It would not be possible to make it illegal to employ others than those with a discharge ticket; the planters themselves must agree upon it. In Pulo Obin he had sufficient coolies; the headmen brought them; there was no legal contract with headmen; their disbursement was examined. The rate of wages was unduly high but paying that rate was the only way to keep them. His coolies were paid for Sunday labour, although they did not work; this had a good effect. Twenty days was the average work of an ordinary coolie; a good man did 24. The only guarantee that a new man came fresh from India was his appearance, which was unmistakable. The tindal made a good profit out of the coolie, no doubt. Government was a large employer; it should agree not to take on men without a discharge ticket. Recruiters did exaggerate but the coolies wrote home telling their friend what they got, and that it was the usual rate of pay. The rate of wages should vary with the price of rice, say from 18 to 20 cents a day. Sufficient coolies would be got without contract or indenture of any kind whatever. The demand at Pulo Obin was not of course so keen as in the Native States, but combination would do much to prevent crimping. The exceptions would be so few that it would not matter. The reasonable cost of a coolie from India would be \$10 to \$12; it varied from \$6 (without passage) to \$17. The Planters' Association could settle as to the amount of wages to be paid for different kinds of work, and it would be fixed by the price of rice. Increased cost of carriage to a distant estate would be a fair charge on the estate.

Mr. W. Turing Mackenzie, manager of Michaelstowe Estate, Johore, and in charge of Drumduan Estate; had been in the Straits two years and 14 years in Ceylon. He had only a few Chinese. He had no indentured Tamils now, though they were nearly all originally indentured, a few being picked up here. He had no experience of indentured Tamils and wanted nothing to do with them. Had never got any new coolies here, though one trial had proved lamentable, five coolies (two persistent malingerers, and two sick ones) having cost \$360. That was partly the fault of the recruiter he sent but partly the fault of Ordinance. He knew the latter was in force but did not know it threw so

many restrictions in the way. There were so many scrutinies, and then useless men were passed. The licensed recruiters interfered with his man, he believed. He was full handed at Michaelstowe, with Kelantan Malays. At Drumduan the tindal could get plenty of men. The rate paid 23 to 24 cents a day was very high; it was wealth to a Tamil, but the remedy was to let the market settle itself, importing plenty of free labour. This could not be done on a large scale but by degrees, as in Ceylon 40 years ago. Everybody should get his own men and not crimp then the rate of wages would settle itself. Government contractors offered a premium to high wages, paying \$9 a month. The coolies liked Government service because they got nothing to do; that was laxity he supposed on the part of Government. He objected to Sunday labour but sometimes it was unavoidable. He objected entirely to the system of Government inspection; it gave the coolie an idea that the Government official was a superior. The estate was put into a ferment and the coolies were perpetually running to him with all sorts of complaints. That was partly owing to the manner of the inspection and partly a factor of the system. Any accounts to be rendered and books examined to see that the coolies were properly paid he did not object to. Would not restrict the number of women on an estate; they could do work with the men. The rations his men got were 10 kati every Saturday, for five days work. For 4 days five kati. On this they could save 10 kati a month. *i. e.*, they lived on \$1.80 a month. Was quite sure they could live well on this. In some respects Ceylon 40 years ago could be compared with the Straits: they were beginning in a small way then as we are now. The place must be advertised in India and people would then come over. He objected entirely however to Government recruiters, who did a lot of mischief.

In reply to Mr. Macgregor, Mr. Mackenzie said it would be more expensive getting them here than in Ceylon; paying for the tindal's passage and the men he got, and then 25 cents a day pay. Tea would not bear the expense; coffee would. He employed nearly all Kelantan Malays at Michaelstowe. No planter should employ a man who could not produce a discharge from his last employer. The Public Works Departments and contractors took away a lot of men; a contractor could not be bound down not to take men away from estates but Government ought to import its own men. He did not object to a contract but "36 months was very like slavery." Three months were sufficient and if a man had not paid off his charges let the man who wanted to crimp him pay it off. He did not think a high rate of wage would have much effect in increasing the regularity of the coolie working. If a man began to save he was willing to work harder to add to his board. His Kelantan men at Michaelstowe average 17 to 18 cents a day; they were much better than Javanese. He thought large numbers could be induced to come down. He had a few Javaese on fixed salaries. There was nothing in the shape of a Planters' Association in Johore; he had tried to form one but it fell through, the distances were great. In the case of Tamils the tindal kept his accounts with the men carefully; there were very few complaints of this. The men signed a promissory note to the tindal but no agreement. A monthly contract would be sufficient, if the coolie had to produce his discharge ticket before getting fresh employment.

The commission then adjourned.—*S. F. Press.*

ADVERTISING CEYLON TEA.

The tea planters of Ceylon are certainly indebted to Messrs. Charles Mackwood & Co. and their manager Mr. Wilson Smith for a capital advertisement of Ceylon tea in the universal notice which has been taken in the home press of the sale of Galbodde tea up to 87s and 110s per lb. Here are a few specimens of the notices. The *Conservative Globe* says:—

That wonderful tea which was sold the other day at £4 7s a pound has changed hands again, it appears, at £5 10s a pound. A profitable transaction that! In this connection, we may observe, a correspondent writes to protest against the imputation of extravagance levelled against those who drink this tea. "Why, in the name of common sense," he asks, "should fault be found with us if we choose to drink tea that costs us eightpence a cup? No one attacks wine-bibbers who pay double that for a glass of some rare vintage."

The *Radical Star* again:—

Tea at £4 7s per Pound. J. S. Holloway, 29, Mincing-lane, writes:—A short time back you made mention in *The Star* of a special lot of tea that sold in public sale at £1 10s 6d per pound. Today (Tuesday) a parcel of golden tips, containing 15 pounds in all, sold at £4 7s per pound. Never since tea has been known has such a price been given. It came from the well-known Gallebodde Estate in Ceylon. A handsome profit has since been offered for it.

The *Chemist and Druggist* has the following notice:—

EXTRAORDINARY TEA PRICES.—The highest price by far ever realised for tea in London, and probably any where else, was paid this week for a small parcel of 15 lb. flowery orange pekoe, from the Gallebodde estate, in Ceylon. This parcel was sold by public auction amid a scene of great excitement at the price of 87s per lb. in bond. The highest price ever known previously was paid a few months ago for an equally small consignment of Ceylon tea from the Hethersett estates, which then realised 30s 6d per lb.—a price that has probably stimulated the Ceylon planters to send over the present parcel. A sample of the tea, which we had occasion to inspect today, shows it to consist mainly of very small tips of a colony resembling that of pale Turkish tobacco. The tips, have been evidently separated from the larger body of black leaves of the tea by the process of pressing a piece of flannel upon the bulk. By this method the tips in question, being covered with a fine down, adhere to the flannel, while the smoother black leaves remain behind. It would, of course, be possible to obtain an almost similar tea from any fine golden-tipped Pekoe on the market, and the price obtained for this particular lot was quite a fancy one, and it will probably not be maintained, by any means, if the Ceylon planters were to send over any large quantity. It is said that part of the consignment, if not the whole, has passed into the hands of the United Kingdom Tea Co. (Limited) of 21 Mincing Lane, and it is added that some of it has since been resold at the extraordinary price of 110s per lb. From China tea no such quality as that sold this week could have been obtained, but some of the better grades of Java tea contain a large proportion of silvery tips, which might be separated by a similar process. The finest teas have hitherto been used, as a rule, we believe, in Russia, Persia, and Morocco. Some twenty or thirty years ago the finest flowery Pekoe from China was regularly shipped to Russia either via Persia or via London, but since then that tea has gone out of fashion among the Russian consumers.

And *Colonies and India* remarks:—

Ceylon tea is certainly booming. At the London Commercial Tea Sale Rooms, in Mincing Lane, the other day, a consignment of tea from the well-known Gallebodde Estate, which experts in the tea trade describe as being the finest tea ever grown, was put up for sale by auction. The bidding for this unique tea caused unusual excitement in the sale rooms, and after being carried on with unprecedented competition between the principal firms in the wholesale tea trade the lot was at length knocked down at the amazing price of 87s. a pound, a figure which has never been anything like approached in the annals of the tea trade. The eventual purchasers of this tea were the United Kingdom Tea Company (Limited). The teas of the most extraordinary quality, the leaves being of the brightest golden colour, in appearance almost resembling small pieces of gold. Uttering care and attention must have been bestowed on its growth, and

it certainly reflects the greatest credit on the manager of the Gallehodge Estate that he has succeeded in producing such a perfectly wonderful and previously unheard of specimen of tea.

THE YATIYANTOTA TEA COMPANY, LTD.

Report of the Directors for presentation to the annual ordinary General meeting of the shareholders to be held on Friday, 13th February 1891, at noon. The Directors have pleasure in submitting to the Shareholders the Accounts of the Company for the past year.

Owing to labour difficulties in the early months of the year the crop secured was less than was estimated, but as the labour supply is now ample for all requirements and as the whole Estate has been recently pruned, it is expected that a large increase in the yield will result in the current year.

The total crop was 154,303 lb. of made tea, which cost, laid down in Colombo, R39,094.35 and netted R68,344.01 or about 44½ cents per lb. as compared with 48 cents per lb. for the preceding crop. The Directors attribute the falling off in the average price to the higher rates of Exchange ruling during the year. The expenditure includes cost of manufacturing 10,728 lb. of tea for a neighbouring estate, credit being given in the accounts for receipts under this head.

After making the usual provision for depreciation of Buildings and Machinery, the net profit for the year (including the balance from 1889 account) amounts to R23,002.87, of which R10,800 has been absorbed in paying an interim Dividend of 12 per cent. The Directors propose to apply R11,700 in paying a further dividend at 13 per cent (making 25 per cent for the year) and to carry forward to next year's account the balance of R502.87, which they hope will meet with the approval of the Shareholders.

Arrangements have been made for planting further 30 acres in tea this year, which will bring up the cultivated acreage of the Estate to 488 acres.

The crop in 1891 is estimated at 180,000 lb. tea against an estimated outlay on the estates of R44,200 and it is anticipated that the sum of R4,000 will be spent during the year on the new clearings of 84 acres.

In terms of the Articles of Association, Mr. A. Thomson retires by rotation from the office of Director, but, being eligible, offers himself for re-election. The appointment of an Auditor will rest with the meeting.

THEFT OF CACAO.

No. 5,802.—Jalaldcen, conductor of the Grove estate, charged one Jeronis Appu of Dumbukola with theft of about a lb. of cacao seed, the property of Mr. J. H. Barber, valued at 50c. The following is the judgment:—

The evidence in this case is meagre, but in the absence of any explanation from the accused as to how he came by the cacao found in his house it is sufficient to convict the accused. Mr. Barber's estate is robbed of cacao on the night of the 20th instant. On the morning of the 23rd, the accused is seen bringing a pot of ripe cacao seeds cently shelled and concealing it in the spout of the house where he is a lodger. He lives within ten chains of the trees from which the pods were broken off. The seeds in his possession appear to have been shelled about three days before they were brought to the house, tallying thus with the time when the pods were stolen. In quantity they answer to the quantity which would be the outcome of the stolen pods. The seeds were obviously put away from observation, for they were concealed inside a spout over which the two eaves of the maduwa and the house meet. That is not a place where an honest man would stow away cacao seeds honestly come by. The poor old woman in whose house the accused lives, frightened by the discovery of the cacao seeds, which she found in the pot the accused was seen stowing away in the spout, calls in a labourer or watchman of Ukuwela estate and gives him information of what she had seen. She is a most truthful old creature and was no doubt impelled to give this information by the thought that if the stolen cacao was found in her house, she may be made responsible for it. At all events, that very day the arachchi comes with the conductor and takes the cacao from where it was concealed. The accused was not in the house at the time, but it is clear that either he or the old woman must have put the cacao there. I believe upon the evidence that the accused put it there. He has elicited from the arachchi of his village by cross-examination what I could not have elicited, viz., that he has the reputation of being a thief in the village. He is besides a convicted gambler. He has practically no defence to make. His witnesses whom he called prove nothing, and he does not in the smallest degree account for the cacao seeds found in his possession.

When within a few days of the theft of cacao from a complainant's trees, the accused is found in possession of cacao seeds, recently shelled, corresponding in quantity to what would be the outcome of the stolen pods—the cacao seeds being further put away into an out of the way place within the precincts of where the accused lives and obviously put away for concealment.—I think I am reasonably entitled to conclude, in the absence of any satisfactory explanation, that the accused is the thief.

I find the accused guilty and sentence him to two months' rigorous imprisonment.

(Signed) J. H. EATON, P. M.

THE CEYLON SPINNING AND WEAVING COMPANY, (LIMITED).

Report of the Directors for the year ending 31st Dec. 1890, presented at the general meeting held at 1 p.m. today.

The Directors now submit the annexed statement of accounts up to 31st Dec. 1890, from which it will be seen that the net available balance is Rs.4,566.63; this is equal to over 5 per cent per annum on the paid-up capital for the five months the Company has been working, but, at this stage of the Company's existence, and in view of its requirements, the Direc-

tors recommend that a sum of Rs.4,000 be placed to a Reserve account, and that the sum of Rs.4,566.63 be carried forward. The erection of machinery occupied the early months of the year, and the getting of the various appliances into working order (necessarily a slow process) cannot be said to have been accomplished till the end of July. The working period therefore comprises the months from August to December inclusive. During that time steady progress has been made in Spinning and Weaving, and it is expected that a gradual increase in production will now take place. The Directors have felt that the prospects were sufficiently encouraging to warrant them in ordering 63 more looms. Six of these have arrived, and the rest are on the way, and will be erected in the existing Weaving Department, thereby filling the present available space in it. In order to pay for machinery, it will be necessary to rise some additional capital, and it is proposed to do this by the issue of debentures, or by such other means as may be considered more favourable in the interests of the Company. The directors consider that the results attained so far go to show that the expectations formed at the formation of the Company are likely to be gradually realised, and they congratulate the shareholders on the prospects before them. The directors who retire are the Hon. J. J. Grinlinton and F. J. de Saram, Esq., and they are eligible for re-election.

RAILWAY TRANSPORT OF CARDAMOMS: THE NEED OF CONSIDERATION AND ATTENTION IN KANDY.

One interested writes to us about a matter which doubtless affects all cardamom owners in the Kandy districts and which, therefore, ought to receive the early attention of the Railway Traffic Manager. The complaint is as follows:—

With cardamoms sent down green for curing in Colombo, quick transport is the essential to success. On an estate 8 miles from Kandy, we send off coolies specially after 4 p.m. with cardamoms who reach Kandy at say 6 p.m. These cardamoms are not forwarded by the Railway authorities till the 1 p.m. goods train of the following day, reaching Colombo

about 7 p.m. (too late for removal), and reach the Colombo store about 10 a.m. on the third day. There is a goods train which leaves Kandy at 5 a.m. in the morning, but all goods for it must reach Kandy before 5 p.m. of the day before, as the goods office closes then. And although we have sent coolies in by night to arrive at Kandy at 4 a.m. goods will not be received after 5 p.m. of the day before for the early morning train.

Now surely some arrangement might be made to allow of quicker transit, either by opening the goods office for a short time at a later hour say 9 p.m. or by allowing goods brought at 4 a.m. to be forwarded by the morning train.

TEA IN LAGGALA, MATALE EAST.

EXTENSION OF CULTIVATION.

There can be no question that Messrs. Barlow & Co. (large Manchester dealers in tea) have got a splendid bargain in the group of properties which includes Brae, Lauragalla, Foyers and Dell, covering some 1,083 acres of which 180 are in tea, the price being £4,500 cash. A short time ago, the group was valued at over £6,000 for a Company. The tea on Brae is very fine, and it is the intention of the purchasers to open and plant some 300 acres additional as soon as possible perhaps this year.

The same firm is likely to purchase the Hattanwella and Rook Park properties in the same district.

CULTIVATION OF RICE IN RUSSIA.—The Russian Agricultural Department is about to attempt the cultivation of rice in the southern provinces. The rice with which the experiments are to be tried is an early and quickly-ripening variety found in China. It is a very difficult matter to obtain this rice, for its sale to private individuals is prohibited.—*European Mail*, Jan. 16th.

VALUE OF MINERALS AND GEMS PRODUCED IN INDIA IN 1889.—The total value of minerals and gems produced in British India during the year 1889 amounted to R1,72,67,357, and those in Native States to R71,70,222, making a total of R2,44,37,579. Bengal heads the list with R58,47,459; next comes Mysore with R51,13,104; then Madras with R33,78,707; Bombay with R21,05,602 (this includes Sindh and Native States), &c., and Coorg R28,185. As regards the production of gold, Mysore stands pre-eminent with a money value of R42,62,050; followed by Madras with R1,39,473. The other places are Punjab R14,866; Kashmir R6,020; North-Western Provinces and Oudh R4,400; Bengal R2,000, and Burma R1,800.—*Indian Engineer*.

CINCHONA BARK AND QUININE.—We call attention to the very full and valuable annual Report afforded by Messrs. C. F. Bohringer & Son, which will be found on page 630. It will be observed that the price of Sulphate of Quinine which was 40s on 1st January 1822 is given on 1st January 1891 at 1s to 1s 1d! The exports from Java have advanced steadily from 420,668 lb. (Amsterdam) in 1832-3, to 4,750,000 lb. in 1889-90, and the sales of bark at Amsterdam show a large rise last year, while those in London are rather less than usual. The exports from Ceylon, India and Bolivia of bark all show a falling-off, while the consumption of quinine in North America has greatly increased last year, thus,—

1889	...	2,825,008	ounces.
1890 to 20th Dec.	...	3,374,300	"

Increase ... 549,292 "
Stock in London of bark show a considerable falling-off—over half-a-million lb. at the end of 1890, as compared with the close of 1889. Altogether, therefore, the prospect is of a rise in the value of bark at an early date.

TEA CULTURE IN CEYLON.

YIELD OF TEA AND COST OF PREPARATION IN MATALE EAST ON OLD COFFEE LAND AND ON VIRGIN FOREST LAND.

We are indebted to Mr. Joseph Fraser of Damboolagalla—one of the finest of Matale East coffee estates thirty to forty years ago—for affording us once again the very carefully prepared and most interesting annual statement of his experience as a tea-planter which we append. We suppose there has seldom, if ever, been published, so detailed and elaborate a return and all interested in our Tea industry may well feel obliged to Mr. Fraser for the trouble he has taken and his readiness to give publicity to his figures. The statement chiefly applies to last year; but we have added comparative figures as given for the previous three years. The steady increase in the yield year by year over all the fields will be specially noted and also the much heavier crops gathered from virgin soil, and land only cropped with cinchona, than from old coffee land. Next the extremely moderate expenditure in proportion to crops, the average cost of 154,964 lb. f. o. b. being only 23-2802 cents. per lb. notwithstanding that more than 16 per cent. of that is for "manuring." With so good a margin, Damboolagalla crop could not fail to pay well. Indeed, we may mention that the net return for the whole crop of 1889 f. o. b. is such as to make the percentage of profit on outlay, we should think as good as that of any of our celebrated Tea Companies. What Mr. Fraser says about his manured fields will be carefully noted and indeed his figures and remarks altogether cannot fail to afford much food for comparison and reflection by practical planters who are striving as well as they can to make the tea industry a profitable one.

In this connection, we have to ask planters firing the *Tropical Agriculturist* to correct an error with their pen, through a figure getting transposed on the first page of the *Tropical Agriculturist* in April 1890,—under cost per lb. Bungalows there is given .712 cent, instead of .172.

ANOTHER VINE DISEASE (GLÆOSPORIUM PESTIFERUM, C. & M.)—We have recently received from Brisbane some Vine shoots and Grapes suffering under the infliction of a new Vine disease, which, if it spreads, is likely to be of a very destructive character. The shoots, petioles, and peduncles present a shrivelled and miserable appearance, sprinkled, in some places densely, with small hemispherical knobs, about the size of a good-sized pin's head, and of a rosy-pink colour. Subsequent examination proved that these knobs were a mass of hyaline fungus spores, which had oozed out of orifices in the cuticle, and hardened by exposure to the air into that form. The cells beneath the cuticle are without any distinct conceptacle or perithecium, and the spores are produced upon short delicate sporophores rising from the cushion-like base of the cells. The spores, or conidia, are cylindrical, straight, and rounded at the ends, from 14 to 15 micromilimetres long and 3 to 4 broad, hyaline and colourless, with rather granular contents. When mature, they issue in a sort of gelatinous mass through orifices broken in the cuticle, and soon harden into the pin-head knobs, which remind one strongly of some of the small forms of Tubercularia, so common in this country. On the application of moisture, the spore-masses dissolve, and the spores are carried away freely wherever the water trickles. In some respects this fungus resembles another of the same genus (*Glæosporium ampelophagum*), common on Vines in Europe and the United States; but it differs in the colour of the exuded spore-masses, and in the dimensions of the spores, which are double the length, and broader than in the European species; besides which, we have no knowledge that the mass of spores in *Glæosporium ampelophagum* ooze out and form such Tubercularia-like masses. The diseased fruit is stunted, shrivelled, and exhibit a few of the spore-pustules scattered over them. It is an unenviable addition to the fungi of Australia.—M. O. COOKE.—*Gardeners' Chronicle*.

NATIVE INVENTIONS.—Mysore seems to be ahead in inventions and manufactures. A goldsmith of the Rampore village is said to have invented a plough that is light and durable and does double the work of an ordinary plough. Another man Rachappa, a resident of Chickaballapur, is reported to be manufacturing sugarcane mills on the English model which are being used in the Province by the ryots.—*Indian Engineer*.

"COCONUTS AND TEA."—We learn from an experienced tea as well as coffee planter that "coconuts and tea" cultivation conjoined is becoming a favourite style of lowcountry plantation with several old hands. In some districts of the Western Province, both products are cultivated together, and we know of one plantation at least in Henaratedoda district, where tea is cropping exceedingly well and coconuts flourishing under this arrangement. In some parts of the country between Hanwella and Moratuwa the same style of cultivation is likely to be freely followed.

ARTESIAN WELLS AND IRRIGATION.—On leaving Colombo Mr. MacBride made his way to Tutuorin and thence to some of the large S. I. Irrigation Works, such as the Godavery Irrigation Works, which he inspected; he also examined and made inquiries concerning a number of artesian wells; while, later on, in the cold districts he was enabled to see borings carried on with the very latest appliances, which are said to be of the most perfect character. Of course, Mr. MacBride will have now to inquire into the general conditions of the Northern Province and we suppose he will pay a visit to Jaffna at an early date to see if such wells are practicable there. If he finds that they are, the insight that he obtained into the boring for coal at the Kauegauge and other mines will prove of service.—*Cor.*

"COCAINE IN DENTISTRY" is the name of a paper read at the 5th annual meeting of the German Association of American dentists by Dr. Blerch, Mannheim, a copy of which is sent to us by Messrs. C. F. Boehringer & Söhne, Waldhof near Mannheim. It runs as follows:—

Employed with proper knowledge and care in minimal doses of 0.190 to 0.385 grain, cocaine is unquestionably one of the safest of drugs, and has the further advantage of being so cheap, that we can give the poorest patients the benefit of it, since even if we receive no payment at all, 0.385 grain of cocaine costs only about a halfpenny. The favourable opinion of the Prague professors concerning Boehringer's Hydrochlorate of Cocaine I can fully confirm.

IS ADULTERATION UNIVERSAL?—Speaking from an experience of fifteen or twenty years, one medical man, at any rate, is able to say that he has not found his fellow-men of the business class half so black as they have been painted. Wines, which are so commonly ordered for sick persons, are seldom or never the poisons they are said to be, unless they are purchased at poison prices. The poor, who cannot afford to pay for good wines and spirits, should leave such things entirely alone if they cannot procure them from charitable friends. An old-established wine merchant admitted to the writor quite recently that poisonous wines and spirits are undoubtedly manufactured; but then they are manufactured because there is a demand for them on the part of people who cannot afford to pay for *bona fide* wines and spirits. Those persons who can pay for genuine articles are just as sure of getting them honest and good as they are of getting honest and capable medical practice when they can offer reasonable fees for it. Exactly the same may be said of teas, coffees, cocoas, beef, juices, infants' and invalids' foods, and their makers. All these things can be, and are obtained of the highest order of excellence by people who are able and willing to pay for them according to their market value.—*Hospital*.

INDIARUBBER.

LONDON, Jan. 16.

Unfortunately my knowledge of what has been accomplished in Ceylon with respect to the growth of indiarubber plants is too restricted to enable me to judge whether you might be either prejudicially or beneficially affected by news reaching us from America as to a syndicate composed both of Americans and Englishmen having been formed with the object of buying up all the indiarubber in the world. This syndicate is said to have obtained control over fully half of the entire production of Pará rubber and that it expects to get the entire monopoly. It is intended to extend its operation, not only throughout America, but also throughout Great Britain and the European continent; and if the syndicate should prove successful, the price of indiarubber is sure to go up largely and the cultivation of the plant on Ceylon estates may be thereby much stimulated. As written above, however, it is not certain in my mind, whether the cultivation of the juice-yielding plant has been persevered with in Ceylon, or whether it has not been altogether abandoned.

THE CEYLON PIONEER IN TEA.

Mr. Leake tells me that he has received instructions from the Ceylon Taylor Testimonial Committee to purchase a silver tea service for presentation to that gentleman, but that the amount of money at his disposition for that purpose is so large that he is completely puzzled how to act. Altogether, the subscriptions out in Ceylon and at home to this fund amount to about £240. We hardly think Mr. Taylor would care to have silver to that amount, and an exceedingly handsome service, silver and everything complete, could probably be purchased for 90 to 100 guineas. So Mr. Leake is, as you will see, suffering from an *embarras de richesse*, and the local Committee here is somewhat puzzled as to how to proceed for the best. I told Mr. Leake it scarcely seemed to me to be advisable to put Mr. Taylor to the risk of keeping too costly an amount of silver in an upcountry bungalow; but he replied that he himself had been married thirty years, had had an entire service of silver in use throughout his residence in Ceylon, and that up to date he had only lost of it a single spoon! All that can be said as to this, in my opinion, is that Mr. Leake has been an exceptionally lucky man.

MANA GRASS AND PAPER.

Discussing with the gentleman last mentioned the probability of Messrs. Curtis & Harvey becoming large purchasers of mana grass in Ceylon for charcoal burning purposes, he mentioned to me that he thought it would be most uneconomical to bring the grass home for burning, and that if the charcoal to be obtained by that operation should prove to be of value, we might depend upon seeing works specially erected in Ceylon for producing it locally. He did not think Messrs. Curtis & Harvey would be alone in appreciating the value of the charcoal if it should prove to be of a very superior quality. There is, Mr. Leake said, a very great and very unsatisfactorily supplied demand for exceptionally fine charcoal for making the filaments for electric lamps. The provision of these filaments is already a very large business, and one that is sure to receive very great extension. If, as seems to be anticipated by experts,—and I believe Dr. Evans is the authority for this anticipation,—the result to burning mana grass is likely to supply this demand, there will be

ample inducement for the establishment of a charcoal factory in Ceylon. Very special furnaces must, however, be required for burning such a light and easily-consumed material as this grass. Any excess of draught over that absolutely necessary for the most gradual combustion would flash it away and no charcoal would be left. I think I told you that Messrs. Curtis & Harvey are hoping to get 2 cwt. of charcoal from the ton of the grass they have received, but at present nothing is known to me of the process of burning by which they hope to secure such a large result.

MESSRS. J. H. ROBERTS AND J. HAMILTON ON CEYLON PLANTING PRODUCTS AND TEA DISTRIBUTION—MR. ROBERTS ON EXPENDITURE FOR "NEW MARKETS" FOR TEA AS A MISTAKE: ALL THE CEYLON TEA FOR MANY YEARS WANTED IN LONDON—CEYLON VS. CHINA.

Mr. Roberts started conversation with the observation that he regarded the expenditure now incurring by your Planters' Association upon the discovery of new markets for your tea as mistakably incurred. "The fact is," he remarked, "we want here in London all the tea Ceylon can send us for many years to come. I do not hesitate to say that if you were to send us eighty million pounds it would not over-tax our capacity for reception. You could not do a more unwise thing than to starve the London markets. For every pound Ceylon sends us a pound of China tea is driven from the sale. Sooner or later, if Ceylon and India send supplies adequate to our needs, China tea will find no place here. Every day sees Ceylon tea more appreciated here, and those who have once tasted it and liked it will drink no other; even now we can barely supply all that is asked for, and we want far more than we get." Mr. Hamilton at this point interposed and observed:—"Though that is all true, a larger supply must mean diminished prices. The present average all round for Ceylon tea is about 10 pence. That is not sufficient to properly remunerate the planter. To do this as it ought to be done the average must be raised to a shilling, and this is only likely to be obtained by placing buyers for foreign markets in competition. The only question to my mind is whether, if that rate were established, the present amount of demand for Ceylon tea would remain."

To this remark Mr. Roberts replied:—"Certainly it would. I feel confident that, so entirely have those who customarily drink Ceylon tea made up their minds to use no other, that even if they had to pay twopence a pound more for it they would still continue to purchase it." "That may be," was Mr. Hamilton's rejoinder, "but it is perfectly certain that it would check development of use and then the increasing production in Ceylon would have to seek other channels for disposal." Mr. Roberts, however, thought that it would be better for the future of the Ceylon tea interest to supply every possible demand for the home market than to obtain a better price by supplying foreign countries. There is undoubtedly much to be said on both sides. We can well understand Mr. Hamilton's desire that your planters should get better prices; but on the other hand we can realize the evil which would possibly follow any curtailment of the English supply and the consequent maintenance of active competition from China, which would otherwise daily slacken, until it had wholly died out. It was singular to see how different were the views taken by two partners in the same eminent firm on this particular subject. You will be better able than myself to assess at their relative values the arguments employed by both Mr. Roberts and Mr. Hamilton.—London Cor.

NOTES ON PRODUCE AND FINANCE.

(From the *H. and C. Mail*, Jan. 16th.)

A COSTLY TEA.—On the 13th inst. Messrs. Arthur Capel & Co. knocked down in their Ceylon sale to Messrs. Whitworth, Hillyard, and Wade, tea dealers, of Idol Lane, E. C., a small lot of extraordinary tea, at 87s per lb. It consisted of only three boxes, each containing 5 lb. of Golden Tip, from the Galleboddo estate. Every leaf was of a bright golden colour, without any brown or black ones to mar the beautiful appearance. This is the tallest price ever paid for a tea within the memory of living men. At this price, and allowing sixty cups of tea to the pound, each cup would cost 1s 6d. *The Times* of yesterday referred to this sale of tea, and the following letter from Messrs. Whitworth & Co., appears in today's issue. "Your interesting paragraph in this day's issue under the above heading would probably much surprise your readers. They will be still more surprised when we tell them, through your kindness, that we, who were the buyers at auction of the tea at £4 7s per lb., afterwards resold it at £5 10s per lb. A figure which has never been anything like approached in the annals of the tea trade will therefore apply to the latter price, and not to the former, as the paragraph implies. At this latter price, cost to the consumer would be about 1s 7d a cup. We trust that Indian and Ceylon tea planters will by this be encouraged to strive after quality in their productions in preference to quantity."

SPECULATION IN TEA.—"Observer" writes to the *Financial News* as follows:—As considerable speculation has recently taken place in tea, and prices in the terminal market have risen 2½d. per lb. above those ruling this time last year, it may be interesting to many of your readers, especially those engaged in the trade, to know the exact statistical position of this article. The figures are taken from the brokers' circulars of January and from the revised estimates of the Indian Tea Association.—Stock of all sorts actually in bond December 31st, 92,800,000 lbs.; arrived, but not included in stock, 1,200,000 lbs.; afloat, all sorts, 23,222,000 lbs.; stock in bond in the outports, about 6,000,000 lbs.; total, 123,222,000 lbs. Balance of Indian crop to arrive, after deducting quantity afloat, as per revised estimate of Bengal Association, 23,000,000 lbs.; Ceylon tea to arrive before June 30th about 20,000,000 lbs.; Now make Congou to arrive before June 30th about 1,000,000 lb.; total, 167,222,000 lbs. Delivery for six months, taken at an increase of 6,000,000 lbs. per annum, 116,200,000 lbs.; leaving a stock in hand on June 30th of 51,022,000 lb. (The new season's China crop arrives in bulk in July.) From the above figures which are taken on the most favourable estimate, it would appear that on June 30 there will be a stock of 51,000,000 lbs in the country, which appears very much more than sufficient, considering the rapid deterioration of tea by keeping, especially Indian and Ceylon tea, rendering the old season's almost unsaleable when the new tea arrives. There is one extraordinary fact in regard to tea, that for forty years there has never been an insufficiency of supply; there have been war scares, failure of crop scares, and insufficient supply scares, under which prices have been raised madly, to the ultimate detriment of all concerned, but there has always been amply sufficient tea, even when our sole source of supply was China. It seems hardly likely that, with India and Ceylon supplying nearly two-thirds of our consumption, and China able to send us as much as ever if prices are high enough, we shall suffer now from any deficiency.

THEN AND NOW.—Three score years ago Great Britain consumed thirty million pounds weight of tea, which was eight million pounds more than all the rest of the world, while in the interval the Colonials and foreigners have done their best to reach the Britisher, with the result that their aggregate consumption vastly exceeds that of Great Britain. But the people of this country now consume close upon 5 lb. per head of the population against 2oz. in 1711 and 20ozs. in 1830. The reduction of duty last year caused an increased con-

umption to the extent of some 5,000,000 lb. while it seems that the combined exports of India and China are likely to be very considerably less than last year.

CINCHONA BARK IN HOLLAND.

AMSTERDAM, Jan. 14th.—All the analyses for the cinchona-bark sales to be held in Amsterdam Jan. 22nd have been published now. The manufacturing bark contains about 7 tons sulphate of quinine, or 3·6 per cent on the average, divided as follows:—About 23 tons contain 1·2 per cent; 52 tons, 2·3 per cent; 43 tons, 3·4 per cent; 33 tons, 4·5 per cent; 11 tons, 5·6 per cent; 8 tons, 6·7 per cent; 12 tons, 7·8 per cent. —*Chemist and Druggist.*

WHAT A CEYLON TEA ESTATE PROPRIETOR DOES WITH SOME OF HIS TEA IN THE EAST OF LONDON.

(Communicated.)

Perhaps your readers will be interested to hear of the undoubted destination of some of the Ceylon tea, as well as of the good work done in East London by Mr. P. R. Buchanan, sometime tea-planter in Assam and proprietor of Blackwater estate in Ceylon.

Unlike some of those noisy shallow philanthropists who, in their ignorance, aggravate in their efforts to cure, the diseases from which our old mother country is suffering, Mr. Buchanan determined to know the poor before he attempted to help them. So he and his wife settled down in East London, simply living among the people, making no fuss, bringing no nostrum, not even enjoying the slight éclat which surrounds the position of the Church of England clergyman even in the poorest parish of East London. Two things he learnt the poor needed (besides, of course, the one thing needful which no man can give his brother)—both of which he could help them to: one was places other than the public-houses where they could meet and have really good fellowship unfettered by any individual's particular fads. So he started a Club which soon became popular in the best sense. The men adopted it as their own, worked for it, cared for it, sacrificed for it. Mr. Buchanan added lectures, classes, a co-operative shoe-making establishment and a co-operative cabinet-making shop, billiard tables, &c. The second need he noticed among the poor was their want of good food, a want hundreds had noticed before him, but which he determined to remedy in a way that could not pauperize. So he started food houses—honest food, honestly cooked, honestly sold, honestly paid for. There a man can get his plate of beef for 2d, his bit of pudding for 1d, his basin of soup for 1½d. "Pay, yes certainly it pays some of us," said Mr. Buchanan, "it pays me, it pays the men, it pays the tea growers, it does not pay the publican." Anyone who buys food can buy tea, 1 lb. of good Ceylon tea at 1s 2d, good dusty at 10d, pekoe at 1s 4d—and excellent it is "Where do you live?" asked the writer, of a dear old woman who was folding ½-a-lb. in her checked and spotless apron. "Out Battersea way—but I always come up once a fortnight to get my tea here; it does me better than anyone else's." To Mr. Buchanan's "Teetotums" working men pay the compliment of using them. Of many philanthropic schemes it can be said that they are used by all for whom they were not intended. But the Teetotums are in this sense exceptional—the lights, the cleanliness, the abundance of the newspapers of the day, the fair weight, the hot food, the air of independence that is in the places are all understandable goods to the workman's mind,

and they come in crowds, bringing often their wives and babies; for in Mr. Buchanan's generous management there is no rule as to one portion one person. No! if a man is in low water he can have one portion or half-a-dozen plates and knives and forks if half-a-dozen mouths are to be fed from the one portion. At first but one Teetotum was opened, but its success was soon a proven fact and four others are now opened in different large thoroughfares of East London. Mr. Buchanan imports his tea direct from Ceylon, from we suppose his own fine plantation in Ambagamuwa, —so he is his own middleman and neither he nor his purchasers lose thereby. Of the value of his work there can be no doubt, for it is a want of good food that too often is the parent of the Englishman's craving for drink. To raise the standard of comfort among the working classes is in itself a good, and one with far-reaching results.

Each Teetotum has its rooms for recreation—billiard and bagatelle tables, draughts, chess, backgammon, &c. Mr. Buchanan has taken care that those who come to play should have the chance of remaining to pray; for in each room there are papers and advertisements about "the Club" into which the men can be drafted or where they can have all those kindly advantages of human fellowship without which in a crowded city it is hard for a man to believe in a Divine and Beneficent Power.

MR. SCHWANN, M. P., ON TECHNICAL EDUCATION.

Pursuant to announcement the meeting arranged by Mr. George Wall for the purpose of hearing Mr. Schwann, M.P., on technical education came off today (Feb. 5th) at 11 a.m. at the Fort Library, under the Chairmanship of Hon. S. Grenier (Attorney-General). There were also present:—Hons. W. W. Mitchell and P. Ramanathan, Messrs. J. B. Cull, George Wall, J. H. Marsh, H. W. Green, H. H. Capper, F. Beven, and C. M. Fernando, Miss Frédox, Rev. W. J. G. Bestall, Messrs. J. L. K. Van Dort, J. W. C. de Soysa, and J. Allport, and a goodly gathering of schoolboys from the Royal College.

Mr. GEORGE WALL briefly introduced Mr. Schwann to the meeting. He said that Mr. Schwann was associated with one of the largest technical institutions in the world, and he had no doubt that they would all be glad to hear him on the subject of technical education.

Mr. SCHWANN prefaced his remarks by saying that he regretted that amongst the many attractions of the island, there was one defect in the very rapid changes of temperature which produced a great effect on one who was not acclimatized. The effect of the temperature had produced a huskiness in his throat, which prevented him from speaking out as forcibly as he would wish in advocating the cause of technical education. He thought it was unnecessary to enter into any lengthy arguments on the subject, or to speak of the advantages of technical instruction, because the subject was not altogether new to the inhabitants of Ceylon. Several gentlemen whom he saw at the meeting (and one in particular) had already advocated the advisability of establishing a Technical Institution. Now it seemed to him that it was advisable to form an Association for the promotion of technical instruction in Ceylon, and the success of that Association would depend on those who composed it, and to this end it was indispensable that they should have gentlemen who were conversant with the subject and who would also be a guarantee to the public that the ends would be carried out in a practical and earnest manner. For the purpose of raising subscriptions and donations they would have to appoint gentlemen of some high position in the city who would be willing to lend their co-operation to the scheme, as it was evident that it was not likely that the public would sup-

port any project which had not among its supporters men who could command the entire respect of the public at large. He believed there was a building in Colombo which might conveniently act as a centre for the Technical School. He meant the Agricultural School. He believed that education in agriculture was imparted in that school, and there was no reason why education in engineering, carpentry, &c., should not also be taught there. He was glad to find that H. E. the Governor was favourably disposed towards the scheme, and he would be only too glad to accept the patronage of such an association. It was also advisable to have a number of vice-presidents—gentlemen who, although they might not take an active part in the work, yet would be desirous to identify themselves with such an institution. But it seemed to him that the chief responsibility rested with the Executive Committee, and that body, he thought, should be specially gifted and strong in their own special subjects, and that Committee should consist of men who were willing to lend their aid towards the inauguration of the scheme and who were able to satisfy the public that the objects would be carried out in a practical manner. Finally, if they got the cooperation of one or two business men, and especially a few gentlemen who were connected with the Spinning and Weaving Mills or any other industry in the town, they could have no doubts as to the success of the scheme. They also required the services of a Director, and an able man who would command the respect of the public. Mr. Mitchell, he heard, was proceeding to Europe by an early mail, and he was certain that he would select a useful man to take up the duties of that important post. He was glad to find that Mr. Green had succeeded in getting them a grant of Rs. 5,000 per annum, which would go towards the salary of the Director. For his own part, he would be happy to render any assistance to Mr. Mitchell when he was away in England, and he had no doubt that Mr. J. E. Reynolds (the Secretary of the Manchester Technical Institute), Sir Philip Magnus, Sir Henry Roscoe, and a few other gentlemen who were interested in the work that was carried on in the Technical Institute at Manchester, would cheerfully lend their assistance to Mr. Mitchell. He thought that some objections might be started against the establishment of a Technical School, but he pointed out the successful character of the industry as carried on in Manchester where an immense number of trades was carried on. There was one department where a number of people were turning out special objects of domestic utility, while others turned out small screws, which were sold to those manufacturers whose attention was solely devoted to the construction of engines, and if the industry met with such encouragement in London, where competition was much greater there than it was here, the Technical Institution was bound to flourish in Ceylon. Without monopolizing the time of the meeting, he begged therefore to move a resolution which was unanimously carried, viz. "That the following gentlemen with power to add to their number do form themselves into an Association for the promotion of technical education with the object of establishing a technical school in Colombo and for the encouragement of any movement likely to assist the application of art and science to the industries of Ceylon:—Hons. S. Grenier, A. R. Dawson, W. W. Mitchell, J. J. Grinlinton, A. de A. Seneviratne, P. Ramanathan, Messrs. George Wall, John Ferguson, H. W. Green, J. B. Cull, J. W. O. De Soysa, H. H. Capper, F. Beven, Edmund Walker, S. Rajapakso, Drs. Rockwood and H. M. Fernando." In explanation of the latter part of his resolution, viz. that the Technical school do also encourage other movements of a similar character, Mr. Schwann said that it was possible that other institutions would like to affiliate themselves with them and therefore it was desirable that a Technical Association in Colombo should have a wide basis. Apart from that fact a great number of the inhabitants of Colombo would like to co-operate with them. As regarded funds, he said that the institution to a large extent depended on the large number of small subscriptions

He would be more thankful if he received small subscriptions yearly, as large annual subscriptions after a year or two died out. By this he did not of course mean to discourage those who were desirous to pay large sums annually. They could get funds through the students' fees and other sources. In conclusion he hoped ere long to receive some information that the school was established, and he promised to render every assistance to them in the matter of getting for them anything they required from the manufacturers in London in order to carry on their work here. (Applause.)

Mr. GEORGE WALL in supporting the motion, said that the importance of the subject had been recognised for a long time, especially by Mr. Green, during the time when he was Director of Public Instruction. It had been said that hitherto the scheme had not assumed any definite form. That was true, but he thought it would have been a mistake to put before the public anything of a particular definite nature until the views of those interested had been ascertained. He thought that after the pertinent, practical observations which had been made by Mr. Schwann they had sufficiently defined the subject and not too much defined, but left in a condition, so that those who had the interests of the scheme at heart could with sufficient freedom of action do what in their judgment seemed wise and good. He had no doubt that the gentlemen who composed the Committee would fulfil most of the conditions that were primarily necessary for the carrying out of the objects they had in view. In their own community there were men who were acquainted with special industries so intimately that their advice would be of paramount value, and he had no doubt but that that advice would be given by them with all cheerfulness. He believed that by the excellent management and thoughtful attention which had been given to the subject by the late Director they were likely to have the use of the necessary building without the formidable cost of having to erect them. He thought that they would have also to obtain appliances to furnish the workshops, and he had no doubt that those who were deeply interested in the project would liberally subscribe towards the purchase of the necessary materials. He believed firmly that when the objects required were more clearly made known to those men, that they would come forward with a liberality which would enable the Committee to go to the Government and say: "We were able to help ourselves to this extent, we pray that you would give us some help;" and he believed that such help would not be wanting. He thought therefore that the resolution proposed by Mr. Schwann would go a long way towards supplying the long-felt want. (Applause.)

The resolution was then put to the meeting by the Chairman and carried unanimously.

Hon. W. W. MITCHELL followed and said that it was not necessary to dilate at length upon the advantages of technical education to be gained by those for whom it was intended. The subject had been occupying a good deal of attention, and the classes for which it was more especially intended were the sons of the better classes for whom it was difficult to adopt the profession of lawyers or advocates. It was desirable that men should be trained to become foremen in some of the large establishments which were being created in Ceylon, and that others who might not occupy that position should be trained to some other work. One thing which had struck him in connection with a technical school was that practical education should go hand-in-hand with theoretical education. It was cheering to learn that Government had promised to cooperate with them in the matter of granting a sum of Rs.5,000 per annum, which would go towards the salary of the Superintendent, and it was very necessary that an able man should be selected for the post for the success of the scheme depended on him. They would of course, require a gallery of illustrations, illustrating the different industries, and they could carry on in the Agricultural School itself such work as carriage-building, mechanical work, engineering, tolographing, &c., and those boys who wished to enter upon commercial pursuits could get a knowledge of

all these subjects. As far as the revenue was concerned, they could make up that from the students' fees and Government grant. He thought that a good deal of progress had been made towards the inauguration of the scheme by two gentlemen who were in the room, and therefore moved the following resolution:—"That the thanks of the meeting be given to Mr. Green, late Director of Public Instruction, for his eminent services on this behalf and to Mr. Cull for his zealous pursuance of the line of policy initiated by his predecessor for the furtherance of a Technical Institution for Ceylon."

Mr. RAMANATHAN in seconding the motion said that the subject had been occupying the attention of the community for many years. It formed the subject of an important debate so far back as 1875 in the Legislative Council, but the gentleman who led the debate, Sir Muttu Coomara Swamy was no longer alive. He believed Mr. Mitchell was also then a member of Council, and he could bear testimony to the fact that he had been greatly interested in the establishment of a Technical Institute for Ceylon. (Applause.)

Mr. GREEN said that on his own behalf and on behalf of Mr. Cull he felt very grateful to them for the compliment accorded to him. He had been working away at the question like a mole for years with a view towards forming a Technical Institute in Ceylon, and like a mole had thrown up a lot of earth, but had only got one step in advance. He thought that Government had done pretty well in giving a grant of Rs.5,000 per annum for the salary of a Superintendent, and there was also the implied promise held out that the Agricultural School might be utilized as a sort of a general Technical and Agricultural School. There was sufficient accommodation for the purpose in the Agricultural School. One wing of the School was left open when the school was being built and he thought that that could be utilized for the purpose and they would have shortly one good central Technical Institute, combining a technical as well as a good general education. They had a capital Professor in the school in Mr. Drieberg, and if Messrs. Schwann and Mitchell sent out a proper man to deal with other branches of the technical side, these two gentlemen would be able to give lectures to the boys of both the Agricultural and Technical sides who wished to acquire a good knowledge of a general education. He had always intended the Technical School to be one side of the School of Agriculture. There were in the country what we might call too many gentlemen and too many coolies and it was very desirable that they should make an effort to combine the two and to get gentlemen not to think it below them to work technically and with their hands, and not to call it "cooly work." They were all grateful to Mr. Schwann for his efforts in the matter, but he thought that they should hold the reins tightly and not go too fast. Some of the speakers suggested that they should have a "Gallery of Illustration," and second-rate Workshops, but he thought it would be better to establish classes and march the boys round to the Government Factory, Messrs. John Walker & Co.'s workshops, the Cotton Spinning and Weaving Mills, so that they might get some practical training in those establishments, instead of having to put up workshops in the school itself, at an expensive figure. He referred to the Industrial School at Tellippalai at Jaffna, where the boys worked at all manner of things from excellent wire-mattresses down to turning out photographs and this he thought should serve as an encouragement to them as showing what could be done even in a mere Industrial school. He was glad that Mr. Schwann had mentioned the question of fees, for when he was Director he was severely anathematized by Managers of Schools for charging fees and he hoped that the Executive Committee would attend to that matter and make it a source of revenue. (Applause.)

Mr. CULL also thanked the meeting for the compliment paid to him and humorously remarked that he once had a peripatetic school of botany, and they had even proposed to have a peripatetic technical school. (Applause.)

The CHAIRMAN said that they all felt grateful to Mr. Schwann for the conference they had held that day. It was a rare event to find a member of Parliament staying here on his travels and taking an interest in what was going on around; and not only were they thankful to him for what he had done already, but for the prospect which he had held out to them. He endorsed what Mr. Wall said, and that was that if they went to Government and said "Now we are able to help ourselves to such an extent, would you supplement what we have by giving extra?" he was sure that the Government would come to their rescue. He impressed on the members that it was of paramount importance to them that they should put their shoulders to the wheel and work with might and main, both by attending meetings and collecting subscriptions from their friends. He concluded by moving a vote of thanks to Mr. Schwann for his efforts in promoting the formation of a Technical School.

Mr. BEVEN in seconding the compliment, said that Mr. Green had rendered very eminent services in connection with the Agricultural School, and it was not his fault that he had been unable to establish a Technical Institute although he had striven assiduously to accomplish that object, but Mr. Schwann had very opportunely come and in the formation of that association they had the nucleus of something which would be very beneficial to the country. As the Chairman had remarked, Mr. Schwann was entitled to a hearty vote of thanks, and he had much pleasure in seconding it.

Mr. SCHWANN acknowledged the vote of thanks and pointed out with regard to Mr. Green's proposal to march the boys out to private establishments that the Managers of these would not like the idea, as they ran the risk of their trade secrets being exposed. Apart from that the students might sometimes saw off a finger or smash their hand on an anvil, and it was better that they should do so on property of their own than on that belonging to someone else. (Laughter.) He thought that it was necessary to have corresponding members, and he would be glad to be made one of them and he had no doubt that Sir Henry Roscoe and the other gentlemen he had named would render them every assistance. In conclusion it gave him much pleasure to propose a vote of thanks to the Chairman. It was a great advantage to have a gentleman of the Chairman's position, for it was a guarantee that the movement was of a serious and practical character. (Applause.)

Before the meeting broke up, Mr. Green suggested the appointment of two Secretaries. He therefore moved that Mr. Edmund Walker and Dr. H. M. Fernando be appointed Secretaries. The motion was unanimously carried.

We venture to append here a letter which we had written to Mr. Mitchell as our apology, for not being able to attend the meeting, but which the hurry of mailday delayed in delivery:

Mount Lavinia, Feb. 4th.

* * * *,—The pressure of work on a day like tomorrow forbids my leaving the desk within a few hours of the mail closing, or I should have been very glad, at your invitation, to make one of Mr. Schwann's auditors and to hear other gentlemen talk over with him what should be done further to extend Technical Education in Ceylon. While I am sure the result will be a very interesting meeting and that Mr. Schwann will be able to give valuable information, I do trust all concerned will be on their guard against considering experience gained in a city of the wealth and intelligence of Manchester or any other large English town as applicable to a poor oriental tropical town like Colombo or such a colony as Ceylon. We published a very sensible letter a few weeks ago from a gentleman who knows what he was writing about, a copy of which I enclose for your guidance; for I see you are credited with the intention of selecting in England in conjunction with Mr. Schwann, a fit Superintendent for the Colombo Technical Institute. But are we ready for the services of such a Superintendent as you would be likely

to select and send out from England? Should it not first be clearly understood what the local want is which such an official is to supply. As Messrs. Green and Cull can tell us, a good deal of technical instruction of a very practical though unassuming character has already been done in connection with the Agricultural and Normal Schools and seeing in how many directions scientific and practical training has become available to lads in Colombo, from competent instructors, it is a question whether a very much progress could not be made, perhaps after a modest but safe fashion, with the material at our hands. Instructors for classes in Chemistry, Botany, Mechanics, Physics, in Civil and Practical Engineering and in a variety of local industries are, I believe, available, and the selection of a Superintendent *pro tem* locally might well be left to the Director of Public Instruction, until it is seen in which direction special experience is chiefly required. It may even be a question whether India (Bombay or Madras) would not supply us with the lead and experience most suited to the requirements of Ceylon better than England. In both these Presidency towns, much has been done in technical instruction.

You, as well as I, have seen so many failures from the rash introduction of "fresh blood" in the shape of "specialists" from the old country, intended to work wonders in new and old official Departments, that I am sure you will agree in the need of acting with full consideration and forethought in the present case.

We should also never forget what has already been done for the youth of the country not simply through local Schools and Colleges,—there are now, available, I believe, science, drawing, painting and music classes,—but also, after an even more practical way by the Government Factory, the Railway Engineering Shops, the large Establishment of the Colombo Iron Works Company and the many Iron and Engineering Workshops in Colombo, Kandy and throughout the planting districts, also by the various Printing Offices and last not least, what may be expected from the Cotton Spinning and Weaving Mills.

Wishing all success to the further development of technical and practical instruction in our midst, &c.,
J. FERGUSON.

NOTES ON POPULAR SCIENCE.

By DR. J. E. TAYLOR, F.L.S., F.G.S., &c.,
EDITOR OF "SCIENCE GOSSIP."

Some twelve months ago I recommended people who suffered from muscular rheumatism to get well stung by a very excited bee—British bees, of course. Afterwards, thinking tenderly both of bees and rheumatic patients, and knowing that the former, if not the latter, lost their lives by the job, I suggested subcutaneous injection of formic acid, which is the real, but not only, cause of irritation of a bee's sting. I have myself tried it on a few friends, not being rheumatic myself. They say it did them good. Most valetudinarians say the same of their last new physic. Anyhow, it has been discovered that a person "stung" by our British bees is "protected" thereby for at least six months—after the law and rule of vaccination. Persons suffering from rheumatism are advised that they must be stung in proportion to the degree of their malady.

A French botanist has recently shown that flowers possess energetic respiratory and transpiratory functions superior generally to those of the leaves of the same plant. The assimilation is generally feeble, and much diminished by the intense respiration. The volumetric proportion of carbon dioxide (the old-fashioned carbonic acid) emitted to oxygen absorbed is always small, and less than unity.

It is now contended that the liquid secreted by the piteher plant (*nepenthes*) is not in itself peptic or digestive. A French chemist and botanist, Professor Dubois, has recently demonstrated that the so-called digestive process is due to bacteria in the fluid. The

bacteria have to account for everything nowadays. I am surprised that General Booth has not made use of them in his new book.—*Australasian*.

CLEANING MACHINERY.—The simplest and most efficacious method of thoroughly cleaning the various parts of machinery that have become gummed and dirty by the use of fat oils for lubricating purposes, is by using a strong soda lye. For each 1,000 parts by weight of water take about 10 or 15 parts by weight of caustic soda or 100 parts ordinary soda. Let the solution boil and enter the parts to be cleaned; either boil them in this lye or let them steep in it for some time. All the dirt and oil resin is completely dissolved thereby, and it remains only to rinse and dry the parts. The action of the lye is such that it enters into combination with the oil and forms soap, which is readily soluble in water. In order to prevent the hardening of the lubricant on the machinery parts, it is only necessary to add about one-third kerosene. An occasional lubricating with kerosene alone is to be recommended.—*American Engineer*.

HOW TO MAKE TEA.

WILL ONE POUND OF TEA MAKE 300 CUPS?

How to Make a Cup of Tea, is a matter the majority of housewives have yet to learn. In the *Public Ledger*, Philadelphia, we find the following:—

Mr. EDITOR:—My attention has been called to a query, in a recent issue of the *Ledger*, as to the accuracy of my statement that one pound of tea would make 300 cups. While the question or individual opinion upon this point may be of but little interest to the public, the actual facts in relation to an article so extensively used may be of value.

My calculation was based upon the following facts: Tea testers ordinarily use a silver 5-cent piece for weighing the exact quantity of tea required for a cup. As there are about twenty-five 5-cent pieces to an ounce, and as there are sixteen ounces to a pound, it follows, that one pound of tea will actually make 400 cups, according to the standard of strength ordinarily required by professional testers. The cups used for this purpose contain, however, one-fourth less than the average domestic tea cups. It will, therefore, be seen that after making due allowance for the difference in the size of the cups, the number will be very close to 300.

The surprise with which this statement is generally received demonstrates how little the economical features of this delicious and wholesome beverage, when rightly made, are known. If the following directions were carefully observed, and a good quality of tea used, no doubt this economical beverage would be much more generally appreciated.

Directions.—Put the tea leaves into an earthen or agate ware pot (never use metal), and stand on back of stove until the leaves get thoroughly warmed. Then pour on water that has been froshly boiled, and which is boiling thoroughly at the time. Let stand on back of stove for about ten minutes, where it will keep hot, but not boil.

At the expiration of that time the tea will be perfect and if you desire it to remain so, pour off the liquor into another vessel, so as to separate it from the leaves. The common allowance is one teaspoonful to each cup, but as some prefer more strength than others, it is evident that each tea-maker must decide for herself whether the teaspoon shall be "slack," "even" or "heaping."

In serving, have the cups and cream warm, and pour the cream into the cup before putting in the tea.

FINLEY ACKER.

—*American Grocer*.

ORANGES.—The *Tavares Herald* says that a citizen of Apopka City, Fla., has started a budded orange tree to be sent to the World's Fair, which contains eighty-five buds, bearing, representing twenty-six different varieties of the citrus family—oranges, lemons, limes, grape fruits, shaddock, etc.—*American Grocer*

BARK AND DRUG REPORT.

(From the *Chemist and Druggist*.)

London, Jan. 15th.

CINCHONA.—The first cinchona auctions of the year were held on January 13th. The quantity of bark offered was hardly so large as might have been expected from the fact that there has been no public sale here since December 16th, and that in the meanwhile the arrivals have been very considerable. The total quantity catalogued consisted of:—

	Packages	Packages	
Ceylon cinchona	... 1,968	of which	1,597 were sold
East Indian cinchona	... 1,147	do	846 do
Java cinchona	... 36	do	36 do
S. American cinchona	... 509	do	410 do
West Coast African cinchona	... 80	do	79 do
Total	... 3,740	do	2,968 do

A dull tone prevailed throughout the auctions, and several parcels were bought in, owing to impossibility of placing them at the limits for which they were held. The unit, though hardly as high as at the preceding sales, is scarcely quotably lower, and may be placed at about 1½d per lb. The assortment of the bark offered was somewhat below the average, although a few lots of fine *Succirubra* barks were shown, which realised high prices. The following are the approximate quantities purchased by the principal buyers:—

	Lbs.
Agents for the Mannheim and Amsterdam works	218,239
Agents for the Brunswick works	131,383
Agents for the American and Italian works	85,938
Agents for the Frankfurt o/M. and Stuttgart works	57,410
Agents for the Auerlach factory	37,550
Messrs. Howards & Sons	34,813
Mr. Thomas Whiffen	3,050
Sundry druggists and spectators	75,337

Total quantity of bark sold	... 643,720
Bought in or withdrawn 142,886

Total quantity offered	... 786,606
------------------------	-------------

A fairly large quantity of bark was seen by the firm of brokers who are reputed to act on behalf of a syndicate of speculators, and who have appeared as purchasers at the auctions of late.

JAVA CINCHONA.—Yellow branch chips 4½d to 5d; fine ground ditto 7½d; fair root 7d per lb.

SOUTH AMERICAN CINCHONA.—The only variety offered of this class of bark consisted of cultivated Bolivian Calisaya, of which about 23,000 lb were sold at from 4½d to 7d for sound broken small and irregular to good bright medium quill. A parcel of fine quality was bought in at 10½d per lb.

WEST COAST AFRICAN CINCHONA.—A parcel comprising 11,228 lb of this bark, recently imported via Lisbon, was included in the auctions. It consisted of fair bright *Succirubra* quill, medium size, and nearly the whole of it sold at 4½d for the best, and 3d per lb for the poorest lots. Chips bought 4d per lb. All the bark was in a more or less damaged condition.

ESSENTIAL OILS.—The market is generally quiet, Citronella being held for 3d per oz on the spot, while the c.i.f. quotation from Ceylon is 10½d per lb for tins, but we do not hear of any business thereat. Lemongrass 1½d per oz on the spot, and 17-18ths d per oz c.i.f.

QUININE.—Business has been dull this week, and so far as we can hear, it has been restricted to a total of about 15,000 oz on the spot (all second-hand)—viz. B & S and Auerbach at 12½d per oz, and later on a small parcel of Brunswick at 12½d per oz. The total imports of quinine into the United States during the year 1890 are returned at 3,384,300 oz. In 1889 they were 2,431,441 oz.

"KEW BULLETIN."—As an appendix to the *Kew Bulletin* for 1890, an index to the *Kew Reports* for 1862—1882 has been published, which will be of great service to those interested in economic botany. The *Bulletin*, it may be added, is intended to furnish in a detailed and timely form the information formerly included in the annual reports. Serviceable as the *Bulletin* is, it does not, however, take the place which the Report used to do, and many interested in the progress of botany and scientific horticulture as illustrated in the gardens, herbarium, library, and museum, would gladly welcome an annual report as well as a monthly bulletin.—*Gardeners' Chronicle*,

TEA CONSUMPTION IN BRITAIN:
RAPID ADVANCE IN THE USE OF
CEYLON KINDS.

The reduction of the duty on tea imported into the United Kingdom from 6d to 4d per lb. seems really and materially to have operated in increasing consumption. The figures for 1887 were 183,561,000 lb. Then came an increase in 1888 to 185,416,000. In 1889 the increase was scarcely appreciable, the figure being 185,600,000. In 1890, however, there was a rise to 194,008,000,—an increase of nearly 8½ millions of pounds. The increase was entirely in Indian and Ceylon kinds, there being a decrease in China of 8,570,000. The increase of 8½ millions, being entirely in the stronger Indian and Ceylon kinds, may be taken as the equivalent of at least 12 millions of lb. had the standard been China. The increase in the consumption of the Indian kinds was from 96,000,000 in 1889 to 101,961,000 in 1890, or not far short of 6 millions, an increase of nearly 6¼ per cent. The increase in Ceylon teas exceeded 6 millions, the rise being from 28,500,000 in 1889 to 34,516,000 in 1890, or an increase of not less than 21½ per cent. So that, comparing the imports of both kinds, Ceylon has been taken in three fold proportion. This fact certainly confirms Mr. Roberts' strongly expressed opinion in favour of the popularity of our Ceylon teas, and this and the present good prices ought to reassure Ceylon tea planters. In the month of December the deliveries of Indian tea were 8,745,000, while the imports were 14,354,000. In the case of Ceylon, on the other hand, the deliveries in the last month of the year came close up to the quantity imported, thus:—Imported in Dec. 2,888,000 lb; delivered 2,772,000. For the last half of 1870 the deliveries of Ceylon teas actually exceeded the quantity imported, thus:—

Imported 23,908,000 lb.
Delivered 24,874,000 „

Excess delivered 968,000 „
In the case of Indian teas we get for the six months:—

Imports 67,924,000 lb.
Deliveries 59,037,000 „

Excess of imports, 8,887,000 „
Of China the record is:—

Imported 54,669,000 lb.
Deliveries 49,919,000 „

Excess of imports 4,750,000 „

and this notwithstanding the fact that deliveries for export are still very largely China: 30,000,000 lb, at least against about 2½ millions Indian and Ceylon, or less; the exports of these kinds for the whole of 1890 being only 2,624,000 Indian and 1,431,000 Ceylon tea.—This seems also to confirm the opinion of both Messrs. Roberts and Hamilton that our lowcountry teas should be well-suited for "export" purposes to the Continent of Europe and Russia especially. To sum up: the consumption of tea in Britain is rapidly increasing, and the increase is chiefly in Ceylon, which for a crop one-third in quantity shows increased deliveries actually in excess of those of Indian, while China and Java are both receding. There are no doubt some good China teas imported, but public taste has settled the degrees of comparison as Indian better and Ceylon best. The prospects before the Ceylon enterprise are certainly bright and encouraging.

After writing the above we read the London *Times'* remarks on the Board of Trade returns, from which we quote as follows, only remarking that if a better demand is springing up for China tea, it is

probably amongst blenders:—

The increase in the imports and consumption of Indian and Ceylon teas is as steady as the downward progress of Chinese sorts. Thus the imports of Indian and Ceylon have risen from 113,600,000lb. in 1888 to 127,000,000lb. and 146,000,000lb. in 1889 and 1890 respectively, while Chinese has fallen from 105,000,000lb. to 88,000,000lb. and 74,000,000lb. The consumption of Indian and Ceylon, which in 1889 was 124,000,000lb., rose to 136,000,000 lb. last year, while that of Chinese fell from 59,000,000 lb. to 55,000,000 lb. These proportions are entirely reversed as regards the exports of tea from this country, the quantity of Indian and Ceylon being only 4,600,000lb., and that of Chinese reaching 31,493,000lb. It is reported, however, that a better demand is springing up in this country for Chinese teas.

MANURES FOR CROPS.

POTASH MANURES.—The quantity of potash in most soils greatly exceeds that of phosphoric acid. Thus while in a fertile soil there may be from 7 to 15 of the former, there may be only 3 to 5 of the latter. The weight of an acre of arable land 9 in. deep ranges from 3,000,000 lb. to 3,500,000 lb., which gives 3,000 lb. to 3,500 lb. for every 0.1 per cent of any constituent. There will therefore be in many soils from 17,500 lb. to 36,000 lb. of potash per acre, against from 7,500 lb. to 12,500 lb. of phosphoric acid. Clay soils are richer in potash than lighter and sandier soils. This abundance of potash is in itself a reason why potassic manures are less effective than some other fertilisers which contain rarer substances. Another fact in connection with potash is that it is for the most part returned to the soil in the form of straw used for litter or food for stock, so that while phosphoric acid is constantly drained off the farm through sales of wheat, milk, and young animals, most of the potash is retained. Again, farmyard manure contains about 0.67 per cent of potash, so that in applying 15 tons of dung we are adding 2 cwt. of pure potash. If farmyard manure may be viewed as a nitrogenous manure, it may equally well be spoken of as a potassic manure. The drain of potash from land is, however, constant although slow. To a certain degree it is washed through the soil in natural drainage, and it is also removed by the sale of crops. Before the discovery of the immense beds of kainit which exist in the rock salt deposits of Stassfurt in Prussia, agricultural chemists looked forward to a time when a potash salts would be in greater demand than were likely to be supplied from existing sources. Potash was then an expensive fertiliser, but since that time and for many years past potash salts have been offered at a reduced price, and are at present quoted at £3-10s. per ton ex ship. Up to the present time the demand has been limited, and it does not occur to the majority of farmers to apply kainit. It is, however, used upon certain light soils which are naturally deficient in potash, and for potatoes, beans, and clover, on account of the large amount of this alkali which they require. A good sample of kainit contains 25 per cent of sulphate of potash associated with 30 per cent of common salt, and about the same proportion of magnesium and lime salts. The remainder is water and insoluble silicious matter. 4 cwt. of kainit, it will be observed only adds 1 cwt. of sulphate of potash to the land, and a much smaller amount of potash. An ordinary dressing of farmyard manure would therefore restore as much potash to a field as half a ton of kainit, and this being the case, it does not seem very likely that the demand for potash salts will increase. The amount of potash in soils has already been stated as from 17,000 to 36,000 lb. per acre. It is not contended that this is all available, although as it is usual only to analyse the fine portions of a soil which pass through a very small mesh, much of it must be attackable by growing roots—the salts of potash being easily soluble.

The following crops are known to absorb large quantities of potash taken from the soil:—

6 tons of potatoes with their tops take up 76 lb. of potash per acre.

30 bushels of beans with their straw take up 81 lb. of potash per acre.

30 bushels of wheat with their straw take up 23 lb. of potash per acre.

The astonishing fact is noted that after eight years removal of crops the final crop was rather larger where no potash had been applied than where 500 lb. of its salts had been annually applied. And yet it would not be wise to conclude that because no effect was produced at Rothamsted that potash salts are therefore not useful. It would be equally foolish to think because a great result should be obtained at Rothamsted we might expect the same anywhere. Each farmer must be an experimentalist for himself, and hitherto we have not seen much evidence of the use of potash salts as manure for ordinary soils, such as we have seen in case of phosphatic and nitrogenous manures. They are most likely to be effective on the lighter classes of land.

NITROGENOUS MANURES.—The two best known members of this group are nitrate of soda and sulphate of ammonia and most of the other nitrogenous manures are refuse materials from animal bodies or from seeds. Such are all the guanos, blood, wool, fish and flesh and cake manures. The efficacy of nitrogenous manures appears to be due to two facts. First that nitrogen in an available form exists in very small quantities in the soil, and, secondly, that it is required in proportionately large quantities by crops. The total amount in the land may in good fields be taken in the top nine inches as 0.15 or one-tenth of the amount of potash. Nitrogen is available chiefly in the form of nitrates, and these are much more liable to wash through the soil than are potash salts. Finally, nitrogen is removed from the farm in saleable crops and in the bodies of animals in larger quantities than potash, which is largely returned both in root crops and straw to the land. There may be other reasons, but these sufficiently account for the great effect produced by nitrogenous dressings of all kinds. So rapid is their effect that it has been called "stimulating" although without sufficient reason. The crops seem to hunger for nitrogen and always present a yellow and starved appearance when it is deficient. A rank dark green appearance always accompanies a full, or over full, stock of nitrogen in the soil. It is to the grasses including the cereals, that these manures are most useful. But wherever leafy growth is desired as in the cultivation of cabbages and rape nitrogen in the form of nitrates may be applied with success. The leguminous crops, beans, peas and clover are not so much benefited by direct dressings, but they require the land to be rich in nitrates, notwithstanding. The absolute necessity of nitrates for the cereals has been amply proved. Wheat appears as if it could be grown consecutively for almost any number of years, on the same land, if only plenty of nitrates are added.

Nitrates, no doubt, if used alone, tend to exhaust the other constituents of plant food if the produce is sold off the farm. If, on the other hand, the produce is consumed at home—or if foods for stock and other manures are purchased in liberal quantities there is no fear of exhaustion. So important are they, that some times it appears as though the entire science of manuring consists in adding nitrates to the soil. The effect is, however, greatly increased if phosphates and, in some cases other mineral manures are added with the nitrates so that heavy as the crops are which may be grown with nitrate of soda, they are eclipsed by a judicious use of nitrates and mineral substances combined. In applying nitrates we prefer to use them in organic combination wherever possible. Nitrate of soda and sulphate of ammonia are both exceedingly useful but are subject to washing through the soil by rain—the first immediately, and the second more gradually as nitrification proceeds. They act rapidly but the effect is not seen after the first season. When nitrogen exists in animal or vegetable matter its action is slower, more uniform, and is continued for an indefinite length of time. Farmyard manure is an example of this action so also are rape cake blood manure, shoddy, guano and many other substances. Such animal refuges can however hardly be classed

with artificial manures, and we therefore postpone their further consideration.

SALT.—Salt is a cheap material which may be employed with good effects upon coarse rank pastures and produces the best effects when mixed with lime. Five hundredweight of salt and three to five tons of lime applied in February or March to such rank grass land tends to produce a finer herbage. Salt may also be used as a dressing for wheat at the rate of about 5 cwt. per acre. Dr. Griffith says salt eradicates couch on land infested with it. If this is the case we have an additional excellent reason for applying it. It is also a good diluent for the better distributing of nitrate of soda and is said to check the disposition to develop too much straw which has been observed after nitrate of soda on wheat. It is also considered by many persons to strengthen the straw of cereal crops and prevents lodging of the crop before harvest. It also destroys slugs and snails and is distasteful to insect life generally. It in this respect resembles soot which is one of the best applications for land affected with these pests.—*Agricultural Gazette.*

THE PLANTS OF THE ANDAMANS.—Dr. David Prain, Curator of the Herbarium in the Royal Botanical Gardens, Seebore, has been studying the growth of new plants "intentionally, accidentally, or naturally introduced" in the Andaman Islands since 1866. A list of the Andaman flora in 1866 recorded 520 indigenous species, and the number has since increased to 600, although four of the naturalised plants noted in 1866 have disappeared. A common Indian butterfly has made its appearance since the plant on which its larva feeds became naturalised.—*Pioneer.*

GRANT OF LAND IN THE EASTERN LOWCOUNTRY.—We hear that Messrs. W. Gow and Gordon Reeves have been applying for a grant of some thousands of acres of land in the lowcountry to the North-eastward of the Knuckles and Kalupahana range, near the junction of the Kalu and Amban gangas before they fall into the Mahaweliganga and we suppose not far off Polonnaruwa. Two young Surveyors are now busy blocking out in that neighbourhood. The soil is said to be very fine, the land flat with very heavy timber, though great parts have been chenaed. Rainfall is confined to the North-East monsoon and there is a great deal of wind in the South-West. Tea would therefore scarcely flourish there, and it has not transpired what products are likely to be cultivated—perhaps tobacco and cotton. Should a grant be made on lease, there will be conditions as to cultivation, as well as about rent. The outlet would probably be via the North road, 20 miles off.

DETAILED ESTIMATES OF PLANTATION CROPS.—We have to thank planters in nearly every district in the island for the readiness with which they have responded to our request for approximate estimates of the outturn of tea, coffee, cocoa, cinchona, &c. during the current year. There are a few districts yet unrepresented in our bulky receipts, so that we must wait a week or two before beginning our analysis and compilation, to see how the results bear out the total estimates we have already put forward. We see our contemporary of the "Times" on the 5th instant arrived at the same figures for probable tea exports this year (namely 56,000,000 lb.) as we gave in our estimate on the 20th Jan., Mr. C. S. Armstrong independently sending us the same figures. We think it quite likely however, that Mr. Forbes Laurie's figure of 58,000,000 lb. may prove nearer the actual result.

MATERIALS FOR ROOF COVERING.

We have been asked to which of the several materials available for covering the roofs of residences in Ceylon, preference should be given if it were entirely a matter of choice. It must be admitted to be difficult to arrive at any decision such as would enable a positive answer to be given to such a question. The selection must be dependent on many varying conditions, chief among these being the character of the climate in which the residence might be situated. Such conditions as they exist between a lowcountry and an upcountry residence differ considerably, and even if a decision could be arrived at subject to such variance, there may be the further point to enter into calculation as to the resources of the district in which such residence may lie.

When writing some time back on the subject of the half-round tiles which are so largely used, we entered fully into the many objections to be taken against them. Theoretically, some authorities are of opinion that for very many reasons the flat roofs so largely employed throughout India and the East generally have much, owing to the character they possess of permanence, to recommend them over every other description of roofing. But, practically, these roofs are insufferably hot. There is no space between their flat surface exposed to a burning sun and the living rooms below in which a circulation of air may be maintained, and it is held that this disadvantage counterbalances every preference which may for other reasons be accorded to them. We may, therefore, for our present purpose, leave roofs of this character out of consideration.

But when we turn to other methods of covering our dwellings, we cannot decide upon one which is wholly free from objection. The objection taken in regard to half-round tiling, or, indeed, to earthen tiling of any description, has been dealt with on a previous occasion. Slate is far too costly a material to receive general adoption here; but many consider it is open to fewer objections than almost any other roofing. Slate is light, the thinness of it does not admit of the great retention of heat which is such an objection to earthenware tiles of any kind, and once fixed it is less likely to become disturbed than almost any other covering. Corrugated zinc is disapproved of from its heat-conducting properties, from its liability to corrosion when exposed to sea air, and, when used up in the hill country, to the intense cold it both accepts and transmits. The relatively large sheets also render it liable to stripping in the case of exceptional winds. Shingles, while admirable in many respects, are from their lightness and difficulty of fixing, also in some districts liable to take to partial flight during the same natural disturbing cause; but the difficulty now is to get a supply of really good shingles. Straw thatch would be perfect as a protection against either heat or cold, but it so rapidly decays as to need constant renewal, and in its dry state is liable to ignition and gives rise to dirt and the harbouring of vermin.

Many old colonists who have had experience all over the island consider that for the *acme* of comfort so long as it can be properly maintained, there is nothing like a well-made cadjan thatching. This is light and it is both warm or cool as occasion or circumstances require. But, unfortunately, it has no permanence, and is besides open to the objection expressed to straw-thatching, that of liability to take fire. The man who by a method of sleeping in some chemical

igneous material could both obviate the liability and arrest the rapidity of decay in the plaited coconut leaves known as cadjans, would, in the opinion of very many, confer a special benefit on residents in tropical countries, and one too that ought to benefit the discoverer and patentee. It seems unfortunate that, with such an unlimited supply of the raw material as we possess in Ceylon, such means have as yet remained undiscovered. Who will be first in the field?

Meantime we are aware that on upcountry estates an experiment is being tried with shingles made of the giant bambu. The large stalks are split in two, the inside divisions are cleared away, the bambu is cut into proper lengths and these are tarred and fixed on the roof. In the earthquake region of Western Java houses are built entirely of bambu and roofed with plaited sections of *nipa* palm leaf, the *nipa* being the *ginpul* of the Sinhalles, known to the English as "the water coconut." The late Mr. Moens was much surprised, as well he might be, that the bambu was not more utilized in the construction of native houses in Ceylon than is actually the case.

Since writing the above we have received the opinion of a practical engineer of much local experience in favour of what are known as Mangalore tiles. He writes:—

"Undoubtedly the best all round material for the covering of roofs whether for the hill or low country is the Mangalore or Cahcut tiles. These tiles are made of the best clay, are well burnt, of good shape and make, and just heavy enough to keep steady under pressure without the aid of weighting down. The Mangalore tiles are non-porous and weather-proof and maintain an even temperature: they are so cleanly made that ceilings are not required in ordinary rooms. As regards cost, the Mangalore tiled roofing with the woodwork complete costs about R4 per square over and above the cost for the ordinary half tiled roofing in Colombo. The tiles are more expensive per thousand, but there is a saving in timber in their favour.

"Many buildings have of recent years been covered with Mangalore tiles in and around Colombo, and their use is being gradually extended through agencies in Co'ombo and Kandy.

"The subject of material for roof-covering is one that should engage the attention of those interested in the Technical Institute. This interest might take a practical form by the introduction of improvements in the preparation of clay for the manufacture of tiles for roofing, as also in the preparation of caustic tiled pavements and terra cotta ornaments for architectural and decorative purposes.

"There is indeed in this direction a large field open to private enterprise, and really good material for the purposes abovenamed may be found at Seddawatte near Colombo, and at Katugastota and Gatembe near Kandy. All that is wanted is a knowledge of the preparation of the material and the aid of the newest plant, backed of course by capital, for developing an industry which would be appreciated throughout the island."

THE AUSTRALIAN SHE-OAK has been acclimatised in Aberdeenshire, and there seems every likelihood that it will prosper apace in that comparatively bleak quarter. The specimens which have so far flourished best on Dee-side have been produced from seed brought over from Tasmania, and the young saplings are reported to make headway at the rate of 18 inches a year. This is as much as they do at the Antipodes, and as the she-oak gives the best firewood the world produces it is to be hoped that its cultivation in the North may extend rapidly.—*E. Mail.*

CINCHONA BARK AND QUININE.

[ANNUAL REPORT BY C. E. BOEHRINGER & SÖHNE : WALDHOF NEAR MANNHEIM.]

Waldhof near Mannheim, 12th Jan., 1891.

QUININE.—At the beginning of the year just past manufacturers of quinine were occupied, even more than the rest of mankind, with the consequences of the influenza. The consumption of quinine during the period that the epidemic prevailed has been calculated at 3,000,000 oz. and that estimate is certainly rather below, than above the truth. We are moreover, of the opinion that since the period in question, the consumption of quinine in general, and especially in Europe has increased considerably. Probably those physicians who were about to relegate quinine to the category of obsolete medicines have since become of a quite different opinion.

During the first three quarters of the year 1890, the movements of the market were perfectly natural, and always the legitimate results of the situation. From 1s 2½d per oz. on the 1st. January, the price rose in consequence of the large demand during the months Jan.-February to 1s 3½d to 1s 4d per oz. and followed the decline of the epidemic during March-April by going back to 1s 2½d, oscillated during the quiet summer months between 1s and 1s 1d, and in August rose again in consequence of large orders from America to 1s 2d. Only in the last quarter of the year was the market "artificially" influenced: heavy forced sales depressed the price down to 12½d to 1s 1d first hand, and 11 to 11½d second hand.

PRICES OF SULPHATE OF QUININE.

On 1st Jan.	per oz	On 1st Jan.	per oz
1891 1s	to 1s 1d	1878	10s 4d
1890 1s 2½d	" 1s 3d	1877	10s 10d
1889 1s 3½d	" 1s 4d	1876	6s 7d
1888 2s	" 2s 2d	1875	6s 4d
1887	" 2s 3d	1874	9s
1886 2s 8d	" 2s 9d	1873	7s 10d

1881 10s 3d	" 10s 6d	1868	4s 8d
1880 11s	" 11s 6d	1822	40s
1879 12s			

Conditions in the producing countries remain subject to the same tendency already indicated by us. The cultivation of the Cinchona in Ceylon steadily decreases, and yields place to the planting of tea and other more profitable growths. The number of two year old Cinchona trees in Ceylon, that as recently as 1868, was reckoned at 70 millions, in 1886 had declined to 35 millions, and at present is estimated at only 19 millions. The falling off in last year's exports of bark from Ceylon compared with 1885 86 amounts to 6,670,000 lb. equivalent to about 2,250,000 oz. of sulphate of quinine.

Java on the other hand sends continually larger supplies of bark:

EXPORT OF BARK FROM JAVA

during the season from 1st July to 30th June.

Amsterdam lb.		Amsterdam lb.	
1889-90	abt. 4,750,000	1885-86	abt. 1,531,156
1888-89	4,415,000	1884-85	1,195,976
1887-88	3,492,913	1883-84	1,104,534
1886-87	2,230,276	1882-83	420,668

From 1st July 30th November.

Amsterdam lb.		Amsterdam lb.	
1890	abt. 2,450,000	1887	abt. 1,781,558
1889	2,019,086	1886	922,141
1888	1,825,273	1885	591,085

In the year 1869 the total export of cinchona bark from Java was only 700 A. lb. In respect to this product, the increasing importance of Java as compared with Ceylon, is further illustrated by a comparison of the London and Amsterdam public sales. The first auction at Amsterdam of 876 kilos of cinchona bark took place on 20th October 1870. Up to 1883 only one or two public sales of bark were held there annually, but since 1889 the number of Amsterdam auctions has risen to ten yearly.

PUBLIC SALES OF BARK IN LONDON.

1890	67,528	packages
1889	70,635	"
1888	90,470	"
1887	99,435	"
of which were sold		
1890	45,460	packages contg. abt. 4,020,000
1889	" 4,350,000

PUBLIC SALES OF BARK IN AMSTERDAM.

	packgs.	with abt. lb.	contg. abt. oz.	Sulph. Quinine.
1890	39,636	7,196,000	4,250,000	
1889	24,749	4,562,000	2,720,000	
1888	18,216	3,158,000	1,880,000	
1887		2,007,000	1,190,000	
1886		1,439,000	858,000	

of which were sold

1890 about 6,384,000 lb. contg. abt. 3,825,000 oz. Sulph. Quinine.

In point of fact therefore, as regards the quantity of quinine contained in the bark sold Amsterdam has almost placed itself on a par with the London market, and this year may very likely overtake it. It were however prudent not to indulge in any exaggerated speculations in this respect, since the outlook in cinchona cultivation in Java seems by no means so rosy as frequently described. The fact that the West Java Cinchona Cultivation Maatschappij has resolved to uproot about 2,000,000 cinchona trees on two of its four estates, suggests at all events the advisability of cautious judgment in the question.

The number of cinchona trees in Java is at present estimated at about 32 millions.

EXPORT FROM MALABAR COAST.

The supply of bark last year was smaller than in 1888-89.

From 1st July to 30th June.

	lb.		lb.
1889-90..	.. 1,833,522	1886 87..	.. 272,048
1888-89..	.. 2,218,700	1885-86..	.. 794,528
1887-88..	.. 1,070,160		

The decrease is very little due to local manufacture of quinine, since in the last year under report, only 234 lb. of quinine were made in the Government factories, and as before at a cost considerably greater than the price of the drug if bought in Europe.

Experiments carried on in India since 1886 have furnished proof of the interesting fact that by manuring the cinchona, its contents in quinine can be increased. The natural cinchona officinalis (11 year old trees) for example, which contains on an average only 3 per cent of quinine, under treatment with manure gave the following results:—

With lime and cattle manure	5.19 to 5.98	per cent
fish manure	5.94 "	6.82 "
bone-meal and cattle manure	5.35 "	5.97 "
bone-meal		4.95 "

With 21 year old trees (renewed bark).

fish manure	8.43	per cent
bone-meal	7.02	"

Mossed bark.

Natural bark.

fish manure	5.97	per cent.	fish manure	5.54	per cent
bone-meal	7.02	"	bone-meal	6.85	"

The agents employed enrich the bark more especially of the fast growing Succirubra, Ledgers and Hybrids, and act more energetically upon younger than older trees.

BOLIVIA

sent last year a larger proportion of its high standard bark to Hamburg, viz. about 2,188 bales of about 70 lb. each. The London receipts were:

1890	5,574	bales.	1886	3,979	bales.
1889	7,552	do	1885	2,599	do
1888	7,810	do	1884	2,856	do
1887	7,190	do	1883	2,774	do

The cultivation of the Cinchona tree is becoming unprofitable also in Bolivia. The number of trees at present under cultivation is said to exceed 15 millions,

about two-thirds of them being in the province of Mapiiri near the northern border whose business centre is Sorrato.

The export of Cinchona bark from the other South American states is inconsiderable.

EXPORT FROM MABACAIBO.	
1889	195,750 lb.
EXPORTS FROM SAVANILLA.	
1889	198,660 lb.
1888	385,836 lb.

JAMAICA.

has not yet realised the expectations entertained. The Government plantations yielded only:

1888	3,321 lb.
1887	17,000 "
1886	12,541 "

PRICE OF CINCHONA BARK IN LONDON.
on 1st January 1891

1891	1 3/4 d to 1 3/4 d per unit
1890	1 3/4 d to 2 d do do
1889	1 3/4 d to 1 3/4 d do do
1888	2 1/4 d to 2 3/4 d do do
1887	3 1/4 d to 3 1/4 d do do
1886	4 1/2 d to 5 d do do
1885	6 d to 7 d do do

AVERAGE PERCENTAGE OF SULPHATE OF QUININE.

	1890.	1889.	1888.	
Ceylon Cinchona bark ...	2 1/2	2 1/2	2 1/2	per cent.
East Indian ..	2	2	2 1/2	do
Java ...	4	4 1/2	4	do
Calisaya cultivated ...	4 1/2	4 1/2	4 1/2	do

Stocks in London show a considerable decrease:

31st Dec. 1890	48,213	31st Dec. 1886	62,350
1889	57,181	1885	61,690
1888	56,754	1884	80,500
1887	59,619	1883	99,667

Estimated in English pounds:

	American	Java, Ceylon, Indian	Total.
1890	3,350,000	5,000,000	8,350,000
1889	4,126,059	5,700,960	9,827,019
1888	4,404,960	5,332,800	9,737,760
1887	5,174,365	4,485,600	9,659,965

Herewith is included a considerable quantity of bark unsuitable for manufacturing purposes. The percentage of the stocks of bark in London, on 31st December 1890, does not probably exceed 2,000,000 oz sulphate of quinine. Regarding the quantity of quinine held at second hand in London, opinions differ greatly. It is however supposed that the major portion is held firmly, and will be brought into the market only at considerably higher rates. Stocks of bark and quinine elsewhere are unimportant.

The consumption of quinine by the world in general is steadily increasing at the rate of about 10 per cent per annum, and under normal conditions (without influenza) is estimated for the present year at about seven million ounces.

The large and constantly growing share of America in the general consumption is best shown by the following figures:

IMPORT OF QUININE IN NORTH AMERICA.

	oz.		oz.
1874 (fiscal year)	68,097	1882 (fiscal year)	794,495
1875	12,279	1883	1,055,764
1876	22,746	1884	1,263,732
1877	75,804	1885	1,390,126
1878	17,549	1886	1,251,556
1879	226,348	1887	2,180,157
1880	416,998	1888	1,603,936
1881	408,851	1889	2,825,008

from 1st Jan. to 20th Dec. 1890 3,374,300

We herewith give a resumé of those statistics as are of chief importance, reduced to ounces of sulphate of quinine.

Export of bark from Ceylon lb.		oz.
1890	abt. 8,800,000	c. 2 1/2 per cent. abt. 3,000,000
Export of bark from Java lb.		oz.
1890	abt. 5,280,000	c. 4 per cent. abt. 3,380,000
		Total 6,380,000 oz.

The supplies from the other exporting countries are about sufficient to cover the demand for druggist quills.

Stocks of bark in London about 2,000,000 oz.

Consumption in 1890	"	3,750,000 "
estimated "	"	1891 " 7,000,000 "

With the help of the given data it will not be found difficult to form an opinion concerning the position of quinine.

COCAINE.—The profits of manufacturers, alike of crude cocaine and of the hydrochlorate, that were greatly reduced already in 1888, were still further curtailed last year. At times indeed, sales could only be effected at a loss to manufacturers, for whilst the high rates for coca leaves were fully maintained, the price of crude cocaine and hydrochlorate fell steadily still further from month to month. We referred already last July to the disproportion between the rates for raw material and the manufactured article. Since then however the position has become greatly changed. Not only coca but also cocaine has risen very considerably in price.

TEA PREPARATION IN CHINA.

It is rumoured, says a Foochow correspondent of the *North-China Herald*, that a few wealthy natives intend to purchase machinery for preparing tea, and set up an establishment for that purpose in Kien-ning Fn. No charges, we understand, will be made to owners of tea for the first year, and thereafter the charge will be far less than the cost of manual labour. The idea is undoubtedly an excellent one, as many tea growers cannot purchase such expensive machinery, and no doubt will be only too glad to avail themselves of an opportunity to have their teas manufactured in a better way than at present, especially if the cost would be, as is said, far less than hand labour. We sincerely hope that the promoters will carry the above plan through, when, we doubt not, many others will follow suit.

THE NON-KEEPING QUALITIES OF CEYLON TEA.

Some months ago our columns contained correspondence and discussion on the subject of the non-keeping qualities of Ceylon tea, and the effect of long or short fermentation as the result. It was held by many that the longer the fermentation the longer would the tea keep its flavour and condition, while the opposite theory was held by more than one experienced taster, and, to test the matter as well as it could be tested, we obtained few samples of tea manufactured from the same roll but subjected to different periods of fermentation. One sample had only half-an-hour's fermentation; another two hours'; a third four hours'; and a fourth six hours'. These four teas were tasted by Mr. Herbert Tarrant on the 29th of August, 1890, and he gave his opinion that the tea fermented for two hours was decidedly better than that fermented for half-an-hour, and that that tea had better quality than the four hours' fermented tea, but was much inferior in strength. The six hours' fermented tea, he said, was much the worst. It should be stated that the length of fermentation was not known to Mr. Tarrant when tasting.

These samples were enclosed in lead and put in tin cases sealed and kept by us in a dry place till yesterday (so that they have been over five months in lead), when they were opened and again liquored. The result was that the half-hour fermented tea was declared to be much the best, having gone off least, and retained its flavor far the best. There was little to choose between the two hours' and four hours' fermented teas. Both had gone off about equally, whilst the six hours' fermented tea had gone off more than any of the others. The following is a tabulated statement of the result:—

Samples manufactured from leaf; medium plucking

elation between 5,000 and 6,000 feet; good soft with; rolled in Jackson's Excelsior; fired in Venetian; temperature during time of manufacture about 86°. After rolling half-hour small sifted out, and large leaf re-rolled another half-hour hard. Samples manufactured from same roll.

Tasted 29th August 1890.

Order of Merit.

A. Half-hour fermented	2nd
B. Two hours	1st
C. Four hours	3rd
D. Six hours	4th

First in order of merit decidedly better than second. Second has much better quality and flavor than No. 3 but is much inferior in strength. Fourth is decidedly the worst.

(Signed) HERBERT TARRANT.

29th August 1890.

The above teas were opened on the 5th of February, 1891—five months afterwards, and the following is the report:—

- A. Decidedly the best. Had gone off the least and still retained its flavor,
 B. } Cannot separate these two teas. Both gone off
 C. } a good deal.
 D. } Much the worst from every point of view.
 Had gone off altogether.

(Signed) HERBERT TARRANT.

—Local "Times."

THE KOLA-NUT TRADE.

At the Liverpool County Court before his honor, Judge Collier, Messrs. Broadbridge & Co., of Liverpool, general produce dealers, brought an action against Messrs. Thomas Christy & Co, London, drug importers, to recover the sum of 30l 10s 2s, the price of nine barrels of kola nuts which were sold by the plaintiffs to the defendants on November 17 last. Mr. Steel appeared for the plaintiffs and Mr. Pickford for the defendants.

Mr. Steel, in opening the case, put in letters and correspondence which had passed between the plaintiffs and defendants in reference to the kola nuts. The plaintiffs on November 7 wrote to the defendants, asking them if they were buying kola nuts, as they were brokers in Liverpool and their friends had some for sale. On November 12 defendants replied that they were buyers of kola nuts, if of good quality and reasonable price. Plaintiffs then sent samples of the nuts to the defendants, and stated that the owners would accept 6d per lb. The samples were sent on November 14th and on the 15th defendants agreed to purchase certain nine barrels. Defendants said that some of the barrels were not as good as the others, and for these they would give 5d per lb., and that if the offer was accepted, plaintiffs were to forward the lot to their address, but the plaintiffs were to examine each lot and see that there was no palm oil on the nuts. There was no palm oil on the nuts and on the 17th the barrels of kola nuts were sent. On receiving the nuts defendants wrote that they were not up to sample and were of an inferior quality. They offered to pay 4d per lb. for certain samples. Plaintiffs replied that their samples fairly represented the bulk, and they could take no reduction. Hence the dispute. Plaintiffs offered according to the conditions of sale of the General Brokers' Association, to leave the dispute to arbitration. Plaintiffs said they did not sell on "guaranteed sound," but "according to sample." They asked for payment of the nuts, as defendants would not have arbitration in the case. On Dec. 3rd defendants sent to the plaintiffs a cheque for 22l 4s 10d instead of the 30l 7s 10d which plaintiffs claimed. They returned the cheque. Defendants had now paid the 22l 4s 10d into court, and they claimed the sum of 1l 1s which they had paid in London to outside brokers to examine the kola nuts there.

George Frederick Howard, a member of the plaintiffs' firm, said: On Oct. 22nd we received a consignment of kola nuts, and sold this consignment as the brokers,

The nuts came from the West Coast of Africa. When the steamer arrived the nuts were stored in Liverpool. They were unpacked and emptied out on the floor in bulk. Each lot was kept separate. On Nov. 12th I gave instructions to my warehouseman to take some samples. Three samples were taken and sent by my foreman to the defendants. I was not present when these samples were taken. I saw the large samples in our office which were brought from the warehouse. The largest sample from five barrels would be about 10 lb and the others much smaller. I examined the samples and found that those from five barrels were bright, clear, good kola nuts, and in good condition. Three barrels and a case were not so bright. The nuts in the five barrels were in a good condition, except a few. Some of them were mouldy and of a dark colour. Fresh kola nuts ought to be of a brightish colour. We cut the dark ones open to see if the damage extended, but found it only existed on the outside. The condition of the other lots was similar, but they had not such a bright appearance. They were of a reddish colour. I did not see the small samples sent to London.

Cross-examined: We sold the nuts as brokers for the firm of Henty & Co. I have not a great experience of these kola nuts. I have sold them before, but not the fresh ones. This was the first lot of fresh ones we sold. I have seen three or four lots of fresh ones. My firm are general produce brokers. I never saw the bulk of the nuts. It is not customary to do so when goods are sold as samples. The warehouseman saw the nuts. After being stored the nuts were out of the barrels all the time. When sold they were repacked. The nuts were good lots. The firm did not sell on "guaranteed sound," but on "sample." The firm knew that a few of the nuts were not sound. The sample was a fair sample of the bulk. The firm took a smaller price for the nuts because they were not so fresh as on arrival. It was true they were deteriorating and beginning to grow mouldy. I do not, however, think that they had deteriorated to the extent of 1d. per lb. When I received the complaint about the condition of the bulk sent to London I did not get them examined on my own behalf, as I desired the matter to go to arbitration. The arbitrators would then have had the samples examined. When I found the defendants would not arbitrate I thought it was no use for me to do anything in the matter. According to the rules of the General Produce Brokers' Association each side in a dispute could appoint an arbitrator. If one side neglected after three days' notice to do so, the Association could appoint one. The defendants sent down samples of what they said the bulk of the kola nuts were like. The arbitrators could have called for whatever samples they liked if appointed. Defendants had the nuts. I am not a member of the General Brokers' Association. I never named an arbitrator because the goods had gone from the firm's possession, and arbitration would have been no good. The defendants ignored everything, and it would have been no good, going on without them. The delay in selling the goods caused them to deteriorate to a slight extent. If they had been quickly sold they could have got 1d per lb. more.

Robert Taylor, the plaintiffs' warehouseman, corroborated the last witness's testimony. He also said the nuts were sampled by means of a spade. They were lifted by a spade into paper. A shovel was employed to get as fair a sample as they could. The general condition of the nuts was good, although some were not sound. The nuts were all mixed through when a sample was taken. After taking the large samples they were taken up to the office.

Cross-examined: I have seen many samples of kola nuts in different warehouses. I have seen fresh ones. The nuts were sampled after they had been lying on the floor for three days. I did not examine the nuts when I put them in the barrels again.

Re-examined by Mr. Steel:—The nuts were brought from the quay on Oct. 27th and were emptied on the floor a week after to keep them dry. The nuts would

be on the quay for about four days before they were removed.

Arthur Broadbridge, a salesman in the employ of the plaintiffs, said he took three samples of nuts on Nov. 12th from the bulk, and on the 14th took three samples from these for defendants. He put his hands in the centre of the pile to see if the smaller samples were as nearly as possible like the big sample retained. Some of the nuts were a little brown and rusty. There were only one or two mouldy ones. One of the marks of the goods were not so good as another.

Mr. Steel:—We took a less price for these.

Cross-examined:—The sample I took was a selected sample from a large sample. I was about ten minutes over it. If I had made a mistake the bulk would not have corresponded with the large sample. The plaintiffs' business was in fibre, oils, &c. He never saw the bulk of the nuts.

His Honor: Are the samples improved by handling?

Witness: No, sir.

Mr. Steel: If you rub a nut you improve its colour

Witness: Yes; but there was only a little mould on some. I took every pains to see that the small samples was similar to the large one.

This was the plaintiffs' case.

Mr. Pickford, for the defence, said he would call evidence to show that the nuts were not up to sample. He submitted that the only question was whether the deduction they had made was correct. Besides this, he failed to see how the plaintiffs who acted as brokers were entitled to sue as principals. The defendants knew more about kola nuts than anybody else in England. They had practically made the trade in kola nuts in this country. They had called in Messrs. Lambert & Strong, who had great experience in these nuts, to see the nuts. Mr. Lambert would tell them that the bulk of the nuts did not correspond with the sample.

The defendant, Thomas Christy, was called, and said: I have had nine or ten years' experience in kola nuts. Until a year ago all the kola nuts which came into Europe passed through my hands. I pointed out to the plaintiffs when they offered the nuts for sale that mouldy nuts were useless, and that I must have them fresh. The nuts are used medicinally, also for refining beer. The nuts prevent people going on drinking. (Laughter.)

Mr. Pickford: How does it do that?

Witness: It makes people nauseate. If a man is lying insensibly drunk on the floor, or under the table, and a nut were put into his mouth, in fifteen minutes the man would rise, and one would not know he had drunk. He would not even have a headache. Even if within four or five days he went to take spirits again, the effects of the nut would still produce a nausea in his throat and mouth. (Laughter.) This was a well-known scientific fact. As the nuts are used medicinally, it is an important matter not to have them mouldy. The samples of nuts I received from the plaintiffs looked very nice. I was attracted by the nice appearance of the nuts, and I entered into negotiations for them. When the bulk came forward, I found they did not agree with the sample at all. The day after the nuts arrived I telegraphed repeatedly to the plaintiffs about them, in order to come to some arrangement. A kola nut, when once it becomes mouldy, changes its character, and becomes a fungus. They are then of no use. The bulk of the nuts were turned out in Mr. Lambert's presence, and they were wet, slimy, and mouldy in many instances. The keeping of the nuts a fortnight in the barrels would have a tendency to deteriorate them. The top of the barrels would be better than the bottom and centre. The nuts on examination had turned out not to be worth as much as the sum sent for them. I sent a letter to the plaintiffs to examine each bag as to their condition, and to see that there was no palm oil upon them.

Mr. Steel: There was none in fact.

Cross-examined: It was not until seven days ago, when the nuts came back from the drier, that I found that they were not of the value of Mr. Lambert's certificate. I know my solicitors have paid the sum of 22l 4s 10d into

court. I sent the mouldy nuts to the driers. Messrs. Lambert & Strong, when they examined the nuts, gave it as their opinion that the nuts were worth the amount certified. I could have bought nuts equal to the sample sent to me for 3d per lb. in London. I gave the higher price for the nuts in Liverpool because I wanted them for growing purposes. I sent them all over the world. At the time I purchased the nuts I looked upon the plaintiffs as my brokers. The money I sent was returned. If kola nuts are bruised or exposed to the atmosphere any time they deteriorate.

Mr. Lambert (of the firm of Lambert & Strong, London) said he had examined the nuts at the request of the defendant, and gave him a certificate of the value. He thought he was called in by both sides as an arbitrator.

Some arguments by the counsel ensued, Mr. Pickford maintaining that the plaintiffs were not entitled to sue, as the plaintiffs could not be brokers and principals at the same time.

Mr. Steel said that the defendants, in paying the money which had been returned to them, admitted that the plaintiffs were the right people to sue. Plaintiffs had the goods consigned to them for sale. He would ask his honor to say that there was no tender.

Mr. Pickford said the defence of tender was no good unless the money was paid into court.

Mr. Steel: The defendants having paid the money into court, we could not get it until there had been a judgment.

His Honor remarked that he thought the contention of Mr. Pickford about the plaintiffs not being able to sue came too late.

Mr. Pickford said that money which was paid into court was paid to the plaintiffs.

His Honor said he must take time to consider the question whether the plaintiffs were entitled to sue or not. He would also require time to consider the question of tender, and would therefore reserve judgment.

By permission of his honor plaintiff was recalled, and, in answer to Mr. Steel, said he received commission from Messrs. Henty & Co. of 1½ per cent for selling on their account.

His Honor: I will consider my judgment, and deliver it on a later day.

JUDGMENT.

(Delivered on Friday, Jan. 2, 1891.)

His Honor said: I find that the nuts delivered were not equal to sample, and that the sum of 23l 5s. 10d. is the sum which the plaintiffs are entitled to recover. The tender of 22l 4s. 10d. was, therefore, insufficient, and my judgment must be for the plaintiffs for 23l 5s. 10d. But, except as to the costs paid into court, I direct that the judgment shall not carry costs, the defendants being practically successful in the action. A point was raised at the hearing, and left for my decision, as to whether the plaintiffs were entitled to recover at all from the defendants, inasmuch as they had acted as defendants' brokers in the transaction. This contention rested on a bought-note dated November 17, which was (so far as is material) in the following terms:—"We have this day bought for you the following goods. Customary allowances and Liverpool general-brokers' conditions of sale. Payment (before delivery if required), cash, in fourteen days, less 2½ per cent., brokerage 1 per cent. Signed, Broadbridge & Co." Prompted I suppose, by the desire to get a commission from both parties (for Mr. Howard admitted that he received commission from his selling principal), Messrs. Broadbridge were induced to represent themselves in this note as the brokers for Messrs. Christy & Co. If they were really so, of course they could not recover in this action, but I think that the correspondence shows that they were acting as

sellers' brokers, with an undisclosed principal; and, although they call themselves brokers, it would be more correct to describe them as factors. And the transaction, notwithstanding the bought-note, was, in my opinion, one of sale and purchase between the plaintiffs, who had possession of the goods, and the defendants; and the defendants, after having received the bought-note, took the same view, for they tendered the 2*l.* 4*s.* 10*d.* I think, therefore, that the plaintiffs are not precluded on this ground from recovering.—*Chemist and Druggist.*

THE BUSINESS OF BROKERS.

Litigiousness is not the prominent characteristic of the fraternity of brokers of our day—at least, not of those whose dealings are chiefly in drugs. Very rarely do we have the opportunity of learning anything about the law which governs their transactions from the conclusive test of a contest in the courts. The case tried before the County Court judge at Liverpool, the report of which we give above, seemed at one time likely to afford an opportunity for a display of ingenious legal lore, and we are a little disappointed that his Honour of that court should have contented himself with so ingeniously gliding round the difficulty which had been raised, in the somewhat uninteresting judgment which we have to record. Whether the sellers and the buyers of the kola nuts in question are equally satisfied, or equally dissatisfied, we do not know; their dispute was not a very imposing one, and onlookers are likely to come to the conclusion that the decision is a practically just one. But, out of curiosity, we should have been pleased to have had a judicial essay on the interesting point submitted to the court whether the brokers, taking as they did, and as is usual in their business a commission from both buyer and seller, were in a position to sue one of the parties as if they were principals. We suppose the custom of the double percentage is so well established, and so universally understood, that there can be no question of its legality for brokers; but there are plenty of cases from which it may be gathered that such a system is scarcely permissible to other persons acting in a fiduciary capacity.

In Judge Collier's view, the plaintiffs in the case reported were to be regarded rather as factors than as brokers. If they were such, they had an undoubted right to sue. But the bought note, in which they expressly held themselves out as the agents, for the buyers, was inconsistent with their legal standing as factors, and had to be regarded with amiable charity by the learned judge. The truth is that the broker's business, as it is now conducted, is not very clearly defined. To a considerable extent it is governed by the Factors Act, 1889, but the generally-understood distinction between factors and brokers is, that factors have possession of the goods they sell, and that brokers have not. When they are not factors in the legal sense, they are simply mercantile agents, and are subject to the ordinary laws, even if these should clash with their own carefully-dvised rules and conditions. Until the Act of 14, brokers in the City of London were under the control of the Corporation, and were liable to a penalty if they assumed the title. They bound themselves by oath to a certain course of conduct, one stipulation being that they should not buy and sell merchandise on their own account. The Corporation did not rigidly enforce its rights, took fees from those willing to pay them, and generally left others alone. The Brokers Act of 1884, by abolishing the control of the City authorities, removed the restrictions on the business as well as on the title,

Brokers have a rather mixed record in our history. The name seems to have come into use in England first in the fourteenth century, and from then on to the sixteenth century the middlemen in trade were called brokers, broggers, and brocars promiscuously. Broggers are mentioned in a statute of Richard II., which requires that they shall not practise as such in any mystery except they be chosen by such mystery. The name is said to have descended from the Norman-French "brokier," and that from the old French "brochier," which meant one who tapped or broached wine. The modern dealers in "wine from the wood" are the original and most genuine of brokers. But as foreign trade grew, and imports from foreign countries became more abundant, the men who found customers for the cargoes reaching our ports became by far the richest and most highly-esteemed of the various kinds of brokers. The business was a very important one in the early part of the seventeenth century, and great was the jealousy between the English brokers and the "sonnes of Aliens" who competed with them. In the Guildhall Library there is preserved a curious "petition of English brokers lawfully admitted to deale betweene marchants in London" to the House of Commons of the year 1620. It humbly sheweth "That for many ages past it was the use and custome of the Cittie of London that none but freemen of the Cittie being Englishmen borne and householders should be admitted to exercise the trade of a Broker between Marchant and Marchant, whereby great commodity did arise to the common wealth for many years together." But now "in these dayes many strangers borne and the sonnes of aliens and others not lawfully admitted doe use and exercise Brocage between Marchants, by which means many intolerable and insupportable mischiefs do daylie happe unto this Kingdom and State." Among the inconveniences enumerated from the conduct of these strangers and sonnes of aliens were that not only in London, but also "in Exeter, Norwich, Colchester, Canterbury, Sandwich, and many other places," they were buying and selling "both in grosse and by retails, . . . driving a wonderfull home trade in this realme, to their private enriching and impoverishment of the English borne subjects." They were said to seek only "the profit of the Marchant strangers, and how to sell his commodities at the uttermost price." Thus they "inhanuced" the value of commodities. Other reasons given to their discredit were that they probably melted down the bullion they obtained and sent it abroad, and that through them the dealings of the Englishe could not be kept secret.

"The Act against Brokers" passed in the reign of James I., and still in force, reflects in its curious phraseology another grievance which the aristocratic brokers seem to have entertained. They evidently did not approve of Dick, Tom, and Harry calling themselves by the title which they had made honourable. "For as much as," declares this statute, "of long and ancient Time, by the divers hundred years there have been used within the city of London and Liberties thereof, certain Freemen of the City, selected out of the Companics and Mysteries whereof they are free and members and the same persons to be presented by at least six approved and known Honest persons of the same Mystery to the Lord Mayor of London for the Time being, and to the Aldermen his brethren, and to be recommended by such Presentors to be persons for their known Honesty, Integrity, and Faithfulness, Persons meet for to be Broker or Brokers." These "having taken their corporal Oaths before the said Lord Mayor and Aldermen to use and demeane themselves uprightly and faithfully between Merchant English and Merchant Strangers

and Tradesmen in the contriving, making and concluding Bargains and Contracts to be made between them concerning their Wares and Merchandizes to be brought and sold and contracted for within the City of London." These persons, the Act goes on recite, "have had and born the name of Brokers, and been known, called, and taken for Brokers, and dealing in Brokerage or Brokery," and they "never of any ancient Time used to buy and sell Garments, Household Stuff," and suchlike. But, the Act goes on to deduce that, "certain Freemen of the City had forsaken their manual occupations, and did daily set up a Trade of buying and selling and taking to Pawn all kind of Worn Apparel, finding that the same is a more idle and easier kind of Trade of Living." These brokers of the baser sort are described as "Friperers and no Brokers," and elsewhere as "upstart Brokers," and they have been found to encourage "bad and lewd persons to rob and steal." The Act does not, as the reader would anticipate from its preamble, make any provision for the protection of the title. Its object is simply to impose a fine on those objectionable furniture and apparel brokers who should receive stolen goods.

That class of dealers had been called brokers for "divers hundreds of years" before King James's day, and the name and occupation still survive among us. In a sense, it will be seen, all middlemen are brokers. Those whose original business was "the contriving, making, and concluding Bargains and Contracts between Merchant English and Strangers," still tend to become merchants themselves, as they did two or three centuries ago, but the middleman or broker would seem to be as necessary now as he was then in various departments of our commerce, notwithstanding the alleged disposition of the age to crush him out.—*Chemist and Druggist.*

SISAL HEMP.

The following detailed particulars of planting, working, general management and final out turn of Sisal Hemp (of commerce) were written in 1886 by Mr. Daniel J. Stoddart, a well known resident of Jamaica:—

INTRODUCTION.

In putting the present work of Sisal Hemp planting into print, and introducing it to the public of Jamaica, I do so with the object of promoting, if possible, the interests of this Island by advising the cultivation of the plant, considering it nothing less than an obligation of mine. I shall endeavour to put before my readers the planting, working, and everything else connected with Sisal Hemp in as few words possible, and yet in as explicit a manner as to be fully comprehensible. When I first landed on the shores of that great hemp country Yucatan, one of the States of Mexico, and saw the immense trade in hemp, by which a large amount of money is put in circulation, and the fibre finding such an immediate sale all over Europe, but principally in the United States of America, the demand being so great, it attracted very much my notice and consequently claimed my attention which I immediately gave.

The importance of this fibre may be judged when it is known as the sole production of Yucatan and the only article of export.

Too much cannot be said of this valuable plant which is the great and only source of wealth on the Peninsula where there are to be seen plantations of pure hemp, comprising each an area of about two thousand acres. The increasing demand for it all over the world is made manifest by the number of new plantations being opened out there. There is no doubt that there are soils in Jamaica highly adapted to the

cultivation of Sisal Hemp, and that the climate is identical with the tropical nature of Yucatan. What makes me more sanguine about its success here is that some time ago I brought out a few of the very young plants, distributed them to friends who planted them, and they are to be seen now growing beautifully and sending out suckers.

My practical experience in Yucatan and day and night work in connection with this hemp, having been in the working and management of it myself, enable me to write fully on the matter. This small pamphlet is specially dedicated to Jamaica, with the hope that those into whose hands it may fall will lose no time in taking up the matter and starting the cultivation. As far as its profit is concerned, putting the expenses at the extreme and the fibre at the lowest price in New York, of $\frac{1}{4}$ cents a pound, Sisal Hemp gives a return of about 75 per cent.

In a part of this book will be found a complete statement of the cost of working, out-turn and details of production, &c. An important point is that a plantation of hundreds of acres producing a good deal for a year's crop requires only a small "plant of machinery," as well as buildings, &c. I speak comparatively. The market for this fibre is already well established; it does not therefore need any introduction but must meet with a ready sale. I do warmly and faithfully recommend the planting of this hemp as a safe and sure investment, there being nothing that can properly be called *risk* in its culture. Several times I have advocated in the papers the cultivation of Sisal Hemp, but space prevented me giving a minute description of it. To remedy this and so as to have the public impressed with the value of it I have selected this medium, wherein is to be seen all the details, which I trust will prove of some interest to my readers, who I have no doubt will agree with me in saying that the establishment of plantations of this sort in our Island will be a fair stride in her agriculture.

CHAPTER I.

DESCRIPTION OF THE PLANT.

The Sisal Hemp plant of Yucatan, *Agave Itxli* or *Henequen*, as it is called there, would in its first appearance resemble our "Keratto," but upon close observation will be found widely different, being of a distinct style of growth; the leaves not growing out so near each other and of a light green, exceedingly thick. For this reason they give so much fibre which for strength exceeds all others. The leaves of the plant, which grow with prickles or thorns on the edges, the thickness of which is greatest at the ends, where they are joined to the tree and tapers off towards the edges and other ends which have hard and sharp points, are slightly gutter formed; they grow first upright, shutting up into one another, then gradually spread open, and finally bend down around the tree.

The hard nature of this plant, which is almost incredible, proves itself beyond a doubt, inasmuch that if rooted up it will remain alive for weeks without being replanted.

There is positively no failure in it as with or without rain, good or bad weather, it grows and flourishes and never dies. It is a "semper virens" in every sense of the word, and in my estimation can have no equal in its life-lasting quality.

For a proof of this I have known during my stay in Yucatan, when it only rained one month in the year, just a few showers, and the remaining eleven months pure dry weather, that the cattle died of starvation; yet, during all that time the plant remained perfectly intact, not the slightest failure—not the least affected by the drought, retaining its greenness, giving its return of every day cutting and working, and as a fact producing more fibre, throwing out less bagasse, and all this in a country devoid of rivers and streams.

Neither ploughing nor manuring of land is required for the cultivation of this hemp plant: no animal of any kind eats it.

When the fields have arrived to "cutting age" and the work once begun there is no "out of crop" but a perpetual work all the year round.

The plant lasts according to the best authorities for at least 25 years in cutting state, pending on the soil and treatment.

It takes at most three years after being planted to arrive to its cutting state. At this stage and onwards during its existence the more a plant is cut the better it thrives, the more leaves it throws out; while if it were to be left uncut it would, in a short time, growing until it finds no other vent, send out a pole from the centre, the appearance of which determines its death although young, and do what you may it ultimately dies,—singularly strange, but really true, so that the greatest caution is to be observed as soon as it reaches this state, which will be found fully explained in the chapter on cutting, &c.

After it reaches the age of 12 months it will, if planted in the proper manner, begin to send out around its root young shoots or suckers; and when it arrives to the age of cutting, innumerable quantities of them, so that when there is no place to be planted they have to be cut off and thrown away, the field not admitting of any more plants than those already set out, and more than that, if these shoots are allowed to remain they greatly injure the mother plant by taking from it the nourishment it needs. Inasmuch as I make these remarks my readers must not for a moment think it a delicate plant; on the contrary, naturally with care it will turn to better account.

To replenish a field it would only be necessary when, after a number of years, the mother plants show signs of fading, to plant at the proper distances, by the sides of the old plants or between them young shoots which three years after and upon the failure of the old ones will be fit for cutting, when a new field will be up without any loss of time or suspension of work. This is undoubtedly the practice carried on in Yucatan, and a very good one, there being no necessity of new lands for the fresh planting, as the old fields suit admirably and give good results.

Old worked lands are known to give the best yield.

CHAPTER II.

THE DIFFERENT SPECIES OF HEMP PLANTS.

There are in Yucatan seven classes of hemp plants with indigenous names, which they retain to the present day. It may not be out of place and uninteresting to give a description of each of them. The following are their names; Saqui, Chelem, Yaxqui, Chuchumqui, Babqui, Quitamqui and Cajum. In the first place is considered Saqui; this name, according to the Indian dialect, signifies white, not by its fibre being white, but because the greenness of the plant is lighter than any other. This class of hemp plant is the one that has been attended to in its propagation on account of all its good qualities, and of which chiefly the plantations consist, forming the article of export in the raw as well as manufactured state and giving all that is desired, viz., abundance, flexibility, whiteness, strength, length and weight. The second Chelem, partly wild, is found in abundance in the woods and is productive. It is held to be of good quality because its fibre is white and strong. Yaxqui takes the third place; this has short leaves, gives a small quantity of filament which is soft, fine and strong. The fourth class, Chuchumqui, is much like the Saqui, with the difference that its leaves are harder and thicker and its fibre coarser and less flexible, which makes it unacceptable.

The fifth class called Babqui has leaves which produce a small quantity of fibre although of good quality. In the sixth place is considered Quitamqui of short thin leaves, producing little fibre, through which it is not appreciated.

In the seventh and last class stands Cajum; this has long leaves, very delicate, of pallid colour and lives a small quantity of fibre.

To return to our object: the first class Saqui, which this work relates to and treats of entirely, is what claims our attention; it is the plant we look for,

the one we want, having in it both quantity and quality, and all otherwise that renders it acceptable and worthy of cultivation. The application of the word "Sisal" to this hemp, by which it is known and called, is derived from a port of Yucatan of that name, whence it used to be shipped formerly, but which has been abandoned for the other port of Progreso, where the total shipping of that State is now carried on.

CHAPTER III.

THE SORT OF LAND AND THE PREPARATION OF IT.

For the cultivation of this plant due regard should be paid to the selection of the lands as well as the locality. Gravely, stony and rocky lands are most appropriate, also any other dry and impoverished soil. Swampy land would be very unsuitable as it keeps unabsorbed a large amount of water. Sisal Hemp planted on rocky lands is perfectly at home and will astonish any one to know how it survived and grew. There is no objection whatever to the poorest land or those worked for many years, even lands that are considered ruined by continual fibres, such as our savannahs.

These are quite suitable for the plant, provided they do not keep water on them very long.

Sugar estates recently thrown out of cultivation are unfit from the nature which renders the land rich, as the consequences would be that the plants grow rapidly, give a large leaf, but produce no fibre. The same would, I consider, apply to the very cool mountain climate of Jamaica where it might grow, but give little or no fibre.

It requires all the heat possible to give good results. It would be necessary in the selection of the lands to have level ones as near as possible, which will admit of the easy and cheap carriage of the leaves from the field to the machine.

The Preparation of the Land.—Of this no consideration needs be taken apart from having the land cleaned up and fenced, ploughing and manuring not coming in the way at all.

After the selection of the land has been made, proceed in the month of June or July, as is customary in Jamaica, to cut down and clean it up, taking care to have the trees cut as close to the earth as is possible, leaving in this way very short stumps, giving room to the play the leaves caught to have. The stumps should be burnt out or taken out somehow, so as to create regularity in the planting; all this should be done and the land made clean to meet the month of September, which generally brings much rain; if a return of very high weed give it a cleaning and so have it prepared for the reception of the plants as this will be the opportune time to put them in, taking advantage of the seasons to make a good start, all the plants being provided in their nursery beforehand.

The land for the planting of Sisal Hemp must be entirely free from all shade as the plant requires very much the aid of the sun to forward its growth and give the necessary result; it would not thrive if shaded, the more heat the more fibre it turns out there being less bagasse.

It may be planted any month of the year, but it is wiser to do so during rainy seasons, for the plants getting a fair start will not be retarded so much in their growth as they would otherwise and consequently will give a return far sooner.

Fences are only required when the plants are young, as being diminutive they would be trampled or knocked out their holes, but so soon as they pass that condition fencing becomes more a luxury than a necessity, the reason of which (already said) is that no animal molests the plant, rather keeping away from it.

CHAPTER IV.

THE YOUNG PLANTS, THEIR SELECTION, THE NURSERY FOR THEIR FIRST RECEPTION, FIELD PLANTING.

In obtaining the young plants the younger they can be got the better it will be, as they grow much more

rapidly and arrive to maturity earlier; on the other hand they should not exceed 25 or 26 inches in height, for these reasons, that they are more productive, being quicker in giving suckers or shoots and a great number of them at the same time growing with more vigor.

If the field be not ready at the time of receiving the plants, the cultivator must immediately establish a nursery for them, which consists in getting a piece of soft land or digging up for the purpose and securing it with a fence; this place must be free of all shade, as this would injure seriously the plant which requires all the exposure to the sun.

In getting the plants it is precisely necessary that their main roots remain on them as being for transportation; they will by this retain their verdure for a long time. In the nursery they must be planted at the distance of 18 inches apart, which makes about nineteen thousand suckers to the acre, and in the following manner: first take off the dry leaves, then cut the main roots clean off and pare as closely to the trunks as possibly all round without injuring them, nor so deep as to allow the leaves to fall off; after this place them in the ground perpendicularly, putting in and covering only the inferior parts of the trunks dirt; all this care and attention in their infancy is the way of having quick returns, and although they be not yet planted in the field still they merit this attention which will amply repay the planter, as they lose no time in developing while in the nursery, which is an advancement in their growth and when transplanted in the field become ripe sooner, whereas if thoughtlessly cast aside to await field planting will naturally be very much kept back.

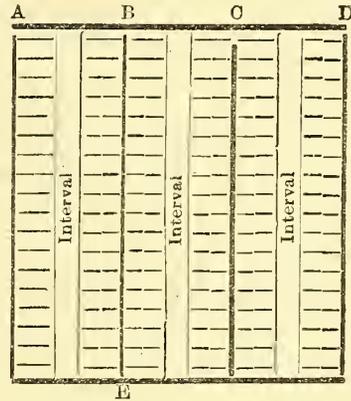

Field Planting.—The idea of taking advantage of the land in setting out a great number of plants has been carried in some cases to such an extent in Yucatan as to be prejudicial not alone in the plants not developing fully but for the material difficulty which is presented in the culture and exploration of them when they are grown up, as the leaves of one plant meeting those of another stop with their sharp points the passage between them, preventing easy approach to the trunks, a thing absolutely necessary for cleaning the field and removing the shoots destined to the reproduction.

The general system now in planting is 12 by 6, i.e., the rows twelve feet wide and the plants six feet apart in the rows which leaves clear passages of 12 feet between the rows, thereby giving sufficient room with facility for the inspection of them and for the pasturage of cattle and horsekind, and spaces of 6 feet between the plants which permit the easy approach to the trunks for weeding and getting out the shoots that spring at foot of plant; experience has proved this the best mode of planting; it also allows the free penetration of the heat of the sun whose effects on the plant are wonderful. The above distances give six hundred and five (605) plants to the acre. Now, after having the field perfectly clean and ready, open the holes for the reception of the plants by first stretching a line with the distances marked off, or it may be pegged out as the cultivator likes, so that it be straight and regular, which must give it a fine view.

The holes to be made can be dug with a hoe or common digger, and must be about as large enough to receive only the lower parts of the trunks of the plants which should be put in a perpendicular manner and the dirt drawn around, leaving exposed as much of the trunks possible which accelerates their growth. The plant must, however, after being taken from the nursery and prior to setting out in the field be pared off end, if found necessary, which will be in the case of any roots sprigging out during its stay in the nursery, must be cut off. It ought to be treated in exactly the same manner as when it was being planted in nursery, which is already explained; it is wonderful to know the advantage it gains by this treatment; it is not too much when I say it puts on a year's growth to what it would have otherwise.

As the spaces above would not be sufficiently wide for the carts to go into without injuring the leaves, it is therefore necessary to have wider ones or intervals

where they may take up to carry to the machine the leaves which are put at those intervals by the cutters; the intervals ought to be wide enough to admit of two carts passing each other freely. For ease to the cutter, as well as convenience and economy to the planter, I suggest a plan of laying out a field of say 31½ chains square, as the following figure shows:—

The field is divided into three sections, each of which measures 10½ chains, and is represented as follows:—

A to B first section, B to C second section, C to D third section; in the middle of each row an interval of proper width having a depth on either side within each section of about five chains. The short lines drawn across indicate the rows of hemp between which the cutter works, and therefore has—while cutting in any section—a distance of not more than five chains to carry the leaves to the interval, where the cart gets loaded. Each section has its boundary line as is shown from B to E.

It will be found, if this plan is adopted, how much the carriage of leaves is facilitated, being done quickly to the great interest of the cultivator.

Cost of paring roots and planting suckers in the field.—They are pared at the rate of one penny half-penny per 100, by which a boy or woman can earn a shilling and one shilling and threepence per day, as one person will pare easily 1,000 plants for the day.

It is worth about four shillings and sixpence per acre (605 plants) or ninopence per 100 to line out, dig holes, drop suckers and plant. One man and a boy can plant at least 300 suckers (½ acre) per day which will give them two shillings and threepence, the boy to assist stretching the line and to drop the plants, one to each hole.

If the suckers are planted in the correct manner there will hardly be any supplying required. I have seen thousands planted, have planted them myself without one failing; more than this, I will at any time guarantee to plant five hundred thousand suckers without the loss of a single one.

CHAPTER V.

AFTER CULTURE, OTHER PLANTS IN FIELD, POLE.

The after culture consists first in attending to the plants in the field and keeping them free from weed.

The number of times a field ought to be cleaned in a year cannot be determined; if the planter wishes to obtain all the results possible he should stick to the rule that "the field be constantly kept in a state of cleanness;" it is not altogether requisite to clean the field when the weeds are below the level of the plants, as at that height they do little or no harm, but they should never be allowed to be on the same height or reach above them. The plant is never moulded in Yucatan; it is considered there that ploughing and moulding (where admissible) would prevent it generating as it ought. In my experience I know as a fact that the less soft the earth the sooner it produces shoots.

Next, the young suckers or shoots that may grow around the mother plant ought to be taken away early for planting other fields; if not required they should still be cut off and thrown away; if they remain they become burly, as they take in the nutriment which the mother plant requires and should have.

In my opinion there would not be any necessity of resorting to the destruction of the plants, for if once started here the owners of plantations would find customers for the purchase of as many as their fields would be capable of turning out.

The purchaser must not at that time forget to take the necessary precautions as are already advised and explained in subjecting the suckers to *Nursery treatment* if the field be not ready to receive them.

There being wide space anything of low growth may be planted in the field up to harvesting which will not choke the plants. I must again advise my readers not to cultivate what will spring above the hemp, for that would keep back the plants.

Pole.—The sign of the termination of the existence of a Sisal Hemp plant is when it sends out a pole from the middle; this happens when the plant arrives to cutting age and the leaves are not cut, for notwithstanding its youth it dies, or in the other case where the tree attains old age, then it is natural. If this pole were allowed to grow it would reach a height of from 12 to 18 feet; in the upper part it throws forth branches with flowers. When the pole begins to come out and gains a length of about 3 or 4 feet is the customary time to cut it off close to the body of the tree without injuring the leaves, which will be matured and taken off before the plant dies altogether; the practice of cutting the pole is to prevent it from flowering, as it is thought that its flowers are injurious to the young shoots at foot of mother plant. In the plant of quick growth the pole, immediately after it comes out, begins to send out small suckers similar to those produced around the root, only very diminutive, but these are of no great value, and if planted would cause a degeneracy; producing none, or if any, very few shoots although they may grow well as plants. This chapter ought not to be closed without recording that apart from the shoots which grow around the root of the plant and those which the pole produces Sisal Hemp possesses another medium of reproduction, and this is in its seeds. These may be found in large quantities in the bagging capsules of the superior ramifications of the pole (when this is allowed to grow) and if they are gathered in a ripe state and dried may be sown in the same manner as any other seed, and it is believed that small plants would be obtained equal to those which are got in the usual manner. I do not doubt the fruitfulness of the seed as, although I have not personally experimented on it, old planters who are reliable authorities assured me that they have been sown and afterwards planted with good results. I mention this merely to show the different ways this hemp is produced, as industriously speaking it would not be of great utility to have recourse to this mode of reproduction when nature has given a style more rapid and efficacious and consequently more adapted to the exigency of its growth.

CHAPTER VI.

HARVESTING OF THE LEAVES, TOOL USED FOR CUTTING, CARRIAGE FROM THE FIELD.

We now arrive to a point which is to show us when the leaves are fit for the machine to extract the fibre, a thing of great importance. For the harvesting of the leaves we must take into account first their length, second their ripeness.

1st. *The Length.*—The length of the leaf matters a good deal as fibre of this class (Sisal Hemp) is only admitted into the market and rendered saleable when it has a length of at least three feet; the leaf generally with good cultivation reaches the proper length at the age of three years and on quick soil before this; the leaf increases in length as the plant increases in years. I have seen fibre 4 feet 6 inches long from hemp a few years old.

The determined length therefore of the leaf as it stands on the tree should not be less than 3 feet, in order that after trimming off its sharp point it may turn out the fibre to the least desired length; this is an invariable rule and of primary importance. I am certain the plant will attain this in Jamaica earlier than it does in Yucatan, thereby yielding its profits sooner.

2nd. *The Ripeness.*—This consists in (A) its position on the tree, and (B) its color, chiefly the former.

(A.) *Its Position on the Tree.*—So soon as the leaf which at first grew upright and afterwards inclined downwards, getting longer during that time, reaches a horizontal from the trunk it may be considered ripe and be at once cut. After it moves from this position towards the earth it grows no longer but begins to shrivel and after its point touches the earth it decays. If allowed to reach this state and cut it will be found after extraction to contain a spotted fibre and less quantity than a ripe leaf; the result of an unripe leaf would be similar in producing less fibre with the exception of not being spotted.

(B.) *The Color.*—The natural color of the leaf is a light green, and this on the leaf maturing will change to a dark green which is easily perceptible and which on the leaf reaching the ripe position, as already mentioned, will show up fully, confirming at once without going any further the truth of the leaf's ripeness. The above description of the length and ripeness of the leaf does not imply that it contained no fibre before this time, quite the opposite, it had all the time, and were a fibre of short length marketable could have been started upon twelve or fifteen months after planting by, course cutting those leaves which are really ripe. From its infancy the leaves are continually falling down and dropping off, given place to the new ones which grow out.

The knife for cutting the leaves from the tree must be of a half round form in the shape of a scythe or grass knife, but of less diameter, therefore smaller, with a short hollow handle to admit of a wooden one, of good length, necessary to reach to the trunk of the plant; and appreciated for its lightness; the knife deserves to be of good steel and kept sharp to give a clean cut and facilitate the cutter.

To cut the leaf in the proper manner the cutter must put himself in such a position as to face the leaf from the side, the last or bottom leaf ought to be cut first so as to prevent any injury to the fibre from the knife slipping and cutting into the next leaf, which would be the case if the top ones were cut first. The knife must be started on the leaf from one side or edge and drawn across, and it will be found to come off freely and nicely. The greatest caution must be observed to cut the leaf as close as possible to the trunk of the tree; neglecting this important duty will end in losses; first, the leaf not cut closely would lose a small quantity of fibre; that arrives to a good deal in many thousands; second, if the stump of the leaf where disunited be any length from the trunk it injures seriously the tree, spoils its vigor and makes its existence a short one.

Immediately after the leaf is cut and before taken away the prickles on both edges also the sharp point at the end must be trimmed off, which can be done with a small cutlass or large butcher knife, but so carefully as not to trespass on the limits of the valuable leaf, barely taking them off. This operation is very necessary for the easy manipulation of the leaves in the field and at the machine. The leaves must now be made up in bundles—head and tail alternately—of 50 or 100, as the cultivator may think fit; this is necessary to count easily and rapidly on receiving from cutters and delivering to operators at the machine, all of whom are paid by the thousand; the bundle of 50 is, I think, more suitable, being of less weight, and the right one of about 75 lb. rendering it handy as well as giving ease to the cutters, cartmen and others, more so the first of these who have to carry it from the rows where cut to the interval.

A tray on good road carries 1,500 leaves at once to the works. Care must be taken to inspect the cutting or the cutter may, to suit himself, cut down green as

well as ripe leaves to avoid too much trouble and make a large profit in a short time.

I must at once take the opportunity of advising my readers as to their close application now. This is the time when if the plant is neglected and the leaves not cut it sends out the pole, the appearance of which, as you are already aware, seals its doom to the sad loss of the cultivator who, after he is sensible of its value, will in no way relish it. Here begins the constant work which is justly so since there is no stoppage as crop goes on from one year's end to another. The proof of this is that a field or plantation started upon cutting at one end will, before the other end is reached, be ready to start over again, and this, too, whether rainy or dry weather; great attention is now required so as not to loose the leaves after cutting nor the filament after extraction. At this time there ought to be a very large number of young shoots around the plants which may be taken away to supply other fields.

CHAPTER VII.

MACHINERY, DRYING STAND, PRESS AND BUILDINGS.

To begin there must be on the spot or as near as possible a good and never failing supply of water for the use of the engine and otherwise. In the selection of the engine it of course depends on the number of acres in cultivation to form the calculation. If the plantation consists of 100 acres it requires an engine of 1 or $1\frac{1}{2}$ horse power to drive the fibre-extracting machine; one fibre machine is allowed to every hundred acres to be driven direct from the engine. There is no actual necessity of my describing the fibre extracting machine of Yucatan when we can have a superior one of modern style, which will suit the work splendidly, and I am sure turn out the fibre to better advantage, creating less waste. I will now give the details of the position, &c. Sufficient space must be allowed between the engine and the cleaning machine to admit of the reception of the leaves on the stand which is fixed not far off the machine, as well as to give room to the operators who take their position there. The machine, which is connected to the engine by means of a driving belt, is made to take a backward motion towards the engine and operators, which must necessarily be so in order that the leaves on being inserted find their way downwards, the refuse or bagasse going under and emptying itself outside. The place where the machine is to be situated ought to have a certain elevation above the general level of the ground for facilitating the descent of the juice of the leaves and of the water which serves for the washing down, by means of natural or artificial declivities which conduct it to the deposits where it ought to be absorbed by the earth, or naturally evaporated by the action of the sun, from a neglect of which I have known many farms to present a disagreeable aspect all round. It is very important that the works be easily accessible to drays by having good roads, through which the work of carting in leaves, bringing in fuel, and carrying away the bagasse, &c., can be easily and quickly done, as on the good operation of these depend in great part the punctuality and exactness of a work like this, which requires the utmost persistence and entails loss in the least mismanagement, as well as for its cheapness and the final out-turn of the business. The exposure of the building necessary to the machine should not be treated with indifference; on it is dependant that the operators be not disturbed by the direct embracing rays of the sun, and to avoid this it is best to make this building face the north as they will not be free from the sun, but the ventilation would be as perfect as possible; if not convenient to get it to face the north adopt in preference the east, so as to participate of the advantage enunciated, avoiding the south and west which would be insupportable for the operators in certain seasons of the year. It ought not to be lost sight of that the rule in Yucatan is that immediately after the day's work the fibre extracting machines are well washed and cleaned as the juice of the hemp ferment-

ed is corrosive for the iron, thus keeping them clean they will work better and last longer. On examining a fibre machine there, after a day's work, it will be found as bright as polished steel, the effect of this caustic juice. The cleaning wheel of the machine used in that place is from 39 to 54 inches diameter; the last size is more used as it is calculated that the wheel of greater diameter cleans the large leaves with more facility, but on the other hand requires greater motive power for maintaining it in point of velocity which the cleaning demands. The number of revolutions in a cleaning wheel calculated there is from 150 to 200 per minute at the least; if not so arranged the extraction of the fibre takes too long and is defective, in which case the combination of the engine and other wheels are reformed until the required velocity is obtained.

Drying Stand.—This is for the purpose of hanging out the fibre to dry in the sun and may be erected by putting up posts $3\frac{1}{2}$ or 4 feet high each at certain distances apart, and nailing small rails on top or against them or, if preferred, wire may be used instead, making sufficient stands as may be required under the circumstance; they can be put close enough as to merely allow of the attendants going between, and must be at no distance from the cleaning machine nor too far from the baling room, free from all shade and exposed in such a manner as to have the benefit of the sun at any hour.

The press is entitled to the next place; this is much needed so as to put in the smallest space possible a certain quantity of fibre for easy and cheap carriage and transmission.

Buildings.—The work can be carried on under one roof or in separate buildings as the planter chooses; the spaces required will be for engine, cleaning machines, baling or press room, artificial drying room (the object of this is explained further on), and an open shed for the reception of the leaves from the field.—*Fiji Times.*

TEA IN 1890.

The violent fluctuations in exchange that accompanied the disturbance of the bullion market by the Windom Silver Bill have reduced commercial operations with the Far East, during the past year, very nearly to a gamble. With silver ranging from 44d to 54d an ounce, and the tael flying about like a shuttlecock between 4s 3d and 5s 3d, anything like sober calculation seems impossible. Yet 1890 will not, we believe, be remembered by China merchants as an altogether unsatisfactory year. Whether by good luck or good management, most things seem to have been "coming out." Certain classes of tea, for instance, have done well. Russian buyers failed to obtain all they wanted on the Hankow market, and completed their purchases in London at rates which gave a satisfactory profit to importers; common kinds have been in fair demand for "mixing" purposes, and the quality of the northern crop, at any rate, seems to have been on the whole better; so that dealers were less disposed to condemn China teas *in toto* as a doomed and depreciated quantity. With all this, however, the change in demand from Chinese to Indian produce has continued. The import of the former, which amounted to 93,000,000 lb. in 1888, having fallen to 83,000,000 lb. in 1889, and to 63,000,000 lb. for 1890; while Indian supplies rose from 73 to 74 and 79, and Ceylon from 20 to 28 and 40 millions respectively. The progress of the change is still better shown by certain statistics, recently published in our columns, giving the proportionate consumption in Great Britain, of China, India, and Ceylon tea, during each year of the thirteen from 1878 to 1890 inclusive. It will be sufficient for our purpose to reproduce here a few of the figures, to bring prominently out the ratio of change,

They are calculated to Nov. 30, and show the percentage of consumption of each kind of leaf.

	1878.	1881.	1884.	1887.	1890.
China ..	77	70	63	49	30
India ..	23	30	36	45	52
Ceylon ...	—	—	1	6	18

That there must be a limit to this decline very few will, we imagine, be found to deny. The reduction in stocks may indeed indicate that it has been approximately reached: for the falling-off in deliveries has not been commensurate with the decline in imports, and a decrease has consequently to be noted in the usual reserve. Many people still prefer China tea; many will drink no other, recognising in it a delicacy of flavour which neither India nor Ceylon can rival. But for the large majority, to whom economy is a prior consideration, the greater strength and flavour of the latter, and its capacity to go on throwing off highly-coloured liquid after several waterings, preclude any question of return to the old order of things. What is wanted—we cannot repeat it too often—is such an alleviation in China as shall give the grower, there, a chance of competing with his Indian rival. We have often pointed out that the increasing demand from Russia has compensated, so far, for the decline in England; but there has been a check, this year, even in that dispensation; and we decline to believe but that India and Ceylon will find a way of cutting into the Russian trade, also, if the Chinese Government persists in maintaining an export duty of nearer 30 than 5 per cent. *ad valorem*, and in allowing its provincial subordinates to pile on *tekin* in addition.—*L. & C. Express.*

NOTES ON PRODUCE AND FINANCE.

THE DUTY ON TEA IN AMERICA.—A telegram from Washington states that the Ways and Means Committee of the House has agreed to favourably report the Bill imposing 10 per cent duty on teas imported from countries which discriminate against the United States. The object of the Bill is to meet the discriminating duty levied by the Canadian Government on tea imported through the United States.

CHEAP TEA.—At a meeting of the Manchester Association of Wholesale Tea Dealers, the subject of inferior tea and unscrupulous advertisements came under discussion. One member thought the time had come when the tea-dealers of this country should warn the public against buying the shilling and one-and-sixpenny rubbish so extensively advertised as tea. The trade was doing itself an injury by quietly allowing such injurious rubbish to be retailed to the public, to say nothing of keeping down profits. It was urged that an effort should be made to show the public that it was really false economy to drink low-priced tea. The president said he thought it would not serve any useful purpose if the association issued a manifesto, for if he were a non-trader, and such a thing as deleterious matter in tea met his eye, he should feel inclined to give up drinking tea altogether. If any proposal were made as to the desirability of using good and genuine tea only, then he would favour such a proposal, but he was not disposed to sanction the publication of a manifesto. Ultimately the matter was referred to a sub-committee.—*H. and C. Mail.*

TEA CURING IN CHINA.

Those who are unacquainted with the method of curing tea in China may feel interested in the following extract from a paper on the subject read by M. H. Frandin, Secretary of the French Legation, at a meeting of the Oriental Society at Peking. Mr. Frandin, after describing the difference between black and green tea, said:—A description of the manipulation to which the tea is subjected will show the green tea is only distinguished from black tea, by the fact that the green has not been torrefied, or dried by heat, in the same manner as the black. The leaves once gathered are spread in light layers on straw mats. They are ex-

posed to the sun until they are withered. They are the put in bamboo trays, and are triturated by the feet. A part of the juice of the leaf escapes, and after this operation the leaves are exposed again, and again triturated and continually agitated. But the drying is still not complete. The drying is still continued in rattan cylinders, which are separated into two parts by a bamboo partition. Underneath the cylinder is a chafing dish of ignited charcoal. The leaves are thrown on the concavity of the separation, which is furnished with a cover. From time to time the cover is raised, and the agitation is continued. When the leaves are completely dried, the cultivator has finished his work.

The tea merchant then takes possession of the tea. He delivers the tea to women and children, who remove the stems of the leaves and the little wooden twigs which often remain attached to the young sprouts. For black teas the leaves thus cleaned are put again in the cylinders above described. They are again dried. They are then gently crushed by the hand, and the operation of heating, or torrefaction, is repeated until all the leaves can pass through a series of holes of different dimensions. The tea is then thrown into a winnowing machine, which separates the heavy from the light leaves and removes the dust. The light leaves and the dust go to make "brick tea." The green teas are first dried in the shade and afterwards dried in the same cylinder, but of which the concave separation is made by a plate of metal. Their colour is preserved by means of indigo. It remains, then, only to make the mixture of teas of different localities. The teas are boxed and shipped all over the world. Teas of first quality are nearly always the product of the first gathering. Sometimes, however, the second is good. Teas exported from Hankow have the generic name of "congou tea." The best comes from Ningchow, but it is also furnished by Hu Kuang and Ho-nan. The best black teas of Fukien are designated by the generic name of "congou tea" and "souchong tea." They come from the districts of Tenmon, Kai-si, Seng Obeng, Cheng Lock, Fockon, Pan Yang, You-kai, Pack Long, Pack-lun. The mean value of the congou and the souchong of best quality is forty taels the picul. Inferior teas of these grades bring 7 taels the picul. Dust tea varies from 3 to 5 taels the picul. The boxes generally weigh 287 kilogs. The superior teas are chiefly bought by the Russians. They are sent to Moscow by land, through Mongolia and Siberia and are called caravan teas. But a great deal of tea is sent by sea to Odessa. In the struggle of the Chinese merchants with the teas of India and Ceylon they mix teas of different prices. The largest part of their consignments ought not to cost more than 20 to 25 cents a pound, delivered in the London market. Frauds are sometimes practised and leaves of other shrubs are mixed with the tea leaves.

The brick tea business is exclusively in Russian hands. The two places at which it is manufactured are Fochow and Hankow. There are three kinds of bricks—(1) the brick of black tea imported into Siberia and some other Russian provinces; (2) the brick of green tea, much sought by the nomad tribes of China and Central Asia; (3) the tablet of superior tea sent to Russia. The brick of black tea is made of the leaves of the second and third gatherings, which are generally over-mature. It contains the light leaves, the stems, the dust, the twigs and residue of the superior teas left over from former years. These substances are all reduced to powder and mixed together. The quantity necessary to make a brick is put into a piece of cloth. This piece of cloth is passed, with its contents, during several seconds in a jet of steam. Then this moist dust is put into a wooden mould which has been covered with a light layer of dry tea powder of better quality than the contents of the cloth, and then is pressed in a steam machine. The brick comes out of the mould as hard as rock. It is dried on planks during fifteen days, and then it is wrapped in paper, properly ticketed, and sent to its destination. Usually sixty bricks are in one package. Bricks are made of different qualities,

The harder the brick the better it is appreciated by the people of Central Asia. It requires an axe or hammer to break one of them. The green brick tea is made in like manner, but of green tea. Green brick tea is made larger than the black. All the brick teas replace money in business affairs in Central Asia. The Mongols divide a brick into thirty equal parts. Each part is called "cha-ra." A sheep, for example, is worth 120 cha-ra, that is to say, four bricks. A brick in Mongolia being worth 15 to 20 cents, a sheep in that wild country would be worth 45 to 60 cents. The Mongolians boil water in a pot of metal, using camel dung for fuel. They break off a portion of a brick and throw it into the pot with milk, butter, sheep fat, and salt. After a few minutes of ebullition, the beverage is ready. Tablets of green tea are made dry, by means of a hydraulic press, out of congo of good quality. A tablet is divided into eight equal portions, like chocolate tablets. It weighs 110 grams (a gram is 15.438 grains troy). Owing to the facility of transportation and its conservation of its aroma, the Russian Government uses it largely for its troops.—*H. & C. Mail*, Jan. 16.

RAINFALL IN KADUGANAWA.

Mr. Wm. MacGregor of Gona Adika favours us with the rainfall, and writes:—The annexed memo. of rainfall for the Kaduganawa district during 1890 may interest some of your readers.

"A nice shower of rain fell last evening registering .90, and it is raining today again. The tea bushes wanted it badly, '75 registered this morning (5th).

MEMO.

	No. of days in each month of which rain fell.	Total rainfall.
1890—January	... 3 days	1.24

LIQUID GUTTA-PERCHA is made thus:—Gutta-percha in thin slices, 1 oz. chloroform, 8fl. oz.; carbonate of lead, in fine powder, 1 oz. Add the gutta-percha to 6fl. oz. of the chloroform in a stoppered bottle and shake them together frequently until the solution has been effected. Then add the carbonate of lead previously mixed with the remainder of the chloroform, and, having several times shaken the whole together, set the mixture aside and let it remain at rest until the insoluble matter has subsided. Lastly, decant the clear liquid, and keep it in a well-stoppered bottle.—*Indian Engineer*.

CINCHONA BARKS—It is strange to see by the following extract from *Chemist and Druggist* that not only Ceylon but Java and Indian bark have, on the average, fallen off in richness last year:—The following figures denote the average percentage equivalent in sulphate of quinine of the principal cinchona barks of commerce during the last three years:—

	1890	1889	1888
Ceylon cinchona bark	... 2½	... 2½	... 2½
East Indian	... 2	... 2	... 2½
Java	... 4	... 4½	... 4
Calieaya cultivated	... 4½	... 4½	... 4½

The following are the unit prices (in pence per lb.) of cinchona bark in London on January 1st of the last seven years:—

1885	1886	1887	1888	1889	1890	1891
6 to 7	4½ to 5	3½ to 3½	2½ to 2½	1½ to 1½	1½ to 2	1½ to 1½

GALL: CACAO.—It will be recollected that, a short time back, reference was made to the existence of cacao at Mapalagama, a little beyond Baddegama, where the trees were said by a correspondent to be of immense size and vigorous growth in spite of the dense jungle which surrounded them, and speculation was then rife as to who could possibly have introduced the product into the district. There can be no doubt that there are trees in the neighbourhood, the value of whose produce the natives have come to recognize to some extent, as a few days ago I am told quite a large number of pods were taken across the ferry, all more or less in an unripe condition.—*Local "Times."*

THE REVIVAL OF COFFEE.—Liberian Coffee clearings in 1891. We learn that, in spite of the alleged failure of Liberian coffee in Kalutara, two estates are opening clearings of it this year, the proprietors being confident that, at current rates and owing to the improving prospects before coffee generally, it will turn out a remunerative cultivation. An experienced Kalutara planter recently expressed the opinion that in topping Liberian coffee in the same manner as we had been accustomed to do the Arabian variety we made a great mistake. In his opinion the Liberian is a forest tree, and if left untopped and planted on suitable soil, would yield excellent returns. We shall watch the experiment with great interest, more especially as several Uva planters have recently expressed the opinion that coffee there was showing signs of a distinct revival owing, doubtless, to the reduction in the area over which it is cultivated. We sincerely hope this may prove to be the case.—*Ibid.*

THE RETURN OF MR. DAVID REID, at this time, when the export of tea has reached such large dimensions, is rather noticeable seeing that he was amongst the first to take up its cultivation on any considerable scale in Ceylon. In this connection it may be of interest to recall the fact that the first estate opened by Messrs. Reid, Rutherford, and Mackay was Dewalakande, in the Kelani Valley. This block of land had been originally acquired by them for the purpose of cutting sleepers for the Nawalapitiya section of the line which they constructed, and much valuable timber was felled by them from it and carted up to the Gingatenne Gap, and so on to Nawalapitiya for use as sleepers, etc. Not knowing what to do with the land, Mr. Reid was advised—by Mr. Jack Tyndall we believe—to plant it up with tea, and so nurseries were formed and the estate was opened. From this small beginning the large Company, which has since acquired so many valuable properties, grew; Mariawatto being afterwards laid down in tea. From that date these indefatigable pioneers of the new cultivation never slackened in their efforts to extend it, and how successful they were will always remain a record in our island's history.—*Ibid.*

A NEW FIBRE.—A new fibre plant has just been discovered that is claimed to be better than ramie. It is a native of the West Indies, having been found on the island of Trinidad. The great advantage possessed by this plant is that the ribbons at nearly all times of the year are easily despatched from the wooden portion by simply stripping them with the hand, and, therefore, a decorticating machine is not required as for ramie. When it is known how readily the stems allow themselves to be deprived of their coating of bark and fibre it will be seen what an advantage this simple fact gives the new product over many of the fibre-producing plants. All that is required is to cut the stems, which are fully ten feet long, split the bark at the larger end, and strip off the bark from end to end without stopping, as fortunately the stems have no side branches. Samples submitted to London brokers were most favourably reported on, and were valued at from £17 to £20 per ton. It is thought that ramie will probably be beaten by this new fibre, when cultivators fully realise the greater ease and consequent less expense with which it can be decorated.—*India Rubber Journal.*

Correspondence.

To the Editor.

INDIAN TEA EXPORTS.

Indian Tea Association, Calcutta, Jan. 12th.

DEAR SIR.—The General Committee have the pleasure to hand you their usual Monthly Return of shipments of tea from Calcutta, and also a Return of Exports of Ceylon Tea for four years up to the 22nd December 1890.

EXPORTS OF INDIAN TEA FROM CALCUTTA.

	1890	1889	1888
	lb.	lb.	lb.
Exports to Great Britain in Dec. ...	14,156,971	11,811,301	11,801,612
Exports to Great Britain from 1st May to 31st Dec. ...	84,428,533	79,935,589	79,340,409
Exports to Australia and New Zealand in Dec. ...	765,156	459,226	369,355
Exports to Australia and New Zealand from 1st May to 31st Dec. ...	4,233,168	2,837,075	2,397,100
Exports to America in Dec. ...	34,158	16,640	23,619

Total Exports from 1st May to 31st Dec. ...	89,592,929	84,185,627	82,465,156

—Yours faithfully, S. E. J. CLARKE, Secretary.

ARTIFICIAL COMBS FOR CEYLON BEES.

Glasgow, January 14th.

DEAR SIR,—I have read with interest in the *Overland Observer* of the 13th Nov. last an article on "Artificial Combs for Ceylon Bees."*

The artificial comb (or comb foundation as it is called) is made of a thin sheet of wax upon which the forms of the cells are impressed, and when first given to the bees it is not ready for the storage of honey. The bees have first to draw out the sides of the cells until they (the cells) are of the usual depth. This, of course, is a great saving of labour to the bees, as the manufacture of wax consumes much of their time and strength.

I do not know anything of the species or habits of Ceylon bees, but unless they differ considerably from those of the bees commonly used in England, (the common black, Ligurian, Cyprian Carniolan, &c.) I fear that, as a method of attracting bees, the hanging of combs in the vicinity of bungalows would not be attended with success.

Supposing that the habits of the Ceylon bees are similar to those of the English they will swarm at a certain time of the year. (In England it is generally in May or June.) The swarm should then be taken and placed in a hive previously fitted up with comb foundation, which the bees would speedily draw out and then commence work in the usual manner.

From your Directory I see that Ceylon "has several useful indigenous bees," and I should be interested by any information regarding the habits and species of these bees and if any have been

domesticated or kept in hives.—Yours, &c.,
APIS.

[We shall send our correspondent some of the back numbers of our *Tropical Agriculturist* with information about bees.—ED. T. A.]

CACAO CULTIVATION AND CRITICS.

Galagedara, January 21st.

SIR,—My attention has been drawn to a letter signed "1873" headed "Planting Notes for 1891" appearing in your paper of 10th inst.*

Under the heading "Cacao" your correspondent, who evidently has got to the bottom of most things, teaches the Galagedara planters *how to do it*.

There is an old and somewhat musty saying—"First catch your hare, then cook him."

Your correspondent tells us, first, how to grow cacao, and make it *crop* (a secret your t'otherest correspondent "Eldorado" appears not to have found out), and then proceeds to tell us how to catch, and afterwards cook, the wretches who steal our crops. Now, sir, it is all very well for "1873" to write to your paper, but I have one or two questions I should like to put to him through you:—

1st. Is it not a fact that he was the manager of the estate quoted by him as losing 50 per cent of its crops, owing to the depredations of thieves, for some time before the "easy-going office man" came out from England to take charge?

2nd. Did not the aforesaid "easy-going office man" oust "1873" for reasons best known to "1873" and the "c. g. o. m."?

3rd. Will "1873" state precisely what his experience has been in this country, with regard to planting cacao and shade: *i.e.* how many acres of cacao has he planted, and what return did he get, when his cacao came into bearing?

4th. Did he ever hear a thief on the Galagedara side, say of "such a one" (the English is "1873"'s not mine) "Don't rob that master, he is kind, is friendly with the headman, unmerciful when he catches us, and relentless in hunting us down. Let us go over to —," and so on?

5th. And, if he never heard a thief say this, (as of course he never did) why does he write such stuff?

I leave abler pens than mine to deal with "1873"'s strictures on coffee and tea growing; and enclosing my card, am, sir, your obedient servant,
GALAGEDARA CACAO.

DANDELION.

Pussellawa, Jan. 26th.

DEAR SIR,—Can you or any of your many readers inform me, if the dandelion plant can be got, and grown in Ceylon? I am anxious to try it, as it makes a very good salad.—Yours faithfully, UPPER NILAMBE.

[The plant is allied to ebicory. We have not heard of its being grown in Ceylon, but we do not see why it should not be successfully cultivated in our hill regions.—ED. T. A.]

COCONUTS:—A FREAK OF NATURE.

DEAR SIR,—Herewith a bunch of coconuts with three fruits, two of which you will find are like the king-coconuts, while the other is quite green, all in the same cluster and from a tree about 40 years old which hitherto never had anything but green-colored nuts, and have about four clusters at present all green-colored. One nut you will note is small; this I believe is attributable to rats making an attempt when the fruit was tender to eat it. There were two other green-

* See page 653.—ED. T. A.

* See pages 569 and 593.—ED. T. A.

coloured nuts on same cluster which unfortunately were destroyed by rats at their early stage. D.

[The cluster of nuts which are a curiosity can be seen at our office.—Ed. T. A.]

POULTRY DISEASE: A REMEDY WANTED.

DEAR SIR,—Can you or any of your correspondents give me some information as to the treatment of a disease which has appeared amongst my poultry? It may be described as follows:—Lumps all over the head, which increase in size until the bird is blinded by them when, of course, it dies of starvation. Some chicks were first carried off, and then it attacked and slew several promising young turkeys. Any advice as to the treatment of the disease will be most gratefully received by a DISCOURAGED HOUSEWIFE.

[This is no doubt the disease, so fatal to turkeys, regarding which we had several letters a year or so ago. Segregation and fumigation with sulphur or tar should be tried.—Ed. T. A.]

DANDELION.

Paradeniya, Feb. 2nd.

SIR,—Your correspondent "Upper Nilambe" can obtain dandelion plants from Hakgala gardens on application. We obtained seed from N. India in 1882, and in my annual reports for that and the succeeding year, will be found, under the heading "Taraxacum," a full account of its progress as a cultivation. The roots do not become very large in our poor soil; but the plant has already escaped from the garden and commenced to establish itself as a wild plant. I observed last September a large colony of it by the side of the Badulla road a little below Hakgala, and it will doubtless in time become a common weed in our high districts as it has already in the Nigiris.—Yours faithfully, HENRY TRIMEN.

OUR JUNGLE TREES AND OTHER PRODUCTS.

DEAR SIR,—Has it never occurred to you while walking through the jungles here, that during almost every month different kinds of seeds are to be found, and, how few planters can tell the names of the trees their seeds came from? These reflections have often led me to wish for some pamphlet or booklet on the subject; and I think, now that the Ceylon Government have so able a staff of Forest Officers, it might undertake the publication of a work in colored illustrations full size of the fruits so far as practicable, and of the seeds of the various useful trees now to be found in our jungles. Such a work ought to have a ready sale in Ceylon, but apart from that, it would be an immense boon to the European and English-speaking natives of the country. In addition to a description of the seed or fruit, there ought to be a short description of the leaves, bark, color of the wood and its uses.

How many planters in Ceylon have been deceived by rascally sawyers and shingle contractors? Is it not the case that many planters must trust to their carpenters' honesty or knowledge of the timber required for building or shingling purposes, and they are scarcely to be blamed if they have no means of acquiring the information, hence I think a booklet of the kind I refer to is much wanted. To give only one instance. The roof of a bungalow scarcely three years shingled with shingles said to be from one tree, is now in such a state of dry rot, that many of the shingles can be broken between finger and thumb like shortbread. The superintendent trusted to his carpenter's knowledge of suitable wood, as the best known shingle trees were perhaps not so plentiful as in the earlier coffee days.—Yours truly, AN OLD PLANTER.

["Old Planter" is making a rather large order all at once on the Forest Department: what is first wanted is a thoroughly reliable Guide

to the various Timber Trees and their native names. For this want, the late Mr. Wm. Ferguson's pamphlet deserves to be reprinted; but from Dr. Trimen's list, as now available, "Old Planter" might learn a good deal. Many Sinhalese can tell him their name for the tree on which any fruit or seed produced, grow and then by referring to the index, he would be able to get the Botanical name. Still there is no doubt that later on we may well look to the Government and their Forest Department for a useful Guide to our jungle trees and products.—Ed. T. A.]

RAINFALL IN KADUGANNAWA.

At the Gate of the Central Province, Feb. 7th.

DEAR MR. EDITOR,—I for one was interested in Mr. Wm. Macgregor's memo. of rainfall * at the Gampola end of Kadugannawa. I thought that the Bukanda hill would have attracted more rain than it appears to have done. Situated as I am in the centre of the district, I often envy my neighbours at Allagalla and Gona Adika, because the rain clouds seem generally to discharge themselves at the extremes of the district, leaving me to mourn over disappointed hopes. I also annex a memo. of rainfall, which may be of interest to someone, should you think proper to print it. I only commenced to keep a register from the middle of 1887, but the six months of that year show what ought to have been a heavy rainfall for the year.

The old district, so favorably known in the days of coffee, is being rapidly opened up for tea, and will yet come to the front. This is undoubtedly the elevation for indigenous tea, and it goes on flushing when all other jats shut up. There was some talk about Government opening up the roads from this to Gampola, but if they are not quick about it, they will have a difficulty in finding it when they do commence.

Kadugannawa village is fairly healthy, but I am surprised it is so, for the drainage and smells are abominable. If the Government Agent came oftener it would be a blessing. He was here the other day, and in anticipation of his visit huts were whitewashed, drains cleansed, and dirt put out of sight. When I saw the change in the aspect of affairs, I began to think that the Cesarevitch, at least, was to honor us with his august presence. We want a police station badly, and a responsible man to look after the sanitation of the place. The villagers on all sides are a lawless lot, and a fine field there is here within a radius of 4 or 5 miles, for the Salvation Army to work in, but they prefer to have a meeting occasionally for the English-speaking population, and the big drum is regularly beaten in the street to the great delectation of the little boys. Excuse these disjointed notes.—Yours truly, KADUGANNAWA.

DECREASING RAINFALL IN MASKELIYA: THE DRY CYCLE?

Deeside, Maskeliya, Feb. 9th.

DEAR SIR,—The rainfall on Laxepana for last year, (see page 621) as against previous average, took you evidently by surprise; but I fancy the rain deposit is greatly decreasing all over the district. On this estate a nine years' average 1874-1882 gives 137.06 inches with a maximum fall in 1877 of 183.83 in. and a minimum in 1875 of 119.55 in. The record of rainfall was continued to end of July 1883 and shows for the 7 months 88.00 in. After that the record ceases until end of 1889, and the 1890 complete record gives a total of 89.92 in., or 47.14 below the 9 years' average and 29.63 below the minimum of the 9 years and no less than 93.91 below maximum of that period.—Yours truly,

WM. MITCHELL.

P.S.—I fear your idea of the gauge being in different positions won't hold "water."

CENTRAL AFRICA COOKERY.—As a rule, only one principal meal is eaten in Central Africa, in the early part of the evening. It usually consists of parrot soup, roasted or stewed monkeys, alligator eggs (also well liked by Europeans), and birds of every description. They also have moambo, or palm chops, and fish. A great delicacy, so considered by Europeans and natives alike, is elephant's feet and trunk. These have somewhat the taste of veal. To prepare them, the natives dig a hole about five feet deep in the sand and in it build a large fire. After the sand is thoroughly heated the fire is removed, leaving only the ashes in the hole. The trunk and feet are placed in this hole and covered with leaves, and afterward with hot sand. In two hours they are done. All carcasses of animals which are to be cooked are placed on a block of wood and pounded until every bone is broken, care being taken not to tear or bruise the skin. They are then boiled or roasted on an open wood fire or in hot sand or ashes, without removing the hide or feathers. The cooking is of a very inferior grade, the only spices used being salt and pepper. The kitchen utensils consist of common earthen or wooden ware. Very little time is taken for setting or decorating the table; knives, forks, and napkins are dispensed with. Africans have several vegetables well liked by Europeans. N'gutti-u-sengo is a dish eaten all over Africa. It consists of egg-plant, small fish somewhat like our sardine, and the roots of the cassava or manioc plant (called n'gutti), which have a knotty appearance and often weigh as much as twenty pounds. As the latter contains poison, the manioc is soaked in water for three or four days to extract the poisonous substance. It is then cut and sliced, and small tomatoes are added. All is placed in a vessel with water, and seasoned with salt and pepper, and boiled. Moabo, or, as the Europeans call it palm chops, is also a favorite dish. The palm nuts are first boiled in water, until the pulpy substance loosens from the pit, then the shell, which contains a very delicious oil, is placed in a wooden mortar and crushed to obtain the oil. Whatever the meal consists of—meat, fish, mussels—is put in a vessel, adding the oil and the pulpy part of the palm nut, also red pepper and salt, and is boiled. Roast or boiled squash (loenge) is generally eaten with it. Sweet potatoes (m'balla bengia) are more farinaceous and sweeter than ours, but do not taste so good. They are boiled or roasted. Bananas (bitaboo) weigh about half a pound each and are about fifteen inches long. When half ripe they are cut in slices and boiled in water with salt and pepper. N'sinsi is a little red bean, which is boiled in water without salt or pepper, and is freely eaten. For peanut bread (chisula) the peanuts are first roasted and then crushed. This mass is then rolled and put into the skin of a banana, adding a little pressure, forming it into a loaf. It readily retains this shape from the pressure of the oily substance in the peanut.—*New York World.*

THE FOREST IN DEHIGAMA'S CLAIM is about 5,000 acres and there are 4,000 acres of patana which would grow very good tea indeed I should think. The total amount is only 12,000 acres and really the fuss made about it is out of all proportions to what it is—many a larger claim has been admitted to natives, but they oppose simply because Europeans have got it.—*Cor.*

EXTENSION OF TEA CULTIVATION IN HAPUTALE.—Mr. Lipton, the proprietor of the estates known as the Dambetenne group, is rapidly extending the cultivation of tea on his places. Nearly 200 acres of forest on Dambetenne and Monerankande estates are to be felled and cleared and tea planted on them during this year.—A new tea factory is to be built on Meriabedde estate, of which Mr. E. H. de Winton is superintendent.—*Cor.*

IN THE NORTHERN TERRITORY the only thing which was found to keep the white ant pest in check was a mixture of flour, sugar, and arsenic, mixed to the consistency of putty with water. A small piece of the mixture should be placed wherever the nest is known to exist. If an examination is made a few days after using this remedy thousands of dead ants will be discovered in the vicinity of the poison.—*Mildura Irrigationist, Jan. 7th.*

CEYLON TEA AT HOME.—Some time back I mentioned that a firm of Mitcing Lane Tea retailers were arranging for stumping the country in the interests of Ceylon tea. The campaign is opened, and on Wednesday night Mr. O. S. Hicks appeared on the platform at the People's Palace and delivered a lecture, illustrated with a large number of lime light views of Ceylon. Mr. Hicks is well known to the habitues of the Lane as the proprietor of the "Dalukola" tea which is, I believe, packed in Colombo by Messrs. Leebman & Co. Another new agency for the distribution of Ceylon tea, has appeared on the scene under the title of the Agra Ceylon Tea Association. This association "guarantees that all its teas are exclusively derived from the four celebrated tea gardens on the estates in the Island of Ceylon, belonging to Mr. H. R. Farquharson, M. P." Numerous branches are said to be in the course of being started and a shop has been already opened in Middle Street, Yeovil. Good luck to Mr. Farquharson and his tea shops!—*London Cor.*

THE DAIRYING INDUSTRY OF VICTORIA has a special interest to us in Ceylon, since if we only could get supplied with butter and cheese, as well as fruit and other produce from the Southern Colonies, the inducement to take off larger quantities of our teas would be greatly increased. Mr. Deakin handed us a paper with a Report on the Victorian Dairying Industry and we quote to show the enormous quantities of butter which passes our door to the United Kingdom. Not only Ceylon but a great part of India might be supplied by shipments through Colombo. We quote as follows:—

I also submit report of the shipment of this seasons surplus butter to England, consisting of 10 shipments. The shipments began with the steamer "Victoria," which sailed on 11th Oct., and the last was by the S. S. "Massilia" on the 17th Jan. The Orient Company's steamers took the remainder every fortnight between these dates. The department gathered it at the refrigerating works, Newport, from all parts of the colony, to be frozen or chilled in terms of the company's regulations previous to shipment. The total quantity sent is 731 tons—nearly double what we considered an enormous export last season, consisting of 21,954 56 lb cases and 17,827 70 lb kegs. The merchants supplied fully a third of this large quantity with what is known in the trade as "mixed butters." Farmers' small lots arriving weekly in a glutted market are bought up, resalted and packed, and where this is done with skill before the butter is stale a fair article is produced. From news to hand of five shipments, we learn that £5 10s and up to £5 16s per cwt., has been obtained. This must be very satisfactory to producer

"APIARIAN":

ARTIFICIAL COMBS FOR CEYLON BEES?

It is marvellous in how many ways the advance and application of science touch industries even the most primitive all over the world. The suggestion we make today (Nov. 5, 1890.) is to take advantage of modern scientific advance in the method of collecting the honey of the wild bees which so musically fill the vast forests of our inland districts with their continuous humming. Our attention has been called to this subject by one who tells us how struck he has been by the large advance made in the quantity of honey exported from Italy since the introduction and use of artificial combs. We believe that it has long been a subject of complaint that many—perhaps the greater part—of our forest fires are due to the means employed by the native bee-hunters to secure the object of their quest. As each year demonstrates to us the necessity for careful Forest Conservation, this particular point becomes one of much importance, and it is one that Colonel Clarke and his Deputies will have carefully to consider and, if possible, deal with. Every traveller through our jungles is pretty sure to come upon one or more trees during the course of his day's journey which have been manifestly destroyed by fire, and it has simply been a fortunate chance, due generally to weather conditions at the time of ignition, that a case of isolated destruction has failed to initiate a far-reaching conflagration. Although along many frequented lines of travel such burned trees have mostly been lighted by the fires of passers-by carelessly placed, those so often met with in the inner recesses of the forests have as a rule been destroyed by the efforts of the bee-hunters to smoke out their intended victims.

We are told that nearly all the honey now consumed in England is derived from artificial combs, in which it is largely imported from the Continent of Europe. It would, therefore, certainly appear that a useful industry might be developed by offering to the Ceylon bee, which provides us with such exquisitely delicate honey, an opportunity for storing his hoards without incurring the preliminary labour of constructing his "safe deposit" cells. The Italian bee, with the keen instinct of his kind, has almost abandoned the labour of cell-making. Directly he lights upon the artificial object, attracted to it by a bait of a dab or two of honey, he recognises the luxurious provision and straightway sets to work storing his honey, and produces,—owing to this saving of his preliminary labour,—more than twice the quantity he could before overtake. We should think that the men who follow the very laborious and risky occupation of bee hunters in Ceylon would gladly see around their huts the millions of bees which, if tempted at the proper season, would swarm to the artificial combs provided for them. We have described the occupation of these men as a risky one. It is essentially so. It is rare in the remotest districts to see a bunter free from scars—the result of his combats with the bears who share with himself a strong desire to secure wild honey. From such contests the comparative domesticating of the wild bees would free the hunter, and his harvest would be a fuller one, be gathered with infinitely less of labour and exposure, and with more of certainty. There is one thing, perhaps, to be said which might negative the advantages we have pointed out, and that is that the production of bees-wax would be lessened by the use of artificial combs. What proportion of value exists between the honey and the wax yielded by a certain weight of comb we do not know, but we should presume the value of the honey must largely preponderate. Meantime, to make a beginning in the experiment, some useful result might follow if one or more of our Assistant Government Agents resident in the bee districts would procure and hang some artificial combs around their bungalows. They would soon have many pleasant neighbours in their comparative solitude, and success might lead to a very wide and paying adoption of their novel devices.

THE ACTION OF LIME ON CLAY SOILS.

That lime promotes the fertility of heavy clay soils is a fact that has for many generations been well known to all agriculturists; but the scientific reason for the beneficial action arising from its application has not, to the best of my belief, been at any time at all satisfactorily explained. The question, however, remains one of first importance in the science of soils and I therefore make no apology for offering an explanation, or rather theory, which, to my doubtless, somewhat partial mind, seems to go a considerable way towards the elucidation of the problem.

I take it for granted that all interested know that a clay soil is not by any means a pure clay (hydrated silicate of alumina), but a mixture of *impure* with pure clay (much more of the former than of the latter), plus sand, iron oxides, organic matter, &c. The clays which form its bulk have been derived from the natural decay or weathering of mineral silicates, containing, besides, aluminium, alkali, or alkaline-earth metals, and they occur in it in all stages of impurity or further decomposition. As an invariable rule, other things being equal, the greater the normal impurity of the clays the greater the fertility of the soil. A *pure* piece of clay is like pure quartz-sand—so much dead, inert matter; a plant can make nothing of it, can take nothing from it. In no fertile clay soil, however, even of the heaviest description, does there occur at any time more than about 10 per cent. of *absolutely* pure clay. Well, then, what is the composition of the average clay particle? That depends on the mineral from which it was derived. If from the felspars, its most common origin, it will be a hydrated silicate of alumina plus silicate of potash, or, instead of the potash, soda and lime. I will suppose, for brevity's sake, that my clay particles have the former composition, and the explanation which I will offer with regard to their behaviour can be applied with very little difficulty to any of the other cases. Clay particles of the above composition, when subjected to the action of water containing carbonic acid gas, lose potash. That I have repeatedly proved by experiment. If the carbonic acid is in fair excess, it comes away altogether as carbonate of potash; but if there is not a sufficiency of this anhydride, it is liberated partly as soluble silicate of potash (soluble glass). Should lime, however, in this latter case be present, the practically insoluble calcium silicate will be constituted, and the potash freed to form a soluble salt with any other acid that may be present and available, such as carbonic, sulphur, nitric, &c. A grass plant growing in clay soil does not, it is evident, send sufficient carbonic acid through its root-hairs into the soil, as many other plants do, to completely convert the liberated potash into carbonate, and the consequence is that the soluble silicate of potash which is permitted to form is drawn into the vegetable, as well as the carbonate of that alkali. Now silica and silicates are decidedly injurious, to all vegetables doubtless, but particularly to agricultural plants. I say injurious; the day has gone by for considering silica an essential, or useful, or even a merely innoxious accessory. A little examination of the plant-physiology shows that it is injurious. The organism tries to get rid of it as speedily as possible—that is, at least to get it out of the way of its general circulation; it unfortunately has no means of casting it off altogether. Here, I need scarcely refer to the well-known experiments which have, over and over again, conclusively shown that the grass plant does not require silica as a supporting or strengthening material. Now we come to see the use of lime in the clay soil, especially in the case of the cultivation of cereals and pastoral grasses. The lime added and mixed up with the soil acts on the soluble silicate of potash as it is formed, and combines with the silica, constituting, as I have already remarked, the practically insoluble silicate of lime, which, of course, being normally indissoluble in the soil, cannot pass into the body of the plant. Therefore, the organism profits by its exclusion, and as a consequence so does the farmer. The energies of the plant are not spent in getting rid of silica if there is

no silica to get rid of, and its ordinary processes of nutrition can progress uninterruptedly.

The breaking up of the soluble silicate* could be as well accomplished by the perfect aëration of the soil so that every particle could be constantly exposed to fresh portions of aerial carbonic acid and oxygen; and this is one great reason why fine deep tillage, where it is possible, so improves clayey soils, but of course a tillage that will bring about the perfect aëration of heavy clay, is all but impossible; therefore the advantage of judiciously using lime.

The soluble alkaline silicate which, when undecomposed, passes into the plant in the water-stream through the roots, is evidently very soon split up by the vegetable, and the silica combined with some substance, such as an aldehyde, and carried on in solution in this state to the peripheries of the stem, &c., where, by the process of practically unrestrained evaporation, the compound is again split up, the aldehyde going off into the air, and the solid silica remaining stranded in the cuticle and the other walls, or occasionally even in the cavities of the epidermal layer.

The silicate of lime formed in the above reaction itself ultimately undergoes decomposition by natural water containing carbonic acid, but the decomposition is always complete; it devolves entirely into carbonate of lime and free insoluble silica.—ALEXANDER JOHNSTONE, Edinburgh University.—*Nature*.

COFFEE CULTIVATION IN SOUTH AMERICA:

A SYNDICATE ORGANISED TO EXPLORE THE EASTERN SLOPES OF THE ANDES.

This mail brought us a letter from an ex-Ceylon planting friend announcing that there was a project on foot in London to send out an exploring or pioneering party to Peru with reference to taking up land suitable for coffee. The great prospective scarcity of this article—prices even now approximate to 140s a cwt.—forms the special inducement or this mission. Its inception seems to be due to men of high commercial standing in "the City" and among the supporters named to us are Sir Alfred Dent and Sir Hugh Low. So much for the mail news contained in our private letter; but a new and more practical interest is given to the scheme by the fact that the London Syndicate have telegraphed out to Ceylon to get the services of Mr. P. D. Clarke of Dr. Trimen's staff, to join the exploring party. Mr. Clarke who is a son of a well-known Curator of the Glasgow Botanic Gardens, has now been 11 years in Ceylon, giving faithful though unobtrusive service for all that period without any leave of absence, in our Royal Botanic Gardens. Under these circumstances, the Government could scarcely do otherwise than grant the leave of absence required to enable Mr. Clarke to discharge the temporary duty now required of him. He gets leave for nine months and goes to London by the Orient steamer "Cuzco" tonight. The expedition so far as Mr. Clarke knows is bound for the Eastern slopes of the Andes near, curiously enough, to the town of Cuzco and no doubt advantage is to be taken of the trans-Andean railway to make the West coast the outlet of such plantations as may be established. The only other member of the Expedition so far as Mr. Clarke knows is Mr. J. L. Shand and "coffee" culture is the main, if not the only object in view. No doubt the duty of Messrs. Shand, Clarke and their colleagues will be to

* Only the alkali metals, of which potassium and sodium are the only two that normally occur in soils, form silicates soluble in water.

report on the fitness of available land for plantation, on the climate, soil, means of access, labour, &c. Possibly, if all go well, nurseries may at once be established and clearings be commenced. With Sir Alfred Dent on the Syndicate, we should suppose there may be an idea of importing Chinese as labourers.

In Ceylon, Mr. Clarke in a quiet way has been giving a good deal of attention to coffee. He strongly shares our opinion that planters of Liberian coffee some ten years ago were in far too great a hurry to give up the cultivation. His own experience last year on half-an-acre planted with Liberian coffee at Peradeniya is worth giving: it is that he netted R222.62 from the crop off half an acre. Allowing for special attention to the trees, there is margin enough here surely to encourage any one to go in for Liberian Coffee on suitable areas of soil in Ceylon.

Meantime we hope to have interesting intelligence of the doings of the Trans-Andean Coffee Expedition of 1891, and we wish the party all success.

COCONUT CULTIVATION IN THE INTERIOR OF THE WESTERN PROVINCE

1890.—The coconut crop of the district has been an average, and the price of copra has kept well up, so that, on the whole, proprietors with mature estates have nothing to complain of; but the deficient rainfall from May to October will tell against the outturn of 1891. That is the season of the heaviest gatherings, and the rainfall at that season regulates the crops of the corresponding months of the following year to a great extent.

Towards the end of the year, leaf disease reappeared, but not nearly to the same extent as two years ago. In some few cases the same trees are affected as suffered then, but not all, and some fresh cases, nothing of any consequence, however. I believe it to be the result of drought on stiff soils that too easily yield up their moisture.

1891 has opened well in the way of rainfall, January having given 3.14 inches and it is thundering all round while I write. W. B. L.

PLANTING IN GUATEMALA.—We learn that Mr. W. J. Forsyth, formerly of Maturata, is getting on well as manager of extensive coffee and cinchona plantations in Central America. Labour is the chief difficulty. We hope to have a letter ere long, bringing up Mr. Forsyth's experience from the date of his last communication.

A THIRTY-FIVE YEARS' CYCLE of wet and dry periods alternately has just been worked out by Herr Bruchen, who shows that,—

In Western Europe and Eastern North America the wet period, he shows, gives from a sixth to a fifth more rain than the dry period. In Siberia and the Far West of North America they give a third to a half more rain. Since 1870 the world has, in his opinion, been passing through one of the wet periods, which has produced bad harvests on the seaboard but greater fertility in the middle parts of the continents. During the first 20 years of the next century he expects another dry period to come, having an annual humidity of from 15 to 20 per cent. less than at present. Herr Bruchen also endeavors to show that the great general migrations of mankind are and have been connected with these periods.

But in the tropics and Ceylon especially, Herr Bruchen would find eleven year cycles nearer the mark for the alternations.

A MINCING LANE SALE ROOM.

The *Daily Graphic* gives an engraving entitled

The Tea Trade: Business brisk at Minoing Lane Sale Rooms yesterday:

"Capel" is in the box. A sample of "the precious stuff" appears on high, and in the foreground is a separate engraving of

Mr. J. Hillyard the dealer who bought the famous sample of Golden Tip.

The letterpress is as follows:—

There is an old story afloat of a Stock Exchange "plunger" who, finding things dull in Capel Court, and hearing of big operations in Mincing Lane, got a "tip" in pepper. Visiting the sale rooms and inspecting the samples, he is said to have given an order for "1,000 tons" of his selection. The remarks of the broker are not recorded. Though dealings are, it need hardly be said, not quite on this colossal scale, there is plenty of excitement to be had in the various produce markets which centre in the Commercial Sale Rooms. The sale of a consignment of tea last week at the astonishing price of 107s. per pound has attracted a good deal of attention to these markets, and revealed interesting possibilities of business and profits of which little is generally known.

Minoing Lane is not as exclusive as the Stock Exchange, and the general public are admitted to the sale rooms if accompanied by a member. On the ground floor is a large hall with a few circular seats surrounding the iron columns of the building. Boards on the walls for quotations and telegrams complete the furnishing, and at one end of the room at a lower level is a spacious refreshment room and bar. Tea seems the favourite beverage in the afternoon, as befits the locality.

The sale rooms, of which there are several, with distinctive numbers, are on the upper floor. Each is fitted with a rostrum, and the desks and seats ranged in a semi-circle and sloping upwards afford an uninterrupted view for all members presented. Catalogues are printed for each sale, but the samples which have been offered for inspection and tasting—in the case of tea—previously are not shown at the time of dealing. The noise and excitement during the bidding far exceed the ordinary notions of sales such as are gleaned from a visit to Christie's or other auction rooms. A strong dash of the betting ring seem to be here infused, and the eagerness of the bids is accounted for by the large amounts at stake. The presiding genius in our sketch is Mr. Capel, of Messrs. Arthur Capel and Co., known as the Father of the Tea Trade, and among the other members several of the leading *habitués* of the rooms will be recognised.

With reference to the special consignment of tea which has created so much interest, we learn that it was comprised in boxes of 5 lb. each consigned to this market from the Gallebadde Estate, Ceylon. Great care had been expended in its production, and the price at which it was knocked down yielded, it appears, a profit to the purchaser, who succeeded in reselling it in the course of the day £5 10s per pound. It is calculated that this represents a cost to the consumer of 1s 7d per cup, which would not be an out-of-the-way price for many descriptions of wine.

CEYLON TEA AT 110s.

Tea at one hundred and ten shillings a pound! It appears that on Tuesday last a consignment of Ceylon tea of superb quality was put up for sale in the City of London, which experts pronounced to be the finest article of the kind ever offered under the hammer. The competition for this unique specimen was so keen that the greatest excitement was occasioned by it, and the lot was at last knocked down at eighty-seven shillings per pound—a figure which during the present century had never been approached in the annals of the tea trade in this or any other country. A letter which appeared yesterday from Messrs. Whitworth, Hillyard, and Wade states, however that they were the purchasers at auction of this marvellous consignment, for

which they gave eighty-seven shillings a pound, and that they have since resold it at one hundred and ten shillings—at which figure its cost to the consumer would be about one shilling and sevenpence a cup. Untiring care and attention must undoubtedly have been bestowed on its growth and preparation in the Gallebadde district of Ceylon, as the leaves are of the brightest golden colour, almost resembling small lance-shaped pieces of the precious metal. We wonder what Dr. Johnson would have thought of serious business men who, at the end of the nineteenth century, would consent to purchase at the fancy price of five pounds ten shillings per pound that leaf which when infused with hot water he loved so well to drink! There is nothing more astonishing than the rapid growth in the consumption of tea by the population of these islands. In 1840, for instance, the tea imported into this country amounted to thirty-eight million pounds, while thirty years later it had grown to one hundred and forty-one millions, and last year it reached nearly one hundred and ninety millions. While our lively neighbours across the Channel and our kinsfolk on the other side of the Atlantic clamour for coffee as the only non-alcoholic beverage which is worth drinking, and denounce tea as "oat-lap" fit only for invalids, the teapot becomes annually more and more of a British institution.

It was one of the best and most sagacious provisions made by Mr. Disraeli in his unfortunate Budget of 1852, which brought Lord Derby's first Administration to a disastrous close, that he suggested a large reduction in the tea duty. On accepting office as Chancellor of the Exchequer Mr. Disraeli found the tea duty at two shillings and twopence farthing in the pound, which he proposed to reduce to one shilling and twopence. Upon succeeding to the Exchequer Mr. Gladstone accepted his predecessor's proposal, remarking in 1853 that he would have gladly reduced the duty by a shilling but for the condition of the Chinese Empire, which was not as favourable to a large extension of supply, as he could have wished. "We cannot," remarked Mr. Gladstone, "entertain sanguine expectations that any very large additions to the quantity of Chinese tea available for the wants of this market will be forthcoming in the next twelve months; but we hope that in a couple of years from now an adequate increase of supply may be relied on from the Celestial Empire." In a subsequent Budget Mr. Gladstone reduced the duty from one-and-twopence to one-and-fivepence in the pound, but it was not until 1863 that, holding up in his left hand a small packet of tea marked one shilling and fivepence, and in his right hand a much larger packet marked one shilling, Mr. Gladstone showed in his Budget of that year how much the reduction of the duty from one shilling and fivepence to one shilling in the pound would redound to the advantage of the purchaser. Two years later the shilling duty was further reduced to sixpence, and so remained until in his last Budget Mr. Goschen made a further concession of twopence in the pound. The result is that the consumption of tea in the United Kingdom has kept pace steadily with the successive diminution in the duty which, catering for the poorest classes of the population, it is the ambition and policy of each successive Chancellor of the Exchequer to continue. Every one is aware that excellent tea is now to be obtained at two shillings, or even at one and sixpence per pound, and it will startle the humble consumer to read that more than one hundred shillings per pound have just been paid for a consignment from Ceylon. In his recent speech at Hawarden, Mr. Gladstone stated that tea now cost one-quarter, and sugar one-sixth, of the price they commanded fifty years ago. Tea, in its rapid advance to ever-increasing popularity, has never been exposed to the attack by which coffee was at first assailed. Thus, we read in Messrs. Thornbury and Walford's "Old and New London" that the rainbow Tavern in Fleet-street was the second coffee-house opened in the Metropolis. Four years before the Restoration, William Farr, a barber, began to offer coffee for sale next door to the Rainbow, trusting to the young barristers in the

Temple for support. It was not to be expected however, that the vintners and liquor-sellers in that bibulous neighbourhood would submit tamely to the introduction of a non-alcoholic beverage. Pretending that their neighbours disliked the smell of the roasting coffee, the Bonifaces of Fleet-street indicted Farr as a public nuisance, and endeavoured to force him to shut up his shop. The indomitable barber, nevertheless, persevered in the teeth of their opposition, and the "Arabian drink" soon became amazingly popular. A satirist, who sympathised with the good old drinking days, was compelled to write regretfully: "And now, alas! the drink has credit got, And he's no gentleman that drinks it not."

Although tea was much slower than the "Arabian berry" in "catching on" with the public, yet having once made a start it soon outstripped its more exciting brother. On the 28th of September, 1660, Samuel Pepys writes in his "Diary": "I did send for a cup of tea, a China drink of which I never had tasted before"; and a little later he adds that, on reaching home, he found his wife engaged in making "tee"—"a drink which Mr. Pelling, the potticary, tells her is good for her cold and defluxions." At that time the price of a pound of "tee," which was almost universally pronounced "tay," was from six pounds sterling to ten pounds; and the consumption was sufficient in 1669 to induce the East India Company to import "the new commodity" for the first time. Their importations came straight from the Flowery Land; but in 1666 Lord Arlington brought over a large consignment from Holland, and sold it as a particular favour to his friends at sixty shillings a pound. It is reported, indeed, by Mr. John Timbs that the first cup of tea ever made in London was drunk by Lord Arlington in Buckingham House, which stood on the site now occupied by Buckingham Palace: Following his Lordship's example, Garraway, the founder of the celebrated coffee-house in Exchange-alley, issued a shop-bill proclaiming that "Tea hath already been sold in England in the leaf for six pounds and sometimes for ten pounds the poundweight, and in respect of its former dearness hath only been used as a regalia at great feasts and entertainments. The said Thomas Garraway did therefore purchase a quantity thereof, and sold it in the leaf from sixteen to fifty shillings in the pound, making it into a drink, according to the directions of the most knowing merchants and travellers into those Eastern realms; and upon experience of his continued care and industry in obtaining the best tea and making drink thereof, very many noblemen, gentlemen of quality, and physicians have sent to him for the same leaf, and daily resort to his house to drink thereof." The experienced tavern-keeper well understood what is often forgotten in these days—that no one can make a cup of good tea without bestowing time, thought, and attention upon the brewing thereof. The demand for tea in now so enormous that other countries have come into competition with China, and more of the leaf is imported from India than from the Celestial Empire. Last year Ceylon alone supplied nearly thirty-three million pounds out of our total consumption of about six times that amount. The amazing price just given for Ceylon tea will undoubtedly stamp it as the best in the world. The Chinese drink has superseded the Arabian to such an extent that there are said to be five consumers of tea against one of coffee in the United Kingdom; and so abundant are the sources of production whence this necessary commodity can be drawn in the future that there is little danger of the humble tea-drinker having to give a higher price for "the cup which cheers yet not inebriates" than she has paid in the past. There is but one country—Australia—which, relatively to population, is a larger tea-drinker than the United Kingdom, seeing that at the Antipodes the annual consumption is at the rate of nearly eight pounds per head, while in this country it is rather less than five. We trust that the tea-planters of India and Ceylon will be encouraged by this extraordinary sale to aim at quality as well as quantity in their future productions.—*Daily Telegraph*, Jan. 17th,

THE HILL-COUNTRY PLANTING REPORT.

MARVELLOUS SALE OF GALLEBODDE GOLDEN TIPS

has brought me the following letter from Col. H. Byrde:—

"Goytry, W. Pontypool, Jan. 22nd.

"In case you should not have received an article published in the *Daily Telegraph* upon a sale of tea from Gallebodde, I venture upon the privilege of old associations and 'ancient' friendship gives me, to send it to you as a clipping from the paper, and as likely to be interesting to you personally, and to the many readers of your valuable paper who are now engaged in the new enterprise of tea cultivation, in which, I am thankful to say, that I have a small interest, for it seems part of my happiness to be still engaged in some enterprise in a country where I began to plant coffee at Black Forest now 55 years ago, and in which I have never been without some agricultural interest.

"Alas! one after another of our old friends are called to their rest, and only last week my dear old and valued friend and brother officer for many years, was called home, Major-General Wm. T. Layard, one of the most genial and pleasant men the Rifles ever found, an excellent officer and a good Christian. We were subalterns together and were associated in after life, and while I mourn the loss of a friend, I cannot but feel that he is one more gone to the heavenly home, whither we shall soon follow.

"I have been glad to see from time to time that you are still blessed with health and strength for the duties of life, and I am thankful for the same blessing, and am actively engaged in County Council work and Magisterial duties, and feel that I, too, should soon 'subside' had I no longer an abundance of work to do; and your weekly issue is more and more valuable as years pass on."

It is surely interesting to know that there is a man living who commenced

COFFEE PLANTING FIFTY-FIVE YEARS AGO,

and who, having seen the collapse of the once great enterprise, with which, from its beginning, his family was so closely connected, has survived to have an interest in what promises to be the still greater enterprise of tea. My own connection with forest pioneering and coffee planting dates back to just the half-century. I was in the Ambagamuwa jungles, then only touched by the axe on their outskirts, in May 1840. In December of that year I entered Uva; and by May I had cut the boundaries of nearly 4,000 acres and "put in" a couple of nurseries. The article sent by Col. Byrde (which you will insert in the proper place) is interesting. We cannot, however, meet the wishes of English writers by growing golden tips any more than the superintendent of a coffee plantation could obey a proprietor who ordered him to

GROW ONLY PEABERRY.

They have a similar story in Australia of the owner of a pastoral run who gave instructions that only "wethers" were to be bred. The crusade against coffee on its first introduction as a beverage reminds me that in my boyhood I read in one of Mrs. Trimmer's books of advice to domestic servants to avoid tea as they would poison and to stick to good honest beer! As an advertisement this astonishing sale of Gallebodde tips must further

THE INTERESTS OF CEYLON TEA,

and I suppose the entrance of Sir Graeme Elphin, stone and Messrs. Figg and Powell Jones in the directorate of Horniman's Tea Company indicates that henceforward Ceylon tea will be more largely than ever distributed by that firm.

PLUMBAGO MINING IN CEYLON BY A NEW COMPANY.

Mr. A. Y. Daniel, Auctioneer and Commission Agent, writes:—"I have to report sale this day by auction of 17 tons uncured plumbago belonging to the Gemming and Mining Co. of Ceylon, Limited at £185 per ton."

A NOVEL ADVERTISEMENT FOR CEYLON TEA.

Our contemporary of the London *Daily Graphic* must, we should think, have been somewhat "cornered" for a subject for its illustrations when it gave place to what, it must be presumed, was a *post factum* sketch of the scene in the Mincing Lane tea-sale rooms on the occasion of the bidding for the lot of Gallebodde tea which has recently fetched such remarkable and previously unheard-of prices. However, there can be no reason why we should decline to welcome such an advertisement of our teas. It will, doubtless, have done much to attract public attention to the high excellence of our island produce, and will almost certainly have induced many to give it a trial—a trial which we may feel confident will go far towards extending the popular taste for Ceylon tea which has been of such rapid spread throughout Great Britain.

Nor, while giving prominence to this particular instance of pictorial advertisement of a group of excited gentlemen all anxious to become the buyers of what is perhaps in itself only a curiosity, should we overlook what has become the subsequent career of the tea itself. Our London correspondent gave us previously a letter to the editor of the *Times* broaching the subject, and he has since sent us an advertisement inserted in the same journal by the United Kingdom Tea Company which was the buyer at second hand and at the unprecedented price for tea of £5 10s 0d per pound, inviting the visit of the curious in such matters to view the sample. Both these notices cannot fail to receive much of public attention, and they must consequently, whilst economically advertising the purchasing Company, enlarge the borders of the popular estimation in which Ceylon tea is held. For all this "much thanks" to the proprietors and manager of the Gallebodde estate! It must remain, however, a moot point, whether those gentlemen will have benefited themselves in anything like the same degree that they have benefited the industry of which they are representative. Our home correspondent quotes to us the opinion of a well-known expert on the subject of this lot of tea, that this particular lot of tea can only have been produced by the sacrifice of the quality of a considerable portion of the estate production. We are informed that the full payment made by the Company above referred to was about £80. At the rate of £5 10s the pound it is evident that about 15 lb. of this special sample must have been brought together, and some feel curious to know how large was the bulk of tea which must have been depreciated in value to obtain this quantity of "golden leaf." That term may be used advisedly—though, in a commercial sense, it may be misapplied, because, on being viewed "the sample looked like small wiry pieces of gold."

Altogether, we feel inclined to remark with the French General who witnessed the grand charge of the Light Brigade at Balaclava that "*C'est magnifique, mais ce n'est pas la guerre.*" Another

French saying occurs to us in this connexion as aptly applying to this venture, and that is that perhaps "*Le jeu ne vaut pas la chandelle.*" That is, however, only immediately a matter for the consideration of the proprietors of Gallebodde. The community will be quite content to accept the probable good results to our industry without caring to raise the question of the purely economic value of the act. But lest other among our planters should be induced to follow their example, it appears desirable that we should ask them to bear in mind that although this special lot has secured a price which will doubtless compensate its growers for their trouble and for the depreciation of some bulk of their produce, any who might be induced to imitate them can by no means rely on future efforts of the kind meeting with equal success. It was the novelty, no doubt, which excited the strong competition witnessed to become the possessors of this abnormal parcel of tea, and it is scarcely likely, we should say, that even a second lot appearing in the market would obtain anything like equivalent prices or attract the public attention in the way this lot has done.

It is amusing to note the ignorance that has been shown at home as to the method by which this fine specimen of our tea has been produced. The *Investors' Guardian* has remarked with respect to it, that "with *connoisseurs* in tea, able and willing to pay such prices, planters should be encouraged to cultivate the finest varieties with the greatest care." All the home papers which have noticed this particular sale have written of it in somewhat similar terms, and it is evidently the widely-diffused opinion at home that this tea has been the result of a specially careful form of cultivation; as, also, that the price paid for it has been due to appreciation by tea drinkers. Both of those conclusions we here in Ceylon know to be fallacious. However cultivated the taste for tea may be, and however appreciative of high merit in the leaf, it is not likely that a drink which would cost the consumers, we are told, something like 1s 9d the cup of infusion would obtain purchasers. This lot of Gallebodde tea, as we have said, must be regarded only as a curiosity. Multiplication of such lots would deprive them of that qualification, and they would no longer serve the purpose of advertisement, either for individual estates or for individual companies or firms. Tea planting must, to be successful, be conducted on purely commercial and not on æsthetic principles. To the latter class we should assign the classification of this curious specimen of Ceylon tea.

RAINFALL IN LOWER MASKELIYA.

ANALYSIS OF RETURNS FOR THEBERTON AND ELEINDALE
ESTATES.

NANUOYA, Feb. 10th.

On the rainfall map of Ceylon, issued with the Surveyor-General's Meteorological Report, the deepest shade of colour marks a comparatively limited space near the centre of our mountain region, if we include the scattered "foot-hills" and detached ranges in the south and east, where the mean annual rainfall is 200 inches per annum and over. In this spot, at the foot of Adam's Peak and along the rivers which flow into the Kelani Valley, the three recording stations are Theberton with an average of 217 inches, Kandaloya 205, and Sembawatta 205. The altitudes at which the observations on these places are taken are:—Theberton, Maskeliya, 3,315 feet; Kandaloya, Yakkessa, 2,400;

Sembawatta, Nawalapitiya, 1,500 feet. It will thus be seen that the altitudes at which the rain-clouds chiefly strike the sides of the mountain ranges in Ceylon and have their vapour condensed into rain vary from 1,500 to 3,300 feet above sea-level. In India the rainiest station, Cherapunji, is at an altitude of about 4,300 feet on the side of the Himalayas; and were an observatory situated at an equal elevation near Adam's Peak, its mean annual rainfall would probably amount to 300 inches, against nearly double that quantity at the Assam station, the rainiest on the globe. Meantime, from figures which have reached me, it seems that ELFINDALE, at 3,000 feet elevation, and about $\frac{3}{4}$ of a mile S. W. of Laxapanagala, which, itself, rises about 3,000 feet still higher and is distinguished by a series of formidable cliffs, ought to be included and given first place amongst

THE RAINIEST POSITIONS IN CEYLON.

Like Theberton it is situated on the side of a valley down which run a series of parallel rivers which have their origin on the Peak ranges, and along which the rain-laden winds of the S.-W. monsoon sweep, depositing liberally their pluvial treasures. From figures for 5 years, with which Mr. Grigg of Theberton has favoured me, it results that the average annual rainfall of Elfindale is no less than 246.45 inches. In the first year of the series, 1886, the quantity which fell closely approached 300 inches.—the actual figures being 294.52 inches. Of this quantity 96.86 came in the first half of the year, with no less than 197.66 in the latter half. In the 4 months June to Sept. of that year, the deposit of condensed moisture was represented by such figures as the following:—

June ..	39.64 inches
July ..	42.59 "
Aug. ..	66.72 "
Sept. ..	41.08 "

Total for 4 months 190.03 inches. A

WET PERIOD

certainly! There is no rainless month in the record, but Feb. 1888 had only 40 cents against an average of 2.21 inches. The highest average 48.36 inches is against June. The variations in the annual rainfall at Elfindale have been from the maximum of 294.52 in 1886 to the minimum of 211.77 in 1889. But there has been no falling-off such as Mr. George Grieg has experienced on Laxapana, for the rainfall of 1890 was 249.33 inches, or 3 inches in excess of the average. The annual average for Elfindale being 246.45, the monthly averages are:—January 2.27; February 2.21; March 4.90; April 13.31; May 26.46 and June 48.36; the average for the first half of the year being 97.53 inches. In the second half of the year, the averages are:—July 33.74; August 35.21; September 33.16; October 27.09; November 12.53 and December 71.8. So much for Elfindale, which would seem to receive

MORE RAIN THAN THEBERTON

in proportion to its higher proximity to the great cooler Laxapanagala. Against $\frac{3}{4}$ of a mile S.-W. of this great and steep mountain, in the case of Elfindale, the rain-gauge at Theberton bungalow bears W. S.-W. from the mountain, distance one mile, with an elevation higher by 315 feet than that of Elfindale. For the 5 years ended 1889 the average rainfall of Theberton was 217.08 inches. For the sunspot period of 11 years, to end of 1890, the average is 221.11 inches: 82.54 for the first half of the year and 138.57 for the second half. In the 11 years

the variations in the annual rainfall have been from 184.10 in 1885, the lowest, to 287.39 in 1882, a year of excessive rain in Dimbula as well as in districts nearer the Peak and its ranges. When we come to

THE HEAVIEST RAINFALL IN ONE MONTH,

Theberton, we believe, beats the record, with 78.81 inches in June 1888, the figure for the whole of that year being however, somewhat below the average, viz: 216.81 against 221.11. It is curious to notice how inequalities are reduced or raised so as to give a return to averages. The excessive rainfall of 1882, when the figure was 287.39, was followed by 205.73 for 1883; 194.40 for 1884; and 184.10 for 1885. Then came a reaction in 1866 to 258.30, followed by 213.80 for 1887. In the past 5 years the rainfall has been below the average, going down to 197.21 in 1890. But there has been no reduction of the general average, to compare with that which Mr. George Grieg lately reported from the neighbouring Laxapanagala estate. There is a Laxapanagala estate, from which we should like to see returns. In 1890 the rain was measured at Theberton Factory, which is at 3,000 feet elevation, against 3,315 at the bungalow, and distant only $\frac{1}{2}$ of a mile from Laxapanagala, against 1 mile in the case of the bungalow. The result was 208.84 inches at the store, against 197.21 at the bungalow, a difference of more than 11 inches. This shows the influence of

POSITION AND TOPOGRAPHICAL FEATURES,

with reference to rainfall. The monthly averages, established by 11 years' observations at Theberton bungalow, are:—Jan. 2.28; Feb. 2.87; March 6.14; April 9.45; May 21.58; June 40.19; July 30.98; Aug. 33.74; Sept. 24.33; Oct. 27.17; Nov. 13.50; and Dec. 8.82. With a record of 5 years' observations, Elfindale, with an annual average of 246.45 inches, is

THE RAINIEST CEYLON ESTATE

of which we have any authentic knowledge, but we repeat our conviction that in some places on the slopes of the Peak and its flanking ranges, Laxapanagala, &c., the annual average must be up to 300. We heard some years ago before it was established that tea could flourish not only in 70 inches per annum, but in 300,—that observations taken on some estates were suppressed for fear of impressions injurious to such estates being formed. To Mr. Grigg's credit it is that he has always published the exact truth regarding the rainfall on Theberton; and now equally authentic figures enable us to say that on one tea estate in Ceylon at least the annual average rainfall is close on 250 inches. Let us now hear Mr. Grigg himself on these interesting returns. In sending them, he wrote:—
"I send you Elfindale rainfall for 5 years and mine at Theberton bungalow for 11 years and at my Factory for 1890. Also a rough sketch of how the rain-gauges stand as to the big Laxapanagala range, the highest peak of which stands above, at some 3,000 to 4,000 ft. (The exact height of the peak has never been properly taken, as it was said by the surveyors, it was impossible to get on the top of it to place a trig which they wanted to do, so they have never bothered to get its height correctly. Last year, however, the Peak was scaled by three young fellows, and a flag placed on the top, distant from Theberton bungalow about one mile, as that old bird the crow flies.) The factory gauge is $\frac{1}{4}$ mile from peak. Elfindale gauge $\frac{3}{4}$ mile from the peak. All are nearly in a straight line from the highest point, which bears W.S.-W. Taking the W. N.-W. wind draught up the valley, this would deflect the S.-W. monsoon rain current to about W.S.-W., or right across our rain-gauges. You will note that Elfindale average for 5

years is 246.45 inches; Theberton for 11 years 221.11,—an increase to Elfindale of 25.34 mean., by being closer to the mountain. 1890 rainfall gave more viz. :—

Elfindale	249.33
Theberton Factory	208.84
Bungalow	197.21

I expect the increase to the nearer station to the mountain would be more or less, as the S.-W. monsoon has more or less southing or westing in it, or maybe when it is stronger, so carrying rain clouds further off. I believe if a gauge was kept on Laxapanaga a say $\frac{1}{2}$ mile west of Elfindale, it would show a much heavier rain fall than Elfindale. Strange at Laxapsnagala bungalow, which is about a mile in a straight line N.-W. from Elfindale, the rainfall is said to be less. This is accounted for by the mountain decreasing in elevation as it runs to the west, below Laxapanaga falls. I should say, they had a much better climate than here, that is still further west—as I note the sun shining often there when we are all cloud and mist here. Though I see in today's *Observer* that at Arslena (which is lower down in Dikoya Valley) the rainfall is very heavy.* The main reason our rainfall being so heavy the hot air is carried right on to the mountain from off the lowcountry without any hills of any considerable elevation taking the moisture out of the S.-W. current. I rather fancy the S.-W. about middle Maskeliya travels across a lot of high land, which wrings the moisture out of it before it falls in the Valley. I trust I am not intruding by sending you these notes. As I know you take great interest in these things I thought you might like to see them. If you think it worth while you might send these notes on to Colombo, Mr. Greig of Laxapana having sent you notes of his rainfall, I thought you would also like to see ours, which in a way are unique. Mr. Galton of Elfindale kindly gave me his rainfall for 5 years. The rainfall has been kept off and on on Elfindale for many years, but I am afraid previous to Mr. Galton's, they are not to be relied on; besides they were kept at the bungalow, which is right under the Laxapanaga cliffs, and I believe the rainfall there was very large. Unfortunately the returns could not have been kept regularly. Tea flushing very well. We have had a bit of red spider and mosquito blight; but since the nice showers we have had this week, the pests are disappearing. Thunder storm last night in S.-W. Looks at present (Feb. 6th) like more rain.

I am sorry to see my good friend Mr. Grigg's reference to red spider and *helopeltis* as having given him trouble. I do not attach much importance to the former, so far as I have seen or heard of it in Ceylon, It seems to come and go away, without doing much harm. The contrary seems to be the case in India, as witness the following extract from a Darjiling letter in the *Indian Planters' Gazette* :—

Mr. Christison, the General Manager of the Lebong Tea Company, has been carrying on a series of experiments with sulphur as an insecticide with especial reference to red spider, which has been working such a vast amount of havoc on very many tea estates in this district. Mr. Christison has always gone thoroughly into everything he takes up since he came to the district, something like thirty years ago, and as he is particularly well up in matters connected with agriculture, the results of his investigations, carried out as they have been during a number of years, over a very large acreage, and very accurately noted are deserving of weighty consideration in all the tea districts. After trying all probable cures for red spider blight, such as tobacco, juice, lime water, kerosine oil, soap suds, and mud and water Mr. Christison found sulphur by far the best remedy for this pest. He has been using it since 1879 up to the present time, and over an area of about 400 acres, so that the trial has been an exceedingly extensive one, and may be looked on as having passed well beyond the merely experimental stage into that

of sound practice. This year the Lebong Company's gardens are being sulphured in downright earnest, as no less than 15 tons (a large order indeed) of it have been procured for the special annihilation of the spider. The sulphur is liberally applied to the bushes in the following manner, which certainly has the advantage of being very simple indeed. As soon as the spider begins to show any signs of life, or when there is a longish spell of dry weather without any wind large garden syringes are brought into use; with these the bushes leaves, stems, branches and all are thoroughly syringed with water, the powdered sulphur is then thoroughly dusted all over the bushes out of a canister or a gauze bag. If no rain falls for some time after the bushes have been sulphured, all the better; so that it is of importance that an appropriate time of year should be chosen, say, from January to the end of April. The advantage of this sulphuring the bushes is that it is inexpensive, is at all events handy, and the requisite labour for carrying out the work is, generally speaking, more available during the cold weather, and up till the end of April, which is a very important point. Mr. Christison tells me that his treatment has a wonderful effect, far exceeding any other cure. The plant so thrives and grows after it for three years that one would almost think it acted as a manure, in addition to killing the spider entirely the first year. The pest does return after three years, but by that time the plants have become invigorated to some extent and can the better grow out of the spiders' attacks. Mr. Christison is inclined to think that in three years the capital expended in sulphuring the bushes will be returned in increased outturn with about 15 per cent. extra, and that the plants at the end of that time will have been vastly improved. The fumes of the sulphur can be smelt from afar as one passes by, 300 yards off, and even can be detected in the factory in April and May. The result of the brokers' valuations and of actual sales have not shown that there has been any deterioration in the quality of the tea sent to market; and as a matter of fact, the fumes have entirely gone off before the tea is finally packed. These carefully observed and recorded facts are deserving the attention of all interested in tea manufacture, and I commend it to their notice through the medium of your columns.

The application of sulphur, after the fashion described, ought to be equally efficacious, I should say, against the "mosquito blight," which, from what I saw of the savages of *helopeltis* in Java and what I have read from its terrible effects on the yield of Indian tea plantations, I consider much the more formidable

ENEMY OF THE TEA PLANT

and the tea planter. But as Mr. Grigg's mention of "the spider and the fly" (beetle, rather) is the first I have seen or heard of for a long time, I trust the attack noticed is isolated, and that it will neither recur nor spread. Up in this region, there is not the slightest trace of any insect or fungoid plague, except a little moss on the stems of the bushes and a little bronzing of old leaves which is of no consequence. Even the moth, which at one time, some years ago, gave trouble in curling up the flush, seems to have entirely disappeared.

KEEPING MACHINERY FROM RUSTING.—A mechanic says that in order to keep machinery from rusting he takes one ounce of camphor and dissolves it in a pound of melted lard, taking off the scum, and mixing in as much fine black lead as will give it colour. The machinery is then cleaned and smeared with this mixture. After 24 hours the machinery is rubbed clean with soft linen cloth, and it will keep clean for months. The same artisan gives the following method of hardening tools: Forge the tool into shape, then melt in a dish sufficient Babbit metal to cover the end of the tool as far as it is wished to harden it. Thrust the tool into the metal and let it cool. This method makes the tool much harder than cooling in oil or tempering by any other process.—*Chicago Tribune*,

* 246.45 inches against 249.33 on Elfindale.

MR. HUGHES AND TEA ANALYSES AND "RAG" MANURE.

Meeting Mr. John Hughes this week, the question was put to him by me as to whether he had yet been commissioned to make the analyses of tea respecting which he had been in communication with your Planters' Association, and which, it seems to be the general opinion, might be productive of very valuable results. Mr. Hughes told me that he had received a very polite letter in acknowledgement of his offered terms for doing this, but that it contained no instructions to undertake the work.

That gentleman further told me that he had at length heard something as to the result to the application of the "rag" manure on the Mariawatte estate. He said he had heard from Mr. Rutherford that, having been applied side by side with a patch which had been treated with cattle manure, the tress on the latter had borne much the more freely. This apparently discouraging result must, however, be largely discounted, for Mr. Hughes observed to me:—"You will recollect when we first talked upon this subject that I told you that one reason why I had recommended a trial of this manure was because it had been ascertained to be so slow in its action. All my experience goes to show that if rapidly forcing manures can be avoided it is invariably better for the cultivation. Now with English farming it is a necessity to use fertilizers that are rapid in their action, that will yield up their constituents to the soil as quickly as possible. When you consider how few months are available for farming here at home, you will see that there is no time available for slow decomposition to work. Horse and cow manure is always allowed a certain amount of decomposition before use in order that it may commence yielding up directly it is applied to the ground, and this accounts mainly for the storage in manure heaps for a long time in advance of actual use. The use of farm litter, too, is largely subsidized in England by mineral manures, such as sulphate of ammonia and nitrate of soda, both of which begin to work directly they are applied. But there is no necessity for you out in Ceylon to demand such quick action. It is always injurious to force anything in nature, and as you have a climate in which your tea bushes can take up nourishment throughout the whole year, it is in my opinion much better to attain results gradually and not to use forcing mixtures. That is the reason why I yet think—in spite of the apparently disadvantageous comparison to be seen on Mariawatte—that the owners of that estate may yet come to acknowledge the superior value of this new manure. I admit that it is twice as bulky as are most mineral manures, and that that constitutes an objection; but on the other hand I believe that mineral manures are very ill-suited to the conditions available under the climate of Ceylon."

COFFEE AND CINCHONA CULTURE.

During our conversation we touched upon the decadence of your coffee and cinchona cultivations. Mr. Hughes said he had never believed in the latter being well adapted to Ceylon soils. These soils were far and away, he said, inferior to those of India for the growth of those trees, and he had not been surprised to hear of the numbers of them which had died out after a certain age of growth. In reply to a question as to what he thought of the probable permanence of tea cultivation, Mr. Hughes expressed the opinion that it had every chance of it. "Indeed," he went on to say, "tea

seems to me to be just the very thing for Ceylon planting. What do you specially observe as the chief characteristic of Ceylon scenery? It is essentially green, that is to say luxuriance of leaf pervades the island. Nature therefore teaches you that to produce leaf is almost certain to be the industry to which it will lend itself in Ceylon. It don't seem to me that a berry like coffee would be as suitable or as reliable as tea, and as to cinchona I have already told you what I think about it. Rely upon it, both the climate and soil of Ceylon are the best adapted for tea. It is essentially a leaf island."—*London Cor.*

MANA GRASS EXPERIMENTS.

Calling in at Messrs. Curtis & Harvey's this week, one of the partners obligingly told me that he had just been to their mills at Hounslow that he had seen the charcoal burned from the ton of mana grass, and that the outturn was satisfactory both as to quantity and as to quality. "But," he said, "I can't give you any opinion as to the suitability of the grass for our purposes until some has actually been made into gunpowder. We expect to commence doing this very shortly, and you shall know the result of our first trials with it."—*London Cor.*

NOTES ON PRODUCE AND FINANCE.

REDUCTION OF DUTY ON TEA INCREASES CONSUMPTION.—That this is the case is fully proved by the fresh strides which have been made in the consumption of tea during the past year as a result of the lowering of the duty in May last to 4d per lb. Prior to the reduction of duty the increase in the consumption was very small last year, but in 1890 it may be said to have suddenly started forward, and the total for that period was 8,386,692 lb. above the corresponding one in 1889.

MINCING LANE BUOYANT.—In Mincing Lane the easy state of the money market has largely increased the speculative business in produce. In the tea market there is much animation, and the volume of business in this article passing through the Produce Clearing House is heavier than at any time since this institution was first used as the channel for speculative dealings. Prices have daily advanced, and now show a very important rise since the commencement of the year.

THE DECLINE AND FALL OF THE CHINA TEA TRADE.—China is sadly worsted in the tea competition by India and Ceylon. The exports of tea show a falling off of 6 per cent against the corresponding quarter of last year.

During the past year a survey of the industries of Lower Burmah has been made, and a Provincial Board is deputed to consider these and advise the Indian Government as to the best means of promoting technical and scientific education in that province.—*Globe.*

COFFEE IN COORG.—There is very little crop, for sale, and the owners of coffee are holding out for 300 rupees a Candy, i.e., quarter of a ton. Intending purchasers fight shy, and don't want to be liberal in the price they will pay. In the meanwhile there is said to be no money in the country, and all trade is driven to the winds. The people are also suffering by reason of the loss of their paddy crops.—*Bangalore Spectator.*

Mr. J. D. Pasteur, Inspector of the Post and Telegraph Service of Java, has sent to Dr. T. A. Jentink a teak telegraph pole from the Kediri Residency, Java, which in spite of its iron hardness has been pierced with holes, near where the insulators were attached, by the beaks of a local woodpecker (*Picus analis*). These holes are also made in the living kapok trees (*Eriodendron anfractuosum*), which are utilised as telegraph poles in Java. In Norway the like thing has occurred, and it is supposed the birds have mistaken the humming of the wire for a nest of insects inside. Large cairns used to prop up telegraph poles in Norway have also been scattered by bears, perhaps for a similar reason.—*Globe.*

**THE HOREKELLY ESTATE COMPANY,
LTD.: ANNUAL MEETING.**

The annual general meeting of shareholders was held at the Company's office this day at 1-45 p.m., Mr. F. C. Loos in the chair, and there were also present Messrs. A. Schulze, Stauforth Green, F. C. L. O., W. B. Baring, F. J. De Saram, E. W. Suhren, V. A. Julius, Stanley Bois, Wm. Law, and R. L. M. Brown (Secretary). The following were represented by their attorneys:—Henry Bois, W. J. Carver E. Christian, E. Daendliker, F. W. Bois, Mrs. F. W. Bois, J. B. Alston, Alexander Gibson, W. G. Ingles and executors of the late Mr. E. Robinson.

THE CHAIRMAN'S SPEECH.

The minutes of the last meeting having been read and confirmed,

The CHAIRMAN said that shareholders would have observed from the report that the expenditure for last year had been somewhat reduced in comparison with that of the preceding year—the expenditure for the year 1889 being R32,448-77, while that for 1890 was R29,492 09. There had been a slight increase in the quantity of copra produced, but there was a noticeable diminution in the quantity of coir fibre made—43,358 ballots having been turned out for 1889, whereas the output for 1890 was only 21,850 ballots—the decrease of production being due to the difficulty of finding an outlet for the fibre, which caused the quantity produced to show a large falling-off. There was one important matter connected with the estate which was worthy of remark, and that was that the Directors had for years past been applying manure to the different parts of the estate, and they found that the return was commensurate with the amount of money spent in applying this manure. The thing had, however, not been done systematically during the previous years, but from this year they intend doing this experiment systematically, and he had no doubt that this statement would meet with the approval of the shareholders. He need scarcely remark that the more manure they applied to their estates, the greater would be the yield and the larger would be their dividend. With these remarks he begged to move the adoption of the Report. (Applause)

DIVIDEND.

The CHAIRMAN said that the next matter was to declare a dividend, whereupon on the motion of Mr. V. A. JULIUS, seconded by Mr. Wm. Law, it was resolved that a dividend of 5 per cent on the paid up capital be declared.

APPOINTMENT OF DIRECTORS.

Mr. BARING moved that Mr. F. J. De Saram be re-elected Director and Mr Percy Bois be elected in the room of Mr. P. Daendliker, the retiring Director—Seconded and carried.

APPOINTMENT OF AUDITOR.

The CHAIRMAN said that they had to elect an Auditor in the room of Mr. S. T. Richmond who was eligible for re-election. He had satisfactorily discharged the audits of his office and he begged to move that Mr. S. T. Richmond be re-elected.—Carried.

THE COMPANY'S REGULATIONS.

The CHAIRMAN said that before they separated he desired to draw the attention of the members to the Company's articles of association, which required the attendance of 17 shareholders to form a quorum. The quorum was formed under the Joint Stock Companies Ordinance; but he thought that seven or eight shareholders would be quite sufficient to convene a meeting. He intimated that he would bring forward a special resolution on the subject for the purpose of reducing the quorum of shareholders in view of the difficulty such as they had experienced that day in obtaining a quorum under the ordinance.

This concluded the business of the meeting.

REPORT OF DIRECTORS.

1.—From the accounts for 1890 now submitted it will be seen that the profit on the year's working amounts

to R19,986-17. Depreciation of plant and machinery at the usual rate has been deducted—viz., R2,000-01, thus leaving (with the balance of R419-11 brought forward from 1889) a sum of R18,986-21 at the credit of profit and loss.

2.—The Directors recommend that a dividend at the rate of five per cent on the paid up capital be declared. This will absorb R17,567, and leave a balance of R892-24 to be carried forward to 1891.

3.—The Crop of the past year must be considered as satisfactory in view of the very short rainfall and prolonged drought, while the Directors are happy to report that the prospects for 1891 point to an increased yield over 1890, if normal weather be experienced.

4.—The difficulty of finding an outlet for coir fibre has caused the quantity produced to show a large falling off, but the production can at any time be increased as opportunities arise for its disposal.

5.—The working of the two seasons, 1889 and 1890 compares as follows (the item of interest being excluded):—

	1889	1890
Expenditure on estate and in Colombo Office...	R32,448-77	29,492-09
Quantity of Copra produced ... Candies	805	941
Do Coir Fibre made .. Ballots	43,358	21,850
Average price obtained for Copra per candy	R39-36	39-94
Average price obtained for Coir Fibre per cwt.	R4-51	6-16

Colombo, 29th January 1891.

CATTLE AND SALT.

The following occurrence which has come within the scope of my observation is not only amusing but also shows how CATTLE are found of SALT especially up here on these hills in the interior where there is little chance of the sea-water spray being carried up by high winds to be deposited on the land in spite of the fact the salt pans at Hambantota can be seen from the Haputale Pass. A man in charge of a cricket grove in this neighbourhood told me that instead of moving the grass on it he had recourse to a much easier plan to make the ground smooth and even. He said he could get the cattle to do it all for him and proceeded to show me how. He took some salt-water and sprinkled it on the green; and what was my surprise to see a number of cattle grazing in the adjoining patana shoving each other and rushing up to the spot where the water was sprinkled and eating off the grass with great avidity, biting it almost to the very root! By thus sprinkling saltwater cattle could be made to graze even on coarse grass which they would otherwise loathe.

The United States Government has appointed a commission to investigate the subject of the irrigation of the States west of the Missouri. The data collected show that no less than two-fifths of the entire area of the United States is arid and dependent on irrigation for profitable farming.—*Globe*.

STENNING, INSKIPP & CO.'S INDIAN AND CEYLON TEA MARKET REVIEW FOR 1890.

ESTIMATED SUPPLY AND DELIVERY to end of Season 1890-91, and probable Stock on 1st June next—

		1st June, 1890, to 31st May, 1891.
	Supply.	Delivery.
Indian	103,000,000	101,500,000
Ceylon	52,000,000	45,500,000
China, Java, &c....	73,000,000	82,000,000
	<u>228,000,000</u>	<u>229,000,000</u>
	1890. Stock.	1891. Stock.
Indian	29,000,000	27,490,000
Ceylon	16,000,000	9,590,000
China, Java, &c....	30,000,000	41,000,000

[No reasons are given for estimating a consumption of 101,000,000 lb. Indian out of 103,000,000 imported, while of 52,000,000 Ceylon imported only 45,500,000 will be used. Why should there be in 1891, a result so different to that obtained in 1890? And why should it be taken for granted that the deliveries of China, Java, &c., should exceed the imports by 9,000,000 lb? We can have no confidence in such an estimate.—*Ed. T. A.*]

EXCHANGE.—The rise in exchange has caused much concern to planters, more especially to owners of those estates which have experienced bad weather, but the fact must not be lost sight of that this rise has been the means of diminishing the China export, thus helping to strengthen the market for Indian Tea, the common grades in particular being benefited.

REDUCTION OF DUTY.—The Tea Duty was reduced on 1st May from 6d per lb. to 4d per lb. The effect has been to enhance the value of common and medium descriptions, more especially Pekoe Souchongs, which are now very largely used by blenders for supplying both retailers and the packet trade.

[A table shows that the home consumption of Indian and Ceylon teas went up from 28,013,000 lb. in 1877, or 18½ per cent of the whole, to 136,500,000 or 70½ per cent in 1890. China, meantime, went down from 123,012,000 lb. to 57,500,000. The increase in consumption in 1890 over 1877 was 44,000,000,—the figure for 1890 being 195,000,000 against 151,025,000 in 1877, a period of 14 years. In 5 years the rise was from 174,665,000 in 1866 to 195,000,000 in 1890, an increase of 20½ millions, or at the rate of 4 millions per annum. The increase being mainly in Indian and Ceylon, may safely be calculated at 6 millions per annum China standard.—*Ed. T. A.*]

CEYLON.

THE COURSE OF THE MARKET.—Business commenced with a good demand, but heavy Auctions supervening together with less desirable quality, caused a lower range of prices, except for a few choice Teas. No change occurred until March, when supplies fell off, and with better quality the demand improved, and values advanced until May, when the enquiry somewhat slackened, but only for a short time, as business again became active; in July the prices of less desirable qualities went weaker; good lignoring Teas were unchanged. Arrivals were smaller in August, and an advance took place which was well maintained until October, when less activity was apparent, and in November a decline, due to a poorer selection, occurred, but the year closed with a firmer tone.

QUALITY.—Has shown a distinct improvement on that of last year, the fermentation having been better than hitherto; flavoury Teas have commanded very satisfactory prices, especially when with thickness of liquor. Owing to the scarcity and dearthness of the higher grades of China Tea, it is very probable that the persistent efforts to introduce Ceylon Teas into the Continent, as well as into other countries, will meet with more success before long.

DELIVERIES.—From 1st June to 31st December deliveries show an increase of 5,706,000 lb., as compared with 6,336,000 lb. same period in 1889. For the 12 months, 1st January to 31st December, the increase is 7,486,000 lb., as compared with 11,615,000 lb. in 1889. We think the cause of this reduction in the rate of increase is due chiefly to the higher range of values for the common grades.

EXPORT.—It is calculated that the crop 1st January to 31st December, 1891, will be about 52,750,000 lb., and that the present area under cultivation may produce in 1891 a total of 74,000,000 lb. The subsequent yearly increase will probably not be very large.

	Average Price.	per lb.
		s. d.
1890 ...	535,611 packages, average	0 10½
1889 ...	431,043 do	0 11
1888 ...	303,234 do	0 11½
1887 ...	182,955 do	1 0½
1886 ...	101,145 do	1 1
1885 ...	58,921 do	1 3½

[In the 5 years between 1887 and 1890, the deliveries of Ceylon tea nearly quadrupled, rising from 9,942,000 lb. in 1887 to 37,652,000 in 1890.—*Ed. T. A.*]

DAVIDSON'S DOWN-DRAFT SIROCCO.

(To the Editor, Indian Planters' Gazette.)

Sir,—Your issue of 20th instant contains yet another letter from "Darjeeling," re my Down-draft Sirocco, and I am glad to see by it the steady manner in which he is continuing to withdraw one by one, each of his original complaints, until the list of his grievances is now reduced to his inability, as he describes it, "to add 2 to 6 annas per lb in value over tea dried by charcoal." This complaint somewhat reminds me of the man who, after having purchased a type-writing machine, said it was a failure, and wanted to return it, because it did not make any improvement in his spelling! But in still further support of my statements that the down draft sirocco, when properly used, does produce the highest class qualities of tea, I may quote the following extract from a letter from a well-known Ceylon Planter addressed to me to Belfast, and which I have only just received.

"After an experience of 18 months of the original small Down-draft Sirocco and 4½ months of the larger one, I am of opinion that these machines are capable of developing a very high quality of tea, while for convenience of working and economy of fuel I know no machine equal to them." (Signed.) J. N. CAMPBELL. Moray Tea Estate, Maskeliya, Ceylon, 12th Nov. 1890.

Mr. Campbell's teas have been selling at the remarkably high average of fifteen pence, and his factory is in the Hills, and at even a higher elevation than that of Darjeeling, and turns out upwards of 4,000 maunds of tea per annum, so that his experience has been gained in the manufacture of much larger quantities of tea than anything "Darjeeling" has had to do with. But "Darjeeling" in his letter under reply objects so emphatically to my quoting testimonials emanating from Assam, Cachar, Sylhet and the Terai, that he will probably also object to my citing any from Ceylon, in which case there is evidently nothing left for me but to quote a testimonial from "Darjeeling" himself as to the general efficiency of the Down-draft Sirocco. This testimonial is embodied in a letter which he, "Darjeeling," in his own proper name, addressed to me personally to Belfast shortly after my Engineer's second visit to his place, and which letter has been forwarded on to me here, it having arrived in Belfast after I had started for India. It is dated—Darjeeling, 21st October 1890, and the following is one of his paragraphs in full, word for word—"I do not wish to run down the Sirocco, which is an admirable machine and, I believe, the best that has yet been brought out, but all machines are susceptible of improvement."

He then goes on to give me his ideas of what those improvements should be, and, while I thank him

or laying them before me, I must nevertheless decline to accept them in the light of "improvements." For instance, he has a special fancy for putting a small pipe on the air exit from the fan. The open area of this pipe he indicates as about 64 square inches, and he says "it does not in the least obstruct the escape of air from the fan." I, however, found it necessary to make this opening with an area of 200 square inches, and yet he reduces it by more than two-thirds and wants me to consider this an "improvement!" If it be so, then why not go on reducing it and thereby increase the improvement, till perfection is reached by closing it entirely? I am, however, well pleased with the testimony "Darjeeling" has given me as to the general merits of the Down-draft. To be the "best tea-drier that has yet been brought out" is no mean praise to bestow on it.

I feel, Mr. Editor, that I have again trespassed too far upon your valuable space, but I anticipate that in your appreciation of fair play you will excuse me seeing that, throughout this correspondence, I have been, and am still, only defending myself and my inventions against the groundless attacks of men who if they possessed the courage of their opinions, ought not to have been afraid, or ashamed, to put their own names to their letters.—I am, Sir, yours faithfully,
C. S. DAVIDSON.

Calcutta, 23rd January 1891.

[The mass of evidence and independent testimony which Mr. Davidson has adduced in his several letters so fully proves the truthfulness of the statements, published in his advertisements, that we feel sure even "Darjeeling" himself must be now convinced he has been mistaken, and we consider this correspondence may now be closed.—*Ed., I. P. G.*]

THE TEA MARKET.

The correspondence in the *Grocer*, discloses the fact that a new element has been introduced into the tea trade, and that there are now, as in other markets, operators for the fall, who are interested as speculators in depressing prices. Facilities for selling "bears," for delivery at a future date, have been given by the inclusion of tea among the articles of produce dealt in through the London Clearing House. Transactions are based upon a "type" of which samples are supplied to all who wish to deal either as buyers for the rise or as sellers for the fall. A "call" is held every day, sometimes twice a day, and prices fluctuate according as buyers or sellers predominate. Operators settle differences on open contracts day by day with the Clearing House as prices change; and as the Clearing House has power to close any operators' account on failure to pay up the difference due, speculation is considered to be made safer, and confined more strictly to those who have means available for the prompt liquidation of losses. On this ground, the formation of the Clearing House is justified by those who support it either as shareholders or as speculative operators through its agency. But a very different view of the whole matter is held by many of the older and most important firms of tea brokers, who (supported by the principle producers, their clients) have steadily refused to associate themselves with the movement or to transact this kind of business, which they deem prejudicial to the best interests of producers. There is reason to think that the value of tea was depreciated unduly in the autumn by the action of speculative sellers, who calculated on lowering prices by persistent selling of tea which at the time had existence only on paper. The "bears," however—who acted on imperfect information, and altogether failed to grasp the altered position of tea—have been caught short of stock, and their efforts to buy back what they have sold have led to a rapid advance in the terminal market. The principal buyers, who have practically cornered the market, are reputed to be substantial firms connected with China. They are strong enough to carry the speculation through, and have now a numerous following of smaller

men, outsiders, and others whose eyes are opened to the remarkable position of tea. The heavy deficiency from Coimbatore—about twenty-five million pounds—and the short crop from India, have brought to pass what we have always been told is impossible, viz., a real deficiency in the total supply required for the world's consumption. From no source can the scarcity which is beginning to be felt be relieved until the closing months of this year. Hitherto these speculative transactions have been very limited in Indian tea, for the "bears" hesitated to sell; but it is on record that in December the type was quoted under 8d, below its value on the basis of public sale rates, and those who did so have now the option of covering at 10s, or of risking still heavier loss. The situation, from whatever point of view regarded, is an interesting one; as, quite apart from the results of speculation, the elements exist for a rise in the value of tea—possibly of permanent duration—exceeding the hopes of the most sanguine; rivaling, it may be, the extraordinary rise in the value of coffee which was brought about a few years ago by a somewhat similar series of events. When it is remembered that the price of sound China Congou is still only 7½d per lb.; good Indian Pekoe Sanchung about 10s per lb.; really good Pekoes at 1s; and fine tea at 1s 6d, it is clear that there is room for improvement, provided there is sufficient reason for it, without fear of any material check to consumption.

In the issue of the *Grocer* of the 24th "Broker," replying to letters depreciating tea writes:—

"A Wholesale Dealer," into whose motives we need not enquire, has done his best through your columns to depreciate the value of tea, and has warned your readers against the tactics of speculators, to whom he is pleased to attribute the upward movement of price.

As a representative of producers largely interested in the steadiness of the market, I ask you to let me join issue with this "Wholesale Dealer," notwithstanding that I cannot claim to be specially anxious for the welfare of your readers. On behalf of those who hold strong views about the market, let me say that their basis is this:—

1. The ascertainment that supplies from all sources this season will be at least 15,000,000 lb. less than our requirements, and possibly 20,000,000 lb. less.

2. The knowledge, derived from the most influential sources, that the retailers throughout the country are lightly stocked, and cannot long hold out against rising prices.

3. The opinion that, with the exception of the commonest qualities, teas are at very low prices in the wholesale market as compared with the prices in retail trade, leaving margin for a considerable advance.

4. The fact that home consumption is rapidly increasing, as shown by the duty payments on nearly two and a half million pounds more than last year, between the dates of Jan. 1st to 20th, following on the very considerable increase during 1890.

5. The impression, based on careful enquiry, that the public are largely buying a better kind of tea than before duty was lowered, taking their two pence out in "quality."

6. Experience of the commercial history of the world which teaches us that articles shipped from silver-using countries, in the long run, rise and fall with the movements, in the silver market. With the rupee and the dollar at their present price, it is certain that "common tea" must either rise on price or cease to be produced. The efforts of Indian and Ceylon growers are being turned towards making "finer tea and less of it," in order to combat the higher cost of their crops caused by the rise in silver.

7. The knowledge that (outside the Clearing House clique) there are no speculative holders of tea at all—speaking, of course, in general terms. If "Wholesale Dealer" knows where tea is held as a speculation, perhaps he will indicate it; if the stocks held by dealers who have had the foresight to acquire them be referred to, they are merely the set-off against those who have run short in the hope of prices falling.

In conclusion, let me say why the Indian sales have

been so large: it is because Indian importers have been advised for years to hold freely whenever demand is strong and on general principles irrespective of prices or statistics; and they have acted on this advice. Having sold 745,000 packages out of the 1,150,000 packages which will be received, they will now be advised to sell the balance quietly between now and July, and take the average of the market for sales spread over that period.—*H. and C. Mail.*

THE VISIT OF MR. POPOFF, THE RUSSIAN TEA BUYER.—We learn from Mr. Popoff, the Russian tea merchant who arrived here on Friday evening from Marseilles in the "Salazie," and concerning whom we had a paragraph in our last issue, that he proposes staying only a short time in Ceylon prior to proceeding to China on his yearly business visit to the tea markets there. He is accompanied on his tour by Madame Popoff and Mr. Jaeger, and wishes to see one or more of the crack tea properties in the island. He brings letters of introduction to Messrs Aitken, Spence & Co. and they will, no doubt, help him to do this, and no doubt the system of pruning adopted by our planters will be shewn him, as it seems he considers it a matter of special interest. When in China he hopes to visit the tea gardens, and to see for himself what changes there may be for amendment in manufacture of tea in that country. He is somewhat reticent as to his opinion on the chances of Ceylon tea in the Russian markets. This is perhaps only natural under the circumstances, but we may form our own opinions from the hint he throws out—that it is quite possible that the next time he visits Ceylon he may remain a much longer time and not go on to China at all. He met Mr. Roguive in Moscow and gives a good report of his health and spirits, and speaks highly of his abilities. Before very long we may hope to see Mr. Popoff or his agent resident in Colombo and buying our best teas for direct export to Russian markets.—*Local "Times."*

GEMMING IN RAKWANE.—Feb. 16th.—A large and successful sale of gems took place at Botiatenne on the 11th instant, several gem merchants from Colombo, Morotuwa, Ratanapura and other places being present at the sale. Among the lots sold, a very valuable sapphire weighing 53 carats was briskly competed for and was eventually purchased by one Mr. Fernando of Morotuwa for R2,700. Besides this gem, two other lots of sapphires were sold for R263 and R204 respectively. Tamby Sinho, the famous gemmer of Rakwane, was the happy finder of these gems, though for some time past he has spent a lot of money without finding a stone of any value. The gems in question were found on Botiatenne, bordering Golden Grove, and there is not the semblance of a doubt but that equally good, and probably better, gems will be found in the grounds of Golden Grove acquired by the Gemming Company. The vicinity has been long known as a spot abounding in gems, and all those that know the place are quite confident that, should operations be commenced there, they would be crowned with success. A few months back a rare sapphire weighing about 20 carats was found at a place close to Golden Grove and eventually fetched about R2,500. It will be very gratifying for all concerned to hear that after all the money spent by Mr. Siedle in the Botiatenne pit he is in a fair way of meeting with success. Under the able management of his present superintendent, Mr. G. H. Osrey, a very large quantity of excellent *illum* of the right sort has been raised, all hands are now busily engaged in washing it, and there is every probability of Mr. Siedle meeting with very successful results. The plumbago pit on Barra estate does not seem to yield such a large quantity of plumbago as was anticipated at first, but it is said that a very rich vein of plumbago still exists at the spot, just on the vicinity of Rakwane. The reports that are received about the finding of gems on Rangwellestene estate are not very encouraging and most of the gems found are not very valuable.—*Rakwana Cor.—Local "Times."*

TEA CULTIVATION AND RESULTS IN UPPER AMBAGAMUWA.

Our tabular statement of the results of Tea Cultivation in East Matale, has brought us another paper from the other side of the country, namely Upper Ambagamuwa, and the figures there given will surely astonish old planters of coffee in that region. The comparison, too, with even the most favoured districts of the country is very favourable, both for heavy outturn of crop, and economy in working. It will be observed that the Ambagamuwa estate has a splendid rainfall, no less than 210 inches in 1890. The information given in regard to manuring will be carefully considered. Similar statements for typical estates in other districts would be very interesting and useful to men anxious to compare expenditure and receipts. Our correspondent writes:—

It may interest your readers to compare results from the quartz and clay of Ambagamuwa with those from the alluvial deposits of the Matale district in which our friends seem to delight on that side of the country. The following are the figures of crop and expenditure of this estate for 1890, viz:—

Cost per lb. of made tea f. o. b. on—Upper Ambagamuwa—384 acres at lb. 366 per acre, equal to 140,742 lb., at 26.35 cents, equal to R37,094.80; plus new clearings: 97, equal to R1,366.29, at 27.32 cents, equal to R38,461.09 total expenditure on estate.

GENERAL EXPENDITURE.

		Cents	R	c
Salaries and Allowances	140,742 lb.	3.89	5,481	60

	do do	27.32	38,461	09

The following figures show the yield per acre, from a field Mookalam ($\frac{2}{3}$ grown jungle) planted in 1880 and all dug over (forked) at end 1883, with the result that it gave 1,004 lb. made tea per acre in 1884. It gave

lb.	lb.
In 1882... 450 per acre	1887... 676 per acre
'83... 672 do	'88... 589 do
'84... 1004 do	'89... 86 do
'85... 605 do	'90... 662 do
'86... 530 do	

9 years' average lb. per acre 671½ equal, to 6,045 lb. Notwithstanding the big yield of 1,004 lb. per acre the year after it was dug, I am of opinion that the field would have shown better results during the 9 years had it not been dug. I believe

in digging when the soil can be thatched immediately after, or on flat land, such as Dambara, Lower Matale, or Kurunegala.

WYNAAD PLANTING NOTES: COFFEE.

Planting has, I regret to say, become of late such a truly dismal subject, that I have positively shied at the idea of discussing it. At present the tiniest rim of silver comes to edge our cloud, for the weather has been unusually propitious, and the spike looks exceedingly promising. It is very dry and hot with us now. The regular old fashion winter suitable for hardening wood and spike, is so far very desirable. But of course such parching heat is very trying to new clearings, and our cattle are suffering terribly already. There has been a tolerably severe outbreak of foot and mouth disease, and this morning I hear of some cases of rinderpest on a neighbouring estate.

I can but give you a woeful account of our past crop season. With the exception of one or two estates, the crop has been past all the experience of the "oldest inhabitant," for badness. Properties which might reasonably have expected 100 tons, have only given 14 and most of us huddle ourselves to the level of from 1 to 3 ton crop—and this scarcity has not been alone confined to coffee; pepper has also failed, and the cinchona disease has ravaged splendid fields, in a heart-breaking manner. Paddy has also been very poor and the natives, like ourselves, suffer keenly from the general badness of the times. There is, however, considerable trust still in Ledgeriana cinchona. Formerly it was considered the most delicate variety, but it has proved the contrary and remains healthy in situations where the *succirubra* has died out wholesale. Unfortunately, the bark market is anything but cheering at present. In fact, Mark Tapley would be in his element in Wynaad just now, and I do think we deserve credit for being as jolly as we are under very decidedly discouraging circumstances. It seems to me that pepper, Liberian coffee, and Ledger are our principal supports; but even more than these, undoubtedly, thrives tea. There are very many of us whose thoughts are turning seriously to this product. It has been proved beyond a doubt that tea grows splendidly in Wynaad and yields infinitely more freely than on the Nilgiri hills. The difficulties put forward regarding it, are the labour or the capital necessary for starting a new industry, and building factories for the preparation of the leaf. There is a great difference of opinion on the labour question, some pointing out the difficulty we already find in obtaining sufficient hands for working our estates during three-quarters of the year, whilst tea requires a continual and regular supply; others saying that a little extra pay will bring in what we require.—*Cor., Madras Times, Feb. 16th.*

NILGIRI TEA.—It is expected that there will be a grand harvest for Nilgiri tea planters this year. A correspondent writes:—"That very good tea (equal to the produce of Ceylon and Assam) can be produced on these hills has lately been proved by several of our planters. Nilgiri planters require to carefully prune their bushes; to pluck quickly and fine, and to provide ample withering accommodation. 500 pounds per acre is possible on these hills to the careful agriculturist."—*M. Mail.*

BARK AND DRUG REPORT.

(From the *Chemist and Druggist*.)

LONDON, Feb. 5th.

ANNATTO. Seeds are firmly held, though the price still remains low. For a parcel of 90 bags good bright red Ceylon an offer of 2d per lb. was refused, as being $\frac{1}{2}$ d below the limit. Twenty-one bags good West Indian seed sold, "subject to approval," at 2 $\frac{1}{2}$ d per lb.; damages at 1d per lb.

CINCHONA.—A parcel of 112 bales South American Guaiacul bark was for the greater part sold today at a decline of about 2d per lb.; bright thin silvery quill 10d to 11d; broken ditto 7d to 8 $\frac{1}{2}$ d; long brown, partly broken quill 5d to 5 $\frac{1}{2}$ d; broken brown stout ditto, and damaged 3 $\frac{1}{2}$ d to 4 $\frac{1}{2}$ d. For a parcel of 45 bales so-called Calisaya, fair bright colour, half hard bald, imported via Hamburg, the price of 9d per lb. was suggested. Sixteen cases East Indian bark, long thin bright druggists' quill, partly mossy Succirubra, sold at 11 $\frac{1}{2}$ d to 12d; and for 13 cases good grey stem quill 1s 2d to 1s 4d per lb was paid.

COCA LEAVES.—Six bales South American leaves were bought in—good greenish but broken Truxillo, of good flavour, at 1s 3d per lb.; thin dull small grey leaves, at 9d per lb.; 8 packages, just arrived from Colombo, were not actually offered.

QUININE.—There has been more business doing this week, about 110,000 oz of German speculative brands, in bulk, having sold for forward delivery (July-September) at 1s per oz. At today's auctions 8,000 oz. Brunswick and 5,000 oz. Zimmer quinine were offered, but only 11d per oz. was bid for them, and the whole was bought in. There are second-hand sellers on the spot at 11 $\frac{1}{2}$ d per oz.

AGRICULTURAL AND TECHNICAL EDUCATION IN THE COLONIES

is the title of a paper by Henry F. Moore, read at the latest meeting of the Royal Colonial Institute, in which we find the following from Ceylon:—

CEYLON.

The Colonial Secretary, Sir Edward Noel Walker, K.C.M.G., has sent me the following excellent report:—

I. General Education.—The population of Ceylon, according to the last census (1881), is 2,759,738. For this population general education is provided in connection with the Government as follows:—

(a) 438 schools, with 35,948 scholars, supported wholly by Government.

(b) 919 schools, with 66,400 scholars, aided by Government: the Government paying a grant on the result payment system after the annual examination of each school.

There are also 2,427 schools receiving no aid from the Government, representing 28,823 scholars. Of these 1,844 schools, with 12,211 scholars, are Pansala schools—i. e. small schools taught by Buddhist monks in their monasteries. The teaching of English was at one time largely carried on by the Government direct in its own Government schools. It has of late years, however, become in a fair way to be self-supporting; and the schools supported wholly by Government are now nearly all vernacular schools, teaching, *in Sinhalese and Tamil only*, reading, writing, arithmetic, geography and history, with specific subjects (animal physiology, sanitation, agriculture, and domestic economy). The teaching of English schools aided by Government, but not wholly supported by Government, is on the following lines in high schools, the whole of the instruction being given in English; in English primary schools the subjects are taught up to the fifth standard bi-lingually—what is read or written in English having to be translated into one of the vernacular languages, so that a native scholar may gain a full understanding of what is taught.

II. Agricultural Teaching.—(a) Generally, the elements of agriculture are taught as a specific subject in Government and aided schools from text-books.

(b) Five years ago a special school of agriculture, wholly maintained by the Government, was opened at Colombo, and the students undergo a two years' course of training somewhat on the lines of Cirencester.

After their training is completed, a certain number are paid by the Government, and are sent out as agricultural instructors into remote rural districts, where they lease land and cultivate it on improved systems, receiving half the profits of their crops themselves, the other half being divided amongst the labourers from the village where the cultivation is worked. By this means, what is learned in text-books at school is brought before the eyes of the villagers. I have not been long at work in this direction, as the experiment is new; but some good has been done already in the few years that have been devoted to it, especially as the crops raised by our instructors have generally been double, and often many fold, of the crops raised on primitive native systems; this provokes imitation. These agricultural instructors are moved about the country after raising a few crops, so as to bring their work before as many villages as possible.

PLANTING PRODUCTS.

(From the *Thirty-seventh Annual Report of the Ceylon Planters' Association*, held 17th Feb. 1891.)

Tea.—The season on the whole has been a satisfactory one especially so in the continued progress made in Markets proving the usefulness of the Tea Fund which paves the way to the introduction of our Teas to all parts of the world. The Ceylon Planters' American Tea Company has been amalgamated with a large American Company and there is every promise of its diverting a considerable share of your Tea to America. A very promising beginning has been made in introducing Ceylon Tea into Russia and you have to thank Mr. Rogivue, who was sent there by the Standing Committee of the Tea Fund, for the very energetic way in which he has set to work. Your best thanks are also due to Lieut. de Frisch for his kind aid in bringing our Tea into notice in Russia, and everything points to considerable progress being made in this Market during 1891. You are also led to expect the advent of Russian buyers to the Colombo Market, and it must be seen to that Teas are sent forward to suit them, which will settle the matter of opening the Russian Market at once. The average for the Home Market was 11d, the same as that of last year; but the Market differed this year from last in that it was a steady one throughout the rise in silver during the latter half of the year, without any compensating rise in the market value of your Teas has of course been a serious matter, and growers must trust to the great and increasing demand for our teas to right this in time. The working results of all local Tea Companies have been satisfactory showing excellent returns. The total crop for the year ending 31st December 1890 is 45,799,518 $\frac{1}{2}$ lb. or an increase of 11,453,766 lb. as against the same twelve months of 1889. The progress made with the Australian and New Zealand markets continues to be most satisfactory, the exports for 1888 being 479,626 lb., for 1889 1,134,156 lb. while for 1890 they are 2,361,433 lb., or more than doubling itself each year. Your Teas taken up by America and Canada for 1890 are 204,223 lb. as against 42,252 in 1889. There has been a considerable increase of Tea coming into bearing during the year and the area now giving yield may be put at 205,000 acres. 1891 will show a still larger increase on this. Tea in many districts has had to suffer from an insufficiency of rain during the South-West Monsoon but owing to the first portion of the year being so favorable the falling off in returns has not been great. A considerable number of properties have changed hands during the year at satisfactory prices. And the enterprise as a whole is on a firm footing with every promise for the future. A further considerable acreage has been planted in tea during the year under review in all the divisions of the principality of Uva, Badulla, Madulsima Haputale, Udapussellawa and the results obtained not only as regards yield but also as regards the quality of the tea compare very satisfactorily

with those obtained in the most favoured parts of the island. The exports for the year 1st January to 31st December 1890 were 45,799,518½ lb. as against 34,345,752½ lb for the year from 1st January to 31st December 1889. You are again indebted to the courtesy of the Principal Collector of Customs for authoritative data of the exports of tea from Ceylon, and your Committee has great pleasure in appending it.

Coffee.—During the twelve months there has been a slight falling off in exports of coffee. For the last three years the returns are as under:—

Exports from 1st Jan. to 31st Dec....	1888...cwt.	137,793
Do	1889... "	89,694
Do	1890... "	90,690

Cinchona.—There has not hitherto been the falling off in the production of this drug to the extent that has been expected; large quantities are yearly harvested; neither has there been any improvement in the prices realized which are still ruling at a figure at which cinchona cannot be cultivated profitably. Owing also to increased supplies from Java the Market for Cinchona throughout the past year has remained in a depressed and unsatisfactory condition, the unit of Quinine ranging from 1½ l to 1½ d. During 1890 large areas of land have been cleared of this product more especially in the Uva Country, and tea planted in its place. Little or no planting of Cinchona has been done in Ceylon in recent years. It may thus be taken for granted that the cultivation in Ceylon is not extending. Upon one point therefore no doubt need exist, the cinchona trees are being gradually eradicated, where shaving and careful covering were performed formerly now the tree comes out roots and stem. Harvesting bark in this manner accounts for the shipments being kept up to the still existing large figures but sooner or later a rapidly falling export, will be shown in the meantime the stem and roots of an uprooted tree supplies fully four times the quantity of bark that could be obtained by merely spoke shaving a portion, and thus chiefly, are the large exports maintained.

The exports for the year 1st January to 31st December 1890, were 8,779,140 lb against 9,455,641 lb in 1889, 12,482,817 lb. in 1888. Showing a falling of 5,896,523 lb. in 1890 over the year 1886 when 14,675,663 lb. were shipped.

Cacao.—The recurrence of droughts particularly in the older planted districts has affected the out-turn of crop very considerably, and the export has not been so large as last year being cwt. 4,073 short of 1889. The younger districts though fairly realizing estimates have not made up for the deficiencies elsewhere. Helopeltis, Borer, and the other pests continue to give trouble in their season, but the gardens generally are looking well. There has been no great addition to the area cultivated but some pretty extensive clearings about Wategama have been commenced. The thefts of this product have become very numerous and serious, involving a great deal of trouble and hardship upon managers as well as loss to proprietors. The receivers of stolen produce hardly seems to have the attention of the Police as much as they might. Prices have been satisfactory having ruled favourably during the year, in the closing months they were exceptionally high, Ceylon Cacao still maintaining the premier place in the Home Market. The Exports for the year 1st January to 31st December 1890 were 15,942 cwt, as against 18,949 cwt. for the year 1st January to 31st December 1889.

Cardamoms.—Do not generally, except in the districts north of Kandy, receive the attention they did but in those parts which appear specially suited to their growth the cultivation is continued successfully and is being extended. Indeed, it may be safely said that three-fourths of the exports of this spice come from the districts lying to the north of Kandy. In the so-called new districts and other parts to the south it is a rare thing to find 10 acres of land now devoted to cardamoms, while in Medamahannuwa, and the Nitte Cave extensive clearings exist. It is hardly probable that cardamom cultivation will extend much further or, that the output from Ceylon in the future will greatly increase for the area of the land suited for their cultivation is not large and the rhizomes become exhausted usually

after the 7th or 8th year, in the some cases before. The present figures of export may however be maintained for some years to come. The exports for the year 1st Jan. to 31st Dec. 1890 were 395,576½ lb., against 466,168½ lb. for the year 1st Jan. to 31st Dec. 1889.

Tobacco.—The cultivation of this product continues to be persevered with. The season has been a most unfavourable one owing to the almost unprecedented drought in all the Tobacco districts. There is no doubt that Ceylon can grow leaf of good quality and give a large yield per acre, but as was the case with our teas at first it will take a little time to find a demand, and the prices so far have not been remunerative owing no doubt partly to defective curing as well as to market prejudice, reports on the Tobacco justifying higher prices than have been obtained.

Minor Products.—*Cotton* has been partially successful and its cultivation is still being carried on both by Europeans and natives. In other parts of the hill country generally however the climate has proved too moist and insects too troublesome to secure any sufficient measure of success.

Croton Seed continues neglected, prices having fallen so persistently low.

Annato has been largely grown, and exported as paste and seed. The market is being overdone and good prices are not now obtainable.

Pepper is being largely planted. It seems a promising article, but so far actual returns have not met expectations.

CUBEBES.—The true plant yielding this valuable berry has still to be introduced into Ceylon, all previous introductions having turned out factitious.

ARCANUTS have cropped well and yielded good price; 1890 being "a lucky year" amongst natives; the demand was good.

KAPOK receives growing attention in the lower districts, but it is doubtful if it would pay as a systematic cultivation.

THE LABOUR LAWS.—In the last Annual Report the Committee saw occasion to congratulate the Association; because efforts which had been extended over nearly two years were thought to have terminated in a legislative measure honourable to employers and employed; and although the law unanimously agreed upon in Council was felt to be in certain points defective and incomplete, it was regarded as the best and most expedient of possible alternative amendments, and not inconsistent with the past traditions and usage which controlled the relationship of the contracting parties. Though it was mentioned in last year's Report that Royal sanction had not then been proclaimed to the Ordinance No. 13 of 1889 which had been unanimously passed in October and had indeed become an operative Law under which cases were decided in the Courts, it was a startling reverse to learn on 16th April, shortly after Council re-assembled, that a despatch dated 29th January 1890 had been received nearly two months previously, not only withholding Royal sanction, but requiring the Governor, if necessary by the vote of the official majority, and whether the official opinions concurred or not, to pass another Ordinance amending No. 13 of 1889 as to its principle. The amending Ordinance No. 7 of 1890 embodying the new principle of terminating the contract by efflux of time, instead of by the amount of work done and wages earned, was passed on 21st May 1890, was allowed by the Secretary of State on 27th June 1890, and was on 15th August 1890 proclaimed and made operative. A meeting of the Association was held in Kandy on 18th April, when the resolution expressing emphatic remonstrance, as reported in the annual proceedings, was passed; and protests with explanations were prepared by the Chairman and the Planters' Representative to be forwarded to the Secretary of State, copies of which are published, as it was felt that the true conditions could not have been fully made known to him. The Ceylon Association in London with several others there interested in Ceylon, were prepared to render such assistance as seemed practicable by means of deputations, &c. At the Committee stage of the amending Ordinance the Planting Repre-

sentative, while continuing to express strong objection to any alteration of the law of 1889, obtained an extension from 30 to 60 days for the period which may elapse after the calendar month expires where the wages were earned, before non-payment frees the labourer, without notice or demand, from all his obligations. In obtaining that extension of periods, the Planting Member intimated that he only accepted it as the best means of giving effect to the Secretary of State's orders, and not because he approved of or agreed to the alteration which had been forced upon the Legislative Council. With the greatest difficulty the Association, by the aid of the Planters' Representative in Council had succeeded in obtaining "a fair law with a continuity of the practice of a quarter of a century," conserving to the coolie "the privileges of a daily laborer, combined with continuity of employment" together with absolute security for his wages but the conditions of the law previously set forth in the last annual report are now varied in this, viz:—That it has been made easy for laborers indebted to the Estate to desert (labourers not in debt rarely or never desiring such opportunity), while the thrifty labourer has been in no way benefited. The avowed object of the less acceptable alternative was to provide a "self-acting" process whereby the labourer, without notice and without any preferred demand to be paid his balance of wages, could be relieved at a fixed time of his liability for obedient service; but, as it well known to practical planters, the previous conditions were just as much "self-acting" and were so upon a sounder basis, viz: the claim to be relieved after so much wages earned or work done, instead of merely time passed in nominal service. Hence the necessity for such a provision only existed in the imagination of those who in their minds confused the inability of certain Proprietors when overtaken by ruin some six years ago, to discharge promptly their liabilities, with a supposititious disinclination to do so; for it was not the case that any planter denied or questioned his duty to pay monthly wages when required so to do. Moreover the Ordinance No. 16 of 1884 had already accorded to the labourers a priority lien upon the estate for double the amount of wages which the rejected ordinance permitted to remain outstanding before the labourer could be relieved of his liability as a monthly servant. In thus reviewing the position of this vexed question your Committee cannot but regret that the Officers responsible for the government and administration of the country should have exhibited so defective a knowledge of the prevailing conditions of the case, and a bearing so unsympathetic and narrow in view towards the Planters and estate Owners as a class.

LABOUR SUPPLY.—In the months of April and May owing in a great measure to the prevalence of influenza and the sickness attendant on it coming as it did when there was most leaf to be plucked the labour was greatly insufficient to the requirements, and a great loss of leaf and consequently of money was sustained by the planting community. This scarcity of labour was increased by the unprecedented and arbitrary action of the Government in wantonly stopping the Northern immigration route, and at the same time imposing vexatious quarantine regulations at Colombo. Representations were made by the Association to the Government and your Committee is pleased to record its appreciation of the very prompt and kindly attention given to the matter by His Excellency the Governor both as regards the stoppage of the Northern route and the quarantine regulations. Your Committee ventures to hope that such vexatious and disastrous checks to immigration will not again be imposed by the Government of Ceylon. Since the throwing open of the Northern route and the introduction of better quarantine arrangements the influx of Tamil immigrants into Ceylon has been considerable and the labour force of the country has been replenished as is seen by the fact that this year the arrivals exceed the departures by 35,242.

COURT ADVANCES.—The question of court advances has been brought before the Association and a circular has been issued by the Association, the recommendations of which will, it is hoped, commend themselves to the community.

IMMIGRATION SERVICES.—Members are well aware that this subject of paramount importance to all Planters has occupied and continues to engage the constant and earnest consideration of your Association. The hardship, great inconvenience and loss endured in the early part of the year under review owing to the sudden unlooked for stoppage of the Immigration Service via the North Road is still fresh in your memory. At the same time you will remember that the Steamer Service via Tuticorin was rendered practically useless owing to the stringency of the quarantine regulations enforced at Colombo. The action of the Association on that occasion took the form of the following resolution which was passed unanimously at a large and representative General Meeting. "That this Association desires to express its strong condemnation of the late unprecedented action of Government in stopping Immigration on the North Road by recently withdrawing their sailing vessels that have for twenty six years been at the service of our coolies without one day's cessation and which withdrawal has unfortunately created a feeling of mistrust, and has been greatly accentuated by the stoppage of the steamer immigration service from Tuticorin to Colombo by the stringent quarantine regulations at the latter port." Your Committee has pleasure in freely recognizing the great interest and concern that His Excellency Sir Arthur Havelock has since evinced in the whole subject, and the steps taken by his Government to facilitate and where practicable increase the efficiency of the Immigration routes. This was evidenced by the Governor's asking for an expression of your opinion as to the relative advantages of the route via the North Road and via Tuticorin. Of such vital importance are both routes to your enterprise that it was felt absolutely necessary to pass the following resolution in reply. "That since the Tamils immigrate to Ceylon of their own free will it is imperatively necessary that the existing routes are kept open, and every facility given to the coolies to avail themselves of them." In acknowledging this resolution the Government stated that there was no intention on its part to withdraw any facility or accommodation now given by either route and submitted a proposal for the consideration of the Association as to the feasibility of a supplementary route for Immigrant coolies into the planting districts from ports in India to Hambantota and Wellawaya. Your Committee unanimously resolved that the opening of an alternative route for Immigrants via Hambantota would be of the greatest advantage to the planting districts and remitted the matter to a large sub-Committee to enquire into the feasibility of the route and to confer with the Chamber of Commerce regarding the immigration routes generally. That sub-Committee has not completed its labours nor has a report yet been presented; accordingly your Committee would recommend the re-appointment of the same sub-Committee to complete the enquiry desired which naturally will take sometime and careful consideration. It may be mentioned that the sub-Committee met at Kandy in November in conference with representatives of the Chamber of Commerce and passed the following resolutions:—

(I) That this sub-Committee strongly recommends the establishment of an additional immigration route via Hambantota and Wellawaya, provided one of the steam shipping companies will undertake steam communication between Negapatam and Hambantota.

(II) The Secretary of the Planters' Association of Ceylon be authorised to communicate with the various Steam Shipping Companies with the view of ascertaining what arrangements they are prepared to make in order to carry out the proposed new Immigration route and to collect all information in reply to the Colonial Secretary's letter of 6th November 1890 relative to the requirements in the way of accommodation and staff for the establishment of the route from Hambantota to Wellawaya.

(III) That a copy of the above resolutions be forwarded to Government and to the Ceylon Chamber of Commerce.

It is further understood that Messrs. Alston, Scott & Co., as representing the British India Steam Nav-

gation Co., and others have been requested to address the Association direct on the subject, and to submit their views and proposals in connection with the question as early as possible.

LAZARETTO.—The opening of a lazaretto for ocolias arriving at Colombo will it is hoped, increase the facilities for immigration by this route by doing away with any necessity for prolonged detention of steamers conveying coolies; and your Committee would record their appreciation of the prompt action of Government in completing the buildings when the need for doing so was recently urged upon them.

FUEL SUPPLY.—This matter has been prominently brought under your notice by the scarcity of fuel, which is absolutely necessary for the manufacture of tea in some districts. There are as is well-known large reserves of Crown forest but the arrangements so far made have not rendered it possible for the planters to avail themselves of the supply which is now in the hands of the Forest Department. The scheme proposed by that department of setting off certain plots of jungle for the use of various estates is impracticable owing to the inaccessibility of the plots and the conditions imposed. Your Committee trusts that the Government will continue to give their best attention to this important matter which might be to them a fruitful source of revenue by the employment of Sinhalese contractors obtain stores of fuel at accessible depots by the removal of some of the most stringent clauses of the Ordinance relating to the removal of timber and by the lowering of the rates on the Railway for the transport of timber develop a trade which would be beneficial to the revenue, the natives of Ceylon, and to the tea manufacturers. The rules at present in force regarding the supply of Firewood to Tea Estates in Central Province will be embodied in the Book of Proceedings for reference; they will also be found in the "Ceylon Government Gazette" No. 5014 of September 19th, 1890.

HOW MANY CUPS TO A LB. OF TEA?

It was said by a London expert when lately stating the cost per cup of Gallebodde tea sold at 110s per lb.,—"this equals 70 cups only to a lb." Now, what is the proper number of cups of tea to be got from one lb. of tea? What says Mr. Street, the Colombo expert?—*Planter*. [Mr. Street's reply to this enquiry is as follows:—"In reply to the question as to how many cups of Gallebodde Tea would go to the lb., I should say about 100 breakfast cups using the quantity of tea we do for tasting purposes. This would make a cup cost about 10½d at 87s per lb."—or 1s 1-5½d at 110s.—*Ed. T. A.*]

TEA AND COFFEE.—It is noteworthy that the reason assigned for the reported increase in the demand of the Parisians for British grown tea is the high price and inferior quality of coffee and wine. As regards the high price of coffee, the same may be said of tea, seeing that the duty is excessive, but as to "quality," that is due entirely to the greed of the shopkeeper class, who have ruined the reputation of French coffee by abominable admixture of ingredients worse than chicory. This has been a prolific source of complaint by English travellers in France for some years past.—"Ceylon Advertiser."

GUATEMALA AND SAN SALVADOR.—According to reports which have reached Mexico, Guatemala has equipped for war with Salvador 25,000 men, who are now engaged in gathering in the coffee crop. It is added that hostilities are expected to be declared in the latter half of February, while Honduras will keep in check Costa Rica and Nicaragua if they attempt to interfere, but otherwise will also attack Salvador, which is preparing for the struggle. Both Guatemala and Salvador are treated to be endeavouring to arrange loans.—*O. Mail*.

CANCER AND FUNGI.—It a loose way, many persons have associated this horrible disease with the presence of a parasitic fungus, but the association has never till recently, been experimentally proved. Recently, however, Dr. Russell, of Edinburgh, availing himself of the methods of staining, now so much in use among microscopists, and by means of which different tissues and growths may be readily distinguished one from another, has succeeded in discovering fungus spores in cases of cancer. Dr. Russell considers that this fungus acts like yeast, and, like it, sets up a fermenting process, accompanied by changes in the tissues. Dr. Russell's experiments will have to be repeated by other observers, and if confirmed will lead, it is to be hoped, to some means of combating this fearful malady.—*Gardeners' Chronicle*.

THE WEATHER AT YERCAUD.—A correspondent writes:—"We are having fine weather these few days, rather unusual for this part of the year. The hot days we had before this reminded us very much of the season in March and planters were apprehensive of there being a thorough failure of crop all round. But the few days rain we got has cheered them up not a little, although it is thought that the season was rather early. It is hoped, however, that the rains would continue; for more rain is wanted to set the blossom. The rain we had on the 19th of last month was thought to do the estates great harm, but the preset rains have tended to bring forward a lot of spikes that were backward then, and in a few days the blossoming season will be over. The weather does not yet look closed up and we are expecting more rain."—*Madras Mail*.

COFFEE SULPHATE FOR LILIES.—Rev. C. Wolley Dod stated recently in the *Garden*, and also at a meeting of the scientific committee, that he has found very good results with common Lilies as well as with Roses by the use of sulphate of copper as a preventive. Three pounds of sulphate of copper, which costs whole sale less than 3d. a pound, are dissolved in water, and two pounds of quicklime, separately. These solutions are then mixed together in ten gallons of water, and splashed upon the young growth, to which it does no harm. "I have found this also very useful for the cure of the mildew (*Peronospora ficariae*), which has proved here so destructive to the large variety of Christmas Roses. Another remedy recommended for mildew is to dress the surface of the ground in early spring before growth commences with finely powdered sulphate of iron. One pound is sufficient to mix in a wheelbarrow load of soil, and will dress a large surface. I have seen this treatment recommended in the *Kew Bulletin* to prevent Potato blight. I have used it for Lilies, and it seems successful."—*Gardeners' Chronicle*.

THE PLANTERS' PRESENT TO THE CZAREWITCH.—The albums of views to be presented to the Czarewitch by the Planters' Association, arrived at Darawella from Colombo during the race meeting, and Mr. L. H. Kelly, the Chairman, being present on the course, a wish was expressed to see it, and he consequently showed it to the Governor and the Czarewitch, informing the latter that it was intended for formal presentation to him in Colombo. H. I. H. however, expressed his willingness to take it at once, remarking that he appreciated the gift very much and would prize it. The presentation consequently took place on the spot. On the silver plate outside the characters "Ceylon, 1891" appeared, and on the inside in gold lettering the fact that it is the gift of the Planters' Association to H. I. H. is recorded. Fourteen of the views show all stages of the tea industries and are those taken by the late Mr. Malcolm Clarke. Some 22 others are by Messrs. Skeen & Co., comprising views of Colombo, Kandy, Nuwara Eliya, tea estates, &c. They are all mounted on black plates with gold edge, and their description is printed below each in gold. The 100 lb. tea in 25 boxes of Ceylon woods like the present, which was given to the Queen will be presented through Lieut. de Frisch;

Correspondence.

To the Editor.

ON THE WEST COAST OF AFRICA: BY AN
EX-CYLON PLANTER.

Essnassie, Gold Coast, West Africa, Nov. 23rd, 1890.

DEAR SIR,—Today being Sunday, I take the opportunity to write you these lines, as promised. We reached Elmina on Saturday, the 1st instant, after a voyage from London of 28 days. This long time is due to the number of small ports the steamers call at. This port is in about the same latitude as Galle, and in an old Dutch fort is stationed a Hawsa regiment with one European officer in command; he being the only white man in the place, and, of course, acting in all sorts of official capacities. Once a week a Mr. Holmes, District Commissioner, goes over there from Oape Coast and holds Court. They were both very kind to me, but this is just what one would expect if the wish of Government is to open up the country.

The natives are in many ways like our Ceylon friends, and those in towns just as cheeky. As labourers they are good out of their own country, but not in it—servants are very good and beat the Tamil appu hollow. The principal articles of export trade are rubber, priced here at 1s to 1s 3d, and palm oil and nuts. They are purchased or bartered for clothes, guns and other articles.

The temperature is about the same as in Kandy, and when at its worst like Colombo, but the evenings are much cooler.

We were detained about ten days at Elmina and then started for this place with our Kroo boys loaded up with tools and stores. I wanted to bring 200 of these labourers from their coast, but I only managed to bring 71 with me, the balance I gave 'books' for. This consists of a letter asking any captain or cruiser to bring a stated number of boys to a stated port and there obtain payment at 15s per head: this price is uniform from the Liberian coast as far as Ockra.

Now about the country: the growth all round beats that of Ceylon, the soil is generally a dark loam for a depth of from 1 to 2 feet, and then a subsoil, as in Dikoya, of a clayey nature. There is just enough slope to permit of good draining, and very little rock; the rainfall and the temperature are about the same as in Kadugannawa. The price of land is nominal, and Kroo labour is good and cheap, costing about the same as the Tamil. Pepper is found wild, and cacao and Liberian coffee grow well, I hear, but I have not seen them yet. Orobua coffee has not been tried, but I have no doubt it will succeed also; I intend to make an experiment. Roads are rather bad and in parts very swampy. I think that the prospects for planting are far more encouraging here than in Ceylon, for coffee and cacao, when they well grow, are far more remunerative and want less labour than tea, but of course, as is the case anywhere else, capital is wanted to make a start.

I have given away a lot of Ceylon tea, and all like it very much. It is bosh about Ceylon tea, not keeping, I have some, the lead of which was broken in packing 5 or 6 months ago, and it is still in very good condition. There is not much chance of a trade springing up yet, but I hope to be able to introduce our tea all along the coast before long.—I am, dear sir, yours truly,
S. W. GANE.

CEYLON TEA AT £5 10 PER POUND.

London, E. C., Jan. 23rd, 1891.

GENTLEMEN,—I send you a cutting of a leading article in the *Daily Telegraph* of Jan. 17th on some wonderful quality of Ceylon tea which has excited special interest.

Messrs. Elliot, Lack & Porter inform me "that this lot of tea consisting of three 5 lb. boxes in all 15 lb. was knocked down at public sale for

87s per lb. and subsequently resold for £5 10 per lb to the United Tea Company of 21 Mincing Lane. The special feature was its exceptionally good make and appearance, being almost entirely 'Golden Tips.' The liquor would naturally be fine but not at all commensurate with the appearance which was primarily the cause of the high price paid."

On receipt of the above information I went round to see this tea, which was publicly advertised to be on view at the Company's offices.—I met a whole crowd of Ceylon men there who all thought that the sample must have been the result of special picking and most careful manufacture, probably a little at a time and by hand. No doubt the final price was the result of competition in order to secure the sample for show purposes; still great credit must be due to the management which has secured 15 lb. of such wonderful tea, and *Gallebodde* estate has certainly made a name famous for good tea which the proprietors should be grateful for, while it should stimulate their neighbours to improve the quality of their tea by greater attention to the cultivation, picking and manufacture under scientific principles.
JOHN HUGHES.

TEA PACKING: LEAD PAPER, SPECIAL PAPER;

London, E. C., Jan. 29th.

DEAR SIR,—I have read your editorial on "lead paper" contained in your issue of 8th inst. I hope the public will understand that this lead paper is entirely a different article to the paper I am introducing. I don't wish in any way to disparage the paper entitled "Clark's Patent," indeed it may be an excellent substitute for all I know, but I wish it to be clearly understood that my paper is quite apart from this, possessing no lead about it whatever. Since last writing you, I have received an application to supply a large group of estates in India with it. The proprietor, who is at present at home, inspected the packing of the Elkaduwa chests on their arrival and was so pleased with the satisfactory condition of the tea and the serious saving in cost that he is adopting the paper on his estates.

I think your idea as to forming a Sub-Committee of the Planters' Association to consider such improvements an excellent one, and I trust it will be acted upon. It is the only proper and practical way to bring the matter clearly before the community. Let such Committee be provided with samples of linings recommended as substitutes for the present lead, and having regard to cost, in conjunction with efficiency, report accordingly. In the meantime I am quite satisfied to utilize my own paper, for until anyone can produce a substitute equally efficacious in preserving the tea and showing a further saving in cost over the present of some 50 per cent. as compared with the ordinary lead lining, I don't look for anything better.—Yours faithfully,
J. M. MAITLAND KIRWAN.

[We should be glad to know if the whole of the tea of any one estate is packed in this paper.—Ed. T. A.]

LIBERIAN COFFEE: PRACTICAL HINTS.

SIR,—Being one of those who rushed into Liberian coffee, a dozen years ago—went out for wool and came back shorn but did so in very good company—I have naturally small confidence in a successful revival of its cultivation even with all the experience gathered in the past time; It would not have been so complete and general a failure over the lowcountry had we known then what we

know now of the character and requirements of the plant. I will certainly not tempt fortune a second time myself under any conditions; but as there are bolder spirits in the field, some of them may possibly profit by the formulating of my experience.

When the plant has had moisture enough to establish itself even in indifferent soil, it flourishes with high promise for the first two or three years unless attacked by hemileia, to which it is even more susceptible than the Arabian kind and succumbs more quickly. It is when it begins to bear that it begins to fail. It does not like the Arabian species respond to the use of the knife, and should neither be topped nor pruned but allowed to grow at its own free will. It can hardly be classed as a "forest tree," but in tolerably favourable situations it may be seen upwards of twenty feet in height. As to climate it probably needs somewhat greater heat than is necessary to the Arabian kind, but it should never be tried in the open in a climate subject to droughts of two or three months' duration, each spell of which leaves it weaker and more bare. The conditions of success in the lowcountry are a deep and tolerably rich soil under the shade of tall forest—the denser the better—that will not interfere with its upward growth. In such a situation the only cultivation required is to exterminate the undergrowth and bury from time to time the fallen leaves, in which case 2 cwt. per acre may be fairly hoped for.

W. B. L. wrote before he saw about the Peradeniya experiment, but that was on a gardening scale, yielding R444 per acre worth of crop.—Ed. T. A.]

INDIAN TEA EXPORTS.

Indian Tea Association, Calcutta, 10th Feb. 1891.

DEAR SIR,—The General Committee have the pleasure to hand you their usual Monthly Return of shipments of tea from Calcutta, and also a Return of Ceylon ten for four years up to the 19th January 1891:—

EXPORTS OF INDIAN TEA FROM CALCUTTA.

	1891 lb.	1890 lb.	1889 lb.
Export to Great Britain from 1st May to 31st January ...	92,956,313	89,129,802	86,828,585
Exports to Australia and New Zealand from 1st May to 31st Jan..	4,345,120	3,204,962	2,750,773
Exports to America from 1st May to 31st January ...	118,510	161,485	143,409
Exports to other places from 1st May to 31st January ...	971,512	1,329,970	757,722
Total Exports from 1st May to 31st January	98,391,485	93,829,219	90,478,489

—Yours faithfully, S. E. J. CLARKE, Secretary.

"JAMAICA SORREL"

Awisawella, Feb. 4th.

DEAR SIR,—In your paper of 24th ult. (see page 596) I notice a foot-note enquiring what "Jamaica sorrel" is. I believe it is the *Hibiscus sabdariffa* or what is commonly known as *Rozella*. It yields a very good jelly, and if the fruit is not too old a very fair jam. This plant begins to flower in December, the fruit ripening in January and February. Tamil coolies value this on account of its acid leaves, and apparently ignore the fruit. In common with all the *Hibiscus* family it yields a good fibre, and I have found the roasted seeds a very fair sub-

stitute for coffee. In a raw state they are good food for fowls, of a nutty and agreeable flavor. In a former T. A. I remember reading that this same plant is much valued in Queensland. The calyces of the fruit are gathered and dried and have a commercial value, besides being used for preserves. A wine is manufactured therefrom.—Yours,
PLANTER.

ROOFING FOR CEYLON: PRACTICAL HINTS;
A TREADMILL FOR PRISONER.

Kinmylies, Travancore, 16th Feb. 1891.

SIR,—With reference to your article on Roofing for Ceylon I wish to say that I hear that many Missions and many Native Companies have been making the Mangalore tile all along this coast of India, and that the supply is very large at present.

It occurred to me when the experiments with mana-grass for making tea chests commenced, that if it were successful, a shingle, or tile, made of that or other Ceylon grown fibre, treated like the Willesden patent paper, ought to follow. I think you did once refer to paper-mâché walls for bungalows or factories as an idea for the future.

With regard to the question of keeping the Colombo lake full by pumping from the Kelaniganga, I would suggest a treadmill on which the Sinhalese felon might take enough exercise to give him an appetite for that plainer food we hear he now enjoys: but he should be exposed to the public gaze though out of the reach of tobacco and betel.—Yours etc.,
E. F. DAVIES.

WOODCOCK IN CEYLON.

Algooteenne, Elkaduwa, Feb. 23rd.

SIR,—It may interest some of your readers to know that I shot a woodcock in my jungle this morning. I saw one in the same spot in 1883.—Yours faithfully,
A. M. HURST.

MONARAGALA: ITS NEWS AND ITS CROPS.

Koslanda, Feb. 23rd.

SIR,—As an example of "English as she is wrote" the reports of your Monaragala correspondent are admirable, and the persistency with which he urges the appointment of a J. P. is much to be commended.

Further, I entirely agree with him that the district will grow excellent tea, though the fact he mentioned the other day that plucking had been begun on some estates with an average of half a pound a cooly may not be in itself convincing proof of this.

But when he speaks of poor crops and makes sweeping if somewhat inappropriate reference to "Pharaoh's lean kine" he should discriminate. There are crops and crops now-a-days, and one product, viz. cacao, is doing very well at Monaragala
A. B.

COCONUTS AND TEA.

DEAR SIR,—I see you have lately been noticing with favour the planting of tea and coconuts together on the same land, in which it appears to me you are somewhat on the wrong side of the line. As a principle nothing is ever gained by the attempts to make land do double duty by planting two or more species of crop, yielding perennial plants as permanent occupants by way

Of having more than one string to the bow. If a given piece of land is believed to be unequal to the profitable growing of tea, for at least one generation refrain from planting it with that product. Those who plant tea and coconuts on the same land must have very little confidence in the former and only use it as a means of making something off the land while the main and permanent plant is coming on, but yielding nothing; and if the coconuts thrive, down goes the tea when it has just reached its prime and is yielding a larger profit than coconuts ever will. Tea is a plant that will not yield its product freely under shade; and at ten years old a thriving field of coconuts throws a dense shade over the whole surface if planted at the usual distance apart. Then as the stems run up the trees shed about 800 heavy leaves twenty feet long annually on every acre, and each one smashes five or six tea plants. This sort of thing is tea cultivation under difficulties, and the object of planting the tea, that of making some profit off the land while the coconuts give none, will be defeated; for the spread of the coconuts will ruin the tea before it arrives at its full yield, and that before its successful rival yields a nut. To those who would have both tea and coconuts on their land, I say, plant them apart on separate fields, and if you do not believe that tea alone will pay do not plant it.

W. B. L.

[Yes; but suppose the coconuts were first planted, and being slow of coming on, tea is added a year or two after and from the third to the tenth year, gives net returns equal to from R40 to R80 per acre without injuring the palms? And then up to perhaps 15 years gives profitable though less returns. We have heard of at least one place that is likely to do this or something like it.—Ed. T. A.]

CEYLON TEA IN RUSSIA.

St. Petersburg, 16/28 Jan. 1891.

DEAR MR. EDITOR,—Allow me to offer you my hearty thanks for the book and the copies of the *Ceylon Observer*, all of which I have safely received. I see by the report in the *Observer* that Mr. Rogivue is at last commencing to introduce the tea in Moscow and other places. In St. Petersburg none of my acquaintance, which is a pretty extensive one, have yet been able to purchase the tea. As Mr. Rogivue cannot be in every place at one time, I should be very glad if he would establish a sub agent here, whom I would be very glad to assist so far as my present duties will permit.

The most suitable person for this post according to the writer's opinion is Mr. Richard Wylie, a well-known broker on the St. Petersburg Stock Exchange.

Mr. Wylie has resided in Petersburg over 20 years and is one of the most influential persons in the British Colony here. As Mr. W— is acquainted with almost every person of importance, he would be a capital agent not only for your tea, but for other colonial productions: coffee, cocoa, cinnamon, cinchona, &c., for which Petersburg is a great market.

Mr W— is the son of a Scotch clergyman and is a gentleman of unblemished reputation. His eldest son is tutor to Lord Rosebery's children. I recommend Mr. W— so strongly to your notice not only on account of his personal qualities, but also because he formerly resided in India and was engaged in the cultivation of cinchona on the Nilgherry Hills where he had 2 estates.

Mr. Rogivue has not yet called for the writer. My idea would be to establish two small shops in Petersburg and Moscow and from these establishments to take orders and sell tea wholesale and

by retail. I would have also had a refreshment room adjoining the shop where the public could taste the tea before they purchased it at a moderate charge. These shops would have been small, but furnished and embellished with all the taste and richness the Sinhalese people are so famous for.

Tea could have been sold at this place and small samples distributed gratis until the public had overcome their old-fashioned prejudices. There would have been no risk in carrying out this plan, whereas I am not so confident that the one that has now been adopted is not somewhat too risky.

But it is not for the writer to criticize. I can only wish you and the planters every success, and that you will be able in the future, to seize a large portion of the Chinese tea trade and by means of commerce enter into more close and friendly relations with the millions of this mighty Empire.—Yours sincerely,

WILLIAM BARNES STEVENI.

P.S.—If you could once get the Russian public to like your tea it would pay (in a commercial sense) to run a railway through Afghanistan and send all your tea to Russia direct by land via Persia or the Transcaspian Railway. India and Ceylon ought to beat China. They are much nearer.

WASTE PRODUCTS: SURPLUS TEA SEED SUBSTITUTES FOR FIREWOOD.

DEAR SIR,—It has often occurred to me that if we only looked about us we might easily find a profitable use for the hundreds of tons of really good tea seed (except for nurseries) which we cannot help growing but for which hitherto no one has suggested a use. I mean, of course, the seed which will insist on growing on our plucking bushes.

Some years ago, a planter of my acquaintance having gathered a large quantity of seed for which he could not find a purchaser endeavoured to turn it to account by converting it into oil. He obtained a common village oil-press, and having thoroughly dried the seed for several days in the sun, succeeded in pressing out about 10 per cent of oil which burnt with a clear bright flame in common oil lamps and which the coolies used greedily for their curries, etc. This particular lot of seed, however, having been carefully gathered and husked had cost a considerable sum, and being still valued at R10 per maund, the experiment was pronounced a failure; but with seed worth absolutely nothing and which would cost a mere trifle to gather and prepare, might not the result be very different? Besides I am of opinion that by fermenting the seeds (and perhaps a gentle roasting) the percentage of oil would be considerably increased.

Of course, the time to gather the seeds for this purpose would be when *pruning* a field, when the whole could be stripped off and thrown on a barbacue where it would remain till ready for the press, requiring no further attention except an occasional turning, as all the ripe seeds would fall out of the husks after a few days' exposure, and a few showers would not hurt the seed (for oil); hence as I said before the cost of gathering and preparing would be a mere trifle.

Then is it not natural to suppose that the oil-cake of this seed would prove to be the best possible manure for tea, and if so it would also be the cheapest to apply, as a lb. or so would probably be sufficient for each bush?

Having thus found a use for the ripe seeds, we should still have the husks and *unripe* seed of which large heaps would soon be collected. I believe this would make a capital fuel and would probably

burn with a steadier heat and give less trouble to the stoker than common firewood.

Apropos of the *burning* question, weeds and all other vegetable rubbish, if pressed into a tolerably firm brick *while green* and then dried, make a fairly good fuel, being similar to the cakes of cow-dung, the only fuel used by the natives over a large part of India, without the objectionable smell.

Mana grass, if cut green and treated in the same way, would, I believe, be equal to the *best firewood*.

A common wooden press, all of which could be made up on the estate (except the screw and worm), would answer this purpose.

Of course, all the above suggestions are more or less problematical, but I give them in the hope they may lead to some practical results by provoking a discussion and perhaps causing experiments to be made.—Yours truly, WASTE NOT, WANT NOT.

CINCHONA BARK CROP IN JAVA.—We have received from the Soekaboemi Agricultural Society their table of statistics of the cinchona bark crop in Java for 1890 and 1891. Of 114 private estates enumerated, the greater number furnished statistics of area, outturn, amount of quinine sulphate in bark, &c. The result of these statistics is to show that in 1890 the actual outturn of bark from private and Government gardens together was about 3,000,000 kilograms containing an average of 4 per cent of quinine sulphate, equal to 120,000 kilograms of quinine sulphate, or about half of the world's annual consumption; while the estimate for 1891 is 3½ million kilos of bark containing an average of 4 per cent of quinine sulphate, equal to 140,000 kilos of quinine sulphate, or nearly 4-7ths of the world's annual consumption.

TOMATOES.—As a result of experiments and observations carried on at the Agricultural Experiment Station, at Cornell University, Ithaca, New York, Messrs. Bailey and Munson conclude that:

1. The Tomato plant is quickly susceptible to careful selection.
2. As elsewhere in the vegetable kingdom, the character of the plant as a whole appears to have more hereditary influence than the character of the individual fruit.
3. Very heavy manuring does not lessen productiveness.
4. Neither nitrate of soda nor muriate of potash alone are profitable Tomato manures upon thin soil.
5. Very early setting of stocky plants in the field, even in dark and raw weather, augmented earliness and productiveness.
6. Seedlings gave far better results than cuttings.
7. Trimming the plants lightly late in summer gave a greatly increased yield.
8. A double or monstrous flower upon a young plant is no indication that succeeding flowers upon the same plant will be double, and produce irregular fruits. But varieties which habitually bear double flowers are also the ones which habitually bear irregular fruits.
9. Cool and dark weather in early fall, and early fall frosts, are the leading drawbacks to profitable Tomato culture in the North. To avoid these dangers as much as possible, plants must be started early and forced rapidly.
10. The essential general points in profitable Tomato culture are these:—Careful selection and breeding; early sowing; frequent, or at least, occasional transplanting to obtain stocky plants; rich soil, well prepared and well tilled.
11. There is evidence that varieties of Tomatos run out, even under good culture.
12. The best market Tomatos appear from our tests to be Ignatum, Favourite, Bay State, Atlantic, and perhaps Ruby among the red varieties; Beauty, Mikado, and possibly Potato Leaf, among the pink or purple varieties; Golden Queen among the yellow sorts.
13. Among the novelties, Ruby and Chemin Market are most promising.—*Gardeners' Chronicle*.

THE TRAVELLING AMERICAN'S FASHION OF MAKING TEA is as follows:—Little perforated silver balls are filled with the dry tea and, being suspended by a chain, are allowed to remain in the cups of boiling water as long as may be required. This mode of preparing tea obviates the risk that callers often run of drinking overdrawn tea.—*Madras Mail*, Feb. 19th. [The silver egg for making tea is a very old invention.—Ed. C. O.]

THE JAVA COFFEE CROP.—According to a telegram from the Governor-General of Netherlands India, dated Jan. 31st last, the next Government coffee crop in Java is estimated at 359,648 piculs which is considerably more than in the preceding year; but further information must be waited for, as the first estimate in 1890 was also much higher, and afterwards great disappointment was occasioned.—*L. and C. Express*, Feb. 6th.

TO PREVENT SLIPPING OF BELTS.—Edwin A. Kimball, instructor in the shops at the University of Illinois, says on this subject:—"I do not know that washing soda may not be as good as castor oil, for I never used the former; but I do know that castor oil is effective and safe in the hands of a competent person. There is no occasion to soak a belt in any sort of oil. A little applied to the surface is sufficient. There is nothing that I have ever tried that is so effective as castor oil, especially for wood-working machinery belts. The way to apply it is to let it run from a bottle in a small stream on the belt while this is in motion, commencing at one edge of the belt, moving the stream over a little at every full travel of the belt, until the width of the belt has received its portion. I know of belts that have been treated in this way for years, and they are whole yet, and doing their work without a murmur.—*Engineering and Iron Trades Review*.

THE AMERICAN FARMERS' ALLIANCE.—Mr. Polk, the President of this body, formulates its demands as follows:—

A system of finance which recognizes and secures to every citizen of this country an equitable, fair and just right to share its benefits, and which will furnish a volume of circulating medium, adequate to the legitimate demands of the country, at a low rate of interest, is the greatest and most urgent need of the times. Let the people here represented continue to reiterate and with increased emphasis demand:

First, That silver shall be restored to its dignity and place as a money metal, with all the rights of coinage and all the qualities of legal tender which gold possesses.

Second, That the currency of the country shall be issued direct to the people at a low rate of interest and without discrimination, and shall be a legal tender for all debts, public and private.

Third, That taxation shall be more nearly equalized by requiring that all property shall bear a just proportion of its burthens.

Fourth, That alien ownership of land should be restricted and prohibited.

Fifth, That public transportation should be owned and controlled by the government.

Sixth, That no class nor interest should be taxed to build up any other class or interest.

Seventh, That public revenues should be limited to an honestly and economically administered government. And for the further security of the public welfare let them demand:

Eighth, A just and equitable system of graduated taxation on incomes.

Ninth, The election of United States Senators by a direct vote of the people.

These demands are the necessary and legitimate outgrowth of our rapidly advancing civilization, and the highest considerations for the public weal and safety should impel us to earnest and persistent endeavour to engraft them upon our governmental policy.—*Florida Despatch*.

TEA AND COFFEE SUBSTITUTES.

So long ago as 1883, I contributed to the *Gardeners' Chronicle* a few notes under the head of "Tea and its Substitutes." These notes appeared on pp. 802-3 in the number of June 23, vol. xix., new series, and on pp. 765-6 in the number for December 15, vol. xx., new series. What was there stated as to the interest of the subject might be repeated here, notwithstanding that seven years have passed since those notes were written, during which time many more plants have come to my notice having similar uses in different parts of the world.

Many changes have taken place in the growth, cultivation, and trade of tea proper during the seven years that have elapsed, and other countries have entered the market as tea producers since that period, the demand for the dried leaves of *Camellia theifera* increasing with the supply. The return of Christmas, when an extra good cup of tea is often included amongst the items of good cheer, seems an appropriate time to return to this subject, not that we think any of those plants to be enumerated would commend themselves for actual use amongst the bulk of our readers, but a record of them will indicate how varied are the sources from whence a refreshing—or, in some cases it may be a medicinal—beverage is obtained.

Twenty-four distinct plants were described in the former notes, and they were arranged under their respective natural orders. The same arrangement is continued in the following notes, and the numbering taken up from thence.

BERBERIDACEÆ. 25. *Caulophyllum thalictroides*, Michx.—A perennial herbaceous plant, with a tuberous root, and stems about 1 foot. It is found in mountainous shady woods in South Carolina, where it is known as Blue Cohosh. The plant also occurs in Japan and Manchuria. The seeds, when roasted, are said to form an excellent substitute for coffee, for which purpose they are used by the natives in North America.

FRANKENIACEÆ. 26. *Frankenia (Bertsonia) portulacifolia*, Roxb.—This is one of the few indigenous plants in the Island of St. Helena, and the genus was named in honour of Beaton, who wrote an account of St. Helena. It is found on rocks by the sea on the south side of the island. The flowers and flower-stalks, when simply dried, are of a brownish colour, and are known as St. Helena tea. There is a sample of this tea in the Kew Museum which was gathered in 1863, and still possesses a strong aroma similar to Chinese tea.

GERANIACEÆ. 27. *Geranium incanum*, L.—A plant with trailing stems. Native of the Cape of Good Hope. In Natal the leaves are used as tea under the name of Natal Wild Tea. There is a sample in the Kew Museum, which was obtained from the Natal Court of the Colonial and Indian Exhibition of 1886, and it possesses a smell not very dissimilar to that of ordinary tea. There is a sample of this in the Kew Museum.

28. *Monsonia ovata*, Cav.—An herbaceous plant of the Cape of Good Hope, where it is known under the name of *Keita* by the Hottentots. The roots and herbs of the plant are very astringent, and are used at the Cape in dysentery: an infusion or tea is made from them, used among the Fingoes to promote abortion.

LEGUMINOSÆ. 29. *Sebania occidentalis*, Pas.—In the Kew collection is a sample of the long slender pods of the above-named plant, gathered on the banks of the River Magdalena, and labelled "Wild Coffee, Café de Buena or Chiluchile."

30. *Abrus precatorius*, L.—This well-known plant, which is found in nearly all tropical countries, and whose seeds are so generally known as crab's eyes, appears at one time to have had a reputation as a tea plant, for Lunan in his *Hortus Jamaicaensis*, quoting from Becham, says:—"I know a gentleman in Jamaica that made a tea of the leaves, and drank of it many years, which he said kept him in good health."

31. *Cassia mimosoides*, L.—This plant is referred to in a list of economic vegetable products exhibited in the Cape of Good Hope collection of the Colonial and Indian Exhibition, 1886, as being used at the Cape as a substitute for China tea, under the name of Bushman's or Hottentot tea.

32. *Acacia myrtifolia*, Wild.—A tall, glabrous shrub of New South Wales, Victoria, Tasmania, and South and West Australia. The leaves are said to be sometimes used as tea.

Amongst other leguminous plants, reference may be made to *Psoralea grandulosa*, which, however, was referred to in our notes in December, 1883. In addition to what is there stated, it may be said that in the Mauritius the plant has not only a medicinal reputation, but is also used as a substitute for Tea. It appears, further, to have been at one time an article of import to this country, judging from a note by Tweedie in the Kew Herbarium, where it is said that the plant was "good for disorders of the stomach," and that "large quantities were carried to England and sold as Radical Tea in the Radical Times."

Two other leguminous plants have recently been used in France in the composition of medicinal teas, under the names of "Thé des Alpes Maritimes," and "Thé Purgatif des Apennins." The first is a composition of broken leaves of a plant which cannot be identified, a few *Senna* leaves, and a free use of the flowers of *Anthyllis vulneraria*, and perhaps *Colutea arborescens*; the second contains a larger proportion of *Senna* leaves, flowers of *Anthyllis vulneraria*, and florets of *Centaurea cyanus*. Whether these flowers possess any direct properties in themselves, or are put in to improve the appearance of the so-called tea, or increase its bulk, is a question not easy to solve.

ROSACEÆ. 33. *Acacia sanguisorbe*, Valet.—A native of Australia, and found in all the Colonies except Western Australia. Maiden, in his *Useful Native Plants of Australia*, says:—"The leaves of this plant have been used as a substitute for tea, and have been highly spoken of by some for this purpose."

34. *Rosa canina*, L. (Dog-rose).—Of this well-known plant, Sowerby says, in his *Useful Plants of Great Britain*, that the leaves have been used as a substitute for tea.

SAXIFRAGEÆ. 35. *Saxifraga crassifolia*.—Under the name of Mongolian tea, the leaves of this plant are said to be used by the people of Siberia.

MYRTACEÆ. 36. *Verticordia pennigera*, Eudl.—Under the name of native Tea, the flowers and leaves of this plant were shown in the West Australian Court of the Colonial and Indian Exhibition in 1886, with a note to the effect that the taste not unlike that of ordinary tea, and that the settlers in the earlier days of the colony used it as a tonic and blood purifier. There is a sample of this in the Kew Museum, which has a faint smell of Chinese tea.

37. *Kunzia Mulleri*, Benth.—The dried leaves of this plant, which have a similar smell to the last-named, were likewise shown in the West Australian collection in 1886, where they were simply described as native Tea, possessing the same medicinal properties as the *Verticordia*.

MELASTOMACEÆ. 38. *Crenaniam theezans*, D. C.—This genus is now placed by the authors of the *Genera Plantarum* under *Miconia*. It is a tree from 12 to 20 feet high, a native of damp places about Popayan, where the leaves are infused and drunk in place of tea by the inhabitants. Boupland says:—"We have often drunk with pleasure the infusion of the *Melastoma theezans*. It has the colour of tea, and is much less astringent, but more aromatic; many persons would doubtless prefer the drink to tea, and I think it will be found as useful in most cases."

TURNERACEÆ. 39. *Triacis micropophylla*, Griseb., which is now put into the genus *Turners*, is said to be used in Hayti as a tea plant, under the name of Thé de Lascahotas. A small sample of this tea is contained in the Kew Museum.—J. R. JACKSON, Kew.—*Gardeners' Chronicle*.

A SUBSTITUTE FOR QUININE has been found in the extract from the root of a shrub called *Pambutano*. According to the *Medical Press and Circular*, the aqueous decoction of this root has proved a remedy in cases of malarial fever where quinine failed. The active properties of the root are obtained by its maceration in alcohol at 60 deg. Fahr. The alkaloid has not yet been isolated.—*Globe*.

THE DISCOVERY OF SPONGE BANKS of a considerable extent and of great yield at Lampedusa. Trapani, Egadi and Pantelleria has come very opportunely and will no doubt exercise a beneficial influence upon the shipping and labouring classes of the coast. The quality of the article brought from Lampedusa is of the very best, and these new supplies will no doubt influence prices all round and everywhere.—Naples, Italy Dec. 11.—*American Mail*.

SARAWAK TEA has been reported on as follows:—"A sample of the Matang tea was handed to an English firm last month. They report upon it as follows:—"We carefully return your most interesting sample of Sarawak tea which we have this morning liquored and are delighted and surprised with it. The preparation and make of this tea are very much to be commended and the liquor we think would have been most marketable had proper precaution been taken in sending the samples in soldered up tin, for the leaves seem to us at present to be in process of decay, we think if this tea had been sound, it should have fetched in Mining Lane, about the same money as two parcels we recently bought, and of which we enclose samples, the Ceylon at 10d and the Indian at 9d."—*B. N. B. Herold*.

ENTOMOLOGICAL SOCIETY, Feb. 4th.—Mr. O. J. Gahan called attention to a small larva which he had exhibited at the meeting of the Society on the 1st of October last, when some doubt was expressed as to the order to which it belonged. He said that Prof. Riley had since expressed an opinion that the larva was that of a dipterous insect of the family Blepharoceridae, and might probably be referred to *Hammatorrhina bella*, Löw, a species from Ceylon.—Mr. C. O. Wat-rouse exhibited specimens of *Scyphophorus interstitialis*, a Mexican species, and *Aceraius comptoni*, a Ceylon species, recently taken by Mr. Bowling in his greenhouse. He also exhibited, on behalf of Miss B. Sharpe, a specimen of *Daphnis hypothous*, Cramer, a native of Borneo, Java, and Ceylon, caught some years ago at Crief, N. B. The specimen had long been confused with *Cherocampa nerii*, under which name its capture was recorded in the *Entomologist*, xiii. p. 162 (1880).—*Athenæum*, Feb. 14th.

CACAO CULTIVATION IN PERU.—Up to a recent date the cultivation of cacao in Peru seems to have been confined more especially to the Transandine slope, in the province of Convecion, in the department of Cusco, not, however, in sufficient quantities to supply the markets of the southern departments of the Republic. The cacao produced is of a superior quality, and could compete advantageously with best descriptions raised at Soconusco and in Venezuela. The excellence of the bean is, however, rather due to the geological and topographical conditions of the valley of Santa Ana than to the efforts of the cultivators—the cacao goes by the generic name of Cusco cacao—but, owing to the cost of production, distance from the sea, and deficiency of transport, cannot compete in price with that imported from Ecuador, consequently the production and consumption does not extend beyond what is requisite for the local demand. Cacao of good quality has also always been raised in the province of Jaen, in the department of Cajamarca, and the cultivation of the plant extends towards the seaboard in the north of the department of Piura, but upon so limited a scale as scarcely to amount to more than an experiment. With a more extended development, cacao could easily be produced in sufficient quantities for the internal consumption of Peru, displacing export from abroad, and perhaps even competing in foreign markets; a future for the industry which appears more than probable when the contemplated irrigation scheme in the department of Piura shall have been carried into effect.—*Foreign Office Report*, Oct. 8.

A BIG AMERICAN PRODUCE COMPANY.—Messrs. S. V. White & Co., New York; Messrs. John H. Davis & Co., New York; Messrs. Connor & Co., New York, are authorized to offer for subscription one million dollars of preferred eight per cent. Cumulative Stock mentioned below. Thurber-Whyland Company. Organized under the Laws of the State of New Jersey.—*New York Press*, Jan. 16.

THE FINEST TEA, in Oriental estimation, is gathered from shrubs which have been kept shaded for three weeks, so that the leaves are partly etiolated or blanched. It is called "flat tea," because the leaves are not rolled they are merely steamed and are never touched by the hand but turned over by the aid of a bamboo stick. After steaming they are merely dried. There is nothing in this process to justify the high price demanded for the tea. A Japanese chemist, Y. Kozai, assistant in the Agricultural Chemical Laboratory, has analysed this tea and found that it contains 30 per cent more tannin than the tea made from leaves grown in the sun. The work done by the chemist appears to be reliable. He analysed the natural leaf and the same manufactured into black and green tea. The chief difference he found was in the quantity of tannin, which was large in the natural leaf and in the green tea, but very much smaller in the black tea. He maintains that there is nothing injurious in faced tea the Prussian blue being only 1,000th part of the weight but he is severe in his condemnation of the practice of mixing with the tea the leaves of other plants.—*Ceylon Advertiser*."

THE MAGAZINE

OF

THE SCHOOL OF AGRICULTURE, COLOMBO.

Added as a Supplement monthly to the "TROPICAL AGRICULTURIST."

The following pages include the contents of the *Magazine of the School of Agriculture* for March:—

WATER IN SOILS.

WATER exists in soils (1) in chemical combination as ferric and aluminum hydrates, and hydrated silicates, and (2) in mechanical suspension as hydrostatic, capillary, and hygroscopic water.

Water in the first condition is found generally at the bottom of soils, and being quite free to obey the law of gravity, it sinks down and is found in the drainage.

Taking up the subject of water in mechanical suspension: permanent hydrostatic water or "bottom water" is that reached when soil is excavated, as in the construction of wells: it is the source of capillary water. Where hydrostatic water exists at a shallow depth, the soil is not of the most profitable nature, unless it be first brought under a thorough system of drainage. Capillary water is held in the pores of the soil by capillary attraction, and is then not free to obey the law of gravity. Its source as before stated is hydrostatic water. Capillary water is of the highest value in keeping soils in a condition of healthy moisture, and its presence can be readily detected in soils.

Hygroscopic water in ordinary circumstances cannot be perceived. Its presence is detected by heating air-dried soil to 100° and holding a cold surface over it to condense the moisture. The loss in weight suffered by the soil through this operation indicates the amount of hygroscopic water it contained. The amount varies considerably in different soils: it usually increases in any one soil during night, and decreases during day. The hygroscopic property of soils or the power

of absorbing water vapour from the atmosphere depends on the chemical and mechanical condition of the soils, as well as on the temperature of the air. Organic substances are more hygroscopic than mineral substances; for instance wool will vary 10 per cent of its weight on different days, and that there would be an advantage in selling silk and woollen goods by weight. The power of soil in absorbing water vapour is generally in the same ratio as that in which it absorbs other gases, such as ammonia. In respect of hygroscopicity soils vary much. Silicious soil may be practicably said not to possess the property at all, calcareous sand shows it in a very slight degree increasing about 3 per cent of its weight, while a good loamy soil absorbs on an average 3.5 per cent, clay 5 per cent, and humus 12 per cent. The green manuring of sandy soils increases their hygroscopic power, and in fact the addition of any organic matter to silicious soils brings about this desirable result. The dryness or humidity of the air affects the rapidity with which soils will absorb water, while the temperature regulates the amount of water absorbed. During the day, when the temperature is high, moisture is lost, and gathered at night.

The capacity of retaining moisture that has been absorbed is also greatest with humus and least with sand. According to Schloesing's experiments as given by Warrington, fine sand saturated with water and thoroughly drained, retained 7 per cent, a clay soil 35 per cent, a forest soil 42 per cent. Additions of organic matter will thus increase the retentive as well as the absorptive power of soils.

Capillarity depends on the porosity of the soil. In sandy soils the pores are large and the hydrostatic water is little drawn up. In a clay of medium texture capillary action is at a maximum, but if the clay be too 'heavy,' the water cannot ascend. The order for capillarity is as follows:—ordinary clay, humus, garden soil, sandy soil. In sandy soils though there is little capillarity, the water is drawn

up fast but not to any height. Evaporation is greater in a soil when it is occupied by a crop than when bare, and the faster the growth the more evaporation will there be. This will be better understood when it is borne in mind that plant food is taken into the growing plant in a state of solution, and that it is the evaporation of the water in the higher parts of the plant and the consequent concentration or thickening of the crude sap that causes the less dense solution of water and mineral matter to pass upwards, by the law of diffusion. In bare land capillarity and therefore evaporation is favoured by a tolerably dense condition of the soil. The operation of ploughing or otherwise breaking-up this soil tends to diminish the amount of evaporation by disturbing the conditions favourable to capillarity; evaporation is also diminished by the presence of stones on the surface of a soil.

OCCASIONAL NOTES.

A meeting, at which was present Mr. Schwann, M. P. for North Manchester, was held at the United Service Library on Thursday the 5th Feb., with a view to considering the subject of Technical Education for Ceylon. Speeches were delivered by Mr. Schwann, the Assistant Colonial Secretary, and others. We had not the pleasure of listening to these speeches, not having had the honor of an invitation to be present on the occasion. We found on enquiry from one of the promoters of the meeting that it was to be of the nature of a "private conference," though it subsequently turned out to be a very public affair, there being present newspaper reporters and a number of students and others. The gentleman referred to was good enough to express a wish to see us at the meeting, but we did not feel justified in being present under the circumstances. It struck us as rather peculiar, to say the least of it, that it should not have been thought proper by the conveners of the "private conference" to invite us, as solely representing technical education in this city. In one way it was fortunate that we were not of the large assembly that met at the Fort Library on the 5th, as we were thus enabled to dispassionately review the speeches delivered on the occasion through the columns of the press, unaffected by the enthusiasm that prevailed at a meeting patronised by an M. P. and a Manchester man to boot.

It is undoubtedly a great matter to hear a man of Mr. Schwann's experience of technical education, deliver himself on his pet subject; but it was a pity that those who should have seconded the efforts of the speaker by helping him to apply the general principles of technical education which he enunciated, to the special case of Ceylon, should have in their enthusiasm forgotten their part. The late Director of Public Instruction, however, as an old educational hand, spoke warily, while Mr. Ferguson's practical letter which was sent to the meeting, was very opportune. A meeting such as this, as giving a fillip to the public of Colombo, cannot but have a good effect; but it is to be hoped that the committee of the Association, which sprung into existence at the meeting, will keep the fire of

their zeal burning till they attain the object of their existence as such.

The urgent necessity there is for constructing and repairing small village tanks has been much dwelt on of late. There are cases within our knowledge of cultivation being entirely at a standstill in places where it existed to a satisfactory extent, owing to the tanks in the neighbourhood supplying no appreciable quantity of water in dry seasons, if any at all. In some of these places it is practically beyond the power of the cultivator to get water from wells owing to the abnormal depth to which he must excavate before he can tap a water-bearing stratum. It is, however to be hoped, from the warmth with which the subject of irrigation is being thrashed out, and from the import of the visit of the Director of Public Works to India, that science will before long come to the aid of the inhabitants of these parts where nature is so hard a mistress.

Common ginger (*Zingiber officinale*) says the Kew Bulletin, as is the case with so many cultivated plants, is unknown in the wild state, but there is little doubt that it is a native of Asia. It was known as a spice to the Greeks and Romans, who received it by way of the Red Sea, and supposed it to be a production of Southern Arabia. It was very early introduced into the West Indies, from which it was shipped for commercial purposes to Europe as early as the 16th century. The dried ginger met with in British commerce is almost entirely derived from the West Indies, Sierra Leone, Egypt and India. It is noteworthy that none is sent to the British Isles from China.

The Kew Bulletin contains a note on Chinese ginger which is exported so largely, preserved in honey. For a long time there has been great doubt as to the plant which produced the large flat finger-like masses which were unlike anything produced by *Zingiber officinale*, the deterrent cause in deciding this point being the difficulty in getting the plant to flower. It has been stated never to flower in China. Dr. Trimen, who received some roots from Kew, succeeded in growing the plant, but could not induce it to put out an inflorescence; and the same was the result at Kew. Now we hear from two quarters, viz., from Dominica and Hongkong, the Chinese ginger plant has flowered, which turns out to be *Alpinia Galanga*, the greater galangal, a plant originally a native of Java and Sumatra and now much cultivated in India for its rhizomes.

The stem eelworm (*Tylenchus devastatrix*) is a minute, transparent, white threadworm, at its full growth scarcely more than $\frac{1}{8}$ of an inch in length, and its greatest breadth may be said in a general way to be $\frac{1}{16}$ of its length. Miss Ormerod recommends that, when a crop is affected by the eelworm, dressings of sulphate of potash, or mixtures of sulphate of potash and sulphate of ammonia, will be found successful in stopping attack, if applied as soon as the first

beginnings of deformed and stunted growth are observable.

At the late Tasmanian Agricultural Conference, Mr. E. H. Thompson, in reading his paper on Entomology, drew attention to the valuable properties of the *Pyrethrum* as an insect destroyer. "This plant," he said, "which forms the basis of all insect powders is easily grown, and is harmless to plant life. The Washington department of Agriculture report that they have found it most effective in destroying insect life, even the most impenetrable scale insects. Every farmer and orchardist should have his patch of pyrethrum, whether *pyrethrum carneum*, *roseum*, or *purpleum*. The flower heads, the upper shoots and leaves, should be carefully cut and harvested, and then an infusion made by pouring boiling water on them, just in fact as tea is made. . . . One ounce of the dried herb should make about 3 gallons of the infusion."

INDIGENOUS FOOD PRODUCTS: CULTIVATED AND WILD.

BY W. A. DE SILVA.

Rubiaceae.

47. *Hedyotis Nitida*, W. & A. Sin. Pitasudupala.

Is a herb growing in both cultivated and uncultivated places. In cultivated places the plants grow luxuriantly and thrive well in fertile spots. The stem is much divided, soft and round, having a pale green colour with pink marks at the nodes. The leaves are ovate and are fleshy. The upper surfaces being pale green, whilst the under surfaces are of an ashy white colour, whence the Sinhalese name Pitasudupala. The flowers which are small and of a pink colour, are borne in clusters. The very small fruits are angular with a mottled appearance, and a slight sticky secretion on the surface.

The leaves of this plant are used as a food: it is eaten along with rice both boiled and in the form of a curry. The whole plant is believed to possess certain well-marked medicinal properties, and is specially valued as a blood purifier. It is also used in nervous diseases and in intermittent fever.

48. *Mussaenda Frondosa*. L. Sin. Mussenda.

Grows in the uncultivated places in the warmer parts of the Island. It is a shrub generally from six to eight feet in height. The leaves are green with prominent nerves, branching from the midrib, placed almost equidistant from each other. This gives to the leaves a sort of freckled appearance. The peculiar characteristic of the plant is the white-coloured bracts. These bracts resemble leaves, but are a little larger in size and are of a pure white colour: they occur along with the flowers. The flowers of this plant are of a purple red colour and are very small. The fruits are of the size of ordinary myrtle berries, but of an oval shape; they are jet black when ripe.

The part used as food in this plant is the white-coloured leaves or the bracts. These are fried in oil and eaten along with rice. The young leaves are also used for dry curries. The leaves are used medicinally as local applications to allay swellings.

NOTES FROM A TRAVELLER'S DIARY.

After the failure of Coffee a great many of the natives of Kotmale have taken up the cultivation of Cardamoms in right earnest, and many have got large profits by this industry. The aspect of the district, its climate and rainfall, favour the growth of the plant, and some of the gardens that I visited are a sight worth seeing.

It takes about 3 years for the plant to bear, and the expenses of putting an acre under cultivation, and also for weeding the land during a period of 3 years, will come to about R80, according to an estimate given to me by a proprietor of some large cardamom plantations in Kotmale. About R160 worth of cardamoms could be gathered from an acre for a year, and the plantation will continue to give a high crop for over a period of ten years.

Two distinct varieties are cultivated, viz., Mysore and Malabar. On the Mysore variety the flower stalks or panicles given off from the root of the plant stand erect, while in the case of the Malabar variety they creep along the ground. The Mysore variety is far superior to the Malabar; its fruits are bigger and they fetch a higher price. The natives, however, prefer the Malabar variety, because it gives a better yield. I saw a few plants of another variety which give off flower stalks both from the top of the stem and the root.

Kotmale is as noted for its cardamoms as Dumbara is for its cocoa. In both districts the cultivation of these plants form the principal industry of the natives.

The cultivation of arecanuts ought to receive better attention from the native community of the hill districts. These districts, as a rule, are unsuitable for coconut cultivation. Arecanuts thrive and bear well on the hill sides, and therefore the Kandyans ought, I think, to pay the same attention to the cultivation of this plant as the lowcountry natives pay to the cultivation of coconut. It takes about 8 years for the arecanut tree to come into full bearing, and each tree will give an income, on an average, of about 50 cents a year from the time it begins to bear.

One great evil in native gardening is want of method. It is sickening to see a garden planted with all sorts of trees but without any order or regard to the growing and feeding space that should be allowed to each tree. There is much to be taught to the goiyas even in the elements of Practical Agriculture. We look to the School of Agriculture for the required improvement in this direction. Agricultural Instructors ought to be sent about the country. They could learn much themselves while imparting useful knowledge, and do an immense deal of good to the country by introducing useful products from one district to another, and showing the people how to grow them.

I wish all Village Schoolmasters were trained agriculturists. We would have had them as such if, as the founder of the School of Agriculture

intended, we had the Normal School also in connection with this useful Institution.

I find that the late Director of Public Instruction has expressed his regret at the closing of the Normal School in several of his reports. Is it too late now to have a class for training teachers also at the School of Agriculture? Now that there is to be a Technical School, it would be advisable to have a class for training teachers in Agriculture and Technology.

There is little hope of teaching Scientific Agriculture to the old goiyas. We must begin with school boys. Every schoolmaster ought to have an experimental garden in connection with his school. If he is a trained agriculturist, he will know what to grow and how to grow. A taste for gardening and a desire for competition could be created in the minds of the boys by holding annual exhibitions and awarding prizes. For all these we ought to have teachers of the right stamp. They could only be got by proper training.

THE CULTIVATION OF GINGER.

(*Zingiber Officinale*.)

BY W. A. DE SILVA.

The ginger plant thrives in warm and temperate climates. It is herbaceous in its nature, but the plant is not an annual, though it is treated as such in cultivation.

The ginger plant was known from times far remote, and ginger was an article of import among the Greeks and Romans. It is supposed by some that the original home of ginger is the country bordering the Red Sea, as it was from the Red Sea ports that the spice was exported. But on the other hand there is every reason to believe as evidenced by historical records, that India was the original home of the plant. The generic name *Zingiber* is derived from the Sanscrit. At the present day the ginger plant is cultivated to a large extent in India, Cochin, Africa, and Jamaica.

The plant is said to attain to the height of from three to four feet, but in Ceylon we do not see it grow to more than half that height.

The cultivation of ginger is carried on in the villages of Ceylon to a small extent as a garden crop. The villages in the vicinity of Cotta produce a large quantity of ginger rhizomes.

As this plant thrives well only on very good soils and produces well under good treatment, the cultivation is confined to small patches on which the cultivators can bestow the care and attention the plants require for their successful growth. However, it is a very paying crop, and on that account the extension of its cultivation is very desirable.

In cultivating ginger in Ceylon, the land is well tilled and covered with leaf refuse which is afterwards burnt. After the process of burning, all pieces of unburnt twigs and bits of root are carefully removed, and the ashes are well mixed with the soil. Then beds are made 3 feet in breadth, and sometimes double that size, from 12 to 24 feet in length as the case may be. After these beds are carefully levelled, the sets of ginger are planted at distances of nine by twelve inches. The sets are selected from thin

rhizomes which are cut into small pieces, leaving one or more buds which spring up a few days after they are planted.

The planting done, the beds are covered with old straw or leaf refuse; the former is preferred, as it could be evenly spread without much difficulty. This process is of great aid to the growing ginger, as by it a check is given to the growth of weeds which, if permitted to establish themselves at this stage of cultivation, are sufficient to spoil the whole crop. Besides, it helps to retain a certain amount of moisture by preventing excessive evaporation in dry weather, and in due time when the plants are most in need of manure, the straw or leaf refuse supplies this want after a process of decay.

Ginger is generally planted by the end of March and April, and the crop is obtained in ten to eleven months. The soil is then dug up and the rhizomes, commonly called roots, are gathered.

A large quantity of ginger sets is necessary for planting purposes, an acre of land requiring from six to ten hundredweights. The results are generally very encouraging, as the yield is from ten to twelve fold yielding eighty to hundred cwt. per acre. Ginger is seldom, if ever, dried by the cultivators of Ceylon. The produce being so limited, it is all consumed in a raw state. The price of a pound of ginger varies from two to eight cents according to the supply in the market.

Ginger is used in all countries as a condiment and a medicine possessing carminative properties. Indian and Sinhalese medical works abound in the uses and the praises of this medicine, and it is known as *Maha-Awushadha*, or the great medicine.

As a commercial product it is known in a dried state; and in chemists' shops is sold in the form of a powder,—the dried root being known as *rais* ginger. There are two kinds of dried ginger, one of a brownish colour and the other white; the white ginger is produced by bleaching the rhizomes in chloride of lime.

The cultivation of this product in an extensive scale would no doubt prove to be a profitable one in some parts of the Island where the soil is rich and the rainfall favourable. It may perhaps be also cultivated with success under irrigation, and its cultivation is to be recommended in the neglected soils of the tank districts.

The curing of ginger for market purposes is very little understood here. When merely boiled and dried in the sun, the rhizomes shrivel up, and turn black. The following process is said to yield very good marketable ginger, and is the process adopted in Cochin and other countries where a large export trade exists.

"The rhizomes of ginger when dug out are thoroughly well scrubbed in water with a hard brush until every particle of earth is removed and then steeped for a night in a pretty strong solution of limewater (one ounce of unslacked lime to the gallon), then well rinsed in clean water and dried slowly."

BUILDING MATERIALS.

SECTION II. TIMBER.

BY A FACTORY APPRENTICE.

There are nearly 90 timber trees in Ceylon, but the following are the chief and the most

extensively used, and with which almost every Ceylonese architect and carpenter is well acquainted.

Halmillilla is extensively used for carts, waggons, house buildings, tubs and casks. This wood is the best for oil casks in the island. On account of its fine grains it is chiefly used for works which have to bear great strains: its durability is from 10 to 80 years.

Palu.—The colour of this timber is a dark red, it is largely used for bridges and buildings, and it can also be safely used for underground purposes. It is the second heaviest wood (Na being the first) in the island: its durability is from 10 to 70 years.

Buruta.—The colour of this timber is a yellowish white, it is extensively used for bridges, waggon wheels, bullock carts, oil presses, buildings and furniture: its durability is from 10 to 80 years.

Na, known as iron wood, resembles *Palu* in colour, it is the heaviest wood (from whence the name iron wood) in the island. Its durability is from 10 to 60 years; it can be used for bridges and buildings, and oil can be obtained from the nut.

Suriya is a timber admirable for carriages, hackeries and gunstocks, but is not so durable as *halmillilla*.

Ramanidella is a timber used for common house buildings. Very durable fences can be made from sticks.

Teak.—There are three different kinds of teak: *Ceylon teak*, *Cochin teak*, and *Moulmein teak*. The first-named is extensively used for bridges and buildings, the second and third for waggons, carts and arrack casks; it is used for arrack casks because the wood imparts a fine colour and flavour to the arrack.

Coconut is an excellent timber for fancy boxes and furniture.

Mal Buruta.—Next to Calamander this wood is the most valuable; it is excellent for furniture.

Kalumediriya (Calamander) is a scarce and beautiful wood, the most valuable for ornamental purposes in the island.

Kaluwara.—A very valuable wood largely used for furniture.

The following woods are used for underground purposes:—*Galmendora*, *Beriya*, *Buruta*, *Kaha Mililla*, *Keta Kala*, *Mi*, *Mian Mililla*, *Muruta*, *Palu*.

NOTES FROM INDIA.

(Being translated extracts from letters by a Sinhalese gentleman.)

The cultivation of the "King" orange is carried on to a large extent in India. These oranges are of excellent quality, and are of the size of an average husked coconut—the price of each fruit being about 3 cents. King-orange is cultivated most commonly in the hill district, and there is no reason why it should not grow well in Ceylon and become a favourite fruit, proving at the same time more paying than our "Sweet-limes."

Gram (cicer) is extensively grown in many parts of India. If it can be successfully grown

in Ceylon, it would be better that the amount required for home consumption should be produced in Ceylon than that large sums of money should leave the Island to pay for the exported article.

Large quantities of pomogranate, which is largely produced in Persia, are brought over to India. These pomogranates have a splendid flavour, and are superior to anything we have in Ceylon.

[We have to thank Mr. Hemachandra Jayakody, of Galahityawa Vernacular Boys' School—the writer of the above notes—for a packet of king orange seeds, some of which have been put down at the School of Agriculture, the rest having been distributed. Mr. Jayakody, we understand, is visiting India to study Sanscrit literature. We hope he will continue to jot down any point of interest to us in his travels, and let us have the benefit of them.—Ed.]

THE GRAPE VINE.

(*Vitis Vinifera*.)

1. BOTANY AND GENERAL DESCRIPTION.—This is a trailing deciduous hardy shrub belonging to the natural order *Ampelideae*, and climbs by means of tendrils. The leaves are alternate, deeply serrated, commonly divided into three and sometimes five lobes, and have long foot stalks. The flowers, arranged in lateral clusters in the form of a raceme, are of a greenish white colour and have a fragrant odour. The calyx is cut into five segments, and the petals, which are whitish and five in number, soon drop. The fruit is a one-celled round or oval berry with a smooth skin. The colour of the berry may be green, white, red, yellow, amber and black, or a blending of two or more of these colours according to the variety. The fruit should enclose five small heart or pear-shaped stones, but as a rule it seldom contains more than three seeds. The size and consistency of the grape vary much according to circumstances.

2. HISTORY.—The age to which the vine will attain is very great. It is supposed to equal, if not surpass, the oak in point of longevity. Vineyards have been known to flourish for hundreds of years, and the vine is said to have been cultivated from the time of Noah. The native country of the vine is considered to be Persia or the South of Asia Minor. From there it passed into Egypt, Greece and Sicily: from Sicily to Italy, Spain and France. It was probably introduced to England by Roman Catholic Monks or Fathers in the third century. To Ceylon and to Jaffna in particular where it thrives so well, it must have also been introduced by them during the rule of the Portuguese. Even at the present day some of the Roman Catholic Fathers are found to be expert in Viticulture. As an instance of this, I quote as follows from "Notes from a Traveller's Diary," on page 22 of the last September number of this Magazine, where the writer speaking of Father Assauw's garden at Wahakotte says:—"What struck me most was a robust grape vine, which had been grown experimentally, laden with fruit. * * * Father Assauw, encouraged by his success, is about to extend his vineyard."

3. VARIETIES.—The varieties of the vine are very numerous, partly from its antiquity, partly from the influence of climates and soils in changing the qualities of grapes, and partly from new sorts being procured from seed by cross-fertilisation. Horticulturists base their classification of grape-vines on the character of the stems, shoots, leaves, flowers, bunches or berries. Clemente, a Spanish writer, describes 120 varieties, comprising them in two sections, downy and smooth-leaved. The Hamburgh and Muscat or Alexandria varieties are among the best.

E. T. HOOLE.

Haputale, 23rd Jan. 1891.

(To be continued.)

NEWS FROM OLD BOYS.

Mr. H. D. Juanis writes:—

Nildandahinna, a village of Walapane, contains only about thirty dwelling-houses, and is forty miles distant from Kandy. The inhabitants who are a very poor and ignorant lot, depend chiefly on kurakkan and Indian corn cultivation. The soil is rich, and is generally of a clay-loam nature. Paddy-fields occupy many of the hillsides, and are laid out in terraces which are irrigated by streams from above: these fields, however, are not very profitable. This month (February) is the sowing time for the maha crop, the weather being now, as it was last month, very wet. The rains extend from December to April. During the latter part of last year I visited a place known as Lemesuriyagama in Uda-Hewaheta, and prepared nurseries and land for tea, coffee, cotton, arecants and paddy, and supervised the laying down of land under grass. The transplanting of the paddy ought to be done now, but is being delayed for want of water, which is a great drawback in that part of the country. The work of cutting a canal from Bodi-ela has been suspended for a time owing to washing away of a part of the excavation by heavy rain a little time ago. The Nildandahinna experimental gardens, known before as the Relief Gardens, Walapane, were originally planted with different varieties of cotton, castor-oil, tobacco and grass. Now they contain dhall, arrowroot, sweet potatoes, betel, yams and native vegetables, and I am preparing more land for sugarcane, tea, &c. I am intending to plant some breadfruit trees which I have applied for. I put down $\frac{3}{4}$ scer paddy in a nursery last month, and the seedlings will be shortly transplanted into a field which is being prepared for them at present.

The Assistant Government Agent, Nuwara Eliya, is making a noble effort to improve the condition and prospects of the unfortunate inhabitants of this district.

Mr. William Abeyesuriya writes:—

Since my arrival in Weligama I have been engaged in cleaning land for tea, sugarcane and dhall. In some parts of my property Indian corn thrives well. In this district citronella is largely grown, and I intended planting up a portion of my land with it. Paddy cultivation is carried on with success though under the old system: and I am trying to introduce the new system of cultivation.

GENERAL ITEMS.

Prof. Wallace has for some time been adopting the plan of delivering a course of about thirty lectures on Agriculture to a batch rural of school-masters every year, so as to better equip them for the work of teaching agricultural science in the schools of the county districts.

Any housekeeper, according to the *Journal of Health*, ought to be able to detect the adulteration of milk without trouble. Let her take a long slender bottle, cleanse it well, and let it dry out. If then it is filled with milk and allowed to stand in a cool place for forty-eight hours, all the foreign fluid will be precipitated, that is, it will settle to the bottom of the bottle. The soured milk will then fill the middle of the bottle, and the fatty substance will be found floating on the top. Sometimes the top will be a layer of cream, then will come a layer of albumen, another artificial device to make the milk look rich; then will come the soured milk, and at the bottom will come the foreign water. The whole scheme of deception can be read at a glance, and though this sort of work is not scientifically satisfactory, it will always bring out the fundamental fact—whether or not the milk is normal.

The story told of Lord Hopetoun's housekeeper, announcing on his arrival after absence from home, that his emu had laid an egg, and that as his lordship was away she (the housekeeper) had put it under the biggest goose she could find, is matched by that told of Lord Rosebery to whom a county schoolmaster who was seeking patronage for a literary work, wrote asking permission to make mention of his lordship's name in his pamphlet on "insect pests."

Two Doctors of Nantes claim to have discovered another cure for tuberculosis, and base their method on the well-known fact that goats are incapable of being infected with tuberculosis. The theory of these Doctors is that inasmuch as the blood of goats must possess prophylactic properties which protect them against tubercular disease, the transfusion of the blood of those animals into that of human or animal sufferers from tuberculosis must give to the latter power to resist the attack of the malady.

Mr. R. Hedger-Wallace, late of Edinburgh and Glasgow, and a student of Prof. Wallace of the University of Edinburgh, has, we learn from an Australian paper, been making a lecturing tour through Victoria and Tasmania.

The second year students at the School of Agriculture include Johannes, Dias, Vairamuttu, Perera, Salgado, Amarawickrama, and Dias Bandaranayake.

The following are the new boys admitted in January:—Dias, Ayaturai, Fernando, Nallatamby, Athpathu, Kehelpannala, Abeyesekere, Banda, Savarimuttu, Kumarasinghe, Alwis, Gunewardene, Romail, Percera, and Thiedman—the last three being day scholars.

At a meeting of the Agricultural Improvement Society held in the School Reading-room, Mr. E. M. Johannes read an interesting paper on "The Fruit-trees of Ceylon."

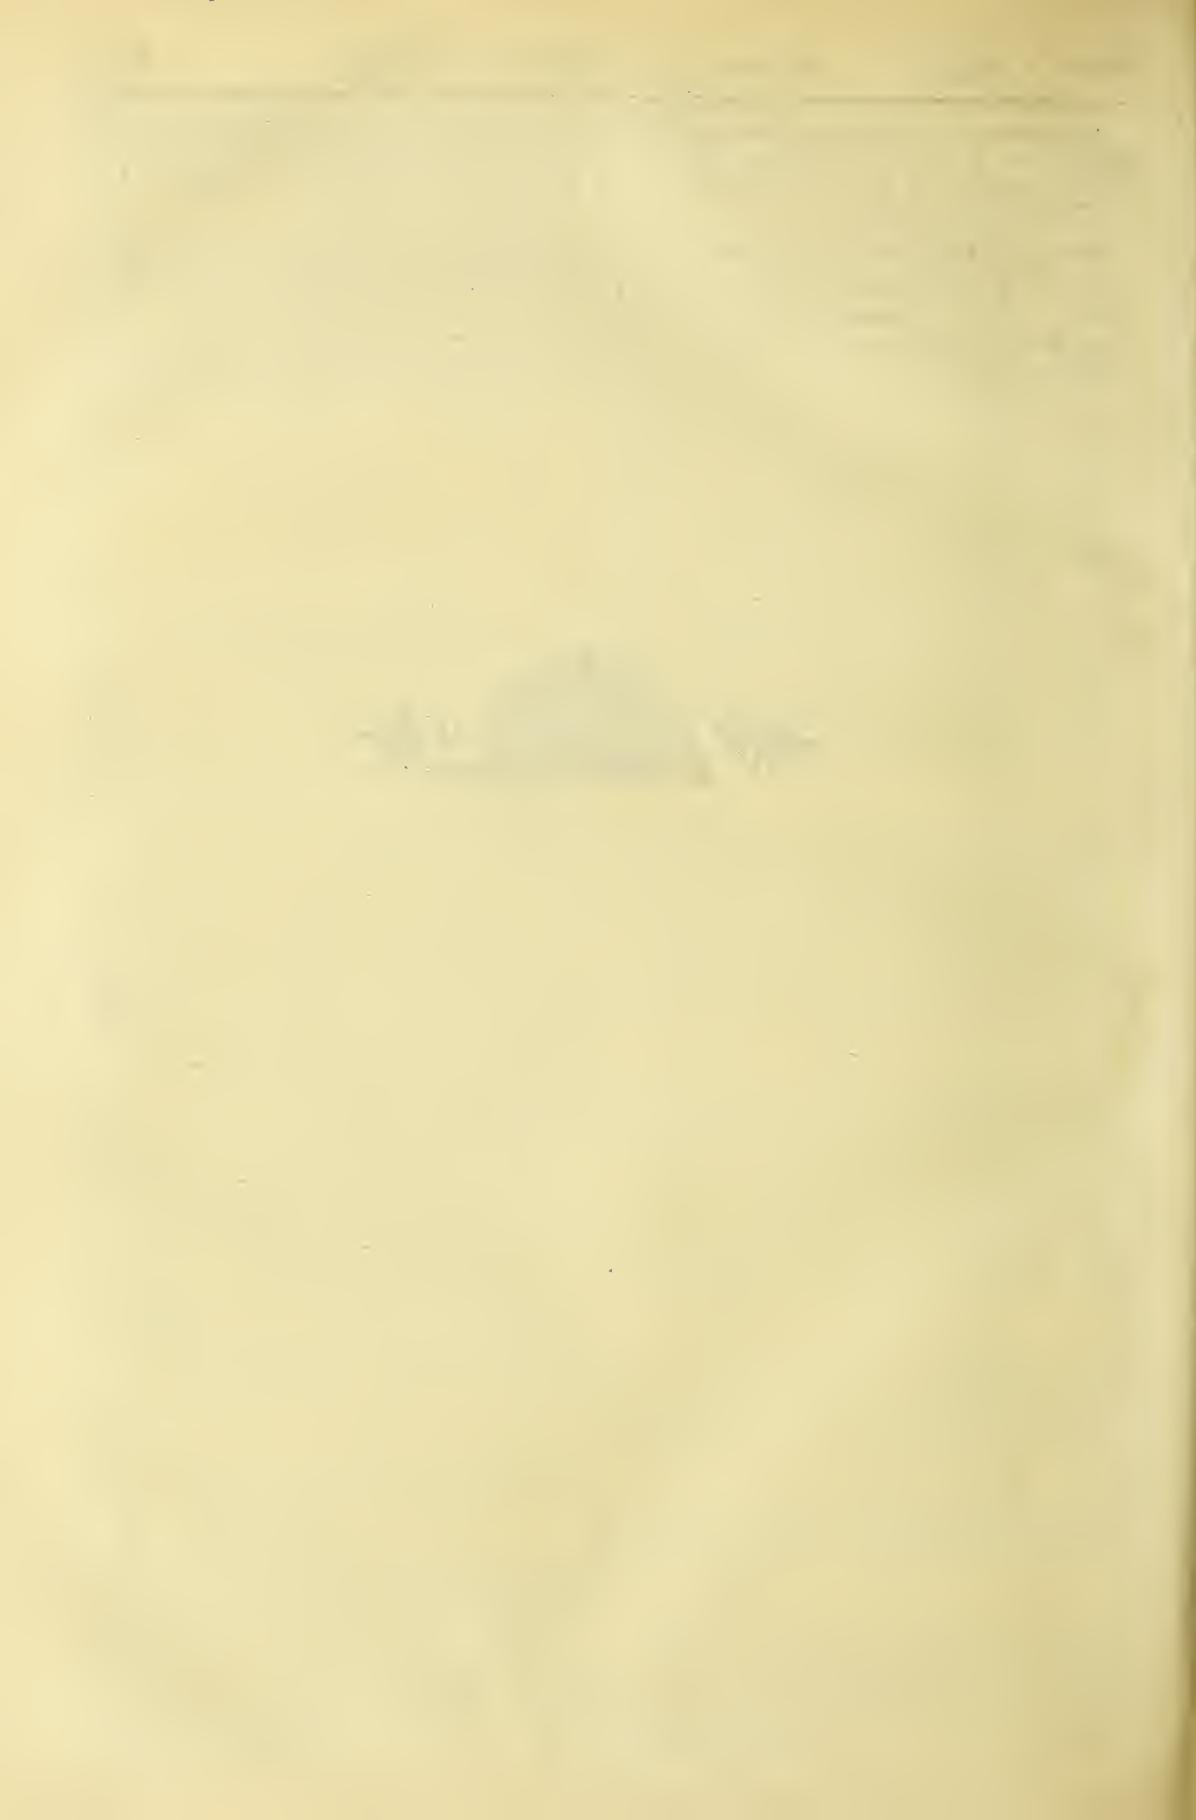

Among the visitors at the school last month were Rev. Dr. Sheshadri, and his son Mr. Sheshadri, M.R.A.C., a distinguished agricultural student. The two gentlemen were on their way from Bombay to Japan, and intend doing a trip round the world.

Received with thanks for the School Museum, 2 fossil shells (gasteropods) and a head carved in limestone, both from India, the gift of L. E. Blazé, Esq.

Acknowledged with thanks, St. Thomas's College and Richmond College Magazines. The former has just entered on its eighteenth year.

Erratum—In January number: in first article, line three, for *south* read *youth*.

THE TROPICAL AGRICULTURIST MONTHLY.

Vol. X.

COLOMBO, APRIL 1ST, 1891.

[No. 10.]

THE BOTANICAL GARDENS OF CEYLON.

FROM [Dr.] Trimen's interesting

Report, of which we give the main portions as a special

Supplement with this issue of the *Tropical Agriculturist*, we gather, that during 1890 quite

a number of plants, which are enumerated, flowered for the first time in the Peradeniya Gardens. Amongst these was that wonder of the vegetable world, the Coco-de-mer palm, to which the eccentric speculations of General Gordon have added a new interest. The abstraction of the flower is discreditable and vexatious. Some readers may need to be reminded that the seed of this palm takes no less than *ten years* to ripen! A specimen of the most imperial of all the palm tribe, the talipot, is, visitors will be glad to learn, in full blossom in the Gardens at Peradeniya. The rainfall at this place, 1,600 feet above the level of Colombo and on the banks of our greatest river, was 82.18 inches, or about $2\frac{1}{2}$ inches under the average, that average itself being lower by $2\frac{1}{2}$ inches than that of the Colombo rainfall. The visitors to Peradeniya (mostly strangers) numbered 1,454. A new and enlarged edition, the 3rd, of the interesting Handbook has been prepared. Large space is devoted to the beautiful mountain gardens at Hakgala, for which Mr. Nock has done so much during the nine years of his incumbency. A bed of the comparatively rare and striking red balsam, *Impatiens Walkerii*, has been added to the attractions of the Gardens, and the grand fernery has been entirely remodelled and greatly improved. With reference to the complaint that there is no demand for 3,000 plants of English oak which are available, and that the Botanical Department has not sufficient means to plant them out, surely this is a work which the Forest Department ought specially to undertake. Planted pretty closely, the trees might be thinned out and their quality as fuel tested. An Assam oak, *Quercus serrata*, has been found by Mr. Gammie of the Darjiling Cin-

chona Plantations to yield a superior fuel when quite young, and this species will be tried in Ceylon, as we had received notice of the posting to our address of 6 lb. of the acorns, just before we sat down to pen this notice. An Indian oak having given such results, the English oak is surely worthy of a trial. It is here, of course, of quicker growth than in its native habitat. When are we to see the Forest Department utilizing on a large scale, for arboreal experiments, the vast tracts of patana land stretching in all directions from Hakgala and Nuwara Eliya?

As we noticed at the time, May 1890 was remarkable at Hakgala for a wealth of floral beauty. On one day 610 distinct species and varieties were in flower, including 60 distinct varieties of roses of which some had hundreds of flowers. Tourist visitors have greatly increased, the names for 1890 numbering 1,319. Elk, porcupines and hares have waged annoying warfare against some of Mr. Nock's plants, and sportsmen ought to wage war against these specimens of our fauna in turn. The monsoon weather of the year was abnormally light in wind and rain, with more thunder, however, than had been observed for 9 years. The air temperature went down to 40° on 23rd December, the thermometer on the grass marking 37°. Sharp frosts occurred at Sita Eliya, close by. The maximum temperature of the air was 78.2 on May 12th. The mean temperature ranged from 58.6 in December, to 66.2 in May. The rainfall for the year was only 79.97 inches, less by 16.55 inches than the average. Interesting details are given regarding the Tropical Gardens at Henaragoda, with a climate hotter by nearly 20° than that of Hakgala, and in connection with the dying of plants in the Anuradhapura Garden, we get a vivid idea of the series of "terribly" dry years, which have nearly evaporated Kalawewa to dryness and left the tanks at Anuradhapura to suffer in sympathy. The Badulla Garden is fast becoming attractive, the one drawback being the ravages, especially in nurseries, of the termites—the "white ants" of non-scientific parlance. Interchanges of plants and seeds have been on a diminished scale, and Dr. Trimen expresses anxiety to see private nurserymen relieve his department of the task of making up warden cases of plants. The wonderful progress of tea is contrasted with the decadence of coffee, of which only 86,000 cwt. were shipped from Ceylon in 1890. Twenty years previously the culminating export of over one million of cwt. was reached and simultaneously the fatal fungus began its deadly work. Much interesting information is given regarding cacao, and Dr. Trimen complains of the absence of visible results from

the large number of seed pods disseminated by his department for the use of the natives. Sanguine expectations are entertained of the success of the Pará rubber tree, if grown by the Forest Department on a large scale. As a result of Dr. Trimen's visit to Java, we may expect the medicinal pepper known as "cubeb" to be added to our economical products, together with other useful plants. Nutmegs are noticed as likely to be profitably grown in the lowcountry. Our own experiments have proved that they are not happy in the ordinary conditions which suit tea and coconuts. They evidently require deep soil or very careful culture. From the information given, New Zealand flax would seem to be the fibre plant to which attention ought to be directed by planters. An experiment by Mr. Nock on a plant grown under favourable conditions showed that an acre of similar plants would yield 54 tons of leaves. Say that 40 tons were the average and that the result in clean fibre was 10 tons, it looks as if this ought to pay? There is a plant of *Phormium tenax* in flower and seed on Abbotsford, just now, and the resemblance to "Indian shot" is striking. The plant grows luxuriantly at high altitudes; and by mere separation of the leaves, good fibre string is obtained. We should like to see an experiment made with the long tough leaves of the "hot poker" (*Tritoma revaria*). The details of the partially successful attempt to grow apples at Hakgala and the most encouraging trials of potatoes are interesting and ought to be useful. The successful growth of "blackberries" (such a favourite fruit in the United States) from English seed is also interesting, and planters ought to have some of these plants in their gardens for dessert and tart fruits. We are glad to see that Dr. Trimen has been aiding to the Flora of Ceylon, and that materials are being got ready for the long-promised Botanical Handbook. When it does appear, we trust it may contain or be accompanied by coloured portraits of some of our most characteristic, beautiful and peculiar plants,—such as the doons, kumbuks, balsams and nilus. The Museum is extending, and the Laboratory is occupied by a fresh student from England. The sales of plants and seeds, which have been decreasing, realized R2,280, while the total cost of the establishments has been R41,535. The money is well spent, and the colony is repaid by the presence and advice of so eminent a scientific expert as the Director; while the Gardens, besides affording means of humanizing recreation to the local inhabitants, add largely to the attractions of scenery and of tropical and sub-tropical vegetation which the island offers to visitors from Europe, America, Australia, India and other countries.

RAKWANA GEMMING OPERATIONS—SALE OF GEMS.—Jan. 14th:—Mr. Justice Dias has been on a visit to his estates, and will see the new factory for them which has been erected since his last visit and fitted up with machinery with the best and latest improvement. Mr. Baddeley proceeded to Colombo a few days ago with a quantity of gems. Fine sapphires are still found on Rangwallatenne estate. Mr. F. L. Shand also went to Colombo with Mr. Baddeley. The natives are pushing on with gemming, but are not doing much. The plumbago pit on Barra estate is being worked vigorously, and a large quantity of plumbago was despatched to Colombo on the 10th inst. Illicit gemming is still going on on Handopanu and the Crown lands. Mr. John Brown of the Commercial Company paid a visit the other day to Hatherleigh estate. On Wednesday last there was a sale of gems on Bobbatenne. The stones were not very valuable and there were only three lots. The first lot fetched R235; the second lot R20; and the third lot R60. Most of the gems sold were sapphires.—Local "Times."

THE ARCHÆOLOGICAL SURVEYOR, MADRAS, during a recent visit to Ramesvaram gained some interesting information on the ceremonies performed by pilgrims while on their journey to and at that shrine. He inspected the sacred bathing place of Dhanishkodi, at present situated at the end of a long strip of sand about 15 miles south-east from Ramesvaram. It is considered sacred as being the meeting place of the waters of the two seas—Mahothathi (north) and Rathnakaram (south). There are no ancient buildings at the present bathing place; and on inquiry he learned that the sea is receding at this point and the land has advanced at the rate of about 5 miles in the last 40 years. A narrow strip of shallow water separates Dhanishkodi from an island about 15 miles long, and when this strip silts up, as it is steadily doing, the pilgrims will have to travel other 15 miles to the meeting of the waters.—*Madras Mail*, Dec. 5th.

SIR CHARLES BRUCE, K. C. M. G., writes in the current number of the *English Illustrated Magazine* on British Guiana—its history, its present condition and its prospects. After briefly referring to the discovery of Guiana by Sir Walter Raleigh and the subsequent visits to the country of other enterprising spirits of the Elizabethan era, Sir Charles proceeds to recount its sessions and retrocessions and conquests, its boundaries, and the physical features of the Colony as it is at the present day. The legislative machinery is also briefly described, together with the people, the fauna, and the religious and educational systems. Sir Charles commends the absence of prejudice against the coloured inhabitants of the Colony, and remarks that the African race is rapidly coming forward in the management of plantations and other commercial enterprise. He thinks that great credit is due to the Dutch for the admirable scientific and technical skill with which they planned and accomplished the settlement of Guiana, and describes the methods of the Hollanders at some length. In the opinion of Sir Charles, the prosperity of British Guiana is the offspring of sugar, and it is only the enterprises and monetary resources of the planters that have saved the Colony from the depression of the sugar industry which has seriously affected the West Indian islands. Among those who have been chiefly instrumental in enabling British Guiana to struggle against the menacing increase in the beet crop, "a prominent place will be universally conceded to Mr. Quinton Hogg, who has spared neither money nor his own intelligent energy in introducing and perfecting the new process by which sugar is extracted from the cane by diffusion." Sir Charles adds that the Government are making persistent and strenuous efforts to develop the vast dormant resources of the Colony, and the low rate at which land can be brought is certainly calculated to encourage the agricultural industry. The discovery of gold gave British Guiana hopes as to its mineral wealth, and mining for the metal is now pursued to some extent, while some regions have but recently been proved diamondiferous. "At a time when much British capital is seeking investment in the sphere of British influence in South Africa, and elsewhere, together outside the sphere of British influence, it may be admitted to be the duty of all concerned in the administration of the outlying provinces of our own Empire to invite attention to fields for the investment of capital within its limits." The Colony at present is too deficient in labour and capital to take advantage of its unquestionable natural wealth, and a more vocal motive, as well as patriotism, should lead British investors to turn their millions into West Indian channels instead of persistently ignoring them for foreign republics.—*Colonies and India*, Feb. 7th.

CEYLON UPCOUNTRY PLANTING REPORT.

P. A. MEETING—LENGTHY REPORT—SUGGESTION—CUBEBS
—P. A. SECRETARISHIP—WEATHER—TEA—DRUNKEN
COOLIES AND DRUNKEN PLANTERS—AN INDIAN STAFF-
SURGEON ON MALARIA—DRINKING GOOD WATER AS A
MEANS OF PREVENTING SUNSTROKE.

Feb. 22nd.

The annual meeting of the Planters' Association is becoming every year more and more dreadful owing to the length of the report. *Forty-five* minutes occupied in reading it, to an audience some of whom were talking, some few listening, many yawning, and all more or less bored; one would think it is hard enough on the Secretary to compile this voluminous record; but to have to read it after it has been got up, seems cruelty. If it be an essential that the report be read it would be a wise thing, I think, to make it the *last* part of the programme; and then, those who really care to hear the record of the year's doings gabbled over can indulge themselves to their hearts' content. As it is at present, much valuable time is wasted, which might well be spent on other and more important matters. The report is no doubt a very praiseworthy production, and the sweep of the net is so extensive that anything that but touches the planter's interest is lauded, and made a prize of. But when you think of the many legitimate topics which rightly call for attention and comment, and that after all life is short, all zeal ought to be repressed. This may be hard on the Secretary; and if he feels aggrieved at not having his full swing, I for my part would willingly vote that Mr. Philip should have more pay, rather than that we should have more report.

As an evidence of this growing evil of over-reporting and the dangers into which it leads, take this passage under the heading of minor products:—

"Cubebs.—The true plant yielding this valuable berry has still to be introduced into Ceylon, all previous introductions having turned out factitious." Without staying to notice this funny use of the word "factitious." I would ask was there ever a finer specimen of the evil I complain of than what I quote? It matches the historic chapter on the snakes in Iceland. There were no snakes in Iceland; and there are no "cubebs" in Ceylon!

If this sort of thing goes on where are we going to end? for the principle which would allow a paragraph on "cubebs," would in the hands of a willing and voluminous scribe like Mr. Philip allow almost anything. To be sure if the report were simply printed, and one could read it or not just as one liked, it would not matter much; but as things obtain at present, if you attend the annual meeting you must hear the report, and what a tiresome time-destroying thing, that is, we all know.

It is hard to imagine the Planters' Association with any other Secretary than Mr. Philip: but of course a time will come—may it be long distant—when the position will have to be filled by some one else. When the necessity arises to appoint a new Secretary, where will the man be found bold enough to undertake the duties? If these yearly reports go on increasing in volume as they do, the very

* Has our correspondent heard how the Yankee puts it: Speeches (or for that matter Report-) should not exceed (so many) minutes; for if "he" is not struck in that time, the speaker or Secretary should give up *boying!*—In respect of the ponderous P. A. Report, we certainly think that after it is gone over in Committee, it should do if the *headings* were read at the General Meeting, and then if any member wishes what is said under any one head, read out in detail, this could be done.—Ed. T. A.

thought of them would choke off all except the rashest.

It is all very well for a man who likes it, to go on using up stationery by the ream, and filling innumerable pages of foolscap with "copy": but is posterity to be wholly ignored? Lord Brougham felt that Campbell's "Lives of the Chancellors" added a fresh sting to death: but these bloated and overgrown reports are death itself: for the post of Secretary will assuredly become extinct, when the present incumbent takes off his mantle and lays down his pen. It is with a view to prevent such an appalling catastrophe, and before things are beyond all hope, that I draw attention to the danger ahead.

The weather has all of a sudden changed, and without any warning we have been dropped as it were into the hot season. I suppose we may get used to it, but meanwhile, the sun is broiling, and the days are hot.

Tea is simply doing wonders, and there has been little or no complaint of the difficulty of finding work for coolies, as often happens at this season. To get round the flush in time is what bothers.

To see ourselves as others see us, is often a revelation. An appu the other day informed his master that the coolies were all drunk in the lines. "Drunk?" queried the planter. "How do you know they are drunk?" "I know they are drunk, you can hear the noise," was the answer. "But there might be noise without the coolies being drunk," continued the planter. "Sir," replied the appu, "when master gets drunk he keeps quiet, but when a cooly gets drunk he makes a noise, becomes quarrelsome and wants to fight."

I remember in the old days, when Colombo Fort was really a fort, hearing of two upcountry men, returning from a convivial evening being challenged by the sentry. "Who goes there?" shouted the guard, and the reply came back "Just twa drucken planters!"

It would seem, in spite of all temperance teaching, that those old worthies—rather unworthies—are not without their representatives today. More is the pity.

A retired Indian Staff-Surgeon was writing last month in the *Lancet* on "Malaria," and giving general advice on the best means for the Anglo-Indian to preserve his health. Now that the hot weather is on us, it may not be out of the way to quote the following:—"Good drinking water plays an important role in the preservation of health, for the incessant drain of fluid from the system by perspiration requires a liberal supply of water, and though the result is prickly heat, the benefit to health is ample compensation. A long drink of cool—not iced—water before and after exposure to the sun is an almost certain protection against sunstroke, *provided the water is not diluted with a little spirit.*" I have taken the liberty to italicize where it seems to me that the point comes in.

PEPPERCORNS.

MINES AND MINING IN CEYLON.

We have frequently had our attention called to the unsystematic mode of plumbago mining in Ceylon, and to the necessity for government interference, more particularly with the view of protecting the health and lives of miners, and secondarily with the view to establishing a systematic mode for the working of mines: we shall begin by describing the common modes adopted by the Cinhalese.

A native usually drives a shaft as far as he can, so long as he is able to contend with the flow of water in the mine. He then stops working, and afterwards drives galleries, and this he continues to do as long

as his lamps will burn, but the moment the lamp are extinguished by the gases collected in the gallery he ceases working in that part and continues upwards refilling the shaft he has dug with the *débris* from the mine. In other cases, instead of sinking a shaft a large open cutting is made, in which they follow the vein and afterwards run galleries as occasion may require.

They have no system for ventilating their mines, and the result is that after a blast much time has frequently to be wasted before the mine is sufficiently cleared of foul gases to allow working to be resumed.

Then as regards the timbering of mines. The great object of the native proprietor is to keep his expenses as low as possible. As to the timber he is using he knows nothing of its strength, and is quite unable to work out the strain it will stand. He doubtless knows certain timber will resist damp, and is stronger and tougher than other woods, and when procurable would probably use such woods in preference, but as the wood is generally green and full of sap it necessarily cannot resist the ravages of damp as it would do if it were properly seasoned. The result of all this is that the shafts and galleries are frequently insufficiently timbered.

The windlass used is frequently insufficiently strong, and has no ratchet-wheel or pawl, so that serious accidents may occur in raising and lowering miners. The rope used is the ordinary coir rope of the country, the strength of which doubtless varies very much though of the thickness, according to where it has been made and the quality of the fibre used.

Instead of the rope a ladder is frequently used by the miners, and these are made of the roughest materials and frequently tied with jungle rope or ordinary coir yarn. There is no regulated distance between the rungs of the ladder, as at home, there the ladders are fixed at some convenient angle with substantial platforms of not more than twenty yards apart. In Ceylon there is a perpendicular ladder to the bottom of the pit, and when it is remembered how highly lubricated the wood must get from the hands and feet of the natives who have been working plumbago, the great danger they run every time they mount and descend can be well conceived.

There is no inspection of the mines, and last year a very serious accident occurred in one of the Rakwana gem pits, leading to death by drowning.

The Government has enacted an ordinance by which they reserve to themselves the right of control over the safety of the miners, but as yet we have heard of no steps being taken to formulate rules and regulations for the management of the mines such as are in use in England.

Of course it is not sufficient for the Government to make rules and regulations without seeing they are carried out, and for this it would be necessary to appoint an inspector of mines whose orders the native headmen should see carried out. A very necessary regulation is an up-cast and down-cast shaft, or in the case of small mines at least of an adit, otherwise in case of an accident in the main shaft the miners may all be buried.

As an example of the want of feeling amongst the natives, we instance the case of a man who was buried in a gallery through the falling of a large mass of earth. His companions, taking for granted he would be dead, were simply going to leave him there, but fortunately for him, a family connection of his insisted on his being dug out—alive.

Probably the Government might fear, when first introducing any new laws and regulations, they might seriously affect the plumbago industry, and consequently the revenue obtained therefrom. This perhaps, might be sufficient to cause delay in introducing them.

The fear that may be entertained as regards any interference with the trade and revenue in plumbago can only be very short-lived, as the new regulations will only weed out of those proprietary miners who have small capital and are unable to do justice to the men they employ; but it will have the good effect of inducing a systematic class of mining which can only bear good fruit. For, from what we have always heard, that the further down the mines are

carried, the larger the plumbago veins and better the quality, so that were our mines worked to anything like the depth of some English mines, we feel convinced that the plumbago would not only be found in larger quantities, but the quality would be better.

We learn from a geological friend that it is his opinion that our metamorphic rocks when they were in a sedimentary form previous to the igneous action which crystallized them, carried a large amount of coal or carboniferous matter, perhaps in the form of lignite, and that the igneous action which crystallized these rocks which must have been under great pressure, converted the carboniferous matter into graphite, and to the same igneous action must be attributed the upheaval of our rocks, and to this must also be attributed the more or less vertical position of many of our graphite veins.

Should our friend be right in his surmises, it will be easy to conceive what large deposits of graphite we may find when mining is conducted more systematically and at greater depths.

There is still another matter we consider deserving attention, and that is the large number of minerals dug out of plumbago mines, and which doubtless have some value, but with which the natives have no acquaintance, and consequently these are sometimes thrown away. We instance amongst other minerals pitchblende, so well known as a valuable ore of uranium and which has been found inside plumbago. The *Daily Telegraph* last year had an article on the subject of uranium, and amongst other matters noted the market price is quoted at about £2,400 a ton.

Then there is the mineral pyrrhotite, which is found largely in plumbago mines, and from which in other countries the greater part of the nickel of commerce is extracted. However, we are unable to state with certainty if the pyrrhotite discovered in Ceylon is nickeliferous, but think in all probability it will be found so. Steatite is, we believe, a common product of plumbago mines. Magnetite, showing strong polarity, is also common in many parts of the island. Chalcopyrite, a mineral that has been found in various parts of the island is one that doubtless can be worked to advantage. These minerals containing such rare elements are columbian yttrium and zirconium, are found in our alluvial deposits, and would probably be found in the matrix were there sufficient demand for them. Mica sometimes in large plates is abundant. Gold has been found in numberless places and in large nuggets in the neighbourhood of Morawaka. Manganese is abundant, and of course Ceylon is specially noted as a gem-producing country, but on this subject we intend writing more later on, and, doubtless, there are numberless other minerals which have escaped notice, and we feel sure that the day is not far off when Ceylon will prove itself much richer in useful minerals than it has had credit for.

The fact that so little is known of the mineralogy of Ceylon is in a great measure due to the want of interest taken in it by Government, whose system has been so far with one exceptional case to leave all such matters to private enterprise.

To those who are acquainted with the Government and history of Ceylon it must strike them as very anomalous that so many new laws and regulations should be constantly enacted by Government in reference to the health and well-being of our imported labourers from India (a class who are more specially well looked after by their masters, and who would have the same care devoted to them irrespective of any Government ordinances), when this same Government neglects the health and welfare of a large proportion of the aborigines, whose lives, we think, should be equally valued with those of their brethren of India.

Should death occur in mining through carelessness on the part of the proprietor, the Government inquiry into the death would simply report it as an unavoidable accident, and Government would, of course, be satisfied with such an explanation. It will not do for Government to compare the statistics as to violent deaths in this country with those of coal mining districts. In Ceylon we never hear of explosions of gas, and those who are poisoned by the

carbonic acid which they have been compelled to breathe in the mines will have their deaths attributed to natural causes, and were inquiry made, it might be found that these would be a larger factor than is generally supposed.

In recommending official interference, we do so advisedly, as we feel sure that Government will not make any regulations other than those necessary to keep the mines in a safe and healthy condition, and for a small sum the ventilation necessary can be very simply applied by using a very small air propeller worked by hand, or where two shafts have been sunk, by having a small furnace at the bottom of one of them. In such mines simple contrivances of this kind would be, we feel sure, quite sufficient to meet the approval of a Government Inspector.—*Ceylon Advertiser.*

THE TALGASWELA TEA COMPANY OF CEYLON, LD.

REPORT OF THE MANAGING DIRECTOR.

I visited this estate on May 7th 1890, and submitted to the Directors a confidential report, having previously not made a personal inspection since the land was cleared. In January, 5th and 6th, 1891, I made my second visit and have to report to the shareholders as follows:—

ACREAGE.—The estate consists of 716 acres cultivated, of which 510 acres were planted with tea in May to July 1888, and are now 2½ years old and 206 acres were planted in 1889 and are now 1½ years old. There are large ravines and swamps about the clearings which were planted with tea, but in which it can never be expected to grow, the subsoil being stiff and damp, whilst there is not sufficient fall to admit of efficient drainage. These swamps are now being planted with areas, and their area will be surveyed, but roughly speaking they are about 35 acres in extent, and reduce the tea clearings to 485 acres, and 196 acres respectively.

SITUATION.—This estate is situated between the Gindura and Bentota rivers, the present outlet is by the former from which the factory is distant about 2 miles. About 15 miles of water carriage brings the produce to Baddegama, which is 6 miles from Hikkaduwa on the Galle road where the Railway will soon be available. An outlet by the Bentota river to Bentota could be made available, this river being five miles distant from the estate.

Rainfall in 1888 was 178.20; in 1889 241.13, falling on 158 days, in 1890 190.93 falling on 153 days. The past year has been a bad one for rainfall at Talgaswela as at many other parts of the country, the S.-W. monsoon months were abnormally dry, and the yield of tea suffered in consequence.

The lay of land is mostly very good for tea, being of a gently undulating character, with a few steep faces only here and there. All the opened land was originally virgin forest.

The Soil is on the whole fairly good, most parts of the estate shewing a really good tea soil, ironstone gravel is very abundant, and experience in the low-country has shewn that this soil is suitable for tea.

Roads and Drains are well cut, and in good order, and all the clearings shew signs of careful work, and have evidently been well opened. I consider that the clearing works reflect credit on the Manager.

The 2½ years old tea is planted in 5 clearings of about 100 acres each, separated by belts of forests. No. 1 is a very fine field of tea, a large portion of it is Manipuri indigenous, which is covering the ground well. No. 2 is also a good field. No. 3 is the poorest of the old clearings, as it was chiefly planted at stake, and the jat is inferior to the rest of the estate. It has been pruned low, however, and has improved greatly in appearance during the last six months. No. 4 is a good field. No. 5 is fairly good but there are a few bad patches in it.

The 1½ years old tea is divided into 2 clearings of about 100 acres each, numbered 6 and 7. No. 6 is almost entirely Manipuri indigenous, and is remarkably regular and vigorous. It was planted with trans-

planters, which have proved a marked success. In No. 7 I regret to say that about 40 acres were again planted at stake, and the original planting was an almost entire failure. About 60 acres of it planted with stumps from an old nursery is most successful. The first supplying during 1890 was very unsuccessful, owing to the partial failure of the S. W. Monsoon. Recent supplyings were more successful, but this work will have to be carefully gone over again this year.

Nurseries are being made in each clearing for 18 mannds seed from Kelvin and Seaforth, and the supplying will all be done with transplanters.

Buildings consist of a well built manager's bungalow, an assistant's bungalow, and various lines, built of cheap materials but sufficient for present purposes as the labour is not resident on the estate.

The Factory is a well built permanent building of brick and timber with an iron roof, 60 ft. long and 40 ft. wide with two withering lofts above the ground floor, one end is temporarily boarded up so that the building can be extended if desired. The machinery at present consists of an "economic" roller, and a double de-seccator, but a "rapid" roller, tea sifter and a roll breaker will have to be erected at once. The total cost of this building, dam &c. has been R16,017.66. The work has been well done, but I do not consider that economy has been studied as it should have been, nor was it necessary to erect rats last year for about 6,000 lb. leaf when only a few hundred pounds daily were expected. No proper estimates were made in advance for the various works connected with the factory, and higher expenditure than was ever anticipated has been the result.

WATER SUPPLY.—This has proved most disappointing. The streams in field 3 which we were led to expect could not have been diverted into the lake, and which were relied on by the engineer, Mr. Lamont, in his report of October 1888, cannot be rendered available without flooding a large acreage of valuable tea, and prohibitive cost; and the attempt to divert them into the lake has been a failure and has been finally abandoned. During October the head of water in the lake fell from the normal amount, 5 ft. 3 in., to 9 inches, with the result that the area of the lake was reduced by ¾ through sloping of the banks, and the Superintendent was unable to roll the 300 to 400 lb. of leaf that was then coming in as thoroughly as he would have wished, the available power being insufficient for the "economic" roller alone. This was due to an abnormally dry season, the rainfall to October 21st being 100 inches less in 1890 than in 1889, but such circumstances may occur again, and it would not be wise to trust to the chance of a wet season to carry us through the new year. I am therefore of opinion that the immediate erection of an engine is necessary, to supplement the water power. The cost of the repairs to dam, sluice, water wheel &c. amount to 2,478, and to this has to be added about R500 for belts, shafting &c. to connect the water wheel with the main driving shaft, or say R3,000 in all. I do not consider that the water power reduced available is in any way proportionate to the money spent, and am of opinion that it would have been more advisable to have erected an engine at once.

The present site of the Factory is a most inconvenient one for the working of the estate. It is outside the tea fields, and transport of green leaf to it, is expensive. The chief fuel supply is also at a distance from it. A most convenient central situation for the factory could have been chosen near the outlet towards Bentota, giving a shorter transport to the Railway, convenient for the transport of green leaf to the factory, and close to the largest fuel reserves. In view of the considerable expense of reordering the water available, and its small and unreliable power now that it is available, I am strongly of opinion that a mistake was made in choosing the present site at all. On the date of my visit the head of water in the lake was 2 feet 6 inches, and the amount flowing in only supplied the loss by evaporation during the day. In the opinion of the Manager this water will last for 10 days, with 500 lb. leaf per day to manufacture, and unless rain fills up the lake mean-

while, hand power will have to be resorted to. It is for such an unreliable source of power as this that R3,000 has been expended, and the factory been placed in a most unsuitable position and one entailing large extra expense in leaf transport, whilst the manager's bungalow being built near the factory, is in a most inconvenient position for the working of the estate.

At present there is no alternative but to erect the engine and continue working in the existing factory, but I am of opinion that at a future date, when the estate is giving a large return and the money can be rendered available, it will be found necessary to erect a large central factory near the Bentota river outlet to which the engine will be moved, the present wheel and factory being kept as a reserve in case of breakdown of machinery.

EXPENDITURE during 1890 has been very low and has shown that expectations formed as to cheapness of labour were well founded. The check roll averages for the month vary from 20 cents to 17 cents per rooly. Plucking including a most expensive transport of leaf and baskets, is cents 2.42 per lb. green leaf for the year; "weeding" has been R4.20 per acre for the year. These figures I think speak for themselves and show that there is every justification for believing that in cheapness of production Talgaswala estate will be unrivalled when in full bearing. The amount of leaf plucked has been 76,944 lb. of which 8,879 lb. were sold to a neighbouring estate, and the balance resulted in 16,977 lb. made tea.

ESTIMATES for the new year have been framed and show an expenditure of R38,339.63. To this has to be added the cost of a "rapid" roller, a sifter and roll breaker, shafting, and a 14 horse power engine, which will probably not fall short of R10,000.

The yield I estimate at 90,000 lb. made tea, whilst there is every indication of a very heavy yield in 1892, before which the bushes cannot reasonably be expected to bear much.

Arocanuts have been planted through many of the ravines, and this work is being continued.

Labour has been abundant.

Health of labourers has been very bad during the year, fever having been very prevalent.

MINING Operations have been carried on by Mr. W. M. Young who has found indications of plumbago. The company have received as arranged 1/10th of the amount of the minerals obtained. The factory has been painted with materials found on the estate, and the paint seems very good and durable.

The general appearance of the estate is most satisfactory; the bushes are vigorous and shew signs of heavy flushes shortly. The plucking has been most carefully done, showing that Sinhalese village labour, with careful supervision, can be made to do most satisfactory work. I consider that the opening work, and the treatment of the bushes up to date shew signs of hard conscientious work, and I think the estate generally is a credit to Mr. Broadhurst, the Manager, and those under him, and to him I think the shareholders owe a debt of gratitude for good work done under circumstances of great discouragement.

T. C. OWEN, Managing Director and Chairman.

Colombo, January 1891.			

COTTON-PICKING by machinery is one of the recent innovations that have come to stay. A bale of cotton is on exhibition at Memphis, Tenn, which was picked by machinery. The bale weighs 475 pounds and was picked in two hours during a rain-storm—equal to the work of fifteen men. The cotton is much cleaner than when gathered in the old way, and will bring nearly half a cent a pound more.—*Planters' Monthly*.

GRAIN DIAMONDS, or rough brilliants, have been discovered in specimens of rock sands forwarded to M. Charles Velain, of Paris, by M. Charles Rabot, from Russian Lapland. The diamond-bearing sand was taken from the valley of Pasvig, and is the debris of granite. M. Velain, in a memoir to the Académie des Sciences, states that the gems, which are very tiny, may have come from the demolition of pegmatite in the district. This is the first time that diamonds have been found in European soil.—*Globe*, Feb. 6th.

THE GIGANTIC EARTHWORMS OF CEYLON.—The *Quarterly Journal of Microscopical Science* for January contains a paper on *Megascolex caruleus*, Templeton, from Ceylon; together with a theory of the course of the blood in earthworms, by Dr. A. G. Bourne (plates vi. to ix.) During a short visit in 1889 to Ceylon the author obtained thirty-eight species of earthworms; only seven of these have been found in India, and about twenty-nine Indian species have not yet been found in Ceylon. The author summarizes his theory of the circulation as follows: the vascular system consists of a portion in the cephalized region, and of other portions metamericly repeated in all succeeding segments. The cephalized portion differs only from that occurring in any other segment in having undergone a synthesis, and also in the presence of contractile hearts. Throughout the body, blood is forced from the contractile vessels into the peripheral networks; thence it is conveyed by a system of intestino-togumtary vessels to intestinal capillaries, and from these it returns to the contractile vessels.—*Nature*,

THE PUBLIC AND PRIVATE SELLING OF TEA.

We had brought to our notice a short time back the opinion held by Mr. J. Roberts of Messrs. S. Rucker & Co. as to the probable effects of the system under which a not inconsiderable proportion of the produce of our tea estates is sold. We are not personally concerned as to whether that opinion can be justified to the extent which Mr. Roberts evidently thinks that it can be; but the views entertained by so good an authority should certainly receive every consideration. But we were not prepared to learn as we have lately done, to how great an extent the system of selling tea through the agency of private friends at home has spread. We have only recently been told—upon good authority—that the produce of one tea estate in Ceylon, which yields annually some 55,000 lb. of made teas, had been sold through such an agency to the large figure of 45,000 lb., and that confident hopes were entertained by its proprietors that the balance which has hitherto had to be parted with in the open market will, during the present year, find customers through the same private channels.

Our informant in this matter tells us that for the quantity thus disposed of privately, the proprietor of this particular estate, netted for the entire quantity fully three-pence per pound more than he would have done had he sent his crop to market through the ordinary channels. If we may accept this statement as being fully reliable, there can be no doubt that the system of distribution adopted must present very enticing advantages and, despite the threat held out by Mr. Roberts that in such cases of its adoption as may become known brokers in Mincing Lane would practically boycott the teas of their offending proprietors, there can be little reason to think these threats can be productive of much effect. Every one of our planters would, if they could, resort to any justifiable means for obtaining the highest returns possible for his teas. But we should be inclined to think that the circle of those who could achieve the success above recorded, must be a very narrow one indeed. As was remarked in London to our correspondent, very many of our estate proprietors are bound by the conditions under which they have obtained financial help, to ship all the tea they can grow to the parties who have so assisted them. This restriction must certainly prevent a very large number of Ceylon tea planters from even attempting to enter on the course of parting with their teas through any private or friendly agency.

Of course we can realize that, as has been pointed out by Mr. Roberts, the brokers in Mincing Lane, the men who make their livelihood by public dealing in tea, must regard with strong disfavour a system which operates to diminish the bulk with which they have to deal. If the fact be as stated that an additional profit can be secured to the grower of three-pence (or even two-pence) per pound on all teas so privately disposed of, we may be sure that to that extent the brokers and other middlemen will be deprived of profit. It must be natural that the trade in London should not complacently view what it will doubtless consider to be an encroachment upon their just rights. Free trade in the abstract has a host of supporters; but when the application of its principle injuriously affects personal pockets, these principles are in such cases not quite so thoroughly appreciated. It would be no surprise, therefore, to us to learn that every legitimate means would be used to prevent their

application in this particular case of the private distribution of tea. While admitting that they cannot help the exercise of private right to dispose of crops to the best advantage of the grower, the brokers, we can well understand, might in self-defence say:—"Well if you *will* go behind our backs and employ what is practically an unpaid agency, to the exclusion of ourselves from sharing in your profits, when you *are* forced to come to us we will soon show you that we will have *all* your favours or none at all. We will not consent to be made a simple convenience of."

So far as we are personally aware there has not as yet occurred a single case of this nature. We have not heard of the product of any Ceylon tea estate having been thus "boycotted" in the Mincing Lane Sale Rooms. Nevertheless it would not be surprising if such instances did eventually come under observation, and those who are practising this system of being their own distributors will have to reckon how far the advantage gained might be counterbalanced by a practical exclusion of their teas from public competition. For, it is possible, that when teas are sold privately in the way pointed out with an established price, any attempt at advantage through a sudden rise in the public price of tea might have to be sacrificed.

THE YATERIA TEA CO. OF CEYLON LTD.

To the Editor of the "Ceylon Observer."

Ce Colombo, Feb. 26th.

DEAR SIR,—I send you herewith report proceedings at the Annual Meeting of the shareholders of this Company held yesterday together with the Report of the Directors.—I am, dear sir, yours faithfully,
B. G. L. BREMNER, Secretary.

GENERAL MEETING.

The third annual general meeting of the Yataderia Tea Company of Ceylon, Limited, was held at the Offices of the Company, 13, Queen Street, Fort, Colombo on February 25th, pursuant to notice.

Mr. H. V. MASEFIELD in the chair and the following shareholders were present:—Messrs D. Fairweather, John H. Starey (Managing Director), J. R. Fairweather, E. S. Anderson, G. W. Carlyon, and B. G. L. Bremner (Secretary), and by Attorney Mr. W. Church.

The Secretary read the notice convening the meeting.

The minutes of the last annual general meeting were duly confirmed.

The report of the directors having been taken as read Mr. H. V. MASEFIELD moved its adoption. The Managing Director in seconding the motion offered the following remarks upon the accounts and business. He had to point out a slight misprint in parenthesis in the profit and loss account: the amount written off for depreciation should be R11,051 instead of R10,826. The actual profit for the year was R34,602.18 being rather over 18 per cent, but in no case would the amount written off for depreciation have been available for dividend in view of the resolution of the two previous general meetings to keep capital account down to R350 per cultivated acre. The cost on Board might be considered satisfactory. The item for interest was not likely to recur. The question of paying an interim dividend last October had been carefully considered by the Board, but as exchange was rising and tea was weak on the market, and as the money must have been borrowed it was decided to defer such a division. The cost of the Factory had been R19,434, which seems large, but it was constructed under exceptional difficulties and is a thoroughly satisfactory building. In expectation of large crops it had been deemed expedient to build another with-

Profit and Loss Account for the year ending 31st December 1890.		R	c.

TEA AND COFFEE IN NUWARA ELIYA DURING THE "FORTIES."

With reference to the tea planted at Nuwara Eliya under the care of the Rev. Mr. Gepp (uncle of Mr. Gepp, Colombo), when living in Sir Anthony Oliphant's family in the early "forties," it is interesting to know that some of the seed or plants of the same or a subsequent supply were given to the late Mr. Cornell who put them in on his Essex property. Mr. A. J. Kellow writes:—"I have now got the local history of the tea plants I lately referred to. Mrs. Bullock tells me that Mr. Cornell planted a few at Essex Cottage (now Naseby) in 1847 and they grew to be very large trees. They were put in where the old bungalow stood and were the same that I wrote to the *Observer* about in 1873. Were you aware that the late Capt. Fisher tried coffee in Nuwara Eliya? The patch is still to be seen, but I do not know if any of the coffee trees are in existence. Mr. Nock and I purpose going up some day to see."

TEA IN THE UNITED STATES seems at length to have taken a start upwards. From a value of \$14,179,000 in 11 months of 1886, there was a fall to \$10,658,000 in 11 months of 1889. For the 11 months of 1890 there was a rise to \$13,400,000. The imports of coffee have gone up from a value of \$39,922,000 in 11 months of 1886, to the enormous figure of \$78,266,000 in the 11 months of 1890, or 6-fold the value of tea.

THE RABBIT PEST IN AMERICA.—It is not only in Australia that rabbits have increased so as to be formidable enemies of farmers. A paragraph quoted in the *Indian Agriculturist* runs thus:—

In many localities in the Western States of America rabbits have become a serious pest. For a time the price paid for them had induced hunters to kill many of them but notwithstanding this they have increased and the larger numbers offered the city dealers have brought prices to the point that will prevent an increase in the number killed. In some places it required four rabbits to bring 5 cents last winter, and the hunters quit in disgust. It is probable that before long several States will find it necessary to take measures for the destruction of rabbits.

SETTLEMENT AND EXTENSION OF NATIVE CULTIVATION IN CEYLON: BIG TANKS A NECESST Y.

We direct attention to the following mature opinions on the best means of promoting new settlements and the extension of native cultivation. They are from a resident as competent as any man in the country—and far more so than speakers and writers who have never spent a month continuously in a purely native district—to advise authoritatively on the subject. What is said about big tanks deserves careful consideration, more particularly when we remember that it took twenty years to demonstrate the full success of the Batticaloa tank works begun by Sir Henry Ward and Mr. J. W. W. Birch.—We quote as follows:—

"I have thought the matter well over; and my conclusion is that (with exceptions here and there) we are settling up the island quite fast enough, and that the only impetus required is to give the land (waste) on very easy terms, whether to the poor man or the capitalist, if he will accept it in unsettled parts, where at present there is no demand. I do not believe in dealing out money to make settlements, though I would give it to a 'Zamin-dar' as they would call a large landlord in India—especially a European, if he would undertake to clear and settle a number of families in any place. Of course they would first come as coolies, and the most industrious would in time become tenants. But disappointment would come I think if money was given direct into the settler's own hands.

"Of course where paddy cultivation is to be encouraged—and it is and will long be the branch of agriculture the natives best take to—irrigation must be provided, and must keep pace with the cultivation which it has not done in the past, coconuts, cotton, &c. follow.

"Wherever the population in the island is dense, there is always not far off a 'hinterland' into which it has been for years spreading, extending and occupying. Open this up with good roads and you will help and attract settlers.

"Matara is now flowing over into the Girawa Pattu; and before many years the country under the Walawe works will be occupied. Civilization it is said spreads from centres, and we must work for the extension of the cultivated area on the same principle in Ceylon. But you must have a bold policy, not hesitating to launch out because there is a doubt if 'it will pay,' and not frittering the revenue over village tanks, which are a snare and a delusion as a rule, and *pro rata* much more expensive than the big works, as was shown in your columns some years ago.

"I see a great deal of nonsense has been recently talked and written about Kalawewa having failed. Of course it will not fill when the monsoon fails, but in the first place such failure is not the rule. Next my experience shows, if the rain does not come at one time, it does at another part of the year, as it has done this year, and having a big reservoir ready, we are able to bottle up a lot and keep it until required, and once you get one of these big tanks full, it is wonderful how it can be eked out. Suppose, as is frequently the case, the rains are short or late, there is little or no cultivation, and much of what did come at length would be allowed to run off. But with a big tank, it is all saved, and with this behind them, cultivators go on merrily. The tanks and works in Batticaloa and Matara were derided just as Kalawewa is now; but they have lived it down and so will Kalawewa."

SHARPE'S PATENT AUTOMATIC TEA DRYING MACHINE.

This is "another Richmond," and the inventor, who is at present amongst us, only asks a fair field and no favour. Mr. Sharpe leaves for the tea districts of India very shortly; meanwhile, he has given Ceylon the first opportunity of seeing what his automatic drier can do.

He has engagements to erect other and larger machines in Assam, and elsewhere, and is full of hope that the merits of his machine will in time win for it a good place in the race. While fully satisfied that the drier is second to none, he does not claim for it that it is yet a perfect machine, but he hopes, that after some little time in use, he will learn wherein it may be improved, and is anxious for practical hints. There is one thing however on which he takes his stand and that is that his drier will be made to turn out the quantity of tea it professes to do—a one maund machine will deliver 80 lb. an hour, and not 60 or 70 lb. If this is done it will be a boon, for how seldom do we find manufacturers' estimates to agree with those of practical men. A description of this new drier cannot be better given than in the words of the inventor. He says:—

The machine consists of a cylindrical casing, in the interior of which a number of horizontal perforated trays fixed on a vertical spindle, are caused to revolve by a suitable system of pulleys, balls and gear wheel. The trays are divided into a number of sectors or flaps, each of which is hinged on the frame of the tray on one of its radial edges, the other edge remaining loose, whilst the sectors are maintained in a horizontal position by flat circular supporting rings of somewhat smaller diameter than, and suitably arranged within, the casing. At a certain point a portion of each of these flat rings is cut away, so that the loose edge of each of the sectors or flaps on reaching that point falls, and the leaf on the sector is deposited on the tray below. The leaf, spread wet on the uppermost tray through an opening in the top of the case, is carried round through one revolution of each tray and then dropped on to the tray below until the bottom tray is reached, the leaf being evenly distributed over the surface of the trays by means of adjustable regulators. The fully dried tea falls from the bottom tray into a spout or shoot which conveys it into a proper receptacle placed to receive it. The fine tea or "dholgoria" falls to the bottom of the machine, where it is received by a non-perforated revolving tray which delivers it automatically into a separate receptacle.

The heated air from the furnace is drawn up through the perforated trays and the superincumbent tea leaf, and is driven out of the casing by means of powerful exhaust fans fixed on the top of the machine, but no light leaf is carried away with the current of air, as is so often the case when exhaust fans are used.

By means of a pair of cone pulleys the speed of revolution of the trays may be varied within all practical limits, so that the duration of exposure of the leaf to the heated air may be regulated with great nicety.

A number of openings are made in the casing, each provided with a close-fitting door, so that the process of drying may be examined at any stage. These openings also give easy access to the interior of the machine for repairs. The lubrication of the bearings is so arranged that no oil or grease reaches the interior of the machine.

The furnace consists of a fire-grate of large area enclosed in a fire-brick flue, from which the heat is conveyed by suitable ports to a brick chamber, in which are arranged a number of cast iron tubes held in position by cast iron tube plates at either end. Baffle plates are so fixed as to ensure thorough circulation of the heat amongst the tubes. A wrought iron chimney, fitted with a damper, secures the necessary draught and carries away the smoke. Openings with doors are provided for cleaning the tubes and flues, and of examining the interior of the furnace.

The machine is attached to the tube plate at one end of the air-heating tubes, the opposite ends being open. The air is drawn through the tubes by the before mentioned exhaust fans, becoming heated on its passage. Special means are provided for making a perfect joint between the tubes and tube plates, so that there is no risk of deleterious fumes or gases from the furnace gaining access to the interior of the drier.

A thermometer is fixed to the machine, by attention to which the furnace attendant may easily maintain a uniform temperature. Should the heat, however, become excessive, it may instantly be reduced by admission of cold air through valves provided for the purpose.

On Wednesday, Mr. F. D. Phillips of Hangranoya on whose estate this tea drier has been put up, had

a public trial, which was seen by a number of planters from different districts. The inventor was somewhat at a disadvantage, as there had been much delay in getting a pulley, and it was only the day before the public exhibition that the machine could be run at all. The tea was fired at a very much higher temperature than we are accustomed to, but at the first trial the maund was not managed by the hour. The tea seemed to run a considerable risk of over-firing. During the second trial, a change was made in the cone pulleys, which brought the tea out very much quicker, but it was hardly fired enough. The quantity however was very much increased, and it was clear that an intermediate pulley would effect that was wanted both as to quantity and condition. If Mr. Sharpe had had more time, this would have been seen to before the public were invited to criticise.

The feeding too was wanting alteration: it was too primitive; but this is to be attended to, in fact an automatic feeder will be supplied. The machine is very strongly built, and it was warm. I don't know that I ever was in a tea house with so high a temperature: a wooden casing with asbestos packing will soon put that to right, and save fuel.

By-and-bye this new machine will have a fairer trial than it had on Wednesday, and it is only when it is in good working order that a reliable report of its doings can be given. Meanwhile it is pretty clear that the principle of the machine is a good one, and it is only minor matters which want a little adjusting. Mr. Sharpe was very anxious for practical suggestions, and it seemed to me that he got this. Perhaps he got more, for the planter is sadly wanting in reverence, and when they gather together in a critical spirit there is a good deal of amusing effervescence.

Mr. Phillips hospitably entertained the company at breakfast and tiffin: at the latter meal, success to the drier and the health of the inventor was enthusiastically drunk. Mr. Phillips' health too was also proposed. Altogether the gathering was an enjoyable one.

COTTON SPINNING IN CEYLON.

Bombay millowners will learn with interest of the early experiences of the pioneers of mill enterprise in Ceylon. A year or two since a Company was formed for establishing a spinning and weaving mill at Colombo, the first we believe in the colony. Some of the lessons taught by Bombay experience have been carefully taken to heart by the Ceylon Company. The quarter-anna per pound rate of remuneration for the agents has not been introduced; if it had been, it was pointed out at the meeting of the company last month, the agent would have "walked away with the whole of the profit balance." In some other respects, however they do not manage things better in Colombo than we do in Bombay. As only half of the capital of eight lakhs has been issued the company is in need of money to pay for its machinery and other purposes, and as the shares are at a discount of nineteen per cent the directors think it better to raise money for immediate requirements either by loan or in debenture stock. If, as one of the promoters said at the meeting the other day, the company can make more than enough to cover bank interest it is better for the existing shareholders not to issue the balance of their capital; but in that case the chairman's reference to the company having been crippled for want of money was much too pessimistic. It seems as though the Ceylon mill were no more free than other mills have been from the inconvenience attendant upon having started with too little capital. The company has difficulties probably not insuperable, in other directions. It has not yet solved the problem of cotton supply, and it has had to solve its labour problems in a somewhat expensive way by importing skilled hands from Bombay and Madras. The labour difficulty is one which the directors do not underestimate. The Cingalese labourer, in addition to being as yet untrained, is very irregular in his atten-

dance at work—a fact which would have to be borne in mind if at the instigation of the Holt Halletts of the future a Factory Act were to be imposed upon the as yet undeveloped textile industry of Ceylon. Apart from these difficulties, however, the company is able to give a good account of its operation and prospects. The manager extols the Ceylon climate as perfect for cotton spinning and weaving. It is never too dry, and the excessive moisture of the rainy season is easily overcome by artificial means. He has some of Dobson and Barlow's best plant to work with, and boasts that the quality of his yarn and cloth is superior to that of the products of the Indian mills, and very nearly equal to English. He would be a singular manager if he said anything less than this. However, the experiment will at all events be interesting enough to be worth watching. Cotton spinning in Ceylon must necessarily be carried on under difficulties, and these have not been reduced by starting the enterprise with something less than half the requisite capital. But the company seems hopeful enough, and if hope could assure success this ought to prove a prosperous concern.—*Bombay Gazette.*

EAST AFRICA;—THE BRITISH, PORTUGUESE AND GERMANS—AND THE PLANTING SETTLEMENTS.

We have had an interesting conversation today with Mr. A. Carnegie Ross, British Vice-Consul at Quilimane in Portuguese East Africa. Mr. Ross is married to the second daughter of the late Mr. R. Boyd Tytler and our readers will remember the graphic description of a Christmas experience at Quilimane by Mrs. Ross which we published a short time ago in our *Literary Register*. The connection of Vice-Consul Ross with Ceylon is therefore a close and interesting one and it is no wonder that when the time came for a holiday and the opportunity of a steamer offering, Mr. Ross should take passage in the S. S. "Clan Mackay" for Ceylon; and after spending a thoroughly enjoyable holiday with his relatives, Mr. and Mrs. Vollar and the Messrs. Tytler here, he is now voyaging to London by the B. I. S. S. "Goorkha" which left here this afternoon. With all the stir about East and South African affairs at home just now, Mr. Ross's presence and experience will be very acceptable.

Mr. Carnegie Ross—who is tall, slim and wiry, a keen hard-headed Aberdonian of the intellectual type,—has been in East Africa for six years. He came out as Agent for the African Lakes Company and later on combined this Agency with the British Vice-Consulship at Quilimane, the capital of the Portuguese Settlements. His office there has, as may be imagined, not been a bed of roses for the past year or so; but though he has had very amusing, as well as perhaps annoying experiences, he has managed to maintain not only peace, but even friendship with the leading Portuguese officials, and he is so well-known among them as well as their half-caste and native employes to be a man of his word, that no interference with him officially or personally has ever been attempted. As administrators, colonists or settlers, or even as merchants and traders, the Portuguese are beneath contempt. They have never done, and never will do, anything with their African territory; and they might as well try to mop back the Atlantic as try to prevent the spread of British and German influence. Mr. Ross expects that with the advent of Mr. H. B. Johnston, C.B., as British Commissioner for the territory, the Zambesi will be thrown open for general traffic for all its navigable length and any barrier attempted by the Portuguese will be promptly though peacefully removed. Mr. Ross speaks very highly of Mr. Johnston's capabilities, as also of Mr. Joseph Thomson, another well-

known explorer and geologist, now at the head of an expedition to the West of the settled territory, among his staff being Mr. J. A. Grant, a son of Colonel Grant (of Speke and Grant African fame); and also of Mr. Cecil Rhodes and the South African Expedition and settlers. Mr. Ross has often made the trip up the Zambesi 400 miles to the Blantyre Mission and the Shiré Highlands, the headquarters of the East African Lakes Company. This is chiefly a Plantation Company, and its leader Mr. Buehanan (although without any experience as a planter) guided by our Ceylon Planting Manuals and the *Tropical Agriculturist* which he gets regularly, has opened and planted a considerable extent with coffee which is flourishing though there is some talk of "borer" and other troubles. Mr. Ross shipped 200 owt. of the coffee in the "Clan Mackay" at Quilimane, and seed he has given Mr. Vollar has already been planted in Dumbara to see how it will turn out. Labour is described as very cheap, a few silver coins a month, or a piece of calico ensuring willing labour. The Shiré Highlands up to 3,000 feet altitude, but some 18° from the equator, seem intended for a coffee country from the account given of them. Cinchona has also been tried on a moderate scale. One Indian planter has established himself near Blantyre (marrying a lady of the Mission) and has now a promising coffee garden. Of course, the cost and difficulties of transport are the great drawbacks. Mr. Ross, with his knowledge of the country and people, has made the journey in three weeks; but ordinarily six weeks are required between the Blantyre Settlement and the Coast. The only Ceylon man who has turned up is Mr. Henry Brown (formerly Inspector of Police in Colombo and coffee planter in Matale). He has gone up the Zambesi in a native boat to get to the planting settlement—this being the cheaper though much longer way of going. By the solitary steamer which runs on the Zambesi for 400 miles at intervals, the passage is £20 sterling. Mr. J. R. W. Pigott, formerly of Dikoya and Matale, is in the employment of the Imperial British East African Company, working much farther north. His station is Mombassa and the Company's work is chiefly administrative so far, no planting having been done. Indeed there is enough to do to keep the Arabs (slave dealers) in order in that district, while farther south near the Zambesi, no Arabs have yet found an entrance and the natives are tractable and easily managed if only fairly dealt by. East as well as South Africa is bound to be opened up and the highlands to be colonised at a rapid rate in the next few years. One drawback at present is that the British India Company have ceased to send their steamers farther south than Zanzibar, while the Donald Currie line seldom come to Quilimane. A coasting service for the whole of the East Coast would be an advantage, and there ought to be abundance of traffic both in passengers and goods if connected with the Cape service and with European lines say at Aden.

We wish Mr. Carnegie Ross a pleasant trip homo and a profitable stay in the old country, and afterwards a return in due season with Mrs. Ross to his adopted home, with speedy promotion soon to follow in view of the rapid development of East Africa both in plantation and mining settlements. We are sure to hear of Mr. Ross's name in responsible positions as time rolls on. His principle of righteous dealing with the natives has evidently been in contrast with some of the doings of Stanley and his followers, and this has served to make his name well-known and appreciated along the Zambesi and neighbouring territories. It is

quite evident that Lord Salisbury does not mean to give up one inch of the territory recently exploited by the South African Expedition. Five hundred carefully selected men of this Expedition since disbanded, have now taken up allotments chiefly for mining purposes and nothing can ever alter the British character of the grand territorial area so occupied and settled. The exports of gold from this quarter will soon show how rich is the country in auriferous wealth and the usual rush of population from Australia and the mother-country may be expected to follow.

PREPARATION OF CACAO IN CEYLON.

[From the "Trinidad Agricultural Record" for Jan. 1891.]

Royal Botanic Gardens, Peradeniya,
24th October 1890.

The Hon'ble the Colonial Secretary, Colombo.

Sir,—In returning to you His Excellency Sir W. Robinson's letters forwarded to me with your letter No. 33 of 20th October, I have the honour to express my pleasure that the information I was able to afford proved so much to the point as regards the inquiry upon which he was engaged. I beg that you will convey my thanks to His Excellency for the copy of his article, and in accordance with his request that I would make a few additional remarks, I beg leave to offer the following observations suggested by its perusal:—

1. Though we have now pretty well settled the point (long in doubt) that the "old red Cacao so long cultivated in Ceylon is that known in the West Indies as Criollo or Caracás," it should be borne in mind that it is now by no means the case that all the Cacao sent from Ceylon to the London Market is of that variety. Of late years a good deal of Forastero (and that of numerous sorts) has been grown: and the opinion of planters is by no means universally in favour of the Caracás variety. For in the market the two sorts are often very evenly priced. Thus, lots of the two kinds grown on the same estate and kept carefully separate and sold on the same day in March last in London, fetched respectively per cwt:—Caracás, average 106/7½; Forastero, average 107/.

I am not aware on what evidence Mr. Morris's statement that Ceylon is indebted for Criollo Cacao to the Dutch is based. It may be correct, but the earliest record I have met with of the plant in the Colony is 1819, and I believe it to have been then quite recently introduced. This would be some twenty years after the British occupation. But there is no record of whence it was obtained, nor is there any certainty that it was of the Criollo variety, though this is probable. What is certain is that the great bulk of the Caracás Cacao in Ceylon is descended from a consignment of seedlings obtained in 1834-5 by Governor Sir W. Horton from Trinidad.

The general difference of the two sorts as grown now in Ceylon could not be better described than in the words quoted in Sir W. Robinson's paper (p. p. 3, 4) from the *Agriculture Venezolano*.

3. His Excellency rightly dwells on the importance of careful artificial drying in wet and sunless weather, but there is another point in which Ceylon practice differs from that followed in the West Indies to which he has scarcely alluded. That is the washing of the seeds. None of the meilage or pulp is ever allowed to dry on the bean; all is carefully washed away by copious and repeated ablutions.* It is this especially that gives the Ceylon product the clean "bright" look that is appreciated in the market. I should, however, remark that the attention of the Trinidad cultivators has been already strongly called to this in an article by Mr. Prestos in the *Trinidad Chronicle* so long back as 1883. HENRY TRIMEN.

* The Editor of the *Trinidad Agricultural Record* holds that there is consequently a loss of 20 per cent in weight and that therefore 61/ per cwt. for Trinidad cocoa is equal to 81/ for Ceylon.—ED. T. A.

It is very important for our readers to bear in mind, that *Criollo* and *Forastero* do not respectively stand for the types of *Ceylon* and *Trinidad Cacao*. Ceylon has both the varieties no doubt *pure* and they may be of equal value—with us both types have degenerated and are characterised by a large proportion of *very flat beans*. That is our difficulty.—Ed.

NATIVE AGRICULTURE IN INDIA.

You may train up a child in accordance with the most beautiful theories in the world, and the result will be disappointing if you do not feed him at the same time. Here in India we have an immense number of people living on the verge of starvation. We cannot feed them, and those who are grown up must continue to find their way to Nirvana with a stomach seldom or never full and very often empty; but if we can bring ourselves to abjure the words of antiquated masters, we may be able to do something for the children of the rising generation by teaching them to find more food for themselves. The discovery of a new art, the adoption of an improved process, the invention of a new implement, each and all are equivalent in an agricultural community to the finding of a great granary, the existence of which was hitherto unexpected, and there is no good reason to suppose that the arts, processes and inventions suitable for the tillage of Indian soil have already been perfected. The native cultivator is no doubt, when the hopelessness of the struggle to better his position does not drive him to despair, wonderfully skilful up to a point; but it is the point where science only begins, and to say that the discoveries of physical and mechanical science have nothing to teach us in agriculture is to shut our eyes to the experience of Europe during the last hundred years. No doubt the native cultivator thinks he has got as far as he can: Squire Western also would have laughed at the notion of a steam plough: but this is no reason why those who know better should agree to think so, or despair of persuading the native to change his mind.

Past experience, however, with its record of abortive experimental farms stored with model implements never leading to copies, shows that to attempt this from the top is to attempt an almost impossible task. We must begin at the bottom: we must take the child, while yet years of routine on the paternal homestead have not induced the conviction that his father knew as much as it was possible to know; we must teach him first of all to look on agriculture as an occupation in which improvement is always possible; and we must impart just such a rudimentary instruction as will give him a glimpse of the direction in which this improvement may lie, and inspire him to take that road. When we have done this our experimental farms, our agricultural exhibitions, our scholarships to send one or two in a hundred and fifty millions to a technical English school, will catch on, if we may use an Americanism, in a way they have never done before. Sir Edward Buck stated that proposals for carrying the recommendations of Dr. Voelker into effect would shortly be made; but whatever the precise nature of these recommendations and proposals, the foundation of all must be laid in the ordinary school. If this is done, the boy who can afford to wait at school and go on to college, will carry with him from the outset the knowledge that success in agriculture is a worthy aim, which demands education as well as clerking, or schoolmastering, or scribbling, or pettifogging: the boy who cannot, will at least carry back to the fields the spirit of inquiry, the parent of progress in agriculture as in every other sphere of human activity and effort.—*Pioneer*,

HOP TEA.

A few months ago we noted that a factory had come into existence at Madestone, in Kent, where the preparation of "hop tea" was being carried on. This product has now been placed on the market by the Hop Tea Company, of Eastcheap, London. It is sold at the rate of 2s. and 2s. 6d. per lb. The blend is made of Indian and Ceylon teas, to which is added by a special process the infusion of hops. It is claimed that some of the worst properties of the tannin are obliterated by the hoppy flavour, and a certain sedative element introduced. It cannot be denied that in the majority of Indian and Ceylon teas there is a rough, strong, taste, which, indeed, has made it one of its chief recommendations to the poorer classes. Anything which in part removes this harshness improves the tea, whilst the suspicion of hops introduced is agreeable, and likely to find favour with many. China tea, it will be understood, does not so readily lend itself to the manipulation, nor, indeed, does it stand so much in need of being softened down. The idea seems to have been a happy inspiration to remove the astringency of the tea and introduce the tonic property of the hop. Medical opinions give it that many persons who have hitherto been debarred from indulgence in tea, owing to its astringent properties, may with greater impunity embark on a trial of the hop-flavoured article.—*L. & C. Express.*

COFFEE.—A small amount of Kona coffee has been imported from the Hawaiian islands, where it is grown, into San Francisco, but so far receipts have been light. An appropriation of \$10,000 was made by the last legislature of Hawaii to be devoted to the encouragement of coffee raising, and the import duty on foreign coffee was raised to 6 cents per pound, an increase of 3 cents. Although coffee is grown in several of the islands comprising the Hawaii group, the Kona district on the island of Hawaii has been found the best producing section on account of most favorable climatic conditions, and it is from this section that Kona coffee comes. The bean somewhat resembles the Costa Rica coffee, but the aroma, odor and flavor are entirely different from either that or any other sort of coffee. It is said that in the islands this coffee is used almost entirely, and strangers, tourists and other visitors who taste it consider that it makes a most delicious beverage.—*American Grocer*, Nov. 12.

MR. HORNE, THE DIRECTOR OF THE PUBLIC FORESTS AND GARDENS OF THE ISLAND OF MAURITIUS, has furnished an elaborate report on the industries which it is desirable to foster in the present depressed state of the sugar trade. Mr. Horne does not doubt but that in the future, as in the past, the cultivation of the sugar-cane must be the principal occupation of the agriculturists of the island, but he points out that many other resources are open to them, and recommends, moreover, the appointment of an agricultural chemist to advise in matters connected with Sugar-cane growing and its management. Mr. Horne suggests, in addition, the extended cultivation of Coconut Palms, Cacao or Chocolate, Coffee, Tea, Dates, Oilnuts, Elais, Betelnuts, and other Palms, various cereals, starches, Indigo, Anatto, oil-seeds of various kinds, Bananas, Pine-apples and other fruits, Ginger, spices, fibre plants, cotton, silk, indiarubber, Tobacco, dyewoods and a variety of other plants and their products—a list which will give some idea of the resources that are open to the cultivator in the tropics if other circumstances be propitious. Cinchona does not prosper in the island.—*Gardeners' Chronicle.*

MINING AND GEMMING IN CEYLON.

In a recent letter our London correspondent referred to the want of success which had attended the gemming operations of the past year, or past few months, in Rakwana, as telling against the credit of this Colony—and especially of local gemming and mining projects—in the City of London. The writer was too polite to say it openly, but he evidently implied that the non-success of the enterprise begun under the auspices of a Limited Company was the more remarkable in view of all that had been written in our columns in support of the industry and the many arguments in favour of investment which we had used. The inference in fact was that experience had shown the fallaciousness of our information and writings and the result threw discredit on any proposal to apply English capital to the development of gemming and mining enterprise in Ceylon. Now we beg most strenuously to object to this line of inference and argument and to protest that, up to this date, there is nothing in the operations undertaken nor the experience gained, which affects the main position we have from the first taken up, and held in reference to this branch of local industry. Our position, so far from being undermined by the work of the past year or six months, remains in fact untouched and we hold to it as strongly in the face of English capitalists as ever we did. The whole tenor of our writings has been to the effect that the Gem-digging industry of Ceylon has given employment to hundreds and thousands of natives, almost from time immemorial—that it is undeniable large numbers of sapphires, rubies and catseyes—not to speak of less valuable stones—are continuously found and sold by the gemmers to native dealers who export and sell them in India or in Europe, without any notice of by far the larger proportion of such exports being recorded in our Customs accounts. The term "precious stones" has been synonymous with the name of Lanka for all the centuries back to, and even before the Christian era, and there is no evidence that our gemming country has been by any means exhausted. On the contrary there is strong evidence to show that considerable areas of gemmiferous land remain untouched to this day. What we pleaded for then was not simply the introduction of English capital to buy up such land and to work it after native fashion—which is all, the Gemming Companies at work (is a small way) have done; but above all the introduction of machinery and of the latest appliances so as to give a fair test to selected fields for the first time in history under the modes of working recognised as successful in the Diamond Fields of South Africa. Now this is exactly what up to date has not been done. Two Gemming Companies with limited capital have been at work—but it has been at work very much after the native fashion, with native contrivances more or less adapted, but still coming far short of the latest European appliances. The consequence has been that no proper scientific tests have been applied, and it has become notorious for native employees to make a bolt, leaving a balance of wages due to them without claiming it. Agaiu, we have heard that all the parcels of stones and gem débris sent down from the only Rakwana Company's pit, on being shown to an expert in Colombo, has resulted in the constant enquiry—"Where have the good large stones gone to?"—this is just the stuff in which they are always found; but there are no stones here save those of little value." Latterly, we understand the Company at work in the field under London auspices,

has started making a new machine to supply the need most felt in and at the gem pits; but it is not yet completed and until it is in full operation, its work cannot be judged. But even then, we question whether this machine constructed on the spot will answer its purpose so well as the complete but expensive machines constructed in England for the South African Diamond Fields. It is such machinery that we should like to see applied and tested in the Gemfields of this Colony. No test worth speaking of has yet been applied. And yet all this time, splendidly fine large stones have been brought to Colombo, exhibited and sold, or sent away privately.

We maintain, therefore, that so far from discredit being thrown on Ceylon by what has taken place in our Gem pits during the past year, we are very much in the same position as when we first called on English capitalists to establish a Syndicate or Company and set to work with proper machinery. We have not written of positive, assured success. That is a matter we left business men and capitalists to judge for themselves from the facts placed before them. All we urged was that Ceylon undoubtedly had further stores of gems, that there is a large profitable digging and export trade and that with the use of the latest and best machinery, there was every reason to believe European Companies could compete and obtain a good return on their investment.

STERNING, INSKIP & Co.,
9, Great Tower Street.

6th February 1891.

THE CONDITION OF ST. HELENA.—Mr. Antrobus, of the Colonial Office, who has lately been acting as Governor of St. Helena, concludes a recent report on that colony by saying that many of the civil servants have to discharge responsible duties with inadequate pay, and all the inhabitants are suffering more or less from the general depression. "It is melancholy to contemplate the present condition of an island which was once so flourishing and still has so many points to recommend it. There are still the wonderfully healthy climate neither too hot nor too cold, the beautiful scenery, the mixture of tropical and temperate vegetation, the rare indigenous plants, the clearly and marked geological structure, and the historical associations derived from the rule of the East India Company, the imprisonment and death of the great Napoleon, and the visits of Halley and Darwin and other distinguished men of science. But the ruins of well-built country houses, and the deserted cottages, which are to be seen in every direction, as well as the returns of the rapidly diminishing revenue, afford evidence of the change which has taken place in all that constitutes material prosperity; and I regret that there is at present no sign of any improvement."
—London Times.

MINING AND GEMMING INDUSTRIES IN CEYLON.

The attention of Mr. Barrington Brown during his presence in the island, seems to have been confined to the province of Sabaragamuwa. No doubt it includes within its bounds, nearly all the recognised and well-established gemming districts, and possibly quite enough to occupy the time of the geological and mineralogical expert during a few months' stay. But it is undeniable that districts in other provinces also deserve the expert's careful examination. In the Galle and Matara divisions of the Southern Province; in the province of Uva; and in the Nuwara Eliya, Pussellawa and Maskeliya districts of the Central Province and again along the course of the Mahaoya to the North-Western Province, "gems" or "gold" are by no means unknown finds. As regards plumbago, again, the Kurunegala and Kegalla districts call for very careful attention, quite as much as the Ratnapura, Kalutara and adjacent divisions.

But even if we confine our attention altogether to Sabaragamuwa—and notably to the Ratnapura and Rakwana districts—we believe we shall find that Mr. Barrington Brown has been able to give the London Syndicate employing him, such information as amply justified his mission and most fully supported the position we have taken up for many years back in regard to our Gemming Enterprise. Of course the expert's attention was mainly directed to certain allotments of land either leased, purchased or under offer to his Syndicate and it is with reference to the value of these, and to the results of various testing operations that his report must be mainly directed. Nevertheless, he was able to enter on some general remarks descriptive of the position of the gemming country examined by him and of the geology of this part of Sabaragamuwa. Gneiss, of course, forms the chief rock encountered. It is of a bedded character and contains layers of graphic granite and hornblende gneiss often seen gradually passing into the gneiss at the planes of contact; while in some few instances there is granular limestone. The expert alluded to the fact that as yet no precious stones have been discovered in the matrix which, in his opinion, will be found to consist of gneiss, graphic granite and granular limestone. The frequency with which garnet crystals of small size occur in the gneiss and granite—a circumstance often remarked upon—*is alluded to.* We believe the special mission of Sir Samuel Baker, the celebrated traveller, on his last visit to Ceylon, was to discover the matrix of some of our precious stones and with this purpose, it was stated at the time, with how much accuracy we cannot say, that Sir Samuel and a well-known enterprising public officer, explored hammer in hand, a good many rocky valleys high up in the Highlands of Uva, Nuwara Eliya and Sabaragamuwa, but apparently without success. Possibly Mr. Barrington Brown would be able to show them that they had not gone properly to work to find the matrix, if indeed it still exists to any extent. For, we know that by the decomposition and disintegration of the mountain rocks, the gems contained therein in crystalline form having been freed and are now to be found in gravelly deposits on hill sides bordering mountain streams—as in so many parts of Rakwana—or in alluvial layers of gravel covered and deposited in the valleys. In the former case, the natives have done a great deal of systematic work in mining and gemming, sinking "shafts" or entering "drives" in the hillsides, while in the valleys, the process is one of dredging with hoes under the river

beds, or of sinking of pits alongside. Meantime; we have the fact before us that by such simple, not to say primitive processes—almost entirely hand labour—the Sinhalese gemmors in Rakwana and Ratnapura have, from time immemorial, obtained precious stones, chiefly sapphires, catsyoes and rubies while still, undoubtedly, there continue to be found many valuable stones of these descriptions.—We may have further information to give in our next.

LININGS FOR TEA BOXES.

The explanation afforded by our London Correspondent in his letter by yesterday's mail will relieve the minds of Messrs. Anderson and Maitland Kirwan of any feeling that the remarks we passed in our article headed 'Lead Linings for Tea Boxes' were of application to the patents these gentlemen severally represent.

As regards Mr. Maitland Kirwan's paper, it was of course, altogether excluded from the category of linings with which our remarks dealt. Reference was intended by that article solely to those forms of linings into the composition of which lead entered. Mr. Maitland Kirwan's material has no such character. It is what seems to be known as a "butter paper," and it is of this lining of which Messrs. Wilson, Smithett & Co. wrote in such complimentary terms in their Produce Circular some time back. But it must be borne in mind that an important element of the question in the relative value of linings of all descriptions is the one of cost and certainly we were not prepared for the revelation as to comparison between the paper and lead now afforded us. We had written previously under the belief that the "paper" would be the cheaper lining of the two. We are told that the rate at which 4-ounce lead can be used is about 1s 3d per chest, while Mr. Maitland Kirwan's paper is quoted—according to our London correspondent—at 1s 4½d per 100 lb. chest. For boxes holding a less quantity our correspondent could obtain no quotation. But when we refer back to the correspondence which arose in our columns in January last, we find that the difference in cost was even then fully apparent. It was stated by planters, without contradiction, that using 5-ounce lead which is now generally preferred, the cost per chest was equal to from 72 to 83 cents on the estate against 1s 4½d for Mr. Maitland Kirwan's paper in London, or probably a figure not far short of a rupee on the estate.

The same element—that of cost—would have excluded from consideration the lead paper known as "Clark's Patent" which Mr. T. O. Anderson has advocated. For this we have from London no quoted price; but as the 4-ounce lead with which this paper is coated is equivalent in substance to that commonly used for lead linings pure and simple, we must presume that the cost of adding that amount of lead to paper must involve a price very materially in excess of the use of a similar weight of lead when applied alone. That the combination employed under "Clark's Patent" may be most useful, and that this fact may well justify the extra cost its employment may involve, we do not deny; but this does not enter into the scope of our present contention. It will, of course, be acknowledged that this question of relative cost is one of primary importance to our planters. What we want to obtain is a lining which, while equally efficacious in preserving tea as is a simple lead lining, shall be superior to it in economical result. This, according to our present information is scarcely obtained by either Clark's lead paper or

Mr. Maitland Kirwan's "butter" paper. Both of them, no doubt, are exceedingly efficient and reliable, but they are both more costly than the material in ordinary present use.

As for the tin-foil paper, which we are told the remarks formerly made were more specially intended to apply, there seems little cause to doubt that it does not afford a reliable lining for tea boxes even though its cost may be below that of our present staple material. It would be poor economy to save a few pence on every chest of tea packed while having no assurance that its contents would reach the London market uninjured. As yet therefore—price for price being taken into account—it must, we fear, be admitted that we are without a satisfactory substitute for lead. Lead has been proved by long experience to be a very efficient material for packing tea in chests. We are reminded, however, that Messrs. Wilson, Smithett & Co. would gladly see something substituted for it. For in the first place, even the best of sheet lead will only bear a certain amount of handling. The packets, it is asserted, which are retailed in lead, deteriorate if they are subjected to a long course of rough handling. Much "pinching"—to use the term which seems to indicate the course of such rough handling—will, if long continued, crack the lead, and the contents of such packets will deteriorate greatly. But Messrs. Wilson, Smithett & Co. point out a second reason why some alternative to lead would be welcomed. This is the fact that, should the wood of the chest be not properly seasoned, and consequently exude any sap, the result is to produce "acetate of lead," which not only destroys the lining but most seriously affects the tea enclosed. It is to such a cause that the "cheesy" smell and flavour of a large quantity of Ceylon and Indian teas returned upon the Brokers' hands, has been attributed. The "butter" paper of Mr. Maitland Kirwan, if used, might obviate all chance of this particular cause of deterioration. Would it not then be possible for this material to be reduced in price? Messrs. Wilson, Smithett & Co. have borne evidence to the protection it has afforded to teas sent home in it, and the objections raised to lead now referred to, do not attend its use. If a longer experience of this "paper" were to justify Messrs. Wilson and Smithett's conclusions, we have little doubt that a reduction in its cost would ensure for it a wide adoption by our planters. Meantime does not the course of this discussion in our columns and the many points which are still necessarily left open questions, show the need, in the planting interest, of that "P. A. Sub-Committee" to enquire into and test new inventions and economical processes, which we suggested some time ago and which suggestion has been supported in our columns by not a few planters. If Mr. Giles Walker distinguished his year of office, by the establishment of such a Sub-Committee, we think he would do a good thing in the interests of the planting community.

ANTIQUÉ DIAMOND DRILLS.—Mr. Flinders Petrie has originated the theory that the ancient Egyptians were familiar with the diamond drilling device. In his "Pyramids and Temples of Gizeh" illustrations are given of samples of work which apparently show the use of jewel points in drilling and sawing. Various samples of this work are in his possession. He cites six examples in the Bulak Museum and at Gizeh. In a temple at Gizeh there is found in one of the lintels of a door a drill hole with the core still sticking in it. A base of a tube drill hole is also found between the feet of a statue of Che'ren now preserved in the Bulak Museum. —*Indian Engineer*,

CINCHONA IN THE DUTCH MARKET.

Amsterdam, February 6th.

The Amsterdam auctions on February 26th will consist of 2,941 bales, 156 cases (about 239 tons) divided as follows:—Java bark: From Government plantations 323 bales, 37 cases, about 28½ tons; from private plantations 2,618 bales, 116 cases, about 210½ tons, African cinchona bark: 3 cases, about 4·29 cwt. Druggists' bark: *Succirubra* quills, 132 cases; broken quills and chips 68 bales; root 23 bales; *C. Schuhkrafft* quills 6 cases; *Lancifolia* quills 5 cases; broken quills and chips 11 bales. Manufacturing bark: *Ledgeriana* quills 10 cases; broken quills and chips 2,165 bales; root 408 bales; Hybrids broken quills and chips, 200 bales; root 56 bales; *Officialis* broken quills 10 bales. Total 2,941 bales, 153 cases.—*Chemist and Druggist*.

NOTES ON PRODUCE.

COFFEE AND CHICORY.—A Liverpool firm has been accustomed to sell the so-called "French coffee" in pound canisters, price one shilling; and, as they took the precaution to affix a label warning the purchaser that he was buying a mixture of chicory and coffee, they probably considered themselves free from either legal or moral offence. As their legal representative virtually put it: "Some people prefer chicory; we sell the mixture; they know what they are buying, and there is an end of the matter." The Liverpool magistrates, however, reason differently, and insist that even under these circumstances "fully one-third, or probably much more," chicory is excessive. Hence they have imposed a fine, but the Liverpool firm have determined to appeal.—*H. and C. Mail*.

TEA IMPORTS, DUTIES AND PRICES IN AMERICA.

Tea importers and dealers are not a little interested in the bill before the House of Representatives to re-establish the former discriminating duty on tea shipped from ports west of the Cape of Good Hope. Prior to 1883 the following provision stood in the tariff law: "There shall be levied, collected and paid on all goods, wares and merchandise of the growth or produce of the countries east of the Cape of Good Hope, except wool, raw cotton and raw silk, as reeled from the cocoon, or not further advanced than tram, thrown or organzie, when imported from places west of the Cape of Good Hope, a duty of 10 per cent. ad valorem in addition to the duties imposed on any such article when imported directly from the place or places of their growth or production." This discrimination in favour of direct imports came down from the early days of the Union, having been established originally for the purpose of encouraging the carrying trade with the East Indies and China. The opposition to it has been based in part at least upon the belief, which the statistics confirm, that it was in reality special legislation against imports from London. At the same time rival commercial interests have come to be involved in the matter.

The imports of tea into the United States in 1889 amounted to 79,575,984 pounds, of which 40,751,789 pounds came from China and 33,303,437 pounds from Japan, 260,927 pounds from the British East Indies and 203,825 pounds from Hong Kong. This leaves but 5,056,006 pounds from ports other than the places of production, and of this quantity England furnished 4,673,864 pounds. The remaining 352,142 pounds is the only evidence which can be furnished that the law would have a general meaning and not a specific one. Under free entry the increase of indirect imports has been very small, but such imports being forced upon the market at critical times have had considerable influence, it is claimed, in breaking values.

The disturbing influences in the tea market have been many, and it is therefore difficult to specify any principal cause as having affected declines or advances in values. The recent advance in silver has

naturally disturbed prices in the East, silver being the sole circulating medium in China. The financial stringency in this country and England has likewise compelled many holders of tea to liquidate, though it is to be said that the fact that failures among tea merchants have been so few is a forcible illustration of the strength of the market. These financial troubles have caused a weakening in prices and checked the advance started through the rise in silver.

The stock of tea in this country is at present very heavy, and prices are in consequence lower here than in England. Hence London merchants are now buying tea in New York. The promoters of the new legislative agitation hope by means of it to buoy up prices and prevent a further decline. But many dealers have been free to predict that no such legislation will be passed by the present Congress: It is claimed by the advocates of the measure that under free entry London merchants are able to place here large quantities of tea whenever the market shows a tendency to advance. London merchants derive an advantage over our importers through the difference in cost of transportation. Freight rates are lower between China and London than between China and the United States. The former duty, of course, benefited to some extent steamship lines running between tea centres in China and Japan and the ports along our Pacific coast. Canada formerly bought the larger part of her supply from the United States, but since 1883 the tendency to buy of London merchants has increased, while the trade with the United States has fallen off. Our imports from London, which comprise about 5 per cent. of the total annual receipts, are mostly inferior teas. To prevent a further weakening in values by forcing large quantities of tea upon the American market shippers are now holding 70,000 half-chests of Formosa tea in Amoy.

The annual imports of tea between 1880 and 1889, inclusive, were as follows:—

	\$		\$
1880 ...	19,782,631	1885 ...	14,047,583
1881 ...	21,004,813	1886 ...	16,020,383
1882 ...	19,392,102	1887 ...	16,771,802
1883 ...	17,302,849	1888 ...	13,360,685
1884 ...	13,636,053	1889 ...	12,654,640 *

Secretary Rusk thus speaks in his annual report of the investigations of his department in regard to the adulteration of beverages: "These investigations show that the adulteration of such articles is not very extensive, and, except in the case of tea, is easily distinguishable. The most frequent one is the introduction of substances to give additional weight, such substances as will attach themselves readily to the leaves, and yet not be easily distinguished by the eye. These substances are mostly of a harmless character, although some of them have been found to be deleterious."

Importers and dealers declare that no foreign substances are added, and the use of the term "adulteration" is misleading. When the leaves of the tea plant become mature no more nutriment is furnished them by the plant except what is just sufficient to maintain life, the sap being supplied to the younger leaves and buds. The older the leaf the less valuable it is, as it becomes hard and woody, and thus loses its nutritious properties. These leaves are frequently worked in with more valuable products, but they are not adulterants under the common meaning of that term. The chemical solutions to which the leaves are subjected, it is claimed, are to give them a uniform color and not to add to their weight. An expert can easily detect the presence of the old leaves. The yield is so abundant that the necessity of adulterating tea is thought to be very small. The production is constant, and not, as in the case of vegetables and cereals, subject to the seasons.—*Bradstreet's*. [True of Ceylon, but not of India and China, which have a winters.—*Ed. T. A.*]

* The figure for 1890 will be over 14 millions of dollars.—*Ed. T. A.*

LINING OF TEA CHESTS: LEAD VS. PAPER, &c.

Every effort has been made by me this week to assure myself respecting the fullness of the grounds upon which the criticisms passed by me in a former letter of mine on the substitutes proposed for the lead lining of tea chests were based, and for the result to which—as set out in your article of comment on the subject—you, with perfect justice, held me to be responsible. I sought in the first place an interview with two old Ceylon planters now at home, both of them men of great local experience in Ceylon and both very largely engaged in dealing with your teas in London. I can best communicate to you their views by giving you as nearly as possible the words of the elder and more experienced of my two interviewers, both of whom—were it authorized to me to mention their names—you would acknowledge to be among the highest possible authorities on such a subject. The senior of these remarked to me:—"I have read all that you and the *Observer* wrote on this subject of lining tea chests, and I may express my fullest concurrence in anything that has been written by you both. Stick to your guns: don't you be driven from the position taken up by you. The particular lining you saw—and which we have all seen—penetrated by innumerable small holes is what is known as a tinfoil paper. None of us will ever use it again, despite the fact that its first cost is much below the cost of 4 ounce lead. I see Mr. Maitland Kirwan complains of the remarks made by the *Observer*. He certainly has no right to do so, for his lining is not a lead paper at all, and your remarks were confined to linings of that character. What Mr. Maitland Kirwan proposes is the 'butter' paper formerly shown you. We have nothing whatever to say against the use of this material save that its cost is higher than that of pure lead, which I use at about 1s 3d the chest, and this fact tells naturally against it, as it does not give better results than lead. Then as to Mr. Anderson's lead paper, that known as Clark's patent, the *Observer* should surely have recollected letters written to it by some planter who has used it pointing out that the cost of it was very greatly in excess of simple lead. This must naturally follow from the fact that Clark's patent adds to the cost of the 4-ounce lead that of backing it with paper. It is no doubt capital stuff, but the cost excludes it from the category of linings respecting which you wrote, as these included only those from the use of which an absolute economy as compared with that of lead was to be anticipated. What we want is a *cheap* substitute for lead. The last answers every needful purpose, and we are not likely to adopt any alternative material in lieu of it which will involve extra cost. In my opinion Messrs. Anderson and Maitland Kirwan, when writing in complaint of the *Observer* article, should not have left the higher price of their materials without mention. The fact that they did so did not enable general readers to fully understand the case."

Immediately after terminating the interview of which the results have above been given, I went and saw both Mr. Wilson and Mr. Smithett on the subject. Those gentlemen told me they had read all you had published relative to it. They kindly looked up their own circular in which they had praised Mr. Maitland Kirwan's lining, and they said that, although their experience of it had fully justified what they had written, they knew nothing as to the cost of it. The teas consigned to them and packed in this butter paper had arrived in admirable condition, and they should be very pleased if fuller ex-

perience should justify the supersession by it of lead. "For," Mr. Smithett remarked, "although we do not believe that the contact of lead with tea is in any appreciable degree injurious, there is no doubt that if unseasoned wood has been used for making the boxes a lead lining is likely to be a very dangerous one. When we lately complained of the 'cheesy' smell and flavour of a quantity of Ceylon teas received by us, we had them submitted to analysis, and it was found that they were strongly impregnated with acetate of lead. This was the result to the action of the acid of the wood on the lining, and it had eaten away the latter and had fouled the tea to such an extent that after sale we had a very large quantity of the chests returned to us, and a very heavy loss had to be borne when finally obtaining a purchaser for it. What we want, therefore, is to see lead superseded altogether. As long as it is liable to action by acid from the wood the danger mentioned will always be present."

After leaving Messrs. Wilson and Smithett I proceeded to call on Mr. Maitland Kirwan. Unfortunately that gentleman was out, but to my request in his office for a quotation of the price of the "butter" paper linings it was given me as 1s 4½d. for a 100 lb. chest. On my asking the price for half-chests it was replied to me that they had no quotation for the lesser sizes. This information was confirmatory of what had been mentioned to me in the interview first recorded. You will see that the question resolves itself finally into this, viz. that there may be efficient substitutes for lead, but that none of them meet what my letter stated to be desired *i. e.* a substitute for it which should be less costly. When my letter to you was written neither Clark's patent nor Mr. Maitland Kirwan's paper were in my mind, and only the second had ever been under my own observation.

UNITED PLANTERS' COMPANY OF CEYLON LIMITED: £250,000 CAPITAL.

There has been a "mighty big thing" in connexion with Ceylon started this week, and this has been done so quietly that even Mr. Leake, on my mentioning it to him this week, told me he had not heard even a whisper about it before my telling him of it. The following referring to this new enterprise is extracted from the *Investors' Guardian* of Saturday last:—

UNITED PLANTERS' COMPANY OF CEYLON, LIMITED.

This company was registered on the 3rd instant with a capital of £250,000, in £10 shares, to acquire properties in Ceylon, and to carry on the business of tea and coffee-planters generally. The subscribers are:—

Shares.	
*H. Brooks, St. Peter's-chambers, Cornhill, merchant	1
Hy. Brooks, St. Peter's-chambers, Cornhill, merchant	1
*H. T. Brooks, Redlands, Upper Long Ditton, Surrey, merchant	1
*J. M. Boustead, Westfield-lodge, Surbiton, merchant	1
A. O. Sheroff, 29, Groombridge-road, South Hackney, clerk	1
I. D. Tarr, 7, Liston-road, Clapham, S. W.	1
P. Pears, 18, Leigham-lane, Tulse-hill, S. W., clerk	1

The number of directors is not to be less than 3, nor more than 7; the first being the subscribers denoted by an asterisk; qualification, £500 in stock or shares; remuneration to be determined by general meeting. Solicitors, Messrs. Parker, Garrott and Parker, St. Michael's Rostory, Cornhill, E. O. Calling the other day at the office of the solicitors to the Company, it was told me that no

prospectus whatever had been printed, that the association was in fact quite of a private character, and that details could not be communicated to me. It was not yet decided whether any public subscription would be sought. If it was eventually decided to do this, it would only be for the sake of obtaining a quotation on the Stock Exchange. But although my inquiries in this quarter had so little of success, it reached me from another that the venture was mainly in the hands of Messrs. Brooks & Bousfield, and the properties with which the Company will deal were mentioned to me; but I was requested not to publish either the names of these or of their proprietors, as to do so, it was thought, might be harmful and might give offence. Most likely the names published in association with the registration of the Company will afford you the clue which it is forbidden to me to give you.—London Cor.

TEA INFUSION.

(From a Correspondent.)

I spent some minutes testing the boiling of water. In these busy times no one could afford to wait long enough for the Japanese third stage referred to by Sir Edwin Arnold. Still for one's own edification, enlightenment, and it may be gratification, I would suggest the testing of this Japanese style of making tea with honorable "old hot water." There may be something in it—who knows? It is a fact that the "G. O. M." does not care to drink tea unless it is prepared for him by Mrs. W. E. G., and yet the old man is very partial to tea. Can it be that Mrs. Gladstone has got some secret, or does she adopt the Jap's plan? If so she should be asked to reveal it *pro bono publico*. I have no doubt she would if she were only asked. Then why not ask her in Ceylon's name, sending her 100 copies of the tea leaflets? We all know that we prefer tea made by some few people to all the tea we are offered by others. So there is an art in the process, and Mrs. G. I have no doubt would readily grant us every assistance. It is worth trying for.

The Tea Leaflet published at your office, I fancy, will have helped to check the baneful practices of taking a second brew and allowing the tea to draw more than 5 minutes. If so it will have done some good and helped on consumption in the U. K. and elsewhere, although the number of consumers may not have very considerably increased. But in the long run deliciously made tea must increase the number of consumers very considerably throughout the world. Attention all round seems now being given to tea—see page 28 top para. in the *World*, 23rd Jan. 1891. "Over the Tea Cups" is Dr. Holmes's new work, and it ought to be good coming from the author of the "Autocrat of the Breakfast Table"; but I suppose it will have very little to say about tea itself?

Considering that Sir Edwin Arnold took the English belt as a tea drinker while he was in Japan lately by drinking about 80 Japanese cups of tea daily, I think the Ceylon Tea Fund made a mistake in not presenting him with a small box of Ceylon's choicest leaf when he passed through Colombo a week or two ago. But Ceylon tea is rushing ahead so steadily in the world's favor just now that it exemplifies the old saying "good wine requires no bush."

You should obtain from Calcutta one or two electroplated *Bengal Tea Sulkies*. They cost but very little and beat the egg-shaped tea leaf dippers hollow. By the aid of these sulkies everyone can make tea to her or his liking and without trouble. The lower portion is of fine gauze wire and far better than china ware.

All you want then is one of Messrs. Walker's American kettles big enough for tea making purposes, of the finest quality of thin sheet iron,—the water boils rapidly,—oval-shaped lid at back and handle in front there is no danger of scalding one's hands by the steam issuing from the lid.

PLANTING PRODUCTS:

COFFEE—CACAO—CINCHONA.

(From the Annual Report of the Badulla Planters' Association, held 14th Feb. 1891.)

Coffee.—Your Committee congratulate you upon the improved appearance of coffee in the districts. Seasons have been more favourable for this cultivation of late, crops are good and prices for the old staple are all that can be desired.

Tea.—Tea now fast becoming our leading product is making most satisfactory progress in all the districts comprising your Association: at the present time more than 10,000 acres are under this cultivation and a large area is being planted up yearly. The exports of tea from Badulla, Madu'sima, Hewa Eliya and Monaragala districts for 1891 are estimated at 2,000,000 lb. This is a good yield considering that so large a proportion of the acreage is only recently planted and is not yet in bearing. Tea cultivation in the Badulla district promises to be exceedingly remunerative in the future, and your Committee congratulate you upon this.

Cinchona.—This product, your Committee regret to say remains in the dull and depressed condition reported last year. No improvement in prices has taken place. The exports from the Badulla and Madu'sima districts for 1891 will be about 2,000,000 lb., a lower total than for some years past. Statistics for cinchona bark are more favourable, but the depressed market, your Committee believe, is owing in a great measure to the fear of increased supplies from Java. No great fluctuations in prices have occurred during the past year, the unit ranging from 1½d to 1¾d. Your Committee are, however, hopeful that with a steady falling off in exports from Ceylon some improvement in prices will take place during 1891.

Cacao.—Your Committee are pleased to report the continued successful cultivation of cacao both in Monaragala and in other parts of the district. The past season has been very favourable, and there has been very little helopeltis: in fact where shade has been used from the first there is none to be seen. As the trees get older the blossoms set more favourably and crop increases. Prospects for the coming year are very good and with the price at 115s per cwt. there is no doubt that cacao is a product second to none. The acreage under this cultivation is from five to six hundred acres.

BARK AND DRUG REPORT.

(From the *Chemist and Druggist*.)

LONDON, Feb. 12th.

CINCHONA.—At Tuesday's auctions a very moderate quantity of bark was offered, the catalogues comprising only:—

	Packages	Packages	
Ceylon cinchona	887	of which	825 were sold
East Indian cinchona	1,440	do	1,183 do
Java cinchona	39	do	32 do
South American cinchona	582	do	39 do

Total 2,928 do 2,079 do

The assortment of bark was rather poor, especially that of Ceylon cinchona, but *Succirubras* from India were well represented, and included one parcel of not less than 20 tons weight from the Wentworth plantation. It was generally expected that prices would rule lower, quinine having been greatly depressed during the week, and it was said that several holders of Indian and Ceylon bark had given instructions to sell at any price. The prices realised were somewhat irregular, but decidedly easier all round, and the unit cannot be placed at a higher average than 1½d per lb.

The following are the quantities purchased by the principal buyers:—

	Lbs.
Agents for the Brunswick factory	157,493
Agents for the Mannheim and Amsterdam works	142,294
Messrs. Howards & Sons	43,015
Agents for the French, American, &c., works	30,682
Agents for the Aurbach factory	27,484
Agents for the Frankfurt o/M. and Stuttgart works	23,995
Mr. Thomas Whiffen	2,440
Sundry druggists and spectators	39,780

Total quantity sold	466,093
Bought in or withdrawn	148,073
Total quantity sold	614,766

QUININE has attracted a considerable amount of attention this week, and the total transactions reported since last Friday amount to about 320,000 oz., of which 130,000 oz. changed hands today. On Monday the drop in price reached its lowest depth, in a small sale of German bulk quinine on the spot, at 10d per oz., a price which beats the record. It is true that the authenticity of this sale is doubted in many quarters, but there is no question that at one moment the drug was freely offering at 10½d per oz. Several buyers then entered the market, which thereupon took a turn for the better, and kept on improving until today, when 10¾d per oz was freely paid for delivery up to May. The price of 11d per oz is now again generally asked. Howard's brand has been reduced to 1s 3½d per oz for bulk, and 1s 5½d for vials.

CINNAMON.—A sale of 100 bales is reported to have been made recently at 6½d per lb., e.l.f. London terms, for February-April shipment, usual assortment.

NOTES ON POPULAR SCIENCE.

By DR. J. E. TAYLOR, F. L. S., F. G. S. &c.,
EDITOR OF "SCIENCE GOSSIP."

I notice in the last number of *The Australasian* to hand that Mr. John McLellan, of Dimboola, has ingeniously turned the tables on the Locusts by planting patches of larkspur among his crops. These voracious insects devour "every green thing," but they could not digest larkspur leaves, so they died. The larkspur is a member of the most poisonous and otherwise objectionable order of plants in the world, the ranunculaceæ or buttercup family. The seeds of the larkspur were formerly ground to powder and used as a vermin killer. So intense is the poison that it is and must be used homeopathically. I mention this because the planting of larkspur indiscriminately may do more harm than the locusts. There is one plant among the vast number composing the natural order leguminosæ, which can lay claim to being a fodder plant and a poisonous plant at the same time. Let some young farmer plant patches of lupins instead of larkspurs. I venture to say they will be equally fatal to locusts, and they have the advantage of being a good sheep fodder, capable of growing on the lightest and hungriest of soils, where few or no other plants could grow.

It is as well to note a fact recently discovered, that artificial stone cements abounding in magnesia have a tendency to expand slowly after the concrete has set in which they have been used. This is a matter that builders and architects should see to, otherwise their completed work will do them anything but credit.—*Australasian*.

"AN INDIAN CINCHONA PLANTATION" forms the subject of four sketches (taken from photographs) in the *Chemist and Druggist* of 31st Jan., with descriptive letterpress. The plantation is one on the Kannan Dovan hills in Travancore, the first sketch giving a general view of the country; while the second shows a clearing in the forest, with buildings; the third women picking tea growing among the cinchona; and the fourth the drying-house and tea factory.

ACTION OF ALUM ON MICROBES IN PORTABLE WATER.—In the *Chemical News* for October, page 177, there is an interesting reference to the use of alum for the removal of organic matter in suspension and in solution in drinking water. It is well known that when alum is added to ordinary water it is decomposed, its sulphuric acid combining with the lime and its alumina being thrown down in combination with the organic substances which are present. Along with this precipitate and entangled with it the microbes are also mostly precipitated.

The *Chemical News* states that since this method has been adopted by the French troops in Tonquin they have enjoyed a nearly complete exemption from dysentery. This method was employed in preference to boiling the suspected water, the facilities for doing which were not always at hand.—*Engineering and Building Record*.

MAURITIUS.

(From the *Merchants and Planters Gazette*.)
PORT LOUIS, FEB. 10TH.

THE WEATHER AND THE CROPS.—We have been threatened by two cyclones within the space of twelve days. They have however fortunately both passed at a sufficiently long distance from the island, and have resulted only in refreshing rain of which the coming crops were in much need after the long drought. The fall in the barometer was considerable during the nights of the 5th and 6th instant, but we escaped, notwithstanding some hours of anxiety. We have unfortunately to expect these terrible visitors until the end of next month.

VANILLA.—Transactions have been very limited since the last four weeks. A few small lots of good quality were sold at R15 per kilo. Vanillous at R8 to R9, according to length and quality. We entirely confirm our last valuations as regards the output of the crop which will not exceed 14,000 kilos.

ALOE FIBRE.—The market is dull. We have to record the sale of a few small lots fine quality at R225 to R240 per ton. Holders prefer to ship for their account rather than to sell off at the above prices. The following quotations are nominal:—

1st quality	R250 per ton
2nd "	R175 "

MINING AND GEMMING IN CEYLON.—We learn that the Syndicate which employed Mr. Barrington Brown and whose local agent is Mr. E. G. Harding, has sent out a mining superintendent in Mr. Bettison who has had large and varied experience, but was never in Ceylon before. Unfortunately, the machinery which was to accompany him in the S. S. "Reva" was shut out at the last moment owing to dock difficulties, but this will follow in due course. Mr. Bettison starts off tomorrow in company with Mr. Chas. Byrde and perhaps Mr. Harding, to inspect plumbago mines, inland from Bentota in the Pasdun Korale. Of course, his operations will be merely preliminary to see how and where improved pumping and other machinery can be applied to plumbago mines.

ROYAL BOTANIC GARDENS.—We have to acknowledge the receipt from Government of the Report for 1890 of Dr. H. Trimen, F.R.S., Director. Dr. Trimen is usually first in the field and as his Report is one of the most interesting and useful, it is well to have it early. Pending adequate notice and very copious extracts respecting the five Gardens as well as Economic Products, we content ourselves today with three small quotations. First as to the drought in the Anuradhapura Garden:—

It is indeed remarkable how comparatively well some trees stand the drought which would have been expected to fail to do so. Thus the breadfruit ripened last year, and a good plantains of the *kolikuttu* variety were abundant.

Next, as regards growth at the Badulla Garden:—

Some of the young trees of *Cedrela odorata* are already 2 feet in girth at the base and 1½ in. at a yard from the ground. Our chief trouble now is the vast abundance of white ants, and these are specially destructive in the nurseries.

And finally a paragraph bearing on the discussion referred to by Mr. Barber in his letter today:—

No doubt crossing goes on freely in cacao plantations even between the two main races, and it is well-known here that seed from a single tree gives a very varied progeny; but a very curious remark has been recently made to me by a large grower, who has great opportunities for observation, that the "Forastero" varieties, which he chiefly cultivates, appear to be gradually changing their characters and becoming more like the "Old Ceylon Rod," the seeds losing their dark colour on section and becoming pale or nearly white. It will be very interesting to observe whether these observations are confirmed by longer experience.

CASTOR AND COCONUT CAKE AS MANURE.

Discussing the communication that appeared some time back in your columns, as to the relative value of Castor and Coconut cakes as fertilising agents, I see it asserted that the latter is possessed of some constituents that render it as valuable as castor cake. If such be the case, surely an Agriculturist of Mr. Hughes' standing would not have overlooked them, and he would not have recorded, what must be regarded as his deliberate opinion, that taking the white castor cake he analysed as a standard of comparison with 100 as its equivalent, Coconut poonac scores only 53.* Unfortunately, the sample cannot be regarded as a fair one, for the stuff was imported and was also damp. Of course, nitrogen is not the only food plants require, but isn't it the chief food of plants? According to my way of thinking, coconut poonac must be less than half the price of castor cake to make it preferable to the latter as a fertiliser, and to permit of the application of twice the quantity of castor cake per acre.

I saw an extract not long ago in one of the local papers that for fruit-bearing trees there was no treatment that answered better than mulching. I am sorry I cannot lay my hand on the extract to find out whose opinion that was. I thought it would have found a place in the *Tropical Agriculturist* for the current month, but it has not. The value of mulching in agriculture is undoubted, although when in the palmy days of the coffee enterprise some estates were mulched with mana grass, planters were found to condemn the system. Their objection was that the operation drew the roots—the rootlets rather—to the surface, and that the later state of the trees become worse than the first. The same objection was urged by those who have the management of the Horrekelle Estate to the use of fibre dust as a mulching. Though these objections have some force, yet they are not of sufficient weight to counterbalance the advantages of mulching. These are manifold. 1. It prevents the caking of the soil. 2. Keeps it open and porous and permits of its being aerated and cool. 3. Prevents too rapid evaporation, and affords moisture to the roots. Though these are not the only advantages of mulching, yet they are of sufficient importance to remove doubts as to its value. It is well known that roots can take up plant food only by absorption. If there be no moisture in the soil, trees must as a necessity starve. All the food in the soil is not present in a soluble form, indeed only an infinitesimal portion of it is in such a state. The preparation of foods goes on continually by the aid of certain agencies, not the least of which are water and carbonic acid and oxygen. Now, if by the aid of mulching moisture is conserved in the soil, and it is kept open and allows the free passage through it of the oxygen and carbonic acid of the air, not to speak of the large quantities of the latter which will be generated by the decomposition of the mulch, I think it follows that mulching is of great advantage in Agriculture. The decay of the mulch, and in fact of all vegetable matter, forms humus. This is an absorbent, and in its dry state takes up ammonia from the atmosphere and gives it to the soil during rains.

In coconut cultivation we have ready at hand material for mulching round the roots of the trees. Before mulching I think it best for the soil to be broken up round the stem as deep as possible, from about four feet from it to the distance of about 8 or 10 feet. The application of manure before the operation will be a decided advantage. After this the branches as they fall and the weeds as they grow can be applied over the broken ground and the soil never disturbed again. Subsequent manurings can take place one year between the rows of trees, and next in the rows. By this means the shock to the tree by the breaking of the roots will be minimised.

* Would that proportion stand in reference to all kinds of fruit trees? If the analysis was not made with regard to Coconuts, it would be an advantage to ascertain the percentage of the constituents in Castor and Poonac which the palm chiefly affects.—Ed. "Ex."

Speaking of the breaking of roots reminds me that Mr. John Ferguson, in his lengthy notes of a trip through the Eastern Province, speaks of the desolate appearance of the coconut plantations there owing to the long continued drought. In one instance he mentions that the effects of the drought had been aggravated by breaking the roots of the trees with an elephant plough. Ponder over that ye prophets who recommend ploughings "annual and oftener" of coconut, and ye their disciples. Mind, I do not say "never break up the soil of your coconut plantation," but as experience and observation both point to the operation being attended by severe shock to the trees, "break," I say, as few roots as you possibly can at a time." The same writer observes that, unlike fruit trees in England, coconut trees seem to resent root pruning. Ploughings, "annual and oftener," represent a very severe form of root pruning and of a quite unscientific description. Besides, it must not be forgotten that there is a vast climatic difference between Europe and the Tropics. There, heavy root and branch pruning must be resorted to check growth, and to give a sufficient shock to the tree to induce it to bear fruit. Here, nature does that in the drought we have, and there is never much necessity to supplement her operations. I very much think that one of the reasons for leaf disease taking such a firm hold of our coffee, was the enfeebled condition of the bushes owing to heavy branch and root prunings—manuring having involved the latter operation.

The warning, if not rebuke, of the veteran Editor of the morning sheet to those whose zeal outruns their discretion in recommending the cultivation of myriad products, is well timed. It comes with singular force from him who, when in the vigour of manhood, was closely identified with our great planting industry and took a prominent personal part in the trial cultivation of many minor products. Because a product does well when cultivated over a small area and receives special and unremitting attention, it by no means follows that it will do equally well over large areas. Indian corn with us is essentially a garden cultivation, and does well on the garden plots that surround the coolies of up-country plantations, as also on the garden plots of the neighbouring villagers. One knows how well these plots are manured naturally and artificially, and how well cultivated they are. Agriculture, except perhaps in the North of the Island, has not with us reached such a stage as to cause us to expect the same careful treatment of the soil over even moderately large areas as in garden cultivation. In times gone by, and perhaps even now, large quantities of Indian corn were grown in the now historic Walapane villages, and found a ready sale on Estates for feeding horses and poultry. The surplus found its way on the heads of villagers to Nuwara Eliya, a distance of about 15 or 20 miles, and over a road infested with dangerous rogue buffaloes and elephants. The markets were the same for all garden produce, including plantains. This, mind you, by villagers who in recent years have been credited with preferring starvation and death to honest labour.

Like the sea-serpent and the monster gooseberry, certain products are discussed here periodically with all the force and freshness of novel ideas. One of these is the Sunflower. At one time its malaria-absorbing properties are trumpeted forth, and the possibilities of reclaiming malaria-laden regions are discussed. At another, the wonderful properties of its seed-fattening poultry and making them lay. At another, the oil-yielding property of its seed, making it an ornamental, useful and valuable economic product. At the present time, when fuel is jocosely said to be a burning question, the value of the stalks for fuel and its extensive cultivation for this purpose is spoken of. Was there not published in the *Examiner* the results of a rather extensive cultivation of this product by the enterprising Mr. de Soysa at Hanguranketa, a few years back? I cannot find this in the *Tropical Agriculturist*. Sunflower as fuel was discussed years ago. Its use as such, and its being equal to coal as a heat-producing agency, were discovered, like all other great discoveries, in America.—B.—Local "Examiner."

FRUIT GROWING IN INDIA.

A short time ago we drew attention in these columns to the importance, generally, of encouraging the cultivation of fruit trees in this country as an industry, and on the present occasion we propose to deal with it more specifically by entering in greater detail into how it should be done, and the varieties most suitable for a commencement. In the forefront of all Indian fruit trees we will place the Mango; not only on account of its being most generally grown all over the country, but also because it is the one fruit tree in which the Natives of India really take an interest. Those who have not had opportunities of tasting good mangoes, have a notion that this fruit is like so much tow and turpentine. A more erroneous idea never was entertained; it would be as accurate to conclude that the characteristics of the crab apple are those that distinguish all the varieties of the apple in England. Even the fibrous uncultivated mango very often has a most exquisite flavour, but the only way to enjoy it is to do as the Native does and suck it! There are mangoes of all shapes, sizes, colours and varieties and they flourish all over India. Some years ago a scheme was submitted to the Government of the N.-W. Provinces for the establishment of a Mango Society, with the object of studying and tabulating the varieties of this fine fruit; of making coloured drawings of them; of forming an extensive orchard where all the known choice descriptions might be collected, propagated and distributed; and for learning by experiments the best ways of cultivating and improving them from seed. The proposal unfortunately did not meet with the approval of Government, and fell into abeyance. Attempts were then made amongst Native gentlemen to promote the idea, but met with no support. The following instance illustrates the right in which some minds regard philanthropy. A certain collector of choice varieties possessed a rare specimen, for a few grafts of which he was asked for planting in a public garden. His reply was that he could not think of parting with cuttings of his unique specimen as it would at once be propagated and diffused and so become common. His one idea was to jealously guard what he had, instead of permitting his fellow men to participate in its production.

In the "Flora of British India" about 20 distinct species of *mangifera* are described, and it is stated that there are about 30 in all. There is, therefore, a fine field for Horticultural Societies in India for their further development. Bengal, Bombay, Madras and the N.-W. Provinces can produce quite 50 different varieties, all well worth sending to Europe, in place of the wretched specimens from the West Indies now to be found in the London shops. In Madras we have the celebrated Salem and Bangalore Mangoes; in Bombay the "Alphonso," the "Paire" and the "Fernandina" are grown; whilst in Benares the "Singra," and in Pattegarh the "Takari," are of delicious flavour. In India mangoes are always plucked when still unripe, and allowed to mature in straw. This habit might easily be taken advantage of for export, and large quantities could be transported to Europe in specially prepared cool chambers. Since Australia can successfully send fresh fruits to England, there is no reason why Bombay, which is but half the distance, should not do the same; and the trade once started would certainly prove remunerative enough to cause a large extension of operations to America and Australia. There is, moreover, room for an extensive trade between Northern India and Bombay. A comparison of prices, shows that whilst in the latter place good mangoes at the commencement of the season sell at R16 per dozen and at the height of the season at R8 or 9 per 100, the choicest mangoes of the N.-W. Provinces may be bought at R1 per hundred. The rail journey occupies under 40 hours, and these facts only require to be known to create a trade. It is always difficult to initiate anything in India without Government support, but if Government would but see fit to move in the matter, say, by inaugurating a show to be held in Bombay, there is little doubt but that the idea would rapidly develop. Natives will not be backward in

taking up new methods of cultivation if such have been proved to them, by means of experiments carried out in Government gardens, to be profitable. At present their ways of cultivation are crude and barbarous. For instance, the leaves that fall in the autumn and winter from trees in orchards are universally swept away and used as fuel. Now in these leaves there are all the ingredients for the nourishment of the tree, whilst they also prevent the moisture from evaporating too rapidly from the ground. Their own fallen leaves go on nourishing the trees for centuries, and an experiment in Lucknow showed how an almost arid bit of ground was turned into all but a tropical garden almost entirely by the use of surface leafage and irrigation. The leaves were first brought from outside and afterwards the trees themselves provided this surface maure, which kept on increasing every year. Another point in which natives are very careless, is irrigation. They almost invariably give the ground too much of it; probably going on the principle that as they pay no more for a lot they may as well have it. Without proper drainage the soil gets waterlogged and the trees become miserable and perish in a few years.

What we have written regarding the prospects of increased cultivation of the mango applies with equal force to many other hardy and universally grown fruits, such as the plantain, the guava, the orange, the red and white grape and the loquat. These trees will grow on all soils; though for the orange a *kunkur* or gravelly one is preferable. A great benefit to orange growing is shade, and no tree is better suited for this purpose than the "bair." Grapes are best grown in localities where the rainfall is scanty, or where the monsoon is late, and the best variety is a thick skinned one which resists the bursting action of the rains. Guavas may be cultivated to a state of great perfection, and in Etawah a species is grown that is almost entirely free from seeds and of charming flavour. A fruit garden should be laid out somewhat as follows:—A high wall should surround it to keep out jackals and protect the trees from storms. Inside it a row of "Jack" trees should be planted and inside them a row of mulberry trees, and inside them again a row of guava trees. This triple row all round the fruit garden forms an admirable screen for breaking the force of hot winds and storms. If the ground be extensive it should again be divided into squares, and rows by avenues of fruit trees, such as mangoes and jichis, which are not injured by hot winds. The squares, thus protected, should be planted with plums, apples, lemons, pummeloes, plantains, oranges, etc. All kinds should not be jumbled into one plot, but a separate plot should be devoted to each kind so as to suit the canal irrigation to the wants of that particular kind of tree. There would then, too, be ample space amongst the trees for pine-apple plants, which prefer a certain amount of shade. On these lines a fruit garden should be a great success. Government might be induced to start a public garden on this plan, instead of maintaining the costly establishment it now does for horticultural gardens, mainly for the supply of vegetables and flowers for sale to European residents. —*Madras Times.*

PROLIFIC MANGO TREES.—An article on the cultivation of mangoes in Florida states:—The trees produce on the average from fifteen hundred to two thousand mangoes each, which sell in Southern markets from one to three dollars per hundred. —*Planters' Monthly.*

PERAK TEA.—We learn that a further consignment of Perak tea has come forward by S. S. "Achilles," which arrived in London on the 2nd inst. It consists of a very choice quality, which has been grown on account of the Perak Government. Mr. Koch, the Government inspector, will arrive here shortly and arrange as to its disposal. The inspector maintains that tea of the very finest description can be grown in Perak, as the soil is of such good and rich quality. —*L. and C. Express, Feb. 13th.*

THE STRAWBERRY GUAVA.

A. K. SMILEY, BEFORE THE REDLANDS
HORTICULTURAL SOCIETY.

The guava belongs to the genus *Psidium*, a name derived from the word *Psidon*, a pomegranate, and belongs to the order *Myrtaceæ* or Myrtle family. There are at least six different species of guava—most of them belonging to the tropical regions. The guava jelly of commerce is principally obtained from *Psidium Guaiava*—a low-growing tropical tree found in the West Indies, and also raised in the southern part of Florida. There are a number of varieties of it, such as the pear guava, with white yellow pulp, and the apple guava with red pulp. This guava has become a necessity to southern Florida, and is to that region what the peach is to more northern climes. The pear and apple guavas prove hardy in this climate, but the reports are somewhat conflicting. Parties at Pasadena, in Los Angeles county, and Ballena, in San Diego county, report it to be hardy.

There is another species of the guava well suited to our climate—a beautiful, thoroughly hardy, easily raised evergreen shrub, fine for lawn or garden, called the strawberry guava, or in scientific terms, *Psidium Cattlejana*. Some authorities say that B azil is its native clime. The fruit is globular, about one inch in diameter, borne in clusters of fine claret color, and flavored like a strawberry, hence its common name. The skin has much the consistence of that of the fig, but thinner. The interior is a soft fleshy pulp, purplish red next to the skin, paler towards the middle and white in the centre. It is juicy and in consistence is much like a Strawberry, to which it bears some resemblance in flavor. The foliage is of a rich dark-green color, thick and shining, resembling the Camelia. This shrub is one of most persistent fruit-producing plants in the whole list. One can frequently find on one plant, flower, half ripened and fully ripened fruit.

The Dictionary of Gardening says that the strawberry guava grows from ten to twenty feet in height. It bears fruit when very young. It can be treated as an ornamental shrub, or planted in rows from four to eight feet apart and raised as currauts are.—*California Fruit Grower*.

SEASON REPORTS ON GRAIN CROPS IN
CEYLON.

From the Abstract of Season Reports, February 1891, published in the *Gazette* of March 6th, we learn that in the Western Province the paddy crop was good or fair, except in the Hapitigam Korale, where it was poor, owing to want of water last September. The dry grain crop was also generally fairly good. In the Central Province, the Matale district was the worst off: for of the paddy crop the report was "poor, worst in Matale North," and of the dry grain crop "very poor." In Walapane too the dry grain crop was reported "poor." In Dumbara the paddy crop was also stated to be mostly a poor one. In the Northern Province the prospects of paddy and dry grain were on the whole good, except in Mannar, where half the paddy crop had failed; and in Vavuniya, where, except in two divisions which had rain, most of the crops must fail. In the Jaffna district tobacco was also extensively cultivated and was looking very promising, also benefited by rain. In the Southern Province the prospects were generally good, except in the Four Gravets and Talpe Pattu of Galle, and the Wellaboda Pattu of Matara, where the drought had affected the paddy; and the Giruwa Pattus, where all the crops were generally bad, owing to want of rain. In the Eastern Province the crops were good or fair. In the Batticaloa district, we are told, "Indian corn and chena products are plentiful and cheap except in Sinhalese villages on borders of Uva, where Indian corn was injured by the drought last

year, and fine grain crops destroyed by locusts in January. Coconut crops promise well." In the North-Western Province crops were mostly very light, being affected by the drought. In the Chilaw district the dry grain crops were good; and we read: "Tobacco crop prospects northern division good." In the North-Central Province the maha paddy crop was nil, owing to failure of north-east monsoon rain for the third time; but the dry grain crop was generally fair. We also read: "Village tanks dry except a few in north-east and two in the south. Tank chenas all lost. Drinking water very scarce; some villages have none. Some partial showers fell during the month, which saved about half the growing kurakkan crop, which was dying. Anxiety about deficient food supply relieved. Prospects of ya'a crop depend on rains in April, May. Heavy rains fell in Tamankaduwa, which will allow of meda crop being cultivated." In the Province of Uva the paddy crops were good; the dry grain crop fairly good; the Indian corn crops everywhere good; and the kurakkan crops just harvested fairly good. In the Province of Sabaragamuwa the crops were good or fair.

THE RAPID OR SLOW ACTION OF MANURES.

We commend to the attention of our planters the remarks recently made by Mr. John Hughes, the well-known Agricultural Chemist, to our London Correspondent, and reported by the latter in his letter by last mail, (see page 660) on the subject of deferred action in the case of certain fertilizing agents.

The special case which has produced these remarks is one on which at the time it was first brought under notice we offered some observations. It may be as well just briefly to recall to the memory of our readers some of the more prominent points connected with that case. Mr. Hughes—whose opinion upon such subjects all will acknowledge to be of the highest value—had, while travelling throughout Italy and Spain, remarked the extremely unpleasant odour pervading many of the olive gardens visited by him in those countries. His inquiry as to the cause of this led to his acquiring the information that the odour was due to the quantity of rotting rags that had been applied with the object of manuring the olive trees. Mr. Hughes saw these, partly buried and in all stages of putrefaction, in the gardens he visited, and his olfactory organs made him well realize the fact of the uncleanly habits of the peasants, whose cast-off garments were thus made to do a final and very useful duty. His knowledge of the constituents best adapted for fertilizing special forms of culture made him fully understand the value of this special application; but to that knowledge he added the important further knowledge that much of the value to be attached to the peculiar form of manuring must be due to the very gradual way in which the constituents were yielded up by the slowly decaying rags. It was this second property which induced Mr. Hughes to suggest the application of a manure having a kindred basis, on the widely celebrated Mariawatte estate. We have waited some time to learn what results have followed this application, and have only now done so. We hear that the manure was applied on a patch adjacent to another which had received a dressing of cattle manure, and that the observed result of a single year showed that the latter had had a far more striking effect upon the tea bushes than the former had had.

To those less acquainted with the science of manuring tea—for it is a science of the highest class—than is Mr. Hughes, this fact would have told against the "rotten rag" fertilizer, That

gentleman saw in it, however, a confirmation of his anticipations as to the peculiar value of this new stimulant. It proved to him that the new fertilizer was acting as had been expected by him, that is to say it was acting but slowly, but that while not stimulating to any sudden development, it was parting with its constituents after the manner which he believes to be best suited to the requirements and conditions of our climate. Mr. Hughes has drawn for us a contrast between the needs of home agricultural operations and those of a comparatively equable climate like that of Ceylon. In England, as he points out, the summer, the season for agricultural operations, is limited to a few months. The manures sought for by the British farmers must therefore be rapid in their action, they must yield their constituents to the soil as quickly as possible so that their effect may be achieved in the few brief months available. Here in Ceylon we are possessed of a climate which enables agricultural operations to proceed throughout the entire twelve months. "The more haste the less speed" is a well-known, trite, and often accurate saying, and in the case of manuring in Ceylon it would seem to be of special application. Undue forcing, as we well know, is injurious in many ways to the enduring strength both of animal and vegetable life. Slow development ensures a longer vitality in almost every instance to both forms of life. Mr. Hughes believes that the application of forcing manures to many forms of cultivation is distinctly detrimental, and this has been found to be the case on many of the sewage farms established throughout England with the object of disposal of town drainage. In cases of the kind where super-saturation has occurred, the plants grown, although large in quantity, have become coarse and incapable to a great extent of reproduction. Whether some such underlying principle as this may, as the result of the use of strongly forcing manure, have been in part accountable for a weakening of our coffee trees which have succumbed to leaf-disease we do not feel competent to decide. We know, however, that the point has been asserted by several among those who have endeavoured to account for our past troubles over this matter. Arguing by analogy, we can conceive it to be possible that the free application of highly forcing manures—and especially of those having a mineral basis—may in some degree have operated to weaken the coffee trees when at maturity, and the chance that this may have been so must make it much to be desired that the ultimate course of effect of the slower acting stimulant applied on the Mariawatte estate should be carefully watched and recorded. Animal excrement applied in England has a peculiar value because it parts so readily with its fertilizing constituents and enables the brief summer to be fully availed of. So with bones made soluble as superphosphate. No such characteristic is necessary or desirable in our own case, and we hope that important knowledge may yet be gained and useful conclusions arrived at from the Mariawatte experiment. It seems to be generally recognized that in the case of our new staple as in the case of coffee, we cannot do better than apply castor cake and ground bones in due proportion. If some fish manure is available so much the better. The bones contain some ammonia besides the phosphate of lime, and the castor cake contains all the potash wanted by a soil supplied by that ingredient from the decomposition of felspar and mica. The effect of such an application is expected to last for three years; at least that of the bones and cake, if the ammonia in the fish should be taken up more rapidly.

ARTIFICIAL DRYING OF "COCOA."

(From the "Trinidad Agricultural Record.")

Government House, St. Anne's, 8th Jan. 1891.

Sir,—You have doubtless heard of the "man in the street," and do not attach implicit reliance to his statement: I think the same may be said of the "Ceylon man." I may have been wrong in assuming that four-fifths of the cocoa exported from Ceylon was dried artificially. If so I freely admit it. What I wished to call attention to was the statement of the Director of the Royal Botanic Gardens in Ceylon that a hot-air apparatus "for drying beans in wet weather is regarded as an absolute necessity and is universally employed." Whereas we have not half a dozen in this island and the result is a loss to us of thousands of bags of good cocoa, and the manufacture of thousands of other bags of different stuff which go to reduce the prestige and average of Trinidad cocoa generally.

I now forward to you for publication further correspondence which I have received from Ceylon on this interesting subject and which I hope will be of use to cocoa planters.

The "Ceylon man" may have the benefit of the excessive rainfall stated by me.

The intention of my brochure was perfectly clear, and the general accuracy of my statements has been admitted at Kow and in Ceylon.—Yours, &c., WILLIAM ROBINSON.

Queen's House, Colombo, 28th November, 1890.

Sir,—In reply to Your Excellency's letter requesting further particulars with regard to the artificial drying of cocoa in Ceylon, I have the honour to annex a copy of a letter received from the Director of the Royal Botanic Gardens at Peradeniya furnishing information as regards the temperature to be maintained for the process.

2. I have also much pleasure in sending you a copy of a Report by the Director of Public Works on my request to him for a model of the Fan and a rough drawing of the arrangement of the stove and air passages,—I have, &c., A. E. HAVELOCK, Governor.

His Excellency the Governor of Trinidad and Tobago.

Royal Botanic Garden, Peradeniya, 13th Nov. 1890.

Sir,—In reply to your letter of 3rd November, I have the honour to inform you that I have made inquiry of several leading growers of cacao as to the point referred to by Sir W. Robinson, and now forward the result for His Excellency's information.

1. No definite temperature is maintained in the house during the process of drying. The object aimed at is to get the room as hot as possible with a good strong current of air passing through. This is practically limited by the comfort of the coolies employed in it. In the small drying house described in my former letter the thermometer is marked at 110° F., and the coolies are instructed not to allow it ever to fall lower. One or two men have to be always inside turning over the cacao, and occasionally moving the trays from the hotter to the cooler end of the house. This is very necessary when there is much wet cacao in the house, as the damp gets down forward by the current and is apt to sweat rather than dry the cacao at the end next the exit of the air. One planter tells me that he has known the temperature in his house as high as 170° F., but there is a general consensus of opinion that 120°-140° is the highest that is required.

2. The main point is to keep the fans going. In the small drying house described this is effected by hand-power; but it is of course much more efficiently done by steam or water-power. Jackson's tea-drier has been found a perfect cacao drier, and the American fruit-drier has also been used here with success.—I am, &c.,

HENRY TRIMEN, Director.

Hon. the Colonial Secretary, Colombo.

(Copy of Report referred to.)

Sir,—I annex copies of letters from Messrs. John Walker & Company, Messrs. W. H. Davies & Co. and Mr. H. J. Vollar of Palakkolly on the subject.

From these it would appear that no special fan or stove is in general use in Ceylon, any ordinary stove and an air propeller to cause a draft of hot air through the room being all that is necessary. * * *—ROBERT MACBRIDE, Director of Public Works.

The Hon. the Colonial Secretary, Colombo.

From John Walker & Co. to R. D. Ormsby, Esq.
19th Nov. 1890.

Sir,—We are sorry we have no fans or stoves in stock. What was used is a Clerihew stove with exhaust fan. We have not made any for some years.—DAVID PAGE, Manager.

From W. H. Davies & Co. to R. D. Ormsby, Esq.
Colombo, 19th Nov. 1890.

Dear Sir,—Referring to your letter of date, if an ordinary stove is erected at one end of a room and a propeller at the other to draw the warm air through the fans on which the cocoa is spread, you will find this all that is necessary. Propellers can be had from any size 12 deg. to 60 deg. diameter. * * *—Yours, &c., W. H. DAVIES & CO.

From Mr. H. J. Vollar to Robert Macbride, Esq.
Pallekelly, Kandy, 19th Nov. 1890.

Sir,—In reply to yours of 15th I would have no objections to any sketches being made of the fans used for drying cocoa. If it is only the fans, however, that are required, it would be unnecessary for you to send any one to sketch them, as Blackman's air propeller is found the most suitable, and one of them should, I think, be easily found in Colombo. * * *—H. J. VOLLAR.

NOTES ON PRODUCE AND FINANCE.

INDIAN AND CEYLON TEA IN RUSSIA.—We understand that the Russian merchants who, only a few months since, so strongly protested against the introduction of Indian and Ceylon tea into Russia are beginning to see the error of their ways, and that since the opening of the magazine for the sale of tea by the Ceylon representative, the prospects for the sale of Indian and Ceylon teas have decidedly improved.

A HIGHER STANDARD.—A correspondent of the *Grocer*, moved by reading an account of the high price realised at the recent sale of the parcel of fine tea, says:—"As an old grocer I cannot but think that the present feeling should prompt the trade at once to graduate their prices and aim at a higher standard of tea altogether; the time and occasion are most opportune, and should be utilised uniformly and universally. The grocer has now a chance of retrieving his long-lost dignity as a tea vendor. Grocers' associations and co-operative societies can do much to counteract the vile stuff as sold by reckless adventurers. Why should tea (the greatest socialising beverage) be made the target of unscrupulous traders?" *Echo* answers why? and the answer is because a large number of people in the tea trade, having no scruples in particular, and being utterly indifferent to all standards but that of the largest profit, sell whatever they can find a market for.

THE PRODUCE CLEARING HOUSE.—Although the facilities for speculative dealing in produce afforded by the Produce Clearing House are not likely to find favour with the steady-going Micing Lane stagers of the old school, the Clearing House is evidently a well-conducted establishment. In his speech at the fourth ordinary general meeting of the Company, the Chairman said that the members felt that their system was a necessity under the new condition of trade, and, time being on their side, their future might be considered as beyond all doubt. Their engagements during the past year had amounted to £36,500,000, and in fulfilling these engagements they had not made a single bad debt, nor had they had a single dispute with any of their customers to refer to arbitration.—*H. & C. Mail*, Feb. 20.

DR. VOELCKER'S full Report on his deputation to India will be published in England and sent out to the Government of India. He left however, an abstract of it with the Government before his departure, and this, together with the recommendations of the Agricultural Conference held at Simla in October last, are now before the Provincial Governments for their consideration.—*M. Mail*.

A WYNAAD PLANTER writes:—"We, the few North Wynaad planters, look forward with hope and say verily the bumper is bound to come next year, not of fever mixture but of coffee. We had a heavy shower last week, which has pushed out a fine show of spike. Coffee is R350 per candy of 660 lb. The pepper crop has been had, very had; but the price is going up."—*Madras Mail*, March 2.

CHINA TEA TO BE BLOTTED OUT OR REVIVED.—The *Foochow Daily Echo* is terribly exercised about the gloomy prospect before China tea and winds up an editorial on the subject as follows:—

If the stern fact of thousands of Chinese who are entirely dependent upon the trade for very existence, being out of employment, and if reports be true, verging upon the brink of starvation and the yearly and serious decrease in the tekin and Export duties levied upon Tea, are powerless to appeal to the hearts, or the pockets, of the Imperial Officials; it is beyond our power to hazard a remote guess as to what can be done, though any body of merchants might advance an army of feasible propositions. At present, the barriers between the introduction of improved methods of growth, cultivation, and manufacture, are impenetrable. No foreigner can acquire land for the culture of the plants under improved methods, nor is there any protection for the investment of capital or introduction of machinery, under European auspices. While even the more intelligent and progressive among Chinese merchants, are themselves afraid to lend their aid toward the desirable end;—standing as they do in dread of the populace, and possibly also of their own officials.

If however, it could be conceived possible, that protection should be accorded them, and machinery such as used in the manipulation of Indian leaf, was allowed to be set up in the various Tea districts,—and provided the same degree of care and attention was bestowed upon the leaf as upon Indian gardens,—or even the plants were allowed to be grown, and the leaf manufactured under experienced supervision, (not necessarily foreign by any means but upon the lines proved by experience to produce better results); then, it is our opinion, that Ceylon and India would find a very powerful and popular rival in the Teas, which we know from experience of long years ago, can be produced in the mountainous districts around us. We submit—that while it is desirable that encouragement, and protection, should be granted to Europeans desirous to acquire land in the interior, it would be a wise measure, on the part of the Chinese Government to first assure such protection to their own people. Also, as far as is consistent with justice, they should insist upon the Tea growers taking more care of their plants, by pruning and weeding, while every encouragement should be afforded to such as desire to adapt their methods of manufacture to the requirements of the age, and produce Teas more in accord with the public taste. Not on European markets alone but in Australia, America, and Canada, the taste for Indian and Ceylon Teas is rapidly increasing, and such once deeply rooted in the public mind, will be extremely difficult to eradicate. Any measures to be taken to revive the taste for, and improve the quality of, China Congou, should be set in motion at once, and before its traditional merits are a matter of history. It is held by some that the panacea for the evil lies in the entire removal, or at any rate modification of the export duties, but we consider that the first and most important question is rather the improvement of quality, to which end strenuous efforts should be made.

THE CEYLON SPINNING AND WEAVING COMPANY, LD.

It has been a subject of considerable surprise to us that in view of the very satisfactory Report given by the Directors at the recent shareholders' meeting, the credit of this Company should be rated so low as it is in our local shares market. The explanation given to us of R100 paid-up shares being quoted at R80 or less, is that the Chetty shareholders are sometimes very impatient of any delay in getting a return on their money. They are accustomed to turn over their capital very quickly in their rice and cotton goods' ventures and do not at all like to have any portion locked up for a long interval. If this be the fact, it is evident that Chetty capitalists are scarcely the society from whom support for Limited Companies can be sought; for there must, even with the most promising, if not successful, Company, always be a preliminary interval to allow of the needful testing and earnings before dividends can be declared. We have been anxious to get the opinion of an outside authority on the Report and balance-sheet of the Company, and have been successful in inducing a gentleman of experience in no way connected with the Company, to put his pen to paper. The following then is the opinion of an impartial and experienced observer of the Report and work done by the Company's mills as recorded at the recent meeting of shareholders:—

"I have no practical acquaintance with cotton mills in the East; and since my day everything at Home has undergone a complete change. Still as you ask me for my candid opinion of the prospects of the Colombo Mills just opened only, I have no hesitation in stating that it is an exceedingly favourable one. The Report and statement of accounts appear to me to be both straightforward and satisfactory; and I have no doubt that ere many years are passed the Company's operations will be on a far more extended scale than they are at present. The climate is everything to a spinning concern. It must be about twelve years ago I pointed out this great advantage of climate possessed by Colombo over India, and I was then urged to interview the late Messrs. De Soysa, Jusey de Silva and other wealthy and influential Sinhalese and endeavour to get a mill started on the lines of those at Madras. My idea then was to locate the mill near to Cotta, where a working population at very cheap rates could, I thought, be counted upon to a certainty. But the mill now erected has secured a better locality, for it has the advantages of both canal and rail, the former at its very doors and the latter nearly so. There have also been in the interval of twelve years extensive improvements in engines and boilers and spinning and weaving machinery generally. The Colombo mill has been able to avail itself of all these, and is therefore better off in this respect than the majority of Indian mills, the bulk of which, however, are nevertheless doing a profitable business, weighted though they are with heavy commissions, &c. The opening up of Colombo into a great port with steam communication constantly available to all parts of the world is also another great advantage, for the mill, in its operations, is not limited to simply a local demand, very often more than over-supplied, owing to keen competition by the production of Lancashire factories.

"The dyeing department ought to be a profitable one now-a-days, thanks to the splendid colors now shipped at cheap rates from Germany and the very simple manner in which they can be used, even after only a lesson or two, by natives without European supervision. In time, no doubt, a large

business will be done in cleansing and redyeing articles of apparel generally; collecting agencies on the Perth (Scotland) principle being distributed over the lines of island railways if not even established at some of the adjacent Indian ports. To emphasize what I say on this head, look up Indian Customs House return and give the figures for values of Dyestuffs imported from Europe during past five years—the increase is astounding I believe. In Bombay the trade has developed enormously—why not in Ceylon?"

In accordance with the request of our correspondent, we append the figures for comparative imports of dyes for nine months of each of the past three years, namely,—

Later on, our correspondent wrote as follows:—

"Cotton Factory.—I forgot when writing to you to include as a favourable feature the tendency of silver to fall to a low point again. The lower that exchange falls the better it will be for the factory for exchange on the cost of manufacturing in Lancashire and on the freight of the goods shipped to the East must, of course, be recovered from the purchasers here. The price of the raw cotton on the spot is scarcely a factor, for a low exchange causes prices to rise equally against those who buy cotton to export and those who buy cotton to manufacture locally."

SALES OF COCONUT ESTATES.

It is satisfactory to find a veteran like Mr. Charles Byrde* going in for fresh plantation property. He has just sold out of Elston in the Kelani Valley for £4,500 and invested part of his money in coconut properties close to Ambalangoda which—bought at R20,000—ought to pay well with a railway at their gate, to carry the produce to Colombo. We wish Mr. and Mrs. Byrde all success. A contemporary records the sale as follows:—

We learn that Sinragoda and Bellevue estates at Ambalangoda, belonging to the Eastern Produce and Estates Company Limited, have been purchased by Mr. Charles Byrde for R20,000 cash. The estates are 290 acres in extent, of which 199 acres are fully planted with coconuts, 33 acres with cinnamon, while 58 acres are paddy fields and waste land. The estate will be 1½ miles from the proposed railway station.

COFFEE, TEA, COCOA, &c.

COLOMBO COMMERCIAL COMPANY, LIMITED.

Report presented to the Sixteenth Ordinary General Meeting of the Company, on Monday, the 23rd day of Feb. 1891, at 12-30 o'clock p.m.

The Directors are now able to place the following

* His brother, Mr. F. W. Byrde, turns out to be the purchaser.—Ed. T. A.

annual accounts before shareholders, viz:—

Profit and loss account for the year ending 30th September 1890. Balance Sheet made to 30th September 1890.

It will be seen from these accounts that the result of the year's operations is a profit of... .. £3,281 11 9

A balance was brought forward from last year of 128 8 9

Making a total at the credit of Profit and Loss of £3,410 0 6

The Directors propose to apportion this sum as follows:—

To the payment in full of the Dividend on the 6 per cent. Preference Shares for the year ending 30th September, 1890 £1,089 0

To the payment of a Dividend of 3 per cent on the Ordinary Shares for the same period 2,100 0 0

To be carried forward to next account 221 0

£3,410 0 6

The General Trading business of the Company has shown an increase during the year, and with careful management the Directors look forward to its steady development. Owing to the rise in the price of Silver, the result from the working of the Company's Estates during the past year was not so satisfactory as anticipated. Silver having now fallen in value, and the market for Ceylon Tea being favorable, the current year's working of the Estates is expected to show a marked improvement. During the past year the area under tea on the Company's Estates has been somewhat increased, and it is the intention of the Board to gradually extend this cultivation as opportunity arises and labour admits. The Coffee Market is very good, and of the small area under coffee still left on the Company's Estates a few fields are producing fair crops but the future of this product in Ceylon is very uncertain, and the Directors do not, therefore, rely on the returns to be derived from it. Mr. John Brown, Chairman of the Board, left for Ceylon in November, and will inspect the properties in which the Company is interested.

A MOST CELEBRATED TEA MARK.

How are the mighty fallen, &c. What is described as a unique opportunity, and a magnificent chance for tea-dealers and grocers, is the sale of the mark T. B., in a diamond in white on a black ground. The handbill announcing the sale states that the Mark has been the leading importing Mark for over thirty years, and is the most celebrated tea Mark in the world, and, if properly advertised, it should at once take up the position of leading retail Mark. We might suggest that a firm which has been so eminent and regular in its sales of tea at the Rooms, now that there are no more chests or half-chests to be sold without reserve, might be true to their old policy, and put up the Mark for sale at the same place, "Fog or no Fog." It would be a novelty, at all events, and enterprising dealers might come and make their bids.—*L. and C. Express*, Feb. 20.

"CEYLON AND IRRIGATION."

is the heading of a further letter by Mr. Alfred Deakin (the probable future Premier of Victoria) in the *Melbourne Age* received by today's mail. This contribution is so full of local colouring and interest that we reproduce it in full. Mr. Deakin, it must be confessed, writes with more accuracy and insight than we could have expected from his short visit to the island. Of course, there are some slips in his letter, but none very glaring, unless it be the statement that the import duty on rice does not affect the scale of wages paid by the planters. That dear or taxed food has a corresponding effect on wages is acknowledged all the world over, nor is Ceylon an exception; for certainly the abolition of our Customs levy would lessen the cost of Indian rice to coolies and planters, and either the former would have to take less wages per day, or the latter would pocket the difference in the cheaper rice which they purchased and supplied to their coolies. Then again, Mr. Deakin heard nothing in Ceylon apparently of the grant-in-aid system through which the Ceylon planters pay in direct contribution half the cost of their district roads. Still more our Australian critic ignores the point of our general revenue being largely benefited through railway profits, these therefore constituting undoubtedly an indirect medium of taxation. Of course, the tea, coffee, cinchona and cacao plantations contribute the vast bulk of railway receipts through rice, machinery, manure and general goods carried up and produce down. If there were a general "land tax," which Mr. Deakin, like everybody else, would consider the proper and scientific mode of raising the larger proportion of the general revenue in Ceylon, undoubtedly railway rates would have to be adapted until no more than working expenses and interest with sinking fund contribution for debt, were provided. But as we personally pointed out to Mr. Deakin, could there be a better or fairer way of dealing with plantations than by a tax which is strictly proportioned to the quantity of crop gathered and despatched, the requirements in rice, &c. being nearly always in proportion to the outturn of produce. Considering the time of Mr. Deakin's visit, it is not unnatural that he should come to the conclusion that "Irrigation" was the one great subject of political and administrative discussion before the Government and public of Ceylon; but had he remained a little time longer, he would have seen how mistaken was this view, seeing that no reference whatever was made to it in the annual Reports of either the Planters' Association or Chamber of Commerce of the Colony. Mr. Deakin as a democratic, practical politician, is keen enough to see the futility of discussing such a one-sided unjustifiable proposal as the abolition of one rice-tax without the other, and he appears to favour a scheme which has for its basis the recommendations of the recent Select-Committee on the subject. To this we take no objection—indeed it is the policy we have all along urged as the best adapted to the case of Ceylon at present and for twenty years to come. Certainly,

it is the arrangement which is best calculated to save the native agricultural classes in the island from a change which they would have reason to regret far more than their experience of the present system of taxation so far as it affects them.

CEYLON AND IRRIGATION.

BY ALFRED DEAKIN.

Those by whom Ceylon has been considered a Crown colony of Oriental stagnation, where a despotic but indifferent Governor presides on the one hand over a handful of effete Europeans enervated by the climate, and upon the other hand over a great body of natives hostile to every form of change, both classes being entirely excluded from participation in the Government of the country in which they live, are cherishing an unpardonable delusion. The natives, it is true, have multiplied rather than advanced, the planters have had a keen eye to their own interest rather than to that of the colored races, and one or two of the Governors have spent their terms of office in mere routine; nevertheless, these have not been the most prominent circumstances in its recent history. The representatives of the Queen have for the most part striven hard to do their duty, and as a rule they have been supported by their white and appreciated by their brown subjects. The industrial vicissitudes which have here succeeded each other with rapidity have only developed among the planters a courage and an energy which reflect honor upon them. Through times of prosperity and times of depression the Government has pursued its way, and undauntedly coped with each crisis as it has occurred. From one motive or another the leading natives have joined to some extent in the forward movement, from which they have incidentally benefited. In spite, therefore, of a few palpable blunders and some intervals of paralysis, the island has been steadily progressive and has evolved by degree a progressive policy worthy of the examination of self-governing colonies.

The population of Ceylon has more than trebled under British rule, and its production has several times trebled. Its revenue from all sources, including railways and water supply, amounts to £1,500,000, two-thirds of which is received for services rendered, and only one-third of which is raised by taxation. Optimists claim that neither race of the inhabitants have suffered from this burden, and that if the Secretary of State for the Colonies assents to a proposal now before him for a further reduction of the grain excise neither race will know that it is taxed at all. There appears to be some ground for this contention. Certainly the indebtedness of the colony is insignificant, since it requires to pay interest upon only £2,300,000, while its railways, upon which £4,600,000 has been spent, pay interest, have repaid a considerable portion of their original cost, and would now sell for much more than the total of the colony's obligations. Financially, therefore, the position of Ceylon is strong and its future hopeful. As a rule its soils are less rich than those cultivated for the same products in India, but constant moisture and constant heat give its climate the effect of a forcing house and render production equable as well as large. The cost of irrigation and the rent of land to the Government are less than the average in the peninsula. In brief, while every prospect pleases as much as in the days of Bishop Heber the more humane conclusion has been arrived at that man is not viler here than elsewhere, and this has been coupled with the further conviction that his labor can be made very profitable to himself and to the empire.

At first sight it may appear remarkable that Ceylon should have required an irrigation policy at all, and still more that it should have come to occupy the most prominent place in its politics. The staple products such as those from the coconut, which with tea, coffee, cocoa and spices furnish the wealth and export of Ceylon, are none of them irrigated, and most of them are grown in regions which enjoy an ample rainfall,

The whole of the crops which the planter raises and Europe purchases are obtained in profusion without artificial watering, and the direct interest therefore which Englishmen or an English Government can have in irrigation is absolutely *nil*.

There is but one product that receives irrigation in Ceylon, and that is rice, a food which can be obtained from Bengal and Burmah, where the yield is much greater than in Ceylon, at a cheaper rate. It is produced and consumed by natives only, since the requirements of the small white population could be more than satisfied by a single shipment in a year. To buy in the cheapest market must always mean to buy imported rice. According to all principles of political economy acknowledged in Great Britain, and also according to the selfish interests of the ruling class, which are certainly as lively in Ceylon as in other parts of the globe, any sanction of the growing of rice in the island should be forbidden, while the expenditure of public money upon works for its encouragement should be stigmatised as utterly indefensible.

The British Government of this tropic colony, however, appears to have set itself the task in this one connection of traversing every accepted university doctrine. It has fostered the growing of rice both by legislative and executive action; has spent public money liberally to encourage and extend the cultivation; and has crowned its edifice of economical heresy by the imposition of an import duty with a protective incidence upon imported rice. That nothing might be wanting which could add to the enormity of its offences and constitute its action the unpardonable fiscal sin it has placed this protective duty and a smaller excise to hoot upon what is and always has been the chief food of its people. To seek to benefit them by taxing the one grain upon which they live, and to procure which they require to devote almost the whole of their labour and their small earnings, is surely a phenomenon that calls for comment from all sorts and conditions of critics. Yet, in the island the principles of this policy are cordially approved, because they are held to be justified by its circumstances and also by results. The policy has not been accepted in silence, though the challenge which it has provoked relates only to the extent of its application. The challenge fortunately puts us in possession of the reasons why the island has dared to strike out for itself a practice suited to its own conditions and people, notwithstanding its conflict with the mathematical axioms of economics, which take account of none of these things.

The first justification offered is truly Oriental. Rice always has been taxed, and to replace the existing imposts by any other, no matter how equitable, would be to create endless discord and disaffection. Hamlet's principle of proffering the ills he had to possibilities of which he was uncertain lies at the very root of the conduct of public and private affairs in Asia, but does not affect the merits of the case.

The second justification for the Government's interference is that though a large part of the revenue derived from taxation is obtained from rice, the grower at all events gets his contribution returned to him. There is an excise on rice grown on the island, which yields nearly £100,000 a year. The argument is that as the natives grow and eat the rice which is so profitable to the State, they are entitled to receive back again a proportion of this profit in the shape of grants. Accordingly, under the law, one-fourth of the receipts from excise is set apart each year for what may be termed the ordinary outlay upon irrigation schemes. In addition to this, about another fourth is voted annually for special works, so that one half the excise is held to be repaid in this way. The proposal now before Lord Knutsford provides for a further commutation of the excise which, if approved, will reduce the net receipts of the State by yet a third fourth of the present receipts, while it is argued that the last fourth, which would be retained permanently, is only fair payment to the Crown for general purposes and all the indirect expenditure incurred in connection with the management of the irrigating works. The

weak point in this calculation is that while all rice growers are taxed, only those who receive the benefit of this Government expenditure have had any return, and these are but a small proportion of the whole body, most of whom receive their water supply from schemes constructed long before the advent of Europeans. In the past no balance of this kind has been kept. From 1884 to 1887 the grain tax yielded £409,000 while the total expenditure upon irrigation works and their maintenance was £168,000.

In reply to such a calculation it is impossible of course, to say that a large portion of the grain receipts are rent for land held from the State directly, and not a tax; but this at best is an imperfect adjustment, and merely relates to that proportion of the excise raised in excess of the sum levied upon private proprietors of land. It would be necessary to prove that it was equivalent to other Government rents in order to give this view much weight. Another contention is, that the natives get the benefit of the import duty, which is to the excise as 10 per cent is to 7½ per cent, and that, therefore, they are 2½ per cent the gainers. The free trader would probably urge that this is unjust to the consumers, who are chiefly natives. While a protectionist would reckon the margin too small to be of any permanent value and urge the abolition of the excise altogether.

The fact cannot be disguised that out of less than £500,000 of taxation rice alone pays nearly £300,000, an excise of £100,000 and an import duty of £200,000. As burdens should be distributed in proportion to wealth this is too large a share. The planters contend that as they are the employers of native labour they pay their share of the rice tax in increased wages, but it is doubtful if these are appreciably affected by either the rise or fall of rice. The 6½ per cent on general imports and a small export duty to cover the expenses of medical supervision of their laborers are all their contributions to the State, in all little more than £150,000 a year, which is not an excessive amount certainly on a capital of nearly £8,000,000. Figures such as these assuredly strengthen the case for a generous outlay upon water supply for the use of the natives.

Further justification—and perhaps it would not be too much to say the real justification—is to be found in the fact that, although the island is exceptionally rich in the coconut, bread and other fruits, as well as in vegetables and yams, which the Sinhalese use, yet rice is their chief food. It produces, at all events, in many parts of the country, the best result for the least labor. Its cultivation has been pursued from immemorial antiquity, and is better understood than any other. The British Ruler has been compelled to adapt his views to the character of his native subjects. Rice growing is an honorable pursuit among the Sinhalese, and they would probably refuse to attempt the raising of any substitute. When they obtain little rice they suffer from pragra, a malarious fever analogous to that known in Italy; when they get none they sometimes die of starvation, and thus to preserve health and life to them rice culture is rendered a necessity. When, in addition, it is remembered that the Government derives so large a revenue from this source there need be no surprise if the industry is fostered to the utmost possible extent, and that the whole weight of the Administration is cast in its favour.

Irrigation has been the chief article in the programmes of successive Governors, and their provincial officers have pushed it enthusiastically. There are six honorary titles in the gift of the Crown which are much prized among native notabilities, and by their means it is said that irrigation enterprise is rewarded and schemes are encouraged. The planters are inclined to complain that the paternal solicitude of the State is devoted too much to this one branch of industry, but taking all things into consideration it is hard to see how it could be otherwise. Other products might be encouraged, it is true, but rice is likely to remain first in the needs and tastes of the people.

The natural difficulties in the way of the cultivation of rice are naturally made much of by the

opponents of irrigation, and even its advocates are unable to ignore their seriousness. It is a thirsty crop, and the provision of a sufficient supply of water by means of storage is therefore most expensive in proportion to the area affected. Then again the rich deltaic soils of the Ganges and the Brahmaputra, with their annual floods richly laden with silt, secure crops which are 50 fold to 80 fold of theseed sown. There is much argument as to what may be considered a fair return in Ceylon, and as rice is grown almost everywhere, there are, as is natural, very different returns. In some districts it is insisted that the harvest gives only 4 or 5 fold, while the average claimed is not more than 15 to 18 fold. It is confessed, therefore, that the island is heavily handicapped in this regard, and cannot compete with the mainland. In 1888-89 India exported nearly 7,000,000 cwt., while Ceylon imported 3,330,000 cwt. Sometimes it has been questioned whether rice growing does not involve an absolute loss to the Sinhalese farmer, and very careful estimates of his working expenses and profits have been made. The result appears to show that in certain districts which are well irrigated, such as Matara and Batticaloa, it pays well, but that in others it yields only a bare profit. The doubt has arisen whether the limit of its payable production has not been reached, and certainly, the fact that some 6,000,000 bushels annually have been bought from India during the past few years would seem to lead to such a conclusion. On the other hand, Mr. Elliott, the Government Agent at Batticaloa has conducted some careful experiments in rice growing by means of hired labor in two districts with which he is intimately acquainted, and gives a balance sheet which shows a profit of 40 per cent. in the one instance, and 70 per cent. in the other. If such profits are open to the average cultivator, as many believe, there is still a fine future before the Sinhalese and Tamils of the low country, and the Government policy is abundantly justified.

The Hon. Mr. Grinlinton, M. L. C., has propounded a scheme which would do much to remove the admitted irregularities in the incidence of the grain tax by adjusting it exactly to local conditions. He proposes that all rice fields yielding less than 4 fold should be exempt from the tax; that those yielding from 5 to 7 fold should pay 5 per cent. on their grain returns; from 7 to 10 fold, $7\frac{1}{2}$ per cent.; and above 10 fold, 10 per cent. If coupled with a liberal irrigation policy such an plan appears to possess much to recommend it. All three can be asked is justice. The alternative would be to omit the taxation and stop expenditure upon irrigation altogether. So far no one has ventured to make such a proposition. Were the import duty allowed to remain, it would then become distinctly protective in its incidence.

There is one tax which already falls upon both races alike, though it ignores all differences in wealth and power of wage earning. It is a capitation tax payable either in labor or cash, giving the option to each citizen of manual work upon some public work for a fixed period in each year, or of paying what is considered the native equivalent, 3s. a week in town or 4s. in the country. The Europeans and well-to-do natives pay this trifling sum, while the less fortunate bulk of the colored people prefer to work. Of course the sacrifice they make in this way is relatively vastly greater than that demanded of the whites, and this may be urged as a further point in their favor.

The magnitude of the rice interest, and therefore of irrigation, must continue to force its circumstances upon public attention. The Government returns give 574,000 acres as now under this crop, while those of the Messrs. Fergusons are 700,000, and their anticipation is that the total will soon reach 1,000,000 acres. The State already exempts from taxation for four years land that is being brought under the plough for the first time; by its system of commutation does much to reduce its demands, upon the cultivators, and by allowing them to make their contribution to irrigation schemes in labor, instead in coin has fostered a feeling of community of interest between them and the Administration. Apparently therefore, there is not a great deal to be done and this may be done without

much difficulty, to convince the Sinhalese and their fellow natives of the absolute equity of the Government under which they live, and of the sincere desire of the whites for their prosperity and progress. To that desire is due the, at first sight, surprising fact that Ceylon is an irrigating country. The public welfare has been held to be the supreme law and that welfare has demanded the adoption of a bold irrigation policy.—Melbourne Age.

MINING AND GEMMING.

A new departure has been taken by the London Syndicate to which Mr. Barrington Brown reported, in sending out a practical mining agent, Mr. Bettison, of much and varied experience. His attention so far is confined to plumbago and he has been visiting some of the native mines, with reference to their working and the application of machinery. But we confess we rather regret to see this Syndicate going to work after what is a "one-horse" style. We had hoped to see Mr. Barrington Brown himself back at the head of an adequate staff and requisite machinery to give both our gemming and mining an adequate trial sufficient to satisfy everybody with good success or the reverse.

OUR BOTANICAL AND ECONOMIC GARDENS.

The publication of the annual Report of Dr. Trimen and his capable Assistants constitutes an interesting event of the week. We issue all the material portion as a *Supplement* and elsewhere review the same. We should like to see more power given to Dr. Trimen to be able to follow up his distribution of seed—of cacao, for instance—with enquiry and inspection to see what was done with it. We require in Ceylon indeed, a far closer relationship and united form of working in respect of the several departments bearing on the promotion of native and State Agriculture:—Revenue-provincial, Forestry, Educational-Agricultural and our Botanic-Economic Gardens in which most of the science is centred. There can be no doubt that if a properly representative "Agricultural Board" existed—such as we have advocated for many years back—a great deal of frittering away of public money and loss of time would be saved, mistakes would not so often occur, and much more good would be done in benefiting the native agricultural community and in developing the resources of the country.

BARK AND DRUG REPORT.

(From the *Chemist and Druggist*.)

London, Feb. 19th.

ANNATTO.—The large quantity of 118 bags bright seed from Ceylon was shown today. The price asked for this article is 2½d per lb., but there were no buyers.

ARCANUTS.—A parcel of 20 bags was shown today, for which the price of 30s per cwt would be accepted.

CINCHONA.—Another heavy arrival of 177 bales South American Guayaquil bark was for the greater part disposed of today at a fresh reduction in price of at least 2d per lb on an average. Good bright quill sold at 1s; partly stout ditto, bright mossy but broken 8½d to 9d; very stout flat split quill 9d; broken and rusty brown at from 6d down to 3½d per lb; 42 bales Maracaibo bark of good appearance were bought in at 9d per lb. Several parcels of flat Calisaya were also bought in, and only 9 serons damaged sold without reserve at 7½d to 8½d per lb. For a new parcel of 116 bales from Kosairo, bright flat orange 1s 5d per lb is asked, an offer of 1s 4d being refused. Some very ordinary red bark, in thin broken quill of every little colour, realised 1s 1d per lb.

COCOA LEAVES.—Some cases Ceylon leaves were shown today. These leaves were of mixed size, Huanoco character, dark in colour, but strong. Most of the leaves were damaged, and an offer of 2d per lb was the best which was made. It was refused. The New York market on February 1st was almost bare, only a few parcels of light-green leaves remaining on hand.

ESSENTIAL OIL.—Of Citronella oil, 50 cases in tins sold today at 3d per oz.; while for oil in bottles 3d is asked by some holders.

COFFEE CONSUMPTION IN THE UNITED STATES IN 1890.

This fell off in 1890, being the slightest since 1887. The figures showing the movement at all ports, exclusive of the Pacific coast, indicate a total consumption of 209,457 tons, against 216,085 tons in 1889; 216,833 tons in 1888; average for three years, 214,125 tons. Prices were higher and this probably accounts for the shrinkage.

The yearly average cost of Fair Rio was 19.64 cents, against 18.55 cents in 1889; 15.35 cents in 1888; 17.80 cents in 1887; 10.32 cents in 1886; 9.01 cents in 1885. It has been a year of reduced supply and high prices. At times a great disparity existed between grades, and prices ruled above the parity of exchange quotations.

The following table exhibits the stocks and distribution of coffee in 1890 as compared with 1889:—

	1890.	1889.
	Tons.	Tons.
Stocks Jan. 1...	23,098	16,213
Imports in 1890.	201,273	222,970
Total supply 1890.	224,371	239,183
Less stock December 31...	14,914	23,098
Distribution in twelve months	209,457	216,085
Less exports in twelve months
Consumption in twelve months	209,457	216,085
monthly average	17,455	18,007

The "December consumption was only 14,078 tons, being lighter than for any other month during the year. The maximum consumption was in April, when it reached 19,521 tons.

Of the total imports of 201,273 tons, there were 173,111 tons received at New York; 773 tons at Boston; 11,179 tons at Baltimore; 16,210 tons at New Orleans. The imports of Brazil coffee reached 152,250 tons, being 75.6 per cent. of the total imports.

Upon receipt of the figures showing the European consumption, we will present the position of the article in greater detail.—*American Grocer.*

CANNING COCONUTS.

A new industry is springing up in Brazil consequent upon the discovery of an ingenious Portuguese. He has struck the novel idea of canning coconuts in spiced syrups, and these are said to be particularly well received in Portugal, to which country consignments have already been made.—*Australasian.*

TEA ADVERTISING.

"What you think of the latest advertisement? Do you know where this *Dalu-kola* Tea Company have their offices?" This from a London merchant to us, refers to a fly leaf circular which beautifully displayed in coloured ink, runs:—

"Childwick Hall, Beekenhall Road, Penge. On Monday evening, February 23rd, 1891, commencing at eight o'clock, O. S. Hicks, Esq. (of the *Dalu-kola* Tea Company), will give his celebrated Lecture, delivered at the People's Palace, and throughout the Provinces, on the beautiful Isle of Ceylon, magnificently illustrated by dissolving views, especially painted for the Lecture at considerable cost, and varied by Songs and Music. Ours will be taken by Bryce Grant, Esq. The Proceeds (after paying expenses) will be handed over to the Funds of the Penge and Auerley Philanthropic Society. Cups of pure Ceylon

Tea given away free by natives in their picturesque costumes. Admission by Ticket 2s, 1s, and 6d; children half-price if accompanying adults."

Whoever Mr. Hicks may be, Ceylon surely is indebted to him for advertising her teas?

THE RUBBER OUTLOOK IN BRAZIL.

Regarding the new companies forming in Brazil to control the rubber trade of the Amazon, Mr. Francis Grauert, who is popularly supposed to be connected with such an enterprise, said one day last week:

"At present there are two of these companies in Brazil, and both working in Amazon River centres now. One of them has a capital of five millions and the other twenty, both more than half paid up. There seems to be plenty of money in Brazil with which to organise such companies, as there have been very prosperous times in that country. Coffee has gone up from 7 cents to 15, which has drawn a great deal of money there. These two companies are however, now in competition and in order to obtain rubber sometimes pay more for it than is necessary. "Baron" Vinna is connected with the smaller of the two. With the capital that these companies have, they are in a position to freely advance money to the gatherers from the time they leave any of the large rubber centres on the Amazon into forests, provide for the heavy transportation charges, and carry the crop without any special anxiety until it is marketed.

"Regarding this year's crop, the Rio papers some time ago stated that the season had been a healthy one and rubber was being freely gathered. This state of affairs seems to have changed for we gather from our last mail advices, that rains began to fall in December, earlier than usual, and that sickness was prevailing among the gatherer on the islands, in consequence of which the collectors had begun to retire. In the wet season malaria is prevalent, which produces chills and fever in a somewhat aggravated form. Our mail advices are confirmed by a cable of the 8th, which states that the weather is bad, receipts were falling off and that the second half of the crop would be short. We do not believe that present prices are high."

—*India-Rubber World.*

BRITISH NORTH BORNEO NOTES—

GENERAL.

February 1st.

At a Meeting of the Lawn Tennis Club, held at the Court House on the 13th January, Mr. Henry King Sturdee the Hon. Secretary on behalf of the Bachelors presented their Handicap prize to Mrs. A. Cook the winner. In handing the cup over, Mr. Sturdee made an appropriate speech, which Mrs. Cook acknowledged thanking the Bachelors, expressing a hope she would long keep it, as a remembrance of the Sandakan Tennis Club and the Sandakan Bachelors. Mr. Cook then invited the gentlemen and ladies present to refreshments provided for the occasion and the Meeting dispersed.

Very heavy rain set in on Thursday January 15th, and with the exception of part of Friday 16th, held continuously up to January 25th. One landslide took place on the road under the new Roman Catholic Convent. Thanks to Mr. Dunnage the main roads where he has lately repaired them have stood the heavy deluge uncommonly well, and thanks to his thorough drainage the water soon runs off, so much so that a few hours sun suffices to put them in hard condition again.

By the steamer "Memnon" which arrived from Hongkong on the 9th January, Mr. J. Robertson returned from leave, looking all the better for his sojourn in a colder climate. Mrs. Robertson accompanied him. Mr. E. F. Skerchley also returned from leave by the same opportunity.

Heavy rains have we hear fallen in the Darvel Bay District. The Tabanac river was in flood for some days, but no damage has been done to the tobacco Estates.—*British North Borneo Herald.*

PAPER VS. LEAD LINING FOR TEA CHESTS.

We call attention to two more letters of interest in this connection further on: first from Mr. T. C. Anderson about "Clark's Patent" paper-lead-tea lining which has the reputation of being a very superior but rather expensive article, and next from Mr. Maitland Kirwan about his paper lining. In this latter we get a very important correction on the previous information which reached us from London as well as locally respecting this paper lining. In place of costing more than lead lining as was last related by our London correspondent, the price is really only about *half that of lead lining*. This makes so great a difference to tea planters that we feel sure trials of the new paper lining will be freely made and the matter fully inquired into. The pity is that a Sub-Committee of the Planters' Association is not at once prepared to take up the enquiry and needful testing. Meantime, Mr. Anderson supplies conclusive evidence as to the superior quality of "Clark's Patent" paper-lead, and if Insurance offices charged less for tea so packed, an equality in cost with ordinary tea lead might be established?

YAMS, GRAPES, MANGOES: PRODUCTS OF NORTH CEYLON.

Mr. S. K. Lawton, the very intelligent Tamil gentleman who acts as agent for the Ceylon Steamship Co., Ltd., at Jaffna, writes to us:—"I send per the S. S. 'Lady Gordon' leaving Jaffna this day a few samples of the food products of the North for your acceptance and trial. Whether it is attributable to its dry climate or the system of careful tillage and well irrigation the food products of Jaffna have peculiar excellence. The 'King' yam has been tried elsewhere, but the yield has been too rapid and watery to be fit for the table, while the grapes and mangoes of Jaffna have been rarely excelled. I find very little of these products are being sent to other parts of the island perhaps owing to their not being sufficiently known. With regular visits of the S. S. 'Lady Gordon' to the different ports it would pay an enterprising Jaffna man to start a supply agency for these articles. Should a regular trade be thus stimulated the hardworking Jaffna cultivator would be able to obtain a better return for his labour than he does at present by supplying a limited local demand."

It is certainly very strange that there is not a regular trade by steamer. We heard the other day that grapes are still carried in the season by the land-route via Puttalam and Chilaw; but surely not from Jaffna? Our informant, a Chilaw planter, has told us that he notices the pingo men regularly passing and they sell at 50 cents a lb. the grapes which are 75 cents to a rupee by the time they reach Colombo. Then as regards the monster king yams and fine Jaffna mangoes—earlier in season than in Colombo,—the specimens Mr. Lawton has sent us are sufficient to show how much the Colombo markets and the Jaffna cultivator might both benefit by a trade in Northern products. Surely the hint now given will not be lost.

MINING AND GEMMING IN CEYLON.

We have already expressed our regret that the London Syndicate should follow up their most excellent first movement which brought so high an authority as Mr. Barrington Brown to our shores, with a one-sided insufficient system of working. Far better, we should think, to delay all operations until they were in a position to send out the expert again with the staff and machinery he might deem necessary

to give due effect to his anticipations, or at any rate to develop and test on the lines of his own Report. We trust, therefore, that the members of the London Syndicate may make up their minds that it is no use expecting a satisfactory trial of our gemming and mining country by going to work after an imperfect dilettante fashion. Nothing should satisfy those concerned, but the despatch of Mr. Barrington Brown, to deal carefully and systematically with the most promising of the selected lots of land, leased or purchased on behalf of the Syndicate by his advice during his stay in Ceylon. Before securing the land in many cases, tests satisfactory to the expert were applied and it is interesting to know that some portions have been leased from the famous "Gem Notary" of Ratnapura, who is credited with having amassed altogether as much as twenty lakhs of rupees, while not less than R800,000 is the amount this prince among "gemmers" states he made out of one famous alluvial mine near the town of Ratnapura! In accompanying the expert on one of his testing expeditions, a relative of the notary showed him a spot under some huge gneiss rocks from which he had washed out R20,000 worth of sapphires. If credence is to be attached to such figures,—and Mr. Barrington Brown apparently saw no reason to doubt them,—it is very evident that there is more than a *prima facie* case available for European capitalists to induce them to deal with this Ceylon Gemming Industry.

It was only natural that the expert should at every turn see openings for the application of machinery; for instance in the case of suitable portions of river beds, a steam dredger that could take up the bottom to the depth of 10 feet, could not fail to deal with a large quantity of material, with every chance of success. Then on the higher gem diggings on hillsides and along mountain streams in Rakwana, the application of hydraulic principles and contrivances after the most improved European fashion must have, again and again, struck the expert. On Butiyatenne and Golden Grove—already secured—the Syndicate would have full opportunity for developing hillside pits. The information available as to "finds" in this neighbourhood was also very encouraging:—cats eyes realizing from R1,000 to R5,000 each have been not unfrequently picked out of the washings, while, as we recently recorded, larger stones of very much greater value are occasionally found. One way of testing the returns obtained by parties of gem-diggers (all Sinhalese) in the Rakwana district, is found in the periodic sales which are held. Three pits at one of these sales gave results equal to R5,100 for seven weeks' work, and later on, one of these pits, in a similar period yielded stones which sold for over R6,000. A good sapphire, it seems, is worth £6 a carat in Ceylon.

It was surely then no wonder that Mr. Barrington Brown, after spending some months in our Gemming country, closely watching the operations of native diggers and gemmers, testing for himself and collecting all available information, came to the conclusion that quantities of valuable sapphires and true cats eyes had been dug up in the gem districts of Ceylon for many years. But of far greater importance is it to know that he is of opinion that after all only a *small, if not insignificant proportion of the deposits have been worked out*. The expert, in fact, is of opinion that there are extensive gem-bearing deposits in certain of our districts and that gems of great value are undoubtedly to be found in such deposits. From the Report furnished to them, the London Syndicate must be well able to judge how far the expert thinks that the lands already secured

by them, share in the valuable deposits to which he refers. For our own part, we consider there ought to be abundant encouragement to induce capitalists to send out Mr. Barrington Brown himself with adequate staff and machinery in order to direct the needful development of a gemming industry on the lands already purchased or leased.

COCONUTS AND CINNAMON.

Kadirana, March 12th.

After three weeks of dry weather there was a good shower on the 7th and a few drizzles each evening since, aggregating 0.95 of an inch. This will help the peeling a little which is just now not good, owing perhaps to a bud now appearing. Cinnamon crops in this district will be much below the estimates on all estates. Coconut pickings are good and will probably continue so till the end of June, but from then to the end of the year they will be very small. Prices are good (R35 to R37.25 per 1,000 on the spot) and should continue so should the price of oil not fall much. Fever is prevalent in the villages.

March 13th.

Fine rain last night; measured this morning 0.69 in.

INCREASING THE SUPPLY OF FISH FOR FOOD.

The ever-increasing work of the fish commissions, state and national, gives ever-increasing cause for public gratitude. This would no doubt be more generally forthcoming were it not for the prevalence of the erroneous notion that the pleasure of sportsmen is the chief object in view. On the contrary, though the angler has his grounds for satisfaction, he is but a secondary consideration in this matter. The main purpose of fish culture is to increase the supply from this economical source of nutriment. As Professor Atwater puts it, "Fish gather materials that would otherwise be inaccessible and lost and store them in the very forms that are most deficient in the produce of the soil." The chief nutrient of fish is protein, in which most vegetables, such as wheat, rye, maize, rice, potatoes, etc., are deficient. It is needless, however, to dilate on the physiological advantages of a protein supply when everybody knows the utility and economy of fish as an article of diet.

Just as trout streams through all the settled parts of the country have been fished out, so the great lakes and the adjacent parts of the ocean have been fished out. The aim of the fish commissions is to renew the supply.

This suggests the most profitable feature of fish culture—the fact that fish is the only crop that doesn't have to be cultivated. To plant and to harvest is all the work. The farms of fresh-water fish, that is to say, the rivers and streams, may be spoiled for them by the offscourings of manufacturing, but that can never happen in the great lakes and the ocean. There is still room and food for as many of them as there were when John Smith could hardly get his ship along for the cod that belabored its sides. But within the memory of living men the supply of food fish has diminished so much as to become a reason for serious alarm.

The work of the state commissions (and most of the states now have them) has been mainly directed to the stocking of rivers and ponds, to the erection of fishways around falls and dams, and to the procuring of legislation forbidding the taking of fish during the spawning season. The

work in New York, which is at least not the most backward in this respect, will serve to illustrate what is going on through all the country. In the year ending September 30, 1890, the New York commission distributed fry and eggs as follows: Brook trout, 2,699,500; lake trout, 7,476,000; brown trout, 1,246,500; frost fish, 3,320,000; sea salmon, 50,000; land-locked salmon, 18,000; white fish, 3,998,000; ciscoes, 2,400,000; smelts, 200,000; maskinonge, 75,000; California trout, 155,000; pike, 4,000,000; shad, 12,238,688; grand total, 39,844,688. As one instance of hundreds that might be cited from various parts of the country showing results already accomplished, it may be mentioned that last summer, when the fishway was put in at the Mechantville dam on the Hudson, in the shoal water created by opening the gates more than 100 salmon were counted, from one to three feet long, and probably weighing from five to thirty pounds. The largest salmon caught there by angling last season weighed twenty-two pounds, and measured thirty and one-half inches. These fish came from fry put into the Hudson seven years ago from the United States hatchery at Gold Spring, L. I.

The United States commission finds its more important field in the great lakes and the ocean. At Put-in-Bay, Ohio, for example, the hatchery recently completed has a capacity of 350,000,000 white-fish eggs, and it is intended to run it to its full capacity. All the eggs are procured from the pound nets in Lake Erie, and taken from the fish that are on their way to market, and would be wasted were it not for the commission. At Wood's Holl, Mass., the most important station of the commission, the work that bids fair to be most profitable is the propagation of codfish, and the officials have strong hope of making cod again as plenty in New England waters as they were three centuries ago. This hope is based on the fact that in artificial propagation there is practically no loss, while the loss under nature's care, or rather, lack of care, is tremendous. In the natural process only a small part of the eggs become fertilized, and so many of the infant cod get devoured that probably only 1,000 or 2,000 out of 1,000,000 survive. The female cod averages 1,000,000 eggs, of which probably 950,000 can be saved in the hatchery. If the commission can furnish to the water as many fish from one cod as nature can from 10,000 or 100,000, it will not take many years to make a big impression on the cod supply. It is the same with the lobster, and with other products of the fisheries. Indeed, there is ground for expectation that ultimately fish may become our greatest and cheapest source of food.—Bradstreet's.

QUININE AT ITS LOWEST?—Where is the fall in price of Cinchona Bark and Quinine to stop? From the monthly report of Messrs. O. M. & C. Woodhouse, dated February 19th, by this mail we learn that

Very few transactions were reported in Quinine, which was quoted nominally at about 1s per oz. for German during the first 10 days of this month, however, some forced sales drove the price down to 10d per oz. (the lowest price on record); this decline attracted buyers, and a large business was done, chiefly at 10½d to 11d; latterly, again the tone has become quiet, and there are sellers at 11d. As will be seen below, the shipments of Bark from Java during December were very heavy, being estimated at about 1,250,000 lb. Quinine at 10d and 11d per ounce! and yet we venture to say, the great majority of retail buyers, in the country districts of the United Kingdom at least, continue to pay 1d per grain or at the rate of 40s per ounce!

WATTLES: TIMBER AND FUEL TREES AND INDISCRIMINATE PLANTING.

(From the Hills.)

THE WEARY BEWILDERING WATTLES.

If, as Professor Maiden of the Sydney Technological Museum indicates, the fine, thin-leaved and small-blossomed specimen he has so courteously sent of the Sydney *Black Wattle* correctly represents the normal *Acacia decurrens*, then, I quite agree with Dr. Trimen that it has not yet been grown in Ceylon. I have grown and seen many of the Australian "wattles," but anything with such minute leaflets as Dr. Maiden's specimen of what he regards as the true *A. decurrens* has never come under my notice. On the other hand we have on Abbotsford some magnificent trees, the foliage and blossoms of which exactly agree with Dr. Maiden's specimen of the "Green Wattle," *A. decurrens*, var. *mollissima*, the prince of all the wattles for yield of tannin. Our Abbotsford trees also agree with Mr. Kellow's and the fine specimen at Hakgala. But I hope to do what Mr. Kellow suggests, take the Australian specimens and some of our own to compare with his. To a non-botanical eye the *mollissima* variety of *A. decurrens* would seem to be the type, luxuriant in leaf and blossom as it is robust of stem. Although it is not tannin but timber and firewood that we want here in Ceylon, we cannot help feeling that Baron von Mueller's *mollissima* is the variety of *decurrens* which we should grow at altitudes about 4,500 feet, for I have heard that at lower altitudes the Australian wattle shave not been a success in Ceylon. What will the Baron say to the variety about whose merits he has written in such enthusiastic terms being botanically abolished? It is beyond measure puzzling to find the Victorian botanist, whose fame is world-wide, after giving a general description of *A. decurrens*, Willdenow, the tan wattle, as a small or middle-sized tree, which, besides timber, "supplies excellent firewood," adding, "the typical *A. decurrens*

WITH LARGER LEAFLETS,

occurs particularly in New South Wales, rises seldom above 30 feet; it has, according to the Hon. Dr. J. Cox, a bark of less tannic strength than the tree distinguished as *A. mollissima*." So that the Victorian *A. decurrens*, probably *A. mollissima*, which we have got in Ceylon, cannot be Dr. Maiden's typical species. If by "larger leaflets," longer branchlets and spines are meant, the statement is quite correct, but with our popular conception of leaflets, those of the var. *mollissima*, certainly convey the idea of being larger because so much denser. Von Mueller also describes the seed of *mollissima* as "somewhat smaller, comparatively shorter, rounder and not so flat as those of *A. dealbata*, while the funicular appendage does not extend so far along the seeds, nor is the pod quite so broad; from those of *A. pyrantha* they differ in being shorter, thus more ovate than elliptical." In our warm moist Ceylon climate *A. decurrens*, like other Australian trees, grows more rapidly and to greater size than it generally does in its native habitat. Von Mueller gives a separate place to *A. mollissima*, and states that "most of the notes under *A. decurrens* refer more particularly to *A. mollissima*." The reason, therefore, why the *A. decurrens* grown in Ceylon is var. *mollissima*, is probably that all the seed was obtained from Melbourne. Maiden says of the normal *A. decurrens*, what is probably true of the variety we are growing in Ceylon, that even in a green state it furnishes an excellent fuel. One of

the merits of *A. decurrens*, so far as my observation goes, is, that it does not send up suckers so freely from its spreading roots as other kinds do, especially that which has formed so dense a grove at the Nuwara Eliya church, and *A. dealbata*. The specimen of this latter species, the silver wattle, sent by Dr. Maiden, is doubtless, as Dr. Trimen stated, identical with the kind grown in Nuwara Eliya which so seldom flowers. It is the least beautiful of all the wattles growing on the Plain. I wish, however, that, besides seed pods, the specimen sent by Professor Maiden showed the inflorescence also, for I am now puzzled what to call the acacia, beautiful alike in stem and leaf and blossom, so flourishing near the church and elsewhere in Nuwara Eliya, and which was popularly known as

"THE GOLDEN WATTLE,"

until the exclusive title of *A. pyrantha* to that name was asserted. The truth is that many, perhaps fifty out of the three hundred or so, of acacias in Australia, bear yellow blossoms and are popularly known as "golden wattles," the flowers being used as a substitute for the "may" or white-thorn blossoms of Britain. What troubles me is the fact that the denizens of Ootacamund, on the Nilgiris, who are waging war against the over-prevalent *A. dealbata*, write of it as "the yellow wattle," a name surely more descriptive of the acacia we have mentioned as forming the grove at the church in our sanatorium, than of the silver wattle which so rarely flowers? *A. dealbata* is described by Baron von Mueller as sometimes attaining a height of 150 feet, and besides being useful as timber, serving principally as

SELECT FUEL OF GREAT HEATING QUALITY.

This would render it very valuable to tea planters, but the inhabitants of Ootacamund complain that when the trees first grown, so long ago as 1840, were cut down, the ground got filled with interlaced roots, from which there have sprung innumerable suckers, so dense in growth as to constitute an insanitary nuisance. On the occasion of a former crusade against the all prevalent and encroaching wattle the Madras *Mail* wrote of the myriads of suckers which come up with renewed vigour and amazing rapidity as fast as they are cut down, and form an *inexhaustible fuel reserve*. Col. Beddome, however, stated that although this wattle grows very readily from the stool (after being coppiced), it comes up in a dense mass of small twig like stems, so that it can only be depended on for *very small firewood*. Dwellers in Nuwara Eliya, before further extending the cultivation of *A. dealbata* and the beautiful golden-blossomed species, which sends up suckers even more readily, may well take warning by the experience of Ootacamund, where the Municipality is invoking the aid of Government to get rid of what all agree has become

AN INTOLERABLE EVIL,

while secondary and indescribably dense stems are not to be compared, so they assert, as firewood with blue-gum, original stem and coppiced. We can testify from our own experience that blue-gum coppices most readily, at almost any age, the secondary stems being even more luxuriant and healthy looking than the original trees. There is one thing to be said, however, as to the encroaching tendency of *A. dealbata* suckers,—that the soil of Nuwara Eliya is considerably poorer,—we speak of the grassy Plain—than that of Ootacamund. Dwellers in the Ceylon sanatorium are not likely, in imitation of those in the Nilgiri health resort, to pass from a perfect *furor* for planting groves of firewood trees, to a wild demand

that a clean sweep or next to that should be made of the woods which they now declare are impeding the circulation of fresh air and stifling them. Considerable space in the *South of India Observer* of Feb. 14th is occupied with the evils produced by the

INDISCRIMINATE PLANTING OF TREES

in Ootacamund, Major-General Jennings had recommended:—

- (1) The restriction of all further planting of trees within Municipal limits.
- (2) The gradual reduction of the existing number of trees to within a certain fixed number per acre.
- (3) The extirpation of the yellow flower Acacia (*A. Dealbata*.)
- (4) The gradual removal of the causes of all undergrowth.

These recommendations were unanimously agreed to by the Municipal Council, at a meeting at which

A paper by Mr. George Oakes giving a description of the Melanoxylon, the Acacia Dealbata and the Eucalyptus, and a brief account of the introduction of these trees into Ootacamund was read, and the Sub-Committee report:—

"The ground within Municipal limits is overgrown with trees to an extent detrimental to health, and incompatible with proper sanitation.

"Large areas of land are shut out from the purifying influences of the sun and wind by trees and the undergrowth from them, which give cover to decaying vegetation, and noxious matter."

"The Melanoxylon and Dealbata which are to be found growing in every direction, possess the property of extending their roots to a considerable distance, and of throwing up suckers therefrom, which in places have become dense thickets. The ground is penetrated in every direction by the roots of these trees and thickets springing up from them may be seen in course of formation on all sides."

"The examination of the ground under the surface reveals a closely interlaced network of roots. The extent to which these roots have grown, can only be realized by inspection. They are ever spreading and increasing, and there are now few spots in Ootacamund to which they have not extended."

"The Committee are of opinion that an evil of serious magnitude has resulted from the planting of the Dealbata and Melanoxylon trees within Municipal limits, and from the excess to which the planting of other trees has been carried; and that unless special measures are adopted, and powers beyond those contained in the Municipal Act conferred on the Municipality to enable it to deal with the evil, it can neither be checked or remedied."

The Sub-Committee suggested:—

(1) "That a restriction should be placed on the further planting of trees within Municipal limits.

(2) That the existing number of trees should be gradually reduced to within a certain fixed number per acre.

(3) That the growth of the Acacia Dealbata within Municipal limits should be prohibited.

(4) That a Committee of five members nominated by Government, viz., the Collector of the District, or the Chairman of the Municipal Council, as may be deemed expedient, and of which the Medical officer of the station and Forest Officer residing at Ootacamund shall be *ex-officio* members, shall be appointed to report to, and advise the Municipal Council, on matters connected with the planting of trees within Municipal limits, and with the working of such by-laws as may be passed on this subject.

(5) That an Inspector, to be appointed by the Chairman of the Municipal Council shall be sanctioned for such time as may be necessary to carry out the provisions of such by-laws as may be passed. Mr. Peet, who we suppose is the Government Commissioner or Collector, wrote a commonsense Minute on the subject, but even he demands the extirpation of *A. dealbata*, which, to our bewilderment he calls, from its flowers, no doubt, "the

yellow wattle," while with us "the silver wattle" seems the more appropriate term, judging from its foliage and not by its flowers, which are, with us, so seldom seen. Mr. Peet wrote:—

"I would remark that I took the opportunity of going round with Mr. Geo. Oakes and yourself (the Chairman of the Municipal Council) to see some of the growth near the station to which attention has been drawn by the Municipal Council, and it is very clear that some remedial measures are called for, particularly with regard to the thickets of Yellow Wattle (*Acacia Dealbata*). The suggestions of the Municipal Council however go rather further than Government is likely to sanction in my opinion.

"I think that suggestion 1 might be feasible and would be advantageous, and that Government might possibly be inclined to limit future planting within Municipal limits.

"Suggestion 2 however does not strike me as practicable. Reading it with the proposed bye-law 2, which proposes that the number of trees per acre should be limited to 50, it seems to me that Government would never sanction such an interference with private property, and that there would be a very large bill for compensation. Looking at the question from a Forest point of view, I find that the following reserves are within Municipal limits, viz.:—A good part of Aramb, nearly half Snowdon, half of Dodabatta, more than one-third of Craigmere, all Elk Hill, half of Lovedale, the whole of Manjankora, Bathal and Feru Hill, half of Cairn Hill and parts of Mathana Sholah and Farlawas.

"Parts of the reserves mentioned are planted with exotic trees, but the greater portion is under indigenous forest growth. Most of these reserves lie at a distance from the more inhabited parts of the Settlement, but as being within Municipal limits would still come under the purview of this far reaching suggestion.

"There is another consideration namely, that trees grown in the open as a rule, branch extensively, and fifty trees put down per acre would with some species have as much effect in retarding air as 200 or more which run up as poles.

"There are numerous other difficulties which suggest themselves, not the least of which would result from a power of requisition being given to the Municipal Council. Again there would be irritation at the power of sanctioning (under Bye-law vii.) an excess of trees in certain places, when another claimant might consider himself equally entitled to favorable consideration, and it must not be forgotten that it would be necessary in very many cases to grant such exemptions, since one of the great reasons for planting originally was to break the force of the wind which would otherwise sweep through the station.

"Dr. Cleghorn records the opinion of three doctors on the subject of tree planting on the Nilgiris, when the experiment was in its infancy. One states: 'I consider the subject to be one of great importance, both in a sanitary and economic view.' He then goes on to state that his opinion was that the larger proportion of disease at Wellington than at the neighbouring station of Coouoor is due, in a great measure to this circumstance, viz: the want of wood; as in all other respects, height, temperature, exposure, &c., there is scarcely any appreciable difference between the two places.

"I think that by planting trees judiciously great benefit would be derived, not only from the shelter they would afford, but from the good effects produced by a moderate quantity of vegetation in purifying the atmosphere!

This reminds us that when the soldiery in exposed barracks in Jamaica were suffering severely and many dying from fever, Sir Wm. Fergusson, the eminent physician, cured the evil by means of

A SHELTER BELT OF QUICK GROWING TREES.

Mr. Peet's Minute proceeds thus:—

"The opinion of the other two doctors coincides in the main with the above. There is therefore something to be said on both sides as to the planting of trees

in high situations particularly, and the power sought by the Municipal Council in Suggestion II. and Bye-law II. does not seem to me what Government is likely to grant.

"Bye-law III. would stand or fall with Bye-law II. Bye-law IV. would be useful in many cases: but might be a dangerous instrument of annoyance. Is it not already sufficiently provided for under the present powers of the Municipality in case there is danger to be apprehended from the growth objected to?"

"I think it would be useful in many cases to save people in spite of themselves, for nothing strikes one with such astonishment as the callous way in which people build or live in houses, under trees which a moderate cyclone would bring down to the entire destruction of the buildings.

"Bye-law V. would be most useful if practicable. If the Municipal Council is prepared to compensate owners for eradicating yellow wattle there is not one word to urge against what would be a most useful provision. If however the Council is not prepared to give compensation I think that an order to eradicate the pest would be rather despotic. That it is a pest I agree most cordially, but I do not see that there would be much chance of getting powers from Government to do more than keep the thickets cut down at intervals.

"It might be possible to get Government to rule that no trees of yellow wattle should be planted, and even that all trees (as distinguished from wattle thickets) should be cut down, in order to minimize the danger of an extension of the roots. I do not think that black wattle *Acacia melanoxylon*, comes under the same category, except under very exceptional circumstances. Bye-law VI. would be useful in many cases, though even that might cause irritation."

So far Mr. Peet. To quote again:—

Mr. George Oakes in his minute remarks:—"That in 1883 the Special Sanitary officer, Surgeon-Major Nanney adopted vigorous measures for the eradication of the *Acacia Dealbata* or yellow flowering wattle, which were fairly successful, but as he was unable to legally insist on land holders clearing their land, several large areas were left to spread. The *Acacia Dealbata* appears to have been introduced some 50 years back, when owing to the scarcity of trees in the station, it was largely planted by holders of property as avenues, and to mark the boundaries of their holdings. The trees originally planted having been cut, and the roots left in the ground has led to the present dense growth of brushwood, which is as unwholesome as unsightly. As regards the value of the tree for fuel and timber, it ranks amongst the lowest of the imported Australian trees, a straight well growing tree being the exception. On these hills it seems liable to canker, which attacks the tree just at the junction of the stem and the roots, and is the cause of their suddenly falling. From the roots left in the ground thousands of suckers spring up, and continually spread. It is noticeable that these suckers seldom grow up into trees, but seem to expend their force in extending their roots, which form as dense a net-work under ground as the suckers do above. There are very dense growths of this tree at Bishopsdown, Greenway, Koodah Cottage, and at the back of the Club; but hardly any property in this station is entirely free.

"Immediate and energetic steps should be taken to eradicate the pest: stem, root and branch.

"The *Acacia Melanoxylon* grows a dense handsome tree, and is useful for fuel and timber if the trees are mature and the wood after being sawn up allowed to season. The great drawback to growing the tree, in the station, is the extent to which it throws out roots—frequently 25 to 30 yards from the trees, from which other young trees spring up which again extend their roots, it is therefore one of the worst trees to plant near buildings.

"The *Eucalyptus Globulus* was introduced subsequently to the *Acacias*, and is now of the three species mentioned, the only one planted to any extent. Within the last fifteen years the very extensive planting of this tree in the station in many cases 3 feet by 3 feet

and within six feet of dwelling houses has had a detrimental effect on the health of the inhabitants.

"The tree in itself is most harmless and the essential oil distilled from its leaves, a most valuable addition to the Pharmacopœia; but the dense plantations of it preventing the sun from reaching the ground and the free circulation of air are inimical to the health of those residing in the vicinity. Apart from the above reasons it is noticed that any springs or wells in the vicinity are quickly dried up!

"The roots of the *Eucalyptus* though large and spreading and dangerous when planted too near buildings have not the habit of throwing up suckers and spreading as do the *acacias*. The wood is the best fuel we have and timber sawn from trees thirty years old is suitable for beams and rafters of roofs; but is of no use if subjected to damp.

"If planted in moderation by these of the residents who wish to have a few trees for shelter or fuel the *Eucalyptus* is the best they could plant, but they should on no account be planted closer than 20 by 30 which will give 48 trees to the acre."

I think it will occur to readers that where the object is to bind loose soil, such as road and especially railway embankments, *A. dealbata* will be of great value; white, finally, although tree planting ought to be carried on with discrimination in Nuwara Elyia, it will be very long indeed before dwellers in our Sanatorium will imitate the Octacumundites in their complaints against too much shade and shelter from the planting of exotic trees. The bareness, rather, of many parts of the grassy Plain needs redeeming by judicious arboriculture;

HAILSTORMS IN MASKELIYA.

March 13th.

The hailstorm on the 28th February must have been very local, or some notice would have been taken of it. I send by post some tea and cinchona leaves perforated that will give you an idea of what the force and quantity of hail that came down was. It made the dogs and fowls hop. In the back verandah half-an-inch of hail stones were on the mats, and some of the largest I have ever seen almost as large as a pigeon's egg. The noise on the shingled roof was a caution. * A few estates down the valley from here neither hail nor rain fell though it poured ("buckets") up the valley. You perceive it went clean through old and hard tea leaves. A carpenter showed me a paper umbrella that the hailstones had gone through, and I must say it looked like it. The perforated holes were from the outside and the appearance of being holed as he described.

COFFEE FROM ABOUT KORAT, SIAM.

It seems likely that a new industry will be added to the wealth of Siam, and that the cultivation and sale of coffee will become an important trade in Bankok.

The more we hear about Korat, from those who have visited that part of the country, the more we are convinced that this large area offers favourable conditions of elevation, soil and climate to open out plantations for the cultivation of the Arabic coffee berry. The culture now seems, says the *Bankok Times*, to have been superseded in Ceylon by tea, for we no longer hear any mention of coffee from the famous old plantations that for so long a time commanded the coffee marts of Europe. Thus the world's supply is diminished by the amount of the falling off from that source. Then year by year the taste for coffee has extended until it is no longer looked upon as an article of great

* The leaves—large ones too—are completely riddled with holes as if shot through. We are fortunate in Ceylon in having a visitation of this kind, so much less often than tea planters in North India.—Ed, T. A.

luxury, but is now classed among the necessities of life. Hence notwithstanding that consumption increases, production has not kept pace with it. The supply now is therefore not equal to the demand, nor can it be expected to overtake the consuming powers of the world's population even under a vastly increased production for the next two decades of time. The outlook therefore is very favourable for the planter as regards a market.

In casting about for new lands possessing all the eligible advantages of aspect and situation, with the essential conditions of temperature and humidity, we can confidently invite his attention to the newly opened up table lands approaching Korat. We are told that, on these table lands the surface formation is of a rich friable loam, with a deep sub-soil, that cracks and opens with the sun in the dry weather; and that it varies in colour from dark brown or chocolate to a reddish yellow according to locality, the former indicating the presence of humus and the latter oxide of iron. Indication of the presence of the mineral ingredients is highly favourable in soils for the cultivation of the coffee berry, as showing a soil less burdened with insect life, and the vegetation less liable to attack from insects. It is also asserted that the railway will pass over country of this character, having an elevation of 1,200 to 1,300 feet for a distance of over fifty miles.

Here the direct communication, which the railway will secure, places all the obstacles of accessibility which generally impede plantation enterprise by Europeans in eastern countries, out of the question; and at once makes easy the way for selecting a suitable strip where operations may be commenced at once. Two conditions which face the planters at the outset are difficulties of access and the preliminary surface examination of a jungle covered country. The railway here sweeps away all obstacles involved in the former and aids in facilitating the latter by placing the planter at any spot along the whole line, obviating all delays in procuring supplies and the conveyance of plant and material, cooly labour, &c. And in respect to cooly labour for any kind of agricultural operations in Siam no great trouble need be feared, and for the cultivation we are now considering there is every probability that all the labour required can be procured in the country abundantly. Indeed, the cultivation of coffee *Arabica* would work in so well in this country as to give employment to a large amount of labour which is not now in demand for more than half the year. The coffee plant being raised in nurseries and transplanted out when attaining to nearly six months old, would naturally be sown just after harvest and be ready to plant out in April with the commencement of the early rains. Meanwhile the land would be cleared and prepared ready to receive the young trees before the breaking up of the land for paddy in May. Hitherto coffee has only been cultivated in a small way by native cultivators but sufficiently extensive and over a succeeding number of years, to satisfactorily prove its capabilities both in respect to soil and climate; it seems, therefore, that were the cultivation entered upon by the skillful planters who proceed systematically, enlarging their fields year by year, coffee growing would be found to provide an additional source of labour without greatly increasing the demand, whereby its price would not be rendered any more costly to general employer, and at the same time Siam might hope, in time, to be included among the coffee-producing countries of the world.—*British Manufacturer.*

RHEA IN CHINA.

A paper on 'The Cultivation and Preparation of Rhea in China' by Mr. Hosie, JI. B. M.'s Consul at Wenchau, was forwarded by the Director of the Department of Land Records and Agriculture, Bengal, with an enclosure from the Government of India. The opinion of the Society was asked whether the renewal of efforts on the part of Government, to introduce the Rhea industry, is required or likely to produce

practical results; the reply sent is given below. Mr. Hosie's paper on the extraction and preparation of Rhea fibre applies more especially to Western China, and to the Province of Chéiang, and deals but slightly with the Central Provinces where the bulk of China grass is grown.

The cultivation of Rhea is referred to in works written before the Christian era, and from these early records downwards there are numerous references to the subject. Mr. Hosie gives an original translation of an article in the *The Nung-Chêng ch-uan shee* or complete treatise on Agriculture, published in 1640, not having M. Stanis Julien's translation to refer to (M. Julien's translation was re-printed in the Society's Journal in 1850). The treatise gives what may be called the standard system and Mr. Hosie's object is to show how the practise differs from this in the Province with which he deals. His notes treat of (i) Soil and climate; (ii) Cultivation of the plant; (iii) Harvesting the crop; (iv) Extraction of the fibre; (v) General; and very full Meteorological Tables are attached by way of appendix. In section (iv) of his notes Mr. Hosie makes the following interesting statements:—"I can confidently assert that a Chinaman can extract fibre from the peel, at the rate of 12½ ounces an hour. There is no cleaning required: the fibre is cleaned in the process of extraction. I give the results of my experiments. A bundle of peel collected from one hundred stems in fifteen minutes, weighed 3½ lb.; after being steeped in the tub of water for some time, it was taken out and found to weigh 4½ lb. The workman at once commenced upon it and in thirty minutes extracted the fibre, which, in its wet state, weighed 1¼ lb. It was then hung over bamboos in the open air and left to dry for six hours, when it weighed 6½ ounces. A similar bundle of peel produced exactly the same result. Working ten hours a day, therefore, one man can produce 125 ounces, or nearly eight pounds of fibre ready for the market, in a day. As a matter of fact, the workman told me that he could extract eight catties or 10½ pounds a day; but I prefer to give eight pounds as a maximum.

Mr. Hosie then enters into some calculations as to the probable outturn per acre. He estimates, from repeated measurements and calculations, that a crop of 80,000 stems can be reckoned per acre giving, on the data shewn above 312½ lb. of dry fibre. As three crops are cut annually, Mr. Hosie considers that the outturn may be held at under 937½ lb.; the third crop being inferior in produce to the two others.

Mr. Hosie's paper will appear in the Journal, Part I, Vol IX.

The following is an extract from the Society's letter to the Director of Agriculture, Bengal, in reference to Government taking further steps to introduce the Rhea industry:—

The Director,

Department of Land Records and Agriculture.

Sir,—I have the honour, by direction of my Committee, to refer to your office memorandum No. 2153 (Agricultural), Proceedings in Original Revenue Department, Bengal, No. 3230 (Mis. F.), dated 8th September 1890, with enclosure, regarding the Rhea plant in China.

2. In my letter, dated the 27th November, I had the honor to state that the Society would have pleasure in publishing Mr. Hosie's interesting report in the next issue of the Journal, and asked that some time might be allowed for the Society to make inquiries before replying to the last paragraph of the Government of India's letter, which formed one of the enclosures, *viz.*, whether a renewal of the efforts on the part of Government to introduce the Rhea industry is required, or likely to give practical results.

3. I am directed to say that the Council of this Society are of opinion that little benefit is likely to result from a renewal of Government efforts in the direction indicated. The Council consider that it is already so widely known that the cultivation of Rhea offers no difficulties, that it is needless to take further steps to prove this; and as regards the offer of Prizes for machines, which can prepare the fibre cheaply and efficaciously the form which Government encouragement has

taken heretofore), the Council are of opinion that should a really useful and practical machine be invented, that the inventor would find it more to his advantage to patent the machine and place it before the public, rather than to claim the Government award, which, unless made an unusually large one, would not be commensurate with the advantages the inventor would then be called upon to resign.

4. From the inquiries made by one of their number during a recent visit to England, the Council have reason to believe that the demand for Rhea fibre for superior purposes is still very limited, and the manufacturers prefer to buy the fibre in its rough state, rather than clean, their profit being derived from cleaning and working this up into thread, between the price of which and clean fibre there is but a small margin.

5. As regards further inquiries into the systems followed in various parts of China, the Council desire me to say that Mr. Hosie's report seems to afford all the information which can be desired, and would indicate that, though the systems may differ locally from the standard, there is not enough encouragement in what is now known of that, to warrant their recommending any large expenditure in acquiring further information.—*From Proceedings of the Agricultural and Horticultural Society of India.*

THE COCOA BEETLE.

His Excellency Sir W. H. Hu chun-on has, it is said, appointed a Commission to enquire into the circumstances of the ravages of the Cocoa Beetle, "probably one or more kinds of longicorn Beetles undetermined," the same as we have here. The *Grenada Chronicle* says that "acres and acres of trees chiefly of young growth have already fallen victims to it and many more are threatened." The plan they have found effectual is the same that we commonly use, and consists in employing numbers of young boys and girls who dig out the larvae from under the bark. The *Chronicle* adds:—

"Unless it is employed generally, however, by every planter and manager it will not be of much avail, for as fast as one destroys the grub on his property the full grown insect produced and nurtured in the fields of his less careful neighbours, will attack his trees and keep up a supply of grubs. United effort on the part of the planting body of our island is therefore absolutely necessary, if a foe that threatens to be desperate is to be suppressed ere it assumes uncontrollable power."

The difficulties with the Cocoa Beetle therefore in Grenada are similar to our own with regard to the Parasol Ant. One thing is certain with regard to this pest, and that is very consoling; the Beetles almost invariably confine their attention to trees 3 or 4 years old. In the last number of *Timohri* Mr. Eliyan Prag reports on the destructive qualities of some minute Scolytid Beetle which have been known only to attack Cocoa plants within the last year, but which, he says have been the cause of death to the plants over a very considerable area of plantations. Mr. C. Waterhouse of the British Museum of Natural History determines them as *Xyleborus perforans*.—*Trinidad Agricultural Record.*

UVA NORTH-WEST, Feb. 28th.—This has been a most abnormal season—a very mild, warm N. E. monsoon. Jan. fine; but first 18 days of Feb. rain every day, 9 inches. old, misty weather since; dry, thin wind, cold. Thermometer seldom went below 60° and as seldom exceeded 70°. A deal of the coffee crop is early but a very ugly sample. Early pruned tea has flushed fairly well, but unpruned shut up. It has been a good season for new clearings, and few supplies should be required. Sinhalese &c. doing their best to get hold of some of our coffee, but our own coolies being the chief thieves they are hard to catch at it; they watch Durai and the watchman! Glad to see some find grevillea shade stops green bug; but it is not so in my experience. Coffee wants to die out.

ARTIFICIAL FERTILISATION OF CINCHONA FLOWERS.—A Mr. J. Bosch has recently suggested a process for the artificial fertilisation of cinchona flowers, which is attracting a great deal of attention in Java, so much so that the Dutch Indian Government have appointed a commission to investigate the process, and report as to the results.—*Chemist and Druggist.*

SOUTHERN INDIAN INDUSTRIES.—The Mysore Government has granted a concession to Mr. W. F. Peter Hay, of Hunsur, of the exclusive right to manufacture sandal oil within the Mysore State for a period of ten years from the date of commencing distillation, subject to certain conditions. A royalty of 3.25 pie per oz. weight of oil manufactured and issued is to be paid to Government once in three months. The concession is conditional upon work being stated within one year.—*Indian Engineer*, Feb. 28th.

"AMHERSTIA NOBILIS."—This splendid leguminous tree is reported to have been seen in flower within the past few days, in the Museum grounds—a very unusual experience in Colombo. It flowers in Peradeniya, but scarcely matures any seed. We quote from the *Treasury of Botany* as follows:—

Amherstia. A genus of the Pea family (*Leguminosæ*), named in honour of the Countess Amherst. *A. nobilis* is the only species. It grows near Martaban, in the Malayan peninsula, and attains a height of about forty feet. When in flower, it is said to be 'one of the most superb objects imaginable, unrivalled in India or in any other part of the world.' The leaves are equally pinnate, large, and, when young, of a pale purple colour. 'The flowers are large, scentless, and of a bright vermilion colour, diversified with three yellow spots, and disposed in gigantic ovate pendulous bunches.' The tree is cultivated in some of the larger English gardens; but requiring so much space is seldom met with in collections. The Burmese name of the plant is *Thoca*, and handfuls of the flowers are offered before the images of Buddha.

SALT FOR AGRICULTURAL PURPOSES.—We have a great deal of sympathy with the object which a correspondent has in view in the letter (see "B.") addressed to us on this subject. The efforts made a good many years ago, by the Planters' Association to get the Ceylon Government to agree to allow salt be used, free of duty, as a manure, were very persistent and forcible. Nor did the Government of the day refuse attention: on the contrary a whole series of experiments were made with the view of seeing how salt could be so mixed and adulterated as to make unfit for human food, while still useful for agricultural purposes. But success in their experiments was not attained. We always felt, however, that the standard fixed was a too stringent one. Practically, we cannot conceive that any estate coolies or other of the lowest of the people would have tried for a moment to utilise for food, some of the manure mixtures then tested. But the Government refused to run the risk and so with superabundant stores of salt available, none can be used as manure, however beneficial it may be demonstrated by "B." and others to be. For this reason, even more than on account of the tax on food, we should like to see the Government monopoly of salt removed. We do not believe any hardship is involved by the tax on the people so far as the condiment is concerned; on the contrary in remote districts we feel sure the poorest of the natives have salt made available to them at far cheaper rates than if, without tax, the distribution were left to private enterprise. But it is certainly very hard that such a tax should prevent salt now lying idle, being utilised in agriculture where its application is desirable.

Correspondence.

To the Editor.

LINING FOR TEA CHESTS: MR. MAITLAND KIRWAN'S PAPER: VERY LOW PRICES.

London, E. C., Feb. 19th.

DEAR SIR,—I notice from certain correspondence in your *Overland* edition that some misconception has arisen as regards the price of my new tea paper, and I fear I myself may have been to blame for this mistake in not showing sufficiently clearly the price of the paper alone apart from the chest. Let me now explain clearly that the paper itself, sufficient to line a 100 lb. chest, costs 8s, say *eightpence*, f.o.b. London, as against say 1s 3³/₄d cost of lead. The paper is supplied in three pieces, one to go round the chest measuring 28 by 87 inches, and the other two for top and bottom, measuring each 17" by 12". A further consignment leaves next week and can be procured from my agents in Colombo. Will you kindly give this letter publication in your next edition.—Yours faithfully,

J. M. MAITLAND KIRWAN.

P. S.—Planters desirous of trying the paper can be supplied with sufficient for a small consignment free of charge.—J. M. M. K.

WOODCOCK IN THE FORESTS OF THE EASTERN LOWCOUNTRY OF CEYLON.

Tricomalee, March 4.

SIR,—Noting your correspondent "B. L.'s" letter regarding woodcock in Ceylon, I may mention that I flushed one in Nov. last, a few miles off the Mahaweliganga, in the forest of Tambalagam Pattu about 10 miles inland. I saw it clearly, as it flew off from near my feet, and it was not the wood snipe. A jack snipe was shot at Kantalay a few years ago by Mr. Colls, P. W. D., and the range of our Scolopacidae probably varies greatly in special seasons. H. N.

CACAO CULTIVATION IN CEYLON:
MR. J. H. BARBER'S EXPERIENCE.

Colombo, March 5th.

DEAR SIR,—The enclosed letter from my agents Messrs. W. H. Davies & Co., coming so soon after your publication of Dr. Trimen's letter to the Colonial Secretary, may be of interest to cacao growers.

Throughout the last season my agents dealt with criollo or Caracas alone, from my properties near Kandy. But last week I sent them a small consignment from the grove Ukuwala which is planted entirely with the "Forastero" varieties. You will see that, although they obtained the same price for the one variety as for the other, yet those most interested in the trade, and therefore best qualified to speak to the market value of the respective varieties, are far from inclined to come to a decision on their intrinsic qualities and claims, from the mere prices obtained for them just now, as Dr. Trimen has done. In fact they seem to think very differently.

I have also to touch on another point advanced by the writer. There is a paragraph in Dr. Trimen's letter raising a doubt regarding Mr. Morris's statement that Ceylon is indebted to the Dutch for the introduction of the Criollo cacao. It may be interest-

ing to have more light thrown on this point. For instance the reasons for the statement of the one and the arguments for the doubts raised by the other. Both are so well qualified to enter into the investigation that it would be a pity to let the matter rest in doubt. As regards one of the statements however made by the latter, that the earliest record to hand dates so late as 1819, *i.e.*, twenty years or so after British occupation, there is this much to be said, that when the British came in, it did not follow that the Dutch vacated the island. So that the island was not solely populated by the British and the natives. Nor could we trace back the date of the introduction or planting from the date of the existence of a tree, so as to say with justice or truth, "I believe it to have been then quite recently introduced." We are talking in 1890 or 1891 of a tree said to have existed in 1819. Who can undertake to say without further evidence on the point, which certainly has not been placed before the public, that the tree referred to was not 20 years old then, and the cacao, after it has attained maturity, is of all trees one about whose age there might be much speculation without certainty. What may be worth inquiring would be as to how much the British nation was interested in the cultivation of the cacao plant in other colonies in the first and second decade of the XIXth century, so as to have known its value as an industry. It may be also germane to the issue to ascertain whether cocoa was esteemed as a beverage in Great Britain, about that time, or whether it was purely a Continental drink.

The names Criollo, Forastero, &c. point to the adoption of the plant by the Portuguese; and when we remember the fact of the Portuguese having been in Ceylon before the Dutch, we can account for the knowledge in Ceylon of the value of the plant even in those early times.—Yours truly,

JAS. H. BARBER.

Colombo, March 5th.

J. H. Barber, Esq, Kandy.

DEAR SIR,—We beg to advise having sold your parcels of Forastero and Caracas cocoa, from Ukuwala and Kandy respectively, at R63 per cwt. We may point out to you that Caracas is most preferred by London buyers on account of its superior quality, though Forastero is occasionally sold at good prices, as in the present instance, owing to its fine appearance. We are, however, informed by those most interested in the trade, that the latter would not fetch anything like the price of Caracas if shipped in large quantities. Kindly note this.—Yours faithfully,

W. H. DAVIES & Co.

CLARKE'S PATENT PAPER LEAD LINING.

Gartmore, Maskeliya, March 9th.

DEAR SIR,—Perhaps the best testimony in favor of "Clarke's Patent" Paper Lead Lining for tea chests as yet received, is the following:—A break of 7,000 lb. of Arslena tea packed in this lining was shipped in the "Nepaul." It was considered like the other lots of tea to be so damaged that the Insurance Company paid up the full amount of the insurance. I now learn from Messrs. Gow, Wilson & Stanton, that the tea, after examination, was fit for sale, and that they sold it on behalf of Insurance Company for 1s per lb. B. Pekoe, 10¹/₂d Pekoe, and 7¹/₂d Dust.

Your London correspondent's friend is mistaken in saying a planter had complained of the excessive cost of "Clarke's Patent" Lining. I have always said it was necessarily dearer than lead alone, but the cost is only a few cents more per chest.—Yours truly,

T. C. ANDERSON.

CACAO CULTIVATION.

Kandy, March 13th.

DEAR SIR,—In the Report of the Director of the Ceylon Botanic Gardens for 1890 there seems to be an error as regards the export of cocoa, the figures for 1889 being quoted as those of last year.

The figures given by the Chamber of Commerce may, I suppose, be taken as fairly accurate:—

1889	cwt. 19,054
1890	„ 15,981

Decrease .. 3,075

This result hardly supports the statement that the industry here may be considered to be in a satisfactory and improving condition.

If the Director had moved as freely amongst the villagers as an "Ideal Planter," he would long ago have fully understood why they have taken so little advantage of his gratis distribution of seeds. The more enterprising natives who went in for cultivating a few cacao trees could, as a rule, obtain all the seed they wanted from the nearest estate, without the trouble of asking for it; while others have usually been able to obtain a few bushels at any time, in the same way, for the mere trouble of picking.—Yours faithfully,

PREDIAL PROGRESS.

[Still, villagers in Kegalla and throughout Sabaragamuwa generally can scarcely be guilty of the thefts in the Kurunegala district? The export in 1889 was equal to 13,159 cwt. so that taking the three years, we have not done so badly; perhaps cacao is to distinguish itself by alternate big and average crops.—Ed. T. A.]

JAVA SUGAR PALM.

Matale, March 13th.

DEAR SIR,—A "gumpty palm" or as some call it the Java sugar palm had flowered and I got the sap drawn from it same as we do with the kital, coconut or palmrah flower, but the result has been very unsatisfactory. Compared with our sweet-toddy, its taste is like dirty tank water. Boiled down to a sixteenth, it was like an infusion of cinchona bark. Is any of your readers able to tell us how the sugar is obtained and whether the sap could be drawn sweet.—Yours faithfully,

A. VAN SPARREX.

CACAO of the Forastero description is, we learn, being planted both in the Negombo and Kalutara districts under the advice of an experienced planter and with the object of giving it a fair trial.

A GUM-PRODUCING PLANT.—In the last part of the *Icones Plantarum* is an account of *Eucommia ulmoides*, a most singular Chinese plant, as yet but little known to botanists, and the true affinity of which has yet to be discovered. "The most singular feature about the plant," we read, "is the extraordinary abundance of an elastic gum in all the younger tissues—excepting, perhaps, the wood proper—in the bark (in the usual sense of the word), the leaves and petioles, and pericarp; any of these snapped across, and the parts drawn asunder, exhibit the silvery sheen of innumerable threads of this gum." The trees are raised from seed by the Chinese (Patung and Szechwan are districts named), and when sufficiently grown, are felled, and the bark taken off. To this the natives attribute wonderful medicinal properties, the value of which has yet to be proved by Europeans. Pattaras were formerly made from the wood, and the young leaves are sometimes eaten. It is hoped that at no very distant date a fresh supply of specimens will be obtained, which will enable those interested in this wonderful plant to prosecute their researches still further. It is to Dr. Henry that we owe what little we knew of this important plant.—*Gardeners' Chronicle*.

"CRIOLLO" AND "FORASTERO" are not Portuguese words, as Mr. J. H. Barber seems to think, but Spanish, meaning simply "indigenous" and "exotic" (literally "home-bred" and "foreign"). Any theory, therefore, as to the introduction of cacao into Ceylon by the Portuguese, founded on the use of these words, is untenable.—*Cor.*

TEA IN UDAPUSSELLAWA is described by a gentleman who has recently travelled for 22 miles along the district road from Nuwara Eliya, as very fine: from the 6th to the 13th mile out, there are perhaps no finer sheets of tea in the island, hethinks, than are to be seen in this splendid undulating upland district.

AT A RECENT MEETING of the Académie des Sciences, Paris, M. Charles Naudin read a paper on the Eucalyptus tree, which contained some interesting observations. He began by remarking that owing to the peculiar tendency of this tree to change with age or climate and to produce crosses, there was only one good work on the subject—namely, the monography of Mr. Ferdinand Müller,* of Melbourne. M. Naudin has made a study of the eucalyptus as transplanted into Europe. At Thuret, near Antibes, in Provence, there is one of the finest collections of the tree in Europe. It comprises eighty species, or about half the total number known to exist. The gum tree was originally confined to Australia and the islands in geographical relation with it. M. Naudin thinks that all its varieties have been derived from a single prototype subsequently to the separation of Australia from the Asiatic continent. But the tree has a great practical value, as it grows rapidly, and furnishes excellent wood for construction or fuel. M. Naudin thinks that all the Southern countries of Europe would profit by its cultivation, and that, above all, the tree may be a boon in the Trans-Mediterranean colonies of France and the roads and settlements of the Sahara and Central Africa.—*Globe*.

SNAKE-VENOM.—Dr. Lauder Brunton has communicated to the *British Medical Journal* a note on snake-venom and its antidotes, in which he reviews the work which has been done to determine the nature of the active principle of venom. Very little that is certain is known about it but probably the substance is an albumose, although globulins also appear to have something to do with the action. For instance, the venom of the crotalidæ contains a comparatively large amount of globulins, and produces local swelling and blackening of the parts, while that of the cobra contains comparatively little globulin, and has little local action. The globulins and albumoses in different venoms are probably not altogether identical, for the albumose of the cobra seems to have a greater power to produce convulsions than that of the rattlesnake. It would appear that there is some resemblance between snake-venom and the albuminoid products of the anthrax bacillus, which like the albumoses of snake-poison, produce much local œdema, sluggishness, coma, and death. Like the venom albumose, its activity is lessened but not destroyed, by boiling. But, in addition to these substances, Dr. Sydney Marten has obtained an alkaloid which has the same action as the albumose, but much more powerful, and this alkaloid, he thinks, is present in a nascent condition in the albumose, and is separated from it by the tissues of the living animal into which it has been introduced. As to the remedies for snake-bite Dr. Brunton seems inclined to pin his faith to the subcutaneous injection of strychnine in small and repeated doses, whisky or brandy being simultaneously administered.—*Chemist and Druggist*.

* Such is true! The gentleman referred to is Baron Sir Ferdinand von Müller, K.C.M.G., F.R.S., &c.—Ed. T. A.

THE SILVER POOL IN NEW YORK.—A telegram from New York in *The Times* announces the break-down of the American Silver Pool. It says: By the defeat of the Free Coinage Bill, the great silver speculation in Wall Street has ended. Millions were lost in the "deal." Last July, when it was thought that the Bill providing for the purchase by the Government of 4,500,000 ounces of silver a month would pass, pools were made up to buy bullion in expectation of a great advance. The conclusion was correct. When the pools began operations, silver was a dollar an ounce. On the passage of the Bill, it jumped to 1 dol. 21½ cents. To make the silver in a dollar worth a dollar in gold it would have to be quoted 1 dol. 29 cents. The men in the pool expected the rise to go to 1 dol. 25 cents, as the law was to go into effect in August. The calculated production of the American mines for the ensuing year would be 65,000,000 ounces. Of this, the Government would be required to purchase 54,000,000 ounces. The arts would use 9,000,000 ounces, and the surplus was reckoned at 2,000,000 ounces. America had previously been a heavy exporter. The pools conducted their negotiations entirely in New York.—*H. and C. Mail*, Feb 27th.

WOOD IN FIRE.—Wood cannot be rendered incombustible, or more strictly speaking, non-alterable by heat; but its non-inflammability may, to a considerable extent be insured, so as to prevent buildings from a limited and temporary fire at any rate until assistance arrives. It is, however, hopeless to expect a building encumbered with inflammable substances to pass through such a test uninjured. The methods of preserving wood against fire are of two kinds; the injections of saline solution and the application of a paint or coating. The former appears but little practical; and, indeed, short of proof to the contrary, it must be considered dangerous in the case of wood of large dimensions. This system is, however, applicable to small pieces of wood. Of all the substances recommended, a concentrated solution of phosphate of ammonia is undoubtedly the best, the use of this substance, notwithstanding its high price possessing such great advantages that it should be employed in all cases where expense is no object. In the majority of cases, however, coating with brush is the only practical solution of the question, and the Ghent professors recommend as the substance suitable for use in this manner, cyanide of potassium and asbestos paint.—*Professors Bondi and Denny, of Ghent University.*—*Indian Engineer.*

FERROID, A NEW ARTIFICIAL STONE.—Under this title Mr. Herman Poole describes in the *Journal of the Association of Engineering Societies* a new artificial stone, which is a compound, partly chemical and partly mechanical, of iron, sulphur, and silicon with more or less foreign matter. It is mainly a super saturated solution of iron in the sulphur with the silica acting as a binder and hardener. Its normal colour is a dark slate, varying somewhat with the manner in which it is dressed, but the colour can be somewhat modified by the introduction of pigments. Successful imitations of various coloured brick and sandstone have been made. It is about the hardness of ordinary bluestone, and can be worked by the usual stone-cutting tools turned in a lathe, or planed. The tensile strength is from 650lb to 1,200lb. per square inch and under compression it endures from 9,000lb to 12,000lb. Its specific gravity is about 2.6. It melts at about 300 deg. F. very slowly. It does not deteriorate under exposure to the weather. As it can be melted and moulded, it is applicable to a great variety of uses to which stone cannot be put, and particularly so for large castings, such as pipes for sewage, &c. Architectural forms can be very conveniently made from it in position if needed. For culverts and bridge foundations the perfect smoothness of which the surface is susceptible is advantageous in lessening water friction.—*Indian Engineer.*

NEW NICKEL MINES.—It is reported that quite an extraordinary discovery of nickel has been made quite recently in Nevada. Among those best informed it is spoken of as "a wonderful development," and this representation is supported by the exhibit of masses of ore. It is claimed that the nickel is found in deposits almost limitless and of such richness that even what is termed the lowest grade yields 8 to 12 per cent. of pure metal. Quantities aggregating hundreds of tons are in sight, which give by analysis from 20 to 35.4 per cent. of ingot metal.—*American Mail.*

COOLIES AND INDIAN TEA.—So far as the Chairman's address to the Indian Tea Association in Calcutta went to show, the coolie difficulty is becoming more pressing than ever to tea plantations. Not only has the increase of acreage under cultivation tended to send up the price of labour, but the new railway and mining enterprises in the District of Chota Nagpur have diverted a large number of coolies. In Ranchi and Purulia as much as Rs 150 a head has been offered for coolies. The District of Ganjam has turned out to be a failure as a recruiting ground. There has however been a constant and rapid increase in the total acreage under tea.—*M. Mail*, March 9.

INCREASING CONSUMPTION OF TEA, COFFEE AND COCOA.—Strong evidence of the advance of the "wave of temperance" and the general increase in the consumption of non-alcoholic drinks of late years, is given by a carefully-compiled table just prepared by Sir Henry Peet. The figures refer to tea, coffee and cocoa, and they embrace a period of fifty years—that is from 1840 to 1890—being the average consumption per head of the population as shown for each year since 1840. The most remarkable progress is to be noted in the consumption of tea. In 1840 the tea consumed was 1.22 lb. per head, in 1850 it was 1.86 lb., in 1860 2.67 lb., in 1870 3.81 lb., in 1880 4.57 lb. and in 1890 5.07 lb. In 1840 the population was 26,487,026 and in 1890 38,227,321. In respect to coffee, the consumption was in 1840 1.08 lb. per head of the population, in 1850 it was 1.13 lb., in 1860 1.23 lb., in 1870 .98 lb., in 1880 .92 lb., and in 1890 .75 lb. Of cocoa the average consumption per head of the population was in 1840 .03 lb., in 1850 .11 lb., in 1860 .11 lb., in 1870 .20 lb., in 1880 .30 lb., and in 1890 .53 lb. Of these three articles together, their total consumption per head of the population was in 1840 2.38 lb., and in 1890 6.35 lb. The chief augmentation has been in tea, which has vastly advanced in popularity in this country.

THE ALLIGATOR AS A COMMERCIAL COMMODITY.—Besides the hides of the alligator, of which 50,000 or 60,000 are annually utilised in the United States, there are other commercial products obtained. The teeth, which are round, white, and conical, and as long as two joints of an average finger, are mounted with gold or silver, and used for jewellery, trinkets, and for teething babies to play with. They are also carved into a variety of forms such as whistles, buttons, and cane handles. This industry is carried on principally in Florida. Among Chinese druggists there is a great demand for alligators' teeth, which are said to be powdered and administered as a remedy. As much as a dollar apiece is paid by them for fine teeth. All the teeth of the alligator are of the class of conical tusks, with no cutting or grinding apparatus, and hence the animal is forced to feed chiefly on carrion, which is ready prepared for his digestion. Other commercial products of the alligator are the oil and musk pods. The tail of an alligator of twelve feet in length, on boiling, furnishes from fifty to seventy pints of excellent oil, which, in Brazil, is used for lighting and in medicine. The oil has been recommended for the cure of quite a variety of diseases. It has a high reputation among the swampers as a remedy for rheumatism, being given both inwardly and outwardly.—*Public Opinion.*

THE CEYLON PLANTING DISTRICTS GENERALLY.

TEA AND TEA PROSPECTS—"NEXT-YEAR" AT LAST—
HLD A GOOD AVERAGE WITH LOW EXCHANGE—TIMBER
TREE GROWING—FUEL AND MANA GRASS—TEA
TRANSPORT AND THE RAILWAY EXTENSION AND
OPENING UPCOUNTRY—LABOUR—MANURES—FREIGHTS
COFFEE—CINCHONA.

(By a Planting Visitor after some years' absence.)

I note with pleasure most marked improvement and progress everywhere in tea and tea prospects, and I have not the slightest hesitation in saying, that I consider the prospects of Ceylon as a tea-producing country have improved during the last two years by 20 per cent and most estates have individually so increased in value. Prospective estimates of some years ago, made by very capable men (such as Mr. Rutherford) have proved, so far as yield goes, far from correct. Upcountry estates more particularly have given, and will give, far larger returns per acre than even the most sanguine could have expected. To Ceylon, I think, the long-looked-for "Next Year" has at last come; and I see

no reason to fear its departure for many a day, but let us "ca' oanny"! Everywhere not only better but good times are apparent; money is being freely offered at low rates (may planters not be led away by such commissions and many eteteras follow; fortunes are seldom made on borrowed capital, while small savings are often lost), estates are changing hands at high figures, folks are going home by the dozen, forgotten furlough circulars from several Companies are being reissued, salaries raised, and liberal commissions given. All this is as it should be, times justify it, and deserving men are remunerated in a measure for the dark days Ceylon has passed through, let us hope for ever.

For some years to come it will not be for our interests to see Ceylon teas averaging more than 11d. High prices will curtail its spreading into channels where it is at present unknown, and 11d, with present exchange ought to be the height of our ambition for a time. I think we shall always find a sympathy between exchange and prices. Undoubtedly at present there is such.

I rejoice to see timber trees being introduced into our tea districts to the extent they are, as not only supplying a want too keenly felt, but with the object of breaking up large areas of one product, and so distributing disease as brought on by insect life in a tropical country like Ceylon. I trust, on another visit, to note the length and breadth of Ceylon's tea districts well covered with timber and fuel trees. Fuel is undoubtedly becoming a serious consideration to many estates. I wonder mana grass is not utilized as a heat generator. I feel pretty certain that in time, compressed blocks, composed of mana grass with something else, say a little tar, will be introduced as a fuel, and I see no reason why it should not be so. Why does that dead-and-alive Government of ours not offer some handsome reward for the introduction of a substitute for wood, as a fuel for tea factories? Compressed mana grass has been tried as a substitute for boards for tea boxes; was successful so far as to show it could be compressed, and if so I doubt not it

would burn well. Any quantity of the article could be grown in the island.

Tea lead will find a substitute shortly I doubt not; the sooner the better. I have long had an idea that our teas could successfully be transported in specially made airtight bags, from the firing machine on the estate to central packing and sorting factories, sufficiently removed from Colombo as to be away from the sea air. The saving thus in transport of packing materials would be immense, to say nothing of innumerable other expenses. At present, with up and down rail rates, we pay on the packing materials about 50 per cent of what the net tea costs us to transport to Colombo. Teas in properly packed airtight bags would not, I think, suffer either in quality or by being broken into dust, even on so badly a worked railway as Ceylon can boast of. Railway extension from Nannuoya seems to make progress. Government has apparently laid down that land above a certain elevation is not to be opened up. A railway is constructed on such land, and so the principle that a railway is to *open up* a country disappears. We are always learning something!

Labor seems by no means too plentiful. Our Government always manages to put some spoke in the planter's wheel to retard his complete progress and the success of the Colony.

Freights seem at present higher and scarce; among other useful works of the C. P. Association, some enterprising line of steamers might be approached with the view of dealing with Ceylon teas exclusively, and not leave us to take "what is left," in the way of room.—Results from *Manufacturing* of tea estates seem so far a success. If labor be plentiful, tea prices and exchange as at present and certain obnoxious manures such as coconut poonac be avoided, the investment is sound.

Of good old *Coffee*, I have seen little; it will be grown again in the island some day, but not I fear successfully till the present specimen has died out, and its bones and disease rotted away.—*Cinchona* has disappeared in two years in a marvellous manner, certainly 50 per cent, and the self-sown plants are not there as they used to be. If the tree will grow, it is no bad investment to grow it, but stocks of quinine are very heavy in London and the Continent, and though constantly changing hands are not used up.

Lowcountry products I shall in every sense leave alone.

HILLCOUNTRY PLANTING REPORT.

NANUOYA, March 17th, 1891.

WHITE CLOVER

to our Irish friends in Colombo (by way of substitute for the true shamrock), until after the tappal was gone. The history of that same white clover is very curious. I got the seed from Australia in 1879 or early in 1880, and sowed it in the valley in which our tank was subsequently formed. There it continued to flourish year after year; and about 1885 we removed plants of it to a lawn in front of the upper bungalow. Subsequently the lawn was dug up, the grass and clover were entirely removed from the soil (so it was thought), and the space was laid out as a flower garden. About a year ago a portion was dug pretty deeply and manured for the reception of flowering plants; when, suddenly, the white clover came up more fresh and flourishing than ever, and filled an entire bed with its snow-white blossoms and its pretty, trijunctive green leaves. We cherish the freely flowering clover for the sake of "Home" associations and also for

* Is it not rather the duty of the Planters' Association?—Ed. T. A.

the illustration it affords of the wonderful vitality of the genus of plants to which it belongs. Have I not read that the roots of the red clover have penetrated the soil from 3 to 4 and even 6 feet down into subterranean drains, and not only that they conserve nitrates in the soil, but that the plants to which they are attached enrich the land in which they grow with nitrogen derived from the atmosphere? The *leguminosae* are now found to be still more valuable in this respect, and some readers of the *Observer* may remember that Baron Liebig, writing to the late Mr. Crüwell, advised the coffee planters of Ceylon to grow lupins between the rows of their trees, to be turned down as green manure, so imparting to the soil their stores of nitrogen. I suppose that tea, which is a leaf-crop, requires even more than coffee

SUPPLIES OF NITROGEN ;

and it would be interesting to know if any experiment has been tried in burying green plants in the soil in which tea grows, before the blossoming or at any rate the seeding stage of such plants. In the experimental station at Cawnpore, hemp has been found an excellent improver of the soil by being buried in its green stage. I have never grown green crops for the purpose of being buried; but early in its existence I treated a patch of tea to an application of green *nilu* plants laid along hollows between the rows, with China bean manure sprinkled over the *nilu*. We believe we see the good effects of that application to this day, a dozen years after the experiment was tried; but, of course, the China bean cake being in itself highly nitrogenous, it is impossible to say what portion of the benefit was due to the *nilu* beyond the mechanical effect of

OPENING UP THE SOIL TO AERATION,

a very important process. If lupin seed cannot be easily procured, or if lupins will not readily grow here, any pea or bean will suit,—chick pea, gram, kollu or even scarlet runners. In our American exchanges we find constant reference to peas grown as green manure for orange and other orchards; and we submit that experiments should be instituted in Ceylon. Clover, as well as beans and peas, might be tried, the only objection being, that, as our experience here has shown, it is easier to get clover into a soil than to eradicate it.

The railway extension, the progress of which towards Uva we watch with interest each morning and evening as it is being completed across Abbotsford, was

PROJECTED TO SAVE UVA COFFEE.

For that purpose it was sanctioned too late, but from those best able to speak with authority, we have recently had the assurance that it is now certain that, in serving the new staple tea, it will receive more traffic than ever could have been yielded by the old. In how many other ways it may serve Uva and other districts on the eastern side of our "Great Divide," who can possibly predict? It will facilitate

THE INTRODUCTION OF MANURE,

labour, capital and European enterprise, and as that enterprise prospers so will all native interests from the growing of rice, maize, legumes and millets to the culture of roots and leaf-vegetables and fruits, for the superior growth of the latter of which the climate is specially favourable. Cattle farming and dairying and even manufactures (that of paper from mana grass to begin with) are pretty sure to follow. Judicious irrigation schemes by all means, until even the arid parts of Uva grow a surplus of cereal food; but for the success of irrigation and all other enterprise, the one desideratum is to be found in

FACILITIES OF TRANSIT AND INTERCOMMERCE,

such as good roads laid the foundation of, and to which the railway puts the crowning top-stone. At Nanuoya, as your readers are aware, our mountain railway attains an altitude of 5,297 feet above mean sea-level. The engine entered Abbotsford eastern boundary, $1\frac{1}{2}$ mile from Nanuoya, at an elevation of 5,497 feet, and will leave the western boundary for the Government forest at a few yards from the second mile, having attained an altitude of 5,558 feet. The gradient at the entrance is 1 in 52.80 and towards the exit it is eased to 1 in 55. There are two large cuttings in this serpentine line of half a mile. One severs a ridge which runs down the estate and across which a foot and horse bridge will be placed to restore the connection. This cutting is over 31 feet high, while the much more formidable cutting at the outlet from the eastern side of the estate (the land runs more than 2 miles from north to south) is about 53 feet in perpendicular height. A still greater cutting beyond the 3rd mile with which Mr. Rosling has to deal, and from which a slip of about 1,000 cubic yards had at one time to be cleared away, is 80 feet perpendicular and fully 100 in the slope. For a little more than a mile beyond Abbotsford, the line goes through

BEAUTIFUL FOREST SCENERY,

the forest sloping up the sides of the Kataphillamana range. It then runs between the cultivated land of Pennynnnydd and Calsay and the forest to the 5th mile. Hence to the 7th there is magnificent scenery of forest, river, waterfall, gorge and ravine. Beyond, the rolling grassy prairies known as Elk Plains open up, framed in by forested mountains. On these Plains the Ambawala station to suit the New Galway and other estates near Hakgala will be placed. The patanas stretch nearly up to summit level, which is practically the height of Nuwara Eliya, and where, we suppose, there will be a station, which the opening up of Horton Plains may yet render important.

Just as I wrote the above I received a letter from a correspondent in Uva about the *damba* tree. He writes:—

"In *From the Hills* in your issue of 10th March you say 'the *damba*, a mere variation of *jambu*, is, I suppose, the *wal jambu* of Trimen's list, but certainly the natives pronounce the name *damba*.' They are right. That is the proper name of the tree. Next to *Millille* and *Leang* it is the best building timber in Uva. One store I built with it 30 years ago is now as sound as ever. It used to abound formerly, you will recognise the name in *Damba-gaha*, *Damba-tienne*, *Dambawelle* and *Damba-gas-talarwa*,—*gas*, the plural of *gaha*—*Jambu gaha* is the tree bearing the *jambu* fruit, sometimes called the rose-apple, bright pink on one side and which I first saw in Bengal before coming here—is a totally different tree growing at a much lower elevation and not choice timber. The *wal jambu* is the wild tree in the jungle and like the wild mango, and wild nutmeg (*molibodde*) next to useless for building purposes. Our tea flourishing all over Uva flushes all through the hot weather and the continuous wet. By the bye, where is Uva, which name is not Sinhalese or English or any known language, is it Euvah or Youvah?" I gather, therefore, that while *damba* is, as I have long known, one of

OUR BEST HILL TIMBERS,

the tree known as *wal jambu* is very inferior. It is curious that Trimen, who gives *dan* and *maha dan* as Sinhalese names for *Eugenia*s, ignores *damba*, which is no doubt the *Elu* form of *jambu* and applied to the mountain species. In Trimen's list the Sinhalese name for one plant is actually *tolol*!

March 18.

Speaking with the reserve begotten of experience, it looks as if the rain burst of March had about

EXHAUSTED ITS MOISTURE STORES.

Yesterday was a genial day, with a few rolls of thunder and a shower in the afternoon which deposited 34 cents of rain: The evening was beautiful, with veils of white mist floating across the faces of the mountains. A golden sunset was succeeded by silvery moonlight, incessant lightning flashes making themselves visible in the south west horizon. This morning is calm and sunny, although masses of mist rest on the brow of Totapola and other mountains which separate us from Uva. The thermometer stands at 55°.

SALE OF ESTATE PROPERTY.

Mr. Withers has sold Adelaide estate, Lower Dikoya, to Mr. H. L. Forbes for the Scottish-Ceylon Tea Co. It is certainly a bargain for the Company as adjoining one of their outlying properties, Benachie, for which it affords waterpower, Adelaide has 158 acres fine tea all but 50 acres in bearing with 47 acres in forest and not less than 25 available chena. The price paid is only R30,000. The secret of such properties being sold at moderate rates is no doubt found in the fact that a tea plantation with fully equipped factory requires to be of a much larger acreage than the average coffee estate, to ensure economical, profitable work. We are pleased to see the process going on which will bring not less than 400 to 500 acres of tea in bearing to each factory.

TEA IN THE GALLE DISTRICT.

What tea can do in the lowcountry is evidenced by the prices obtained yesterday by Messrs. Forbes & Walker for "Fred's Ruhe" which is only about 130 feet above sea-level, close to Galle, owned by Mr. Wm. Abeyesundra of the P. & O. Co. The prices were as follows:—

1,110 lb. B. B.	60 cts.	885 lb. Broken Tea	37 cts.
2,500 lb. Pekoe	45 "	165 lb. Dust	31 "
2,501 lb. P. S.	40 "	82 lb. Red Leaf	32 "

These rates compare favorably with many of those realized for tea from the high districts, and seeing that the cost of laying it down in Colombo is under 30 cents per lb. there is an excellent margin for profit. "Fred's Ruhe" estate comprises about 270 acres, of which 210 are in full bearing, the output being manipulated by a Brown's Desiccator and Blackstone Roller propelled by steam power. The results obtained from this estate should be welcome to the shareholders of the Tal-gawela Tea Company and other low country concerns, which are now coming into bearing. Who dare despise the lowcountry after this?

THE MARKETS FOR TEA—AND PROSPECTS.

(By one interested as a grower.)

The latest London statistics and reports show that Chinese low priced teas are still urgently wanted by the trade (not necessarily by the consumers). In the late spurt Chinese congou rose rapidly until about 80 per cent from lowest point was reached. This is unfortunate and augurs not well for India and Ceylon in the near future. This great rise took place too when exchange dropped to its lowest. No doubt some large orders went out to China for "more" for mixing purposes.

America unfortunately appears to be chockfull of tea just now, and prices there are said to be lower than in London. 70,000 half-chests said to be kept

back by American buyers at Amoy, for they fear to ship and depress still further prices in America!

Australia is said to be threatened to be almost surfeited by shipments from India, and prices there are soon, it is stated, likely to be lower than in London.

So Russia at present seems to be the great point to make for Ceylon, but their stewing process in place of 5 minutes' infusion, and only one brew does not augur well for a Russian demand for strong teas from India and Ceylon. Still the Russians must be converted at any cost—Ceylon cannot do without some very large market in addition to the United Kingdom.

If in the present season Ceylon ships 55 millions and India 115 millions—not at all unlikely—to the United Kingdom, and China shipments begin to swell out again under the impulse lately given, who shall prophesy as to what prices may be a year hence! China is still the unknown quantity, and until fairly ousted from the United Kingdom (to begin with) must always remain a disturbing factor so long, of course, as thousands of unblinking blenders continue to flourish.

VALUE OF VEGETABLES AS MEDICINE.

There can be no doubt that many of the ailments we suffer from are the result of abstinence from vegetable diet, or a too great indulgence in animal food. Custom has made the potato an essential at the dinner table, but rarely do other vegetables find their way there. The following notes as to the uses of vegetables are from the *California Farmer and Dealer*:—

Spinach has a direct effect upon the kidneys.

The common dandelion, used as greens, is excellent for the same trouble.

Asparagus purges the blood.

Celery acts admirably upon the nervous system, and is a cure for rheumatism and neuralgia.

Beets and turnips are excellent appetisers.

Lettuce and cucumbers are cooling in their effect upon the system.

Onions, garlic, leeks, olives and shallots, all of which are similar, possess medical virtues of a marked character stimulating the circulatory system and the consequent increase of the saliva and the gastric juice promoting digestion.

Red onions are an excellent diuretic, and the white ones are recommended to be eaten raw as a remedy for insomnia. They are—tonic and nutritious.

A soup made from onions is regarded by the French as an excellent restorative in debility of the digestive organs.—*Mildura Cultivator*.

GARDENING: OUR REVIEWER.

FIRMINGER'S MANUAL OF GARDENING, for Bengal and Upper India,* has recently seen its fourth edition and is this time very carefully and ably revised, corrected and amplified by H. St. John Jackson, late editor of the *Indian Agriculturist*, and for several years Superintendent of the Public Gardens at Jeypore.

This is a most useful and valuable book, supplying all the information that an amateur horticulturist can wish for, and thus it certainly fulfils the intention of its author. The botanical names are also correct. The notes on the cultivation of each genera are really first-class, and it would be hard to improve them, and cultivators will be sure of success if they faithfully carry out these instructions. There is something said about nearly everything that is at all likely to do in the East, and the book is so well arranged that any information one may want is very easy to find.

Firminger's book is an old favorite with Indian residents; the plan of the book in this new issue is somewhat altered and improved. It is divided into four parts, viz., (1) the operations of gardening; (2) the vegetable garden; (3) the fruit garden; and (4) the flower garden. An appendix has been added

* Thacker, Spink & Co., Calcutta, 1890.

giving the recent introductions among flowering and ornamental-leaved plants; also new chapters are introduced dealing in considerable detail, with grass conservatories, orchid houses, fernery and propagating frames, with illustrations. The largest additions will be found in part IV., where new chapters are given on Ferns, Orchids, Mosses, Roses, Aroids, Palms and Crotons, &c. The volume consists of 662 pages; the type is clear, and the binding substantial.

The first chapter treats of Climate, Soils and Manures, and this latter subject is treated very fully, the directions about preparation of charred vegetable manure, about the mixture and due proportion of fertilizers, and the relative values of various applications are all practical, and can easily be followed and carried out. Vegetable, mineral and liquid manures are separately treated. In Chapter II. are treated the Laying out of a Garden, Lawns, Helges, Irrigation, Conservatories, Betel-Houses, Implements, Vermui, &c., &c. The information on the erection of Grass-Conservatories or Betel-Houses may have practical interest for some Colombo residents. We quote from it as follows:—

“Some time ago the happy idea occurred to Dr. Anderson that structures, somewhat similar to those in which the natives of Beugal have from time immemorial grown the Pan, or Betel plant, might be employed with advantage in the cultivation of plants that in nature exist in a climato nearly alike to that in which the Betel thrives. The attempt was made and proved a wonderful success. The structure in itself is a simple and inexpensive thing. On a piece of ground, measured out according to the space required, stout bamboos are driven at intervals, so as to stand erect about seven feet high. To these a lattice of split bamboos is attached, much in the way in which enclosures for fowls are usually made in this country. Over the whole lattice, on the sides as well as the tops, a layer of *Ooloo* grass is bound, just so thin as to allow of an equal proportion of sunlight and shade, producing a kind of subdued light. Stages are then erected, either of brickwork or wood to rest the potted plants upon, with space left for paths around or between them.

“When about to erect a grass conservatory, select a piece of ground away from the shade of large trees. Its length should, if possible, run north and south. The size will depend upon individual taste, and local circumstances and surroundings. 50 feet by 30 feet is a convenient size.”

The tat-house is, indeed, already introduced into Colombo, and ferns and sellagicellas thrive well in it; but to those who have not seen them, the hint may be useful. Most interesting are the succeeding chapters on the various ways of multiplying and propagating plants, on cutting, budding, layering, grafting, &c., &c.

On one of the operations of gardening, *i. e.*, Root-Pruning, it is remarked that the Indian practice is the reverse of the English; instead of removing the soil at some distance from the roots, they dig up close around the stem, clear away some of the small roots, and after a week or two fill in with manure and cover over again with soil. The object is to make fruit-trees healthy by keeping their roots near the surface.

Then follows next a calendar of operations for every month in the year for Vegetables, Fruits and Ornamental Plants. And then comes the Vegetable Garden. Every kind of vegetable and of fruit-tree is named, and the due treatment of each is given.

The remaining portion of the book is devoted to the Flower Garden, including Ornamental Annuals, Ornamental Trees, Shrubs and Herbaceous Perennials, a very full list, and the directions for the cultivation of each are complete.

CINCHONA IN UVA is fast becoming a thing of the past, and although the young clearings on Canaveral's afford a picture of robust health, yet the laird now looks forward to the day when tea may take the place of cinchona. Mr. Macfarlane, on the whole, has been, we suppose, the most successful grower of cinchona in Ceylon on a considerable scale.

NOTES ON POPULAR SCIENCE.

By DR. J. E. TAYLOR, F. L. S., F. G. S. &c.,

EDITOR OF “SCIENCE GOSSIP.”

An American professor of agriculture, Professor Atwater, has just published the result of a series of experiments concerning the proportion of NITROGEN taken up by PLANTS. He showed that with nitrogenous fertilisers the proportion of nitrogen in the produce, both stalk and seeds of crops, was notably larger than in similar produce where no nitrogenous fertiliser was used. Comparing American with European crops, Professor Atwater demonstrated that in respect to their relative richness in nitrogen the crops from the liberally fertilised soils of Europe yielded considerably more than the same crops in America. From this it appears that nitrogenous fertilisers vary and increase the food value of feeding crops without increasing the yield in weight.

Professor Bruckner, a Swiss artist of Berne, has recently called attention to the existence of CLIMATOLOGICAL PERIOD OF ABOUT 35 YEARS FOR THE ENTIRE GLOBE. These periods are, of course, more marked in the interior of continents. The years 1700, 1740, 1780, 1815, 1850, and 1880 appear as cold, wet periods; whilst the years 1720, 1760, 1795, 1830, and 1860 were warm and dry universal periods. During the warm periods, the passage of oceanic air to the continents has been hindered, and during the cold periods it has been favoured, increased rainfall taking place in the latter case.

PAPER PULP is one of those things a good many inventors think of. It promises to lend itself (like a professional politician) to anything—from cellulose or artificial ivory knife and fork handles and billiard balls to railway waggon tires and rails. It is a carbonaceous raw material cut of which a good deal can be made—a kind of manufacturing protoplasm in short. I refer to this fact because of a paragraph, which appeared in a French technological journal last week, announcing that a certain French manufactory is now bleaching paper pulp by ozone. The latter is a powerful bleaching agent, as many Lancashire and Yorkshire bleachers know. In the French manufactory, it is stated the ozone is prepared by passing electrical discharges through oxygen, whilst the paper pulp is passed continuously through a chamber containing it. This process is said to be far more rapid than that by chlorine (hitherto the latter has been chiefly used in our Lancashire bleach-works), and far more convenient. Moreover, the ozone does not attack the cellulose itself, as is almost necessarily the case with the chlorine process. It only abstracts the native or raw colouring matter. This new process will probably startle our Lancashire and Yorkshire bleachers.—*Australasian*.

RIO JANEIRO.—The Vicomte de Saint Leger has just established in Rio a company under the title of the Companhia Floricultora Brasileira, for the purpose of providing amateurs with Orchids and other plants. The capital is 500,000,000 reis, or 1,250,000 fraucas = £50,000.—*Gardeners' Chronicle*.

CEMENT.—Professor Alex. Winchell claims to have a cement that will stick on anything. The recipe is as follows:—Take two ounces of clear gum arabic, one and a half ounce of fine starch, and half an ounce of white sugar. Pulverise the gum arabic and dissolve it in as much water as the laudress would use for the quantity of starch indicated. Dissolve the starch and sugar in the gum solution. Then cook the mixture in a vessel suspended in boiling water, until the starch becomes clear. The cement should be as thick as tar, and kept so. It can be kept from spoiling by dropping in a lump of gum camphor, or a little oil of cloves or sassafras. This cement is very strong indeed, and will stick perfectly to glazed surfaces, and is good to repair broken rocks, minerals, or fossils.—*Indiarubber Journal*.

"NATIVE GUANO"

is one of the manures competing for public favour in our market. Messrs. W. H. Davies & Co. advertise it as

A safe and Reliable Fertilizer for Tea, Coffee, Coconut Trees, Potatoes and Kitchen Garden Produce, Grape Vines, Fruit Trees, Tomatoes, Roses, Lawns, Chrysanthemums, Pot Plants, &c.

and from a pamphlet of testimonials by British farmers, orchardists and gardeners which has reached us from the firm named, it seems fully to deserve this character. It is prepared from sewage by the Native Guano Company, Limited, London, Kingston-on-Thames and Aylesbury. In the English pamphlet sent to us by Messrs. W. H. Davies & Co. for notice, we observe that the

Price at the works at Kingston, (Surrey), or Aylesbury, (Bucks), is £3 10s per ton, in 2 cwt. bags. Orders not exceeding 10 cwt. are charged at the rate of £4 per ton. Carriage paid within 100 miles of Works on Cash orders of 2 tons and upwards. A single cwt. Sample bag sent, carriage paid, to any Railway Station in England on receipt of Postal Order for 5s.

Even allowing for the depreciation of the rupee, the local price of R110 per ton, delivered at the railway station, Colombo, seems high, especially in view of the fact that ground bones and white castor cake can be obtained for as nearly as possible half the money. The justification of the high price must be sought for in the greater richness of the Native Guano in active fertilizing qualities. We find Dr. C. Mynott Tidy and Professor Dewar reporting on the substance thus:—

"The percentage of combined nitrogen in the manure is consequently remarkably constant, and amounts to an average of 3.8 per cent reckoned as ammonia in the perfectly dry manure, or if with 20 per cent of water to 3 per cent of available ammonia."

The analysts add:—

"As the phosphoric acid is also an important ingredient from a manurial point of view, it was estimated in four samples of the manure taken from different parts of the heap, an average of 5.0 per cent reckoned as tricalcic phosphate of lime being found. As to the manurial value of the Native Guano, we are strongly of opinion that this must be judged rather by the practical results of the agriculturist than by presumed theoretical values based on analytical data, and on the price of ingredient not necessarily in the same physical or chemical condition. Our research tends to show that very small changes brought about in soils may have very important indirect effects."

The Company themselves state:—

"The Guano is dry, lustrous, and its fertilizing properties are great. It contains nitrogenous matter as well as phosphates, alkaline salts, saponaceous compounds, &c., and has a combination of manurial elements in such proportions as suits the crops, and produces satisfactory results, fully bearing out the following opinions of Baron Liebig:—

"In the solid and liquid excrements of men and animals, we restore to our fields the ashes of the plants which served to nourish those animals."—*Liebig's Chemistry of Agriculture and Physiology, Page 126, 4th Edition.*"

"It is of great importance for agriculture to know with certainty that the supply of ammonia is unnecessary for most of our cultivated plants, and that it may be even superfluous, if only the soil contains a sufficient supply of mineral food of the plants when the ammonia required for their development will be furnished by the atmosphere. It is also important to know that the rule usually adopted in France and in Germany of estimating the value of a manure according to the amount of its nitrogen is quite fallacious, and that its value does not stand in proportion to its nitrogen."—*Liebig's Chemistry of Agriculture and Physiology, Page 212, 4th Edition.*"

We are, therefore, led to infer that the value of the manure is not to be judged by the proportions of nitrogen and phosphoric acid shown by analysis (potash is not separately specified) but by the general combination of manurial elements and their potent action, on soils and on plant growth. Appeal is made to the long list of testimonials received as to the results obtained by those who tried the manure on widely varying products, such as cereals, roots, fruits and flowers; and certainly a large proportion of the testimony is unqualified as to the valuable effects of the preparation. It not only promotes the growth of vegetation and the formation of fruit, grain and roots, but it is described as "an effectual remedy for fly, slug, wireworm and garden pests." It may be applied advantageously to wet soil, as liquid manure, or with its own bulk of fine earth. So applied, its effects were as follows:—"Only a cottager," having by its aid obtained very good potatoes, good onions and splendid turnips, describes it as a very cheap and durable manure. A gardener testified:—

Used for cucumbers, melons, tomatoes, vegetables and pot plants in general. Results: very good. Tomatoes, cucumbers, celery grown entirely without any other manure have turned out excellent. I added about 1 lb. of Guano to 1 bushel of pure loam for tomatoes, and top dressed them afterwards at intervals of a fortnight with a fair sprinkling of Guano mixed with fine soil. The result was an enormous crop; quite surprised many gardeners in this neighbourhood. Another:—

Used for cauliflowers, spring cabbage, carrots, radishes, onions, Brussels sprouts, and vegetables generally, also for flowers. Results: very good and satisfactory. I have had this garden 10 years, but never had such crops before. My neighbours speak well of it.

Another reports splendid crops and that the guano produces much finer crops than those grown with stable manure. To quote again:—

I have only used your manure for pot plants at present, and, so far, I am in every way satisfied with it. I use it mixed with the potting soil, and in liquid form for watering. In this it has a great advantage in settling quickly, enabling one to use it as soon as mixed. I have used other manures, but never had such results as from this.

Finally a Scotch testimonial:—

The Native Guano was used here for turnips, the field being dressed with farm yard dung in the autumn and ploughed in the spring. Part of the field was sown in the drill with Native Guano at the rate of 10 cwt per acre, costing £1 per ton, and part of it sown in the same manner with other Guano at the rate of five cwt. per acre, costing £10 10s a ton. The turnips on the ground dressed with Native Guano being a better crop than that done with the other Guano, considers the Native Guano a very useful manure for all kinds of farm crops. The soil here heavy coarse clay.

Messrs. W. H. Davies & Co., tell us they are supplying the Native Guano for tea and cacao as well as for garden produce; and we presume the results have been satisfactory. For estate purposes as well as for fruit orchards, vegetable gardens and grass lawns and pasturage, the substance certainly deserves a trial. To facilitate this, Messrs. W. H. Davies & Co. indicate that they supply sample casks containing about 100 lb. at R10 each. Meantime it would be interesting and useful to have the testimony of those who may already have tried the Native Guano (native to Britain), because in such reports there may be encouragement not only for the use of the manure imported and sold by Messrs. W. H. Davies & Co., but for the ultimate formation of a local company to prepare really native guano from the sewage of Colombo and our other larger towns. The Chinese are far before more civilized races in their careful conservation

of manurial matter and its return to the soil. The difficulty is to retain manurial matter in an active condition and yet inodorous, and in this respect the Native Guano Company seem to have been successful.

CULTIVATION OF INDIARUBBER.

In *Nature* of January 15, in a note on p. 355, a statement is quoted, to the effect that some few attempts have been made to cultivate indiarubber, but as yet not very successfully. As, however, there are extensive flourishing plantations of *Ficus elastica* in Assam, a short account of their origin and present condition may prove interesting.

After some preliminary experiments on a small scale, the Government of Assam in 1873 determined to plant caoutchouc in the Charduar Forest at the foot of the Himalayas, north of Tezpur. Mr. Gustav Mann, the Conservator of Forests, gave me the necessary instructions to start the work in November of that year, and I remained in charge of the plantation till September 1875. The Charduar Forest has an essentially damp climate, the average rainfall at the caoutchouc plantation having been 94.65 inches during the years 1878-85, and during 1886-89, the annual rainfall was distributed as follows:—

Winter Rainfall.	1886-87.	1887-88	1888-89
November till March...Inches	4.87	7.38	4.78
Summer Rainfall	1886.	1887.	1888.
April till October... „	99.30	71.55	82.39
Total ... „	104.17	78.93	87.17

Data for the temperature of the Charduar Forest are not available, but the following average figures for ten years, for Sibsagar, which lies to the south-east of Tezpur, across the Brahmaputra River, will give sufficiently approximate results:—

Average annual temperature	73°.4 F.
Average monthly for January (lowest)...	59° 0 F.
Average monthly for July (highest) ...	83° 7 F.

The absolute maximum and minimum temperatures for Sibsagar are not given in the meteorological tables from which the above figures are taken, but quoting from memory, they are for Tezpur about 95° and 42° respectively.

The relative humidity for Sibsagar averages 83 per cent., being lowest in March, 79 per cent., and highest in January, September, and December, at 85 per cent. It is certainly not less than this in the Charduar Forest, where the moist hot atmosphere in the summer months resembles that of a forcing house. The Charduar Forest contains a vast number of woody species, both evergreen and deciduous, but chiefly the former, nearly pure woods of *Mesua ferrea* and *Altingia excelsa* prevail in the higher parts of the forest, and the undergrowth consists of dwarf palms, small bamboos, and evergreen shrubs, *Coffea bengalensis* being abundant in places, whilst cane palms are found in the damper parts of the forest, and festoon the trees in company with other huge climbers. A few enormous old rubber-trees are disseminated here and there throughout the forest. *Ficus elastica* has here been measured 129 feet high, with a girth around the principal aerial roots of 138 feet, whilst the girth of its crown was 611 feet.

A rubber-trees cannot stand shade, and the seedlings damp off unless fully exposed to light and well drained, the natural reproduction of *Ficus elastica* generally takes place in the forks of stag-headed or lightly foliated trees high up in the crown, where seeds are left by birds; and from such a site the aerial roots in process of time descend to the ground, and develop into a vast hollow cylinder around the foster stem, which is speedily inclosed and completely killed by the vigorous crown of the epiphyte, which eventually replaces it in the forest. In its epiphytic growth, the aerial roots of *Ficus elastica* may take several years to reach the ground, but, once well rooted, nothing can probably surpass it in its native habitat for rapidity of growth and vigour.

As, owing to the above mode of growth, rubber trees are so sparsely scattered in the Assam forests, and it is therefore extremely difficult to protect them from being tapped in a wasteful manner, the plan of concentrating them in artificial plantations, as proposed to the Government by Mr. Mann, was carried out as follows:—

At first, attempts were made to propagate by cuttings, which struck readily, but it was soon discovered that rubber-seed germinates freely on well-drained beds covered with powdered charcoal or brick-dust, and that the seedlings, though at first small as cress, grew rapidly, and became about 2 feet high in twelve months, and were much hardier against drought than plants produced from cuttings. The base of the stem of the seedlings swells out like a carrot, and this fact, no doubt, enables them to tide through the dry season in safety, for, in spite of the humidity of the air, the nearly constant sunshine from November till March is trying to young plants.

In order to imitate nature as much as possible, some strong seedling rubber-plants were placed in the forks of trees in 1874, and by 1885 only a few of them had reached the ground and were growing most vigorously.

As this method, though much more economical than planting on the ground, gave such slow results, and it was found easy to produce plants in any quantity from seed, large nurseries were formed, in which the plants are now retained until they are 10 feet high, as smaller plants were browsed down by deer when planted out in the forest. The planting lines are cleared to a breadth of 40 feet in strips, separated by alternating strips of untouched forest 60 feet wide.

It was found that the rubber-plants did not get sufficient light with lines less than 40 feet broad, whilst the strips of forest kept the soil and atmosphere moist, and afforded side shelter to the plants, forcing them to grow upwards, instead of branching out near the ground. As this method involves considerable expense in clearing the lines, and wastes the wood, which is frequently unsaleable, Colonel, now General Keatinge, the Chief Commissioner of Assam, in 1874, directed that plantations of *Ficus elastica* should also be made in grass-land near Tezpur. It has been, however, found that large rubber-trees in Tezpur, when tapped, yield scarcely any rubber, the difference between them and the rubber-trees of the Charduar Forest being probably due to the greater dampness of the atmosphere and soil in the latter locality, as compared with the Brahmaputra Valley.

An area only of 8 acres was therefore planted out near Tezpur, whilst the area of the Charduar plantation in 1889, was 1,106 acres, and contained 16,054 plants, besides large nurseries with 84,000 seedlings.

Local Governments in India, which have to find funds for all sorts of administrative purposes, are naturally inclined to economize, and Sir Charles Elliot, when Chief Commissioner of Assam, about ten years ago, proposed to stop further work on the Charduar plantation, but this was vigorously opposed by Dr. Schlich, the Inspector-General of Forests, and at his advice, the Government of India directed the further extension of the plantation. Apparently, however, little progress was made between 1881 and 1888, when an additional area of 63 acres was planted up. Regarding the growth of the plants, the following figures, taken from Mr. Mann's report on the Assam forest administration for 1888-89, give the average height and girth, up to April 1889, of 50 trees in each year's planting:—

Year when planted.	Average.		Growth since last year.	
	Height. ft. in.	Girth. ft. in.	Height. ft. in.	Girth. ft. in.
1874-75	61 11	11 5	6 1	0 9
1875-76	57 6	7 10	5 2	0 6
1876-77	55 10	7 5	3 7	0 6
1877-78	53 9	5 11	5 3	0 7
1878-79	46 2	4 6	4 0	0 5
1879-80	44 10	5 2	5 9	1 2
1880-81	38 7	4 2	6 7	0 8

Thus, we see that the present average annual growth in height and girth, taken from 350 plants, are respectively 5 feet 2 inches and 8 inches.

In the small Tezpur plantation, where there are now 794 plants, all of 1874, the average height and girth are 47 feet 3 inches and 10 feet 10 inches respectively, the average growth in one year being 4 feet 4 inches in height.

The up-keep of the plantation consists chiefly in clearing the lines round the plants, but four years after planting the undergrowth is well kept down by the shade of the rubber-trees.

Experimental tappings were made in 1883 and 1884 on 50 natural grown rubber-trees in the Charduar Forest, the total yield being 438 pounds in 1883, and 206 pounds in 1884, giving an average yearly yield of 6½ pounds per tree. Further information regarding the yield of rubber from trees in the Assam forests would doubtless be procurable from the Assam Forest Office, as well as statistics of the cost of the plantations, which are not given in the papers at present before me.

W. R. FISHER.

—*Nature*. Cooper's Hill College, February 18.

COTTON AT WATTEGAMA.

Sir,—I was interested in your article appearing in this morning's paper on the cotton enterprise.

I have recently had the pleasure of visiting Captain Gwatkin's Estate at Wattegama where he has planted over 200 acres of cotton, meant principally as shade for cocoa. Most of this cotton is from New Orleans seed with a sprinkling of Sea Island. The greater part was planted towards the end of September last, and during the month of February 19,000 lb. of seed cotton was taken from the trees, worth about 7 cents per lb. Picking was continued this month at about the same rate until the rains came, when the plants began to throw out leaves and fresh blossom.

If the rain will now cease there must be another heavy crop during April and May, and probably a heavier crop after the S. W. Monsoon. This cotton has had the advantage of land thoroughly cleaned and kept weeded. Captain Gwatkin has done everything thoroughly well, and he will be well repaid. He has a large-sized double acting knife roller gin with engine, and is doing his own ginning. The Spinning and Weaving Co. has bought the whole crop, and the seed is being sold in the district for R3 per cwt.

The cotton is beautifully clean and free from stains; and is in every way a credit to the grower and the district.

I am sure European Planters would find it worth while to grow cotton for shade. It grows very quickly and gives quick returns.

For natives it ought to be very suitable, but for them I should recommend the Kidney kind if seed could be obtained. It will grow almost anywhere, is hardy, bears well, and is perennial. The Spinning and Weaving Co. can buy all clean cotton grown either from America, Kidney or Egyptian seed. The Sea Island kind is too long in the staple for our use, and unless specially fine and regular in length and colour does not sell well in England.

Yours faithfully,

Celombo, March 18th 1891.

H. ATKINSON.

—*Local "Independent."*

LONGEVITY OF TEA.—It is interesting to be reminded that Chinese tea "crofters" or gardeners regard their tea bushes even when a hundred years old or over, as still far from being beyond bearing. Many of them say that tea never requires renewal but will go on, like Tennyson's brook, "for ever."

TEA IN UVA.—A Dimbula planter who has been visiting Uva is loud in praise of the splendid growth of tea and especially the fine widespread bushes he saw in Haputale and Badulla districts. The plucking surface on individual bushes will, he thinks, be much larger in Uva as a rule than elsewhere in Ceylon.

STRUCTURE AS A GUIDE TO CULTIVATORS OF PALMS.

We have been favoured with a note on the structure of Palms in relation to their cultural requirements, which originally appeared in the *Bulletin della R. Societa Toscana di Orticultura*, and which is amply worth bringing before our readers:

"Italy is one among the few States of Europe which, by virtue of its climatic conditions, has been able to extend hospitality to a very considerable number of species of that princely family—the Palm. With the dwarf indigeous form (*Chamaerops humilis*, L.), there has been associated for centuries the majestic *Phoenix dactylifera*, L., but it is only during the last decade that, through the general march of horticulture and the special efforts of enthusiastic amateurs, about 40 species have been successfully introduced into those localities specially favoured by nature with mildness of climate. The Italian horticulturist cannot find greater satisfaction than in carefully and intelligently studying the requirements of this plant, in order that he may treat them in a suitable manner. Let us begin by observing the Date-palm (*Phoenix dactylifera*, L.). A well-known Arab saying gives briefly the requirements for Date-palm culture in the words, 'Feet in the water, the head in the fire.'

"If we substitute sunshine for fire, we may, to be consistent, render water as moist soil, especially since this Palm is certainly no aquatic plant, but, on the contrary, suffers from excess of moisture at the root, unless the soil be naturally porous and sandy. From this we might proceed to argue that a moist soil is indispensable to the life of the Date Palm, but this conclusion is far from being in accordance with our knowledge of the facts. We find rather in the *Phoenix dactylifera*, as in many other plants long acclimatised, a capacity to adapt itself to diverse circumstances, in which it may have been forced to live, provided only that the temperature permit (minimum 25° to 20° Fahr., i.e., 6° to 7° frost) modifying its structure according to the local conditions. Examining the structure of its leaves, we find that these are in every part so constructed as to receive, hold, and conduct to the stem the atmospheric moisture which falls upon them in the form of dew or rain. In fact, it may be observed that every leaflet adhering to the rachis is moulded to the form of a V-shaped channel, in which a film of dew, however thin, concentrates itself in drops, which, arriving at the base of the leaflet (furnished with a gland probably able to absorb a minute quantity of water) find their way down the leaf to the trunk. The leaf itself is provided with shallow flutings, both upon its upper and its lower surfaces, by which more or less quickly (according to the inclination) they again discharge themselves upon the trunk. The dense fibrous coat which clothes the stem is designed for three distinct functions, viz., to defend the young leaves against inclemency of the weather; to shield the trunk not yet arrived at the indurated stage from bruises; and finally to absorb and retain the water received from the leaves to the furtherance of vegetation throughout the plant.

"A phenomenon most deserving of attention on dewy mornings is the appearance of sparkling drops chasing one another down the leaves towards the centre of the plant, so that the thick web upon the trunk becomes perfectly saturated with moisture, whereas the bark of other trees remains almost completely dry. This faculty of appropriation of moisture from the air explains why the Date Palm—which might be called a 'dew-funnel'—can grow in places deficient in water, so far as the soil is concerned. The inner layer of fibre becomes rotten, little by little, owing to the presence of the water introduced by the leaves, becoming thus reduced to vegetable mould, which is kept in its place by the exterior web or fibres yet remaining intact, and also, indeed, by the dried leaves which hang from the stem. To this mould, formed out of the fibre of the plant itself,

is added sand carried by the wind. By means of this atmospheric agency and that of birds, seeds of small plants are very often introduced, which, by growing as well as possible, under the circumstances, increase the bulk of earth around the trunk.

"In time of drought, the Palm, not deriving sufficient nourishment from its terrestrial roots, will put forth aerial ones numerous enough to sustain itself with the assistance of this humus and the nightly dews.

"Glancing now at the other kinds of Palm, *e.g.*, genus *Cocos*, we find very different—I may say entirely opposite—characteristics. In these everything indicates their absolute dependence upon the soil in which they live. In truth, their leaflets and their rachides instead of being conduit-shaped, V, as in *Phoenix dactylifera*, are the very reverse—convex, or fashioned like a roofing tile, A, in such a manner that rainwater and dew fall from them to the ground. The sparse fibrous material at the base of these leaves evidently serves only for resistance or the defence of the leaves against impetuous winds. Furthermore their stems are not capable of putting forth aerial roots, as is the case with the Date Palm."—L. WINTER, *Bordighera*.—*Gardeners' Chronicle*.

TEA AND COFFEE SUBSTITUTES.

(Continued from page 674).

CAPRIFOLIACEÆ.

40. *Triosteum perfoliatum*, L.—An herbaceous plant of North America, where it is known as wild coffee, fever root, or wild *Ipecacuanha*. The hard seeds when roasted and ground are said to be a good substitute for coffee.

41. *Viburnum dilatatum*, Thunb.—This plant was first noticed as the source of a peculiar kind of tea in a report in 1885 by Mr. Alexander Hosie, of a journey through Central *Tsu-ch'uan*. It was noticed in a communication by myself to the *Gardeners' Chronicle* for September 26, 1885, p. 402, and to make these notes more complete, I reproduce it here. Referring to the discovery of this tea by Mr. Baber, Mr. Hsie says, "If my memory is not at fault, he (Mr. Baber) was regaled by a priest on Mount O-mei, with tea possessing both the flavour of milk and sugar. It may have been in the very Temple on the mountain's side, in which I am now writing, that Mr. Baber was agreeably surprised. At any rate, I am sipping an infusion, which is, without doubt, sweet, and which is declared by the priest to be brewed from a naturally-prepared tea-leaf. It is a large dark-brown leaf, and is very sweet when chewed. The people at the bottom of the mountain, whom I first questioned regarding this tea, asserted that the leaves were sweet because they were first steeped in molasses; but the balances of evidence, as I have since found from extensive enquiry, is against such artificial preparation. The tree is said to grow in only one gorge on the mountain, whence the leaves are brought for sale." We are indebted to Mr. Hsie for a sample of this tea, which consists of the entire leaf rolled up loosely into little balls, and almost black in colour. Upon chewing a portion of a leaf, it was found to be decidedly sweet, with a strong suspicion of liquorice rather than molasses, as stated by Mr. Hsie. Upon soaking the leaves and flattening them out, they were found to be those of *Viburnum dilatatum*, Thunb. To prove that the leaves of this plant possessed no natural sweetness, we obtained a few leaves from a growing plant and dried them, and found that neither in their fresh, and still less in their dried state, have they any marked flavour. Moreover, the leaves of the Mount O-mei Tea are transparent, as if they had been steeped in some solution, while those which I gathered and dried are opaque, and yet retain their green colour. It seems certain, then, that this singular tea owes its sweetness to some foreign substance, as stated by "the people at the bottom of the mountain, and that substance may be molasses, but is in all probability liquorice."

RUBIACEÆ.

42. *Oxyanthus Gerrardii*, Loud.—Under the name of Wild Coffee from Natal, there are some fruits of this plant in the Kew Museum. These fruits are about the size of a Coffee berry, and contain about six hard brown seeds, somewhat resembling in size and appearance a small shrivelled sweat Pea. They are, however, horny, like the true coffee, and upon roasting give off a burnt-like odour; this, however, might be more fragrant if carefully done in a closed and revolving vessel, and considering that the plant is a near ally to the true coffee, it might perhaps be made a useful substitute.

43. *Diplospora Sphærocarpa*, Datz.—A small Indian tree of the Western Peninsula or the Western Ghats, from Bombay southward. It seems to be known as Jungle Coffee in Ootacamund, and the fruits, which in shape and size are like a coffee berry, contains a number of small seeds, which upon roasting develop a strong aroma like coffee, and when ground can scarcely be distinguished from genuine coffee. Samples of fruits and the prepared coffee are shown in the Kew Museum.—JOHN R. JACKSON, Museum, Kew.—*Gardeners' Chronicle*.

OUR LABOUR SUPPLY.—We confess to greater anxiety than we felt at the opening of the year as to a sufficient supply of labour for our growing tea industry. The news of distress in Southern India made us then feel sure that Ceylon would be favoured with a large influx of coolies and that the usual flow back would be very much diminished. But the very latest return, that up to the end of February last, shows no fewer than 10,007 departures against only 6545 arrivals, and from different planting districts come complaints of "crimping," unsettlement of Kangnies, &c., sure signs of labour being in keen request. One explanation given of coolies not coming to Ceylon so freely as was expected is that they are now leaving Southern India for other countries—Burma, The Straits, West Indies &c.—far more freely than they used to do. This is a point on which the Planters' Association might well make enquiry.

TEA TRANSPORT AND FINAL TEA PREPARATION NEAR COLOMBO.—Our planting "Visitor" propounded an idea in his letter [see page 725] which is enough to frighten Mr. Pearce out of his propriety,—to make

—each particular hair to stand on end,

Like quills upon the fretful porcupine!

It is nothing less than that the carriage by rail up-country of tea-boxes, hoop-iron, lead-lining, and all the et ceteras, including a great deal of machinery, should be dispensed with! [What would become of the railway revenue then?] And that tea in a semi-prepared state should be forwarded in air-tight bags to the vicinity of Colombo—some of our stores, at any rate, are supposed to be too much under the influence of sea air—and there finally prepared with a refining and then packed in the boxes for despatch to England. Thousands of men, women and children in the Colombo district, would rejoice in the revival of a Preparing and Packing Industry of this kind, and the division of labour might no doubt, be a great relief to harassed estate managers upcountry, especially at a time when labour is by no means too plentiful. But we much fear the realization of "Visitor's" thought, is still far off. An experiment to some extent in sending down tea leaf by rail to a Colombo store has been tried, but with results not encouraging to any extension of the business. The case might be different with partially prepared tea in air-tight bags, and at any rate there can be no harm in making a trial, *malgré* the General Manager!

Correspondence.

To the Editor.

COFFEE FREE FROM DISEASE: SHOULD SEED BE GOT FOR CEYLON?

Sydney, New South Wales, March 2.

DEAR SIR,—I have just read a paragraph in your *Overland Observer* of 5th Feb. on the "Revival of Coffee" (in Ceylon); and thinking it might be of value to those about to plant coffee again and knowing the interest you take in such matters, I venture to state that I have seen in my travels since I left Ceylon, twelve months ago, fine healthy Liberian coffee trees, untopped and bearing a large crop, grown in a country absolutely free from leaf disease. I have as well seen *Coffea arabica*, where there is no disease of any kind, *Hemileia vastatrix* included, and I would be obliged if you would let me know if seed from such trees would be required in Ceylon, as I can, I believe procure some; at the same time would be glad to know the best means of packing the seed as they would be perhaps five weeks in transit.—Yours faithfully,

O. P. ATKINSON.

[As Mr. Atkinson is returning to Ceylon in April, there can certainly be no harm in his bringing some of the coffee seed he refers to—though we should not recommend his investing in much. It should be packed in charcoal. Seed from coffee trees free of disease—Mocha and Liberian—was freely imported into Ceylon in the "seventies," by Capt. Bayley among others; but the resulting plants were at once covered with *Hemileia vastatrix*.—Ed. T.A.]

INDIAN TEA EXPORTS.

Indian Tea Association, Calcutta, March 10th.

DEAR SIR,—The General Committee have the pleasure to hand you their usual Monthly Return of shipments of tea from Calcutta, and also a Return of Exports of Ceylon Tea for four years up to the 23rd February 1891:—

EXPORTS OF INDIAN TEA FROM CALCUTTA.

	1891 lb.	1890 lb.	1889 lb.
Exports to Great Britain in Feb. ...	3,983,534	5,833,908	4,433,555
Exports to Great Britain from 1st May to 28th Feb. ...	96,944,877	94,963,710	91,260,140
Exports to Australia and New Zealand in Feb. ...	203,47	177,049	105,765
Exports to Australia and New Zealand from 1st May to 28th Feb. ...	4,543,267	3,382,011	2,556,538
Exports to America in Feb. ...	13,152	212	12,375
Exports to America from 1st May to 28th Feb. ...	131,662	164,697	155,784
Exports to other places in Feb. ...	113,511	62,034	97,256
Exports to other places from 1st May to 28th Feb. ...	1,081,278	1,392,004	854,978
Total Exports from 1st May to 28th Feb. ...	102,709,829	99,902,422	95,127,440

—Yours faithfully, S. E. J. CLARKE, Secretary.

SALT FOR AGRICULTURAL PURPOSES: IN COCONUT CULTIVATION ESPECIALLY.

Veyangoda, March 12th.

DEAR SIR,—I mean this to be an appeal to the daily newspaper to help me to secure for the agriculturist salt on special terms. I may mention at the outset that I am not personally interested in the subject. My interest in it is indirect. My objects are (1) to benefit Agriculture; (2) the revenue.

Before I proceed to discuss the subject, it is necessary to say that it was discussed *ad nauseam* about a couple of years ago, when I started it. The then Governor or his advisers did not seem inclined to make the concession prayed for. My reviving it so soon after will, I trust, be looked upon as a measure of my earnestness on the subject, of my belief, by the light of experience and observation, of its very great value in agriculture under certain circumstances, and of my determination to do what I can to obtain the concession from the Government.

Of the value of salt in agriculture there are no two questions. On its value in coconut cultivation it would be absurd to dilate. But I am forced to it, as those who joined in the discussion when I started it before, taking their stand on works on Agricultural Chemistry which treat chiefly on the cultivation of roots, grasses and cereals in European countries, argued that as these state that the small quantity of salt discovered in the ashes of plants is invariably conveyed to the soil by natural agencies, therefore it is absurd to say that, in our little island, swept as it is by both monsoons, there can be an insufficiency of salt in the soil, and this argument is extended to inland districts under coconut cultivation, where, it is contended, it is not necessary to supply salt by artificial means! Arguments such as these can be used only by those who blindly follow the dicta of science, without adapting them to varying circumstances.

As we all know, the home of the coconut palm is where the "sad sea waves" break at its very roots. Without entering on the vexed question as to whether the East or the West is the original home of the palm, I may state, what everyone will accede to, that the natural home of the plant is by the sea shore, and that its extension to uninhabited coasts was by the agency of waves and currents. Its cultivation inland was the work of man.

Let us now examine the natural conditions under which the palm grows and aye, flourishes. It grows on a perfectly free soil through which the roots roam unrestricted in search of food and water; (2) in situation where the downward roots have a perennial supply of water; (3) in a soil impregnated with salt; and (4) in an atmosphere saturated with saline spray. Now we all know, or at least ought to know, that in cultivating a plant or tree we ought, as far as lies in our power, to conform in everything to the natural conditions under which it grows, if we wish to cultivate it successfully. Of course, it is not always possible to conform in every particular with its natural requirements; but the process by which trees or plants adapt themselves to their surroundings is a slow one and by no means violent. In process of time a tree can be made to grow under conditions which to it are unnatural, but not all at once.

When the cultivation of coconuts was first undertaken in this island, it was on the seashore. It was gradually extended inland, but on the seaboard where the four natural conditions I enumerated existed, though in a modified degree, but where the soil being chiefly alluvial was far richer than on the almost pure sand of the sea-shore. As the low-lying lands on the seaboard became exhausted, the cultivation was carried further and further inland, till at the present time coconuts are cultivated under conditions which do not conform in any one particular with the natural conditions under which it grows. It is cultivated in stiff clays, gravels and cabooks, where water is seldom or never within reach of the downward roots, and where neither the soil nor the atmosphere is largely charged with salt.

That the coconut tree resents the gross violation of its requirements, all will agree who will intelligently compare trees as they grow, say in Colombo, and as they are grown even in the most highly favoured districts inland. For a comparison to be of any value, it must be made between trees growing on soil of equal richness. But if it be made between trees growing on rich and poor soils, and if it be in favour of the latter, then we may well stay to inquire the reason why. I think it will be admitted on all sides that the soil of the Cinnamon Gardens at Colombo is about the poorest, if not the poorest, to be met with

in the neighbourhood. It is what is described as a hungry soil, is very poor in organic matter, and owing to its composition has very little retentive or capillary powers. And in many parts of the Cinnamon Gardens a layer of hard sandstone underlies the sand at a few feet depth, and has to be broken through to make holes for plants to be put down. A comparison between trees growing on such a soil, with those growing generally in the most highly favoured of inland districts, will therefore be a crucial one. I have a tolerable acquaintance with the inland districts where coconuts grow, and I think have visited all, if not nearly all, the crack estates. As a result of very close and careful observation, I unhesitatingly say that, taken as a whole, the trees in the Cinnamon Gardens are, for habits of growth and productiveness, superior to those in the best inland districts I have visited.

It will be useful to enquire into the reason for this, but the results will be purely inferential, for unfortunately I cannot lay claim to any but the most rudimentary acquaintance with the principles of Agricultural Chemistry. But I do lay claim to the close observation which I have brought to bear on a tolerable knowledge of practical agriculture. To be concise; I think the reason for this is to be found in the fact that in the Cinnamon Gardens, an exact counterpart of two of the natural conditions under which coconuts grow is to be met within a free soil and easy access of the roots to water, while the atmosphere and soil of the Cinnamon Gardens can never be wholly devoid of salt, and in the S.-W. monsoon months must be charged with it. This is the inference I draw from a comparison of the growth and habits of the trees in the poor sandy soil of the Cinnamon Gardens with those grown in the rich, and in some instances, alluvial soil inland.

Abundance of moisture plays an important part in the economy of the coconut palm. The palm is a huge pumping machine for sending up water for the formation and development of its nuts. An examination of the roots will show how admirably adapted they are for this purpose. The trunk too is a soft spongy mass reeking with moisture. An examination of the fronds and their disposition will show that nature intended them to act as so many ducts to catch and carry rain water down the stem to the roots. It ought, therefore, to be the aim of the skilful agriculturist, whenever coconuts are grown in situations where moisture does not abound, to aid nature to obtain the necessary moisture.

As I said more than once before, the habits of trees grown in the inland districts are quite different from those growing on the seashore. The most noticeable is their inability to support their bunches of fruits without artificial aid. Props to support bunches are the exception on the seashore, but the rule inland. Bunches, however small they may be, invariably snap at the stem if not propped up when the nuts are a few months old. This till the trees arrive at maturity at 20 years of age and over. What is the reason for this? I hazarded the guess that it may be owing to a deficiency of silica, for that constituent is necessary to stiffen all forms of vegetation. Against this has been triumphantly quoted recent experiments of cereals grown in soils devoid of silica and yet having their stems stiff. I cannot see how these experiments affect the question at issue. In the same way that earthy matter imparts to bones their hardness, so does silica to vegetable matter. It toughens and strengthens vegetable tissues, and remember the strain the stem of a coconut bunch has to bear is infinitely more, proportionately, than that of the stem of cereals. A young coconut weighs from 10 to 15 lb. and bunches with 10 to 20 nuts are not exceptional. A simple sum in multiplication will at once give us an idea of the weight the stem of a bunch has to support. I will not anticipate what I will say hereafter by mentioning how the supply of silica can be increased. Another bad habit of coconut trees grown inland, is their inability to support their fronds as soon as dry weather sets in. This may be due as much to deficiency of silica, as it undoubtedly is to an insufficiency of moisture, to the

balance between evaporation at the leaves and absorption at the roots being disturbed. At this season of the year, the drooping of branches and the dropping of nuts inland is usual. An old Sinhalese man lately mentioned to me, as proof of the severity of the drought recently on the seashore, the dropping of nuts from old trees, a circumstance not within his experience previously. This is not uncommon inland, and is instanced to prove how important water is to the coconut tree.

These remarks, for the length of which I apologize, are introductory to my subject, which I shall treat of in a future communication. Till then I crave a suspension of editorial comment.—Yours truly, B.

THE ADVERTISEMENT FOR CEYLON TEA THROUGH GARTMORE TEA SELLING AT £10 12s 6d PER LB.

London, E.C., March 13th.

DEAR SIR,—You will see by our circular the remarkable price (£10 12s 6d per lb.) we realized at public auction for a little lot of Gartmore tea. We send you cuttings from the London press on the subject as they may interest your readers and show how much good is done to Ceylon tea by the attention of the public being called to the splendid quality that can be produced if they are willing to pay something over the usual 1s 8d per lb. to 2s per lb.—We are, dear sir, yours faithfully,

GOW, WILSON & STANTON.

In addition to the *Times* from which a quotation was made in our London Letter on Monday, the other leading newspapers in London have published articles referring to the extraordinarily high price of £10 12s 6d per lb. realised at the recent sale of Gartmore tea in Mincing Lane. The *Daily News* alluding to the sale says:—"Probably never been heard of until yesterday even in the early days of the importation of the leaf; though, of course, if the difference in the value of money is considered, the apparently lower prices of the days when tea was at its dearest would be found to be in reality very much higher. The price ranged from 6l to 10l in these early days. When Garway wrote that tea, in respect of its scarceness and dearness, 'hath been only used as a regalia in high treatments and entertainments, and presents made thereof to princes and grandees,' it was sold to the public at from 15s to 50s a pound. The East India Company's presents of tea to Charles II. in 1664 cost them 50s. Quite recently some special tea was sold at only half-a-crown less than 5l a pound, and, on being resold at about 7l., was talked of as one of the marvels of the day. Now that a price of over ten guineas has been reached we may ask, are we on the eve of a repetition of the tulip mania, with tea instead of tulips as the craze."

In an article which appeared in the *Daily Telegraph* it is said:—"In the olden times connoisseurs paid fancy prices for rare vintages of port or claret. Nowadays the taste seems to have changed, and tea takes the place of wine in the high figures of the auction mart. Some days ago 'all the world wondered' when a pound of tea sold at a public sale for £4 7s 6d, but yesterday saw the same quantity of tea-leaf from Ceylon vend for more than double that sum. * * * * Should the value of the Eastern plant continue to advance by similar leaps and bounds, a tiny cup of tea may soon be expected to form the rarest liqueur served at select City banquets."

The *Daily Oracle* records an interview on the subject of the sale from which we extract the following:—"This sample of tea sold was grown at a high altitude. Its purchasers are the Mazawattee Ceylon Tea Company. This company is attracting attention to the hotter class teas. People seem to have got into the idea that it is only necessary to pay from 1s 8d to 2s per lb. for tea. They cannot get the finest qualities at the price. Tea is actually sold in Mincing-lane in bond for much higher figures. A large quantity of tea is sold

in the Lane at from 1s 6 to 3s per lb. It is used for blending, so that the public do not get this finer tea pure at the lower rates. There is no doubt about the hold which Ceylon teas are obtaining on the popular taste, the Indian teas are also fetching as good prices in the market. I think the two teas go very much hand in hand so to speak. Of course, better Ceylon and Indian teas will be produced if planters are stimulated by more remunerative prices in the market. I don't suppose that such a price as we obtained yesterday can always be obtained. There is no doubt that better prices can be made. * * It is to the interest of the public as well as the planters that higher priced teas should come into the market. * * "It is an extraordinary thing to me, the way in which Ceylon and Indian teas have crept up, and China teas crept down. China not so long ago had the field all to herself. China teas, however, fell off in quality and into public disfavour. Ceylon teas have only been cultivated during the past 20 years, and Indian tea for not more than half a century. We do not sell China tea at all. We only sell the Ceylon and Indian teas, both of which possess intrinsic merit."

Comments also appear in the *Globe*, *Financial News* and *Daily Graphic*; and Messrs. Geo. White & Co, who are qualified to speak with some authority state in their India, Ceylon and Java Tea Memoranda:—"To avoid disappointment to future shippers of fancy lots it should be borne in mind that under ordinary circumstances such tea in larger quantities would probably not fetch title of price quoted.

Nature says:—"The tea ought to have very special qualities"; and the *Chemist and Druggist*, alluding to the sale as "the sensation of the week," observes—"This price which far exceeds that paid for the two previous lots, is, of course "fancy" one and has been conceded in all probability with a shrewd eye to advertising advantage. In quality the tea resembles the "golden tips" sold two or three months ago at what was then the highest price on record but it is rather brighter."

The London correspondent of the local "Times" has given the following account of the sale:—"The bidding mounted up by ten shillings in place of the usual farthing, and as each of these was proclaimed it was received with a burst of cheers which increased in volume as the former high record of £5 10s 6d was passed. By that time some of the buyers became less urgent, and when at length £8 was reached several dropped out of the running. Much amusement at this point was caused by a broker of rather nervous temperament who became so excited that, standing up on his chair, he became suddenly deadly pale as though about to faint, when acting by the ordinary sale rule of farthing bids, he found sufficient voice to cry a little above a whisper "eight pounds and a farthing"; which materially evoked shouts of laughter and which someone capped by a bid of "eight-ten," and so the bids went on until the unprecedented price of £10 12s 6d was reached, a bid which was received with rounds of cheering and shouts of laughter. The result of this sale was at once wired to New York; and by the following morning an order came back to secure a quarter of a pound of the precious article at any price a commission which I do not believe will be executed."

In a Leeds newspaper, the following appears:—"How very precious tea-growing land in Ceylon must be! A gold mine is nothing to the riches here inviting the cultivator who gets hold of the right soil, and has intelligence in the management of the plants and the garnering of the precious leaves. Recently a consignment of Ceylon tea was sold for something over £5 per pound, and was re-sold for more. The inflation of Ceylon qualities is by no means over, for yesterday (March 10th) in London a small sample of what we must presume was superb and in comparable tea fetched the astounding price of £10 12s 6d per pound! Tea of indescribable superiority is thus becoming almost worth its weight in gold. Nevertheless for ordinary people inherently deprived in taste, tea at from two to three shillings per pound is wondrously refreshing. The high-priced tea referred to may be considered cheap at three shillings per cup."

CACAO CULTIVATION.—STEALING NOT CONFINED TO KURUNEGALA.

Kandy, March 17.

DEAR SIR,—With reference to your footnote to my letter of 13th instant (see page 723) I think you are in error in suggesting that the Kurunegala District is the only one where cacao-stealing is general. What about Dumbara and Matale, where even the Buddhist priests have taken to the new industry?

As regards the returns from cacao cultivation, are we to conclude that a yield of 1½ cwt. per acre in alternate years, constitutes a big crop?—Yours faithfully
PRÆDIAL PROGRESS.

[Are we safe in taking all the acreage as in full bearing and under proper shade cultivation?—Ed. T.A.]

CACAO CULTIVATION: MR. HOLLOWAY'S EXPERIENCE.

Franklands, Wategama, March 18th.

DEAR SIR,—I noticed lately a great deal has been written for and against cacao (Croico, Forastero, and Caracas), especially "Eldorado"'s attack, and I have thought proper to test and prove that cacao does and will pay if carefully cultivated, even on soil condemned by would-be experts if you only know how to treat that soil, assist your plants with proper shade, and nourishment, and prune your trees at the proper time. When plucking on 11th inst. I selected 100 hybrid Forastero pods: they weighed 200½ lb. on evening of 12th when pods were broken up and put to ferment. On morning of 15th seed was washed, and was dried in good sun to 1 p. m. this day. Seed now weighs 12¾ lb.—204 oz. or—2 oz. to one pod; this takes 896 pods for one cwt. Some good old Forastero trees on this estate gave 100 pods each and are over five years old, averaging 2lb. each—same kind long pink pods as the 25 exhibited at the Matale Show from above estate two years ago. Plants from seed of selected pods from this estate supplied to and planted in a nursery on Ukkuwala estate, close to railway line, are now a picture to look at. The tamby just now offered to pay at the rate of R65 (sixty-five) per cwt. for this cacao. A sample of ½ lb. is sent by this post.* I firmly believe 200 to 300 pods per tree can be got from this variety of cacao trees after the 6th year with proper cultivation per annum.—Yours faithfully,

J. HOLLOWAY.

MR. HOLLOWAY'S CACAO FIGURES.

SIR,—I am not alone in my condemnation of the inferences Mr. Holloway would have us to draw from the figures given in a letter of his, published as recently as 20th inst.

He may, for all I know, be merely calling attention in an innocent way to the superiority of his cacao seed, but it is very undesirable that such inflated and preposterous reasoning should go unchallenged.

There are, I believe, about 300 cacao trees per acre on an average. Mr. Holloway gives figures showing his belief that a 6 year old tree will bear 200 to 300 pods, and that 896 pods go to 1 cwt. of dried seed worth now R65 per cwt!

I ask you in all commonsense not to allow any intending cultivator to be misled by such absurd statements issuing from anyone setting themselves up specially as cacao growers.

At the rates named above the yield of an acre of cacao would be above 100 cwt. and over R6,500 value per annum per acre.
PLANTER.

* The sample, a very fine one, so far as we can judge, can be seen at our Office.—Ed. T.A.

SALT IN AGRICULTURE: No. II.

Veyangoda, March 18th.

DEAR SIR,—My excuse for prolixity in my previous communication, is that, in order to show that salt is indispensable in coconut cultivation, I thought it necessary to point out the natural habitat of the tree, the conditions under which it flourishes, and its habits.

In the generality of instances, trees grown inland have none of the natural conditions under which this palm grows. The results of this are self-evident to those engaged in its cultivation. How to overcome these should be their aim. To make a stiff soil free, is not as easy a job as those who glibly recommend its being broken up to the depth of 18 inches and limed imagine. The initial cost will be between R25 and R30 per acre. I should be happy to form the acquaintance of the man who will incur this over an appreciable acreage. Besides, to counteract the effects of sun and rain, and of the action of the feet of cattle, the work will have to be continuous. It is, I think far better to recommend something practicable than what, though highly desirable, will not be undertaken. Next, as to a plentiful supply of water. Unhappily, every coconut estate proprietor has not the energy, pluck, enterprise, or command of capital of an Akbar, even though many have the Mahaaya or other rivers skirting their estates. So that that, too, must be dismissed like the altering the mechanical condition of the soil, as being outside the pale of "practical politics." The salting of the soil is then the only operation left us, in the way of conforming with the natural conditions under which the coconut palm grows, and I say it is the most important. In low-lying flats inland, we meet with free sandy soil, having water within easy reach of the roots of coconut trees, and yet the trees growing on them have not the ability to carry their bunches unaided. We may well enquire how this is, seeing that in such situations two of the natural conditions under which the palm grows are present. I think the inevitable conclusion is an insufficiency of salt for its requirements.

Under the circumstances I have detailed at such great length, I call upon the gentlemen of the Press to make a united application to Government to issue salt for agricultural purposes at wholesale prices. Situated as I am away from Administration Reports, I cannot say precisely what wholesale prices are, but I believe they are somewhere about 40 cents per cwt. The cost of manufacture I believe is well within 25 cents per cwt.; so that the margin of profit is not to be despised, if Government can be induced to follow a liberal and progressive policy and encourage the use of salt extensively in agriculture, instead of as now standing stolidly in the way. Of course, safeguards against the revenue suffering would have to be adopted; but the devising of these will surely not be beyond the ingenuity of the legal advisers of the Government. It can be issued only to men of standing, or to those whose respectability can be vouched for by two men of standing. A declaration on honour will have to be given that the salt will be used exclusively for agricultural purposes, and an undertaking to pay a penalty representing the difference between the price it was issued at and retail price for the full quantity issued, if it be proved that, owing to the want of reasonable precautions, any part of it was used for culinary purposes. These are safeguards enough, but another and an indispensable one must be that, before issue, the salt be mixed with some offensive stuff like night-soil at the Government Store and under the supervision of its own Storekeeper, the latter to be supplied by the purchaser in proportions to be fixed upon by the Government. Every practical man who is intimately acquainted with the natives and their deep-rooted prejudices will agree that the last precaution will remove all chances of the salt being used for human consumption. Let not the Government harp on the well-worn string that it is possible to purify and render fit for consumption salt so treated. Let the Government, composed as it is of practical men, deal with probabilities and not possibilities.

To say that an increased consumption of salt will

mean increased revenue, is to state an axiom. The increase will not be sudden, but it will be slow, till the benefits of salt in agriculture have been demonstrated. Then, there is the residual salt of the pans, which a glance at the Administration Reports of the Government Agent of the Northern Province and of the Assistant Government Agent of Puttalam will show is destroyed at a high cost. This cannot be characterized as other than a sinful waste of a useful article of consumption and of money. It has been established that this residual salt can, when mixed with bulky manure, be used as a manure. Why not save the money expended in its destruction and turn this substance into an item of revenue?

It will be necessary for me now to detail the value of salt in agriculture generally. In doing this, I will be forced to repeat all the information I collected at much trouble, and what has become available since.

Salt has a two-fold action on the soil, mechanical and chemical. Besides this it is hygroscopic, and has a value all its own. By its property of absorbing the moisture of the atmosphere, it alters the texture of the soil, and always keeps it moist and true in dry weather. Chemically, it has the property of rendering soluble the Phosphates, Nitrates, Silicates and Potash in the soil. A sour soil is by its application rendered sweet, and the coarse herbage growing in it is rendered fit for cattle. Vegetable tissues are by its application rendered tough and stiff, possibly by the large quantity of silica it enables trees to take up as food. Though experiments have proved that plants can be grown in soils devoid of silica, yet silica is known to help plants to assimilate other plant food. Therein possibly lies the secret of the vigour it imparts to vegetation, and the reason it acts as a stimulant. The late Mr. Davidson, a coconut planter at Jaffna, who shows by his writings a considerable acquaintance with agricultural chemistry, wrote:—"Were I to say salt acts as a stimulant, I might state what I could not explain; but I could point to its operation in the animal economy as proof of its possessing properties adapting it peculiarly to a tree in which the ever-circulating sap is perpetually varying in constitution and density. We can then understand why the coconut tree thrives best when it feels the influence of the salt spray. By its ability to supply, or rather to absorb, moisture in dry weather, it helps greatly in proper nourishment and formation of fruit. It can be applied profitably in soils rich in organic matter. It operates on the soil with an influence not produced by any other stimulant, mineral or vegetable."

I think I have said enough to demonstrate its great value generally in agriculture, and of its indispensability in coconut cultivation inland. The Superintendent of the School of Agriculture and at least one of his Assistants have borne willing testimony to its value in agriculture, and have recommended its issue at reduced rates. It is now left only for the gentlemen of the fourth estate to formulate a united appeal to the Government, and for those interested in agriculture to back up that appeal, so as to induce the Government to abandon its dog-in-the-manger policy with regard to this question. By aiding agriculture in the way I have indicated, it will increase the revenue directly by the increased sale of salt, and indirectly by increasing the earnings of the salt manufacturers and of landed proprietors, thus increasing the circulation of capital.—Yours truly
B.

HIGH PRICES FOR CEYLON COCOA.

Colombo, March 23rd.

DEAR SIR,—A great deal has been said about a parcel of cocoa belonging to Mr. Payne having sold at R65 and another parcel of Mr. Barber's at R68, but I think if anybody has to be congratulated it is the proprietor of Wiharagame, whose cocoa I sold last week at R73 per cwt.,—the highest price I believe, ever paid in Ceylon for cocoa. I have sold several parcels since at R70, 71, and 73, and have not heard of any sales to come up to that.—Yours faithfully,
R. HDLEY.

THE TAXATION ON TEA LAND IN CEYLON ;
TOLLS, &c.

DEAR SIR,—A great deal has lately been written about the taxation of paddy ; but no one seems to have examined the incidence of taxation on tea cultivation. From figures at my disposal I have endeavoured to ascertain as nearly as possible the amount per acre contributed by a tea estate, and the following is the result given approximately :—

	per acre.
	R c
Rice Import duty ...	3 25
Tolls on tea, rice, lead etc., ...	3 00
Stamp duties on deeds, cart notes, insurances bonds, agreements etc. ...	50
Customs duty and tolls on consumption of salt, salt fish, cotton goods and other dutiable articles by coolies and superintendent.	2 75
Export duties ..	50
Total... R10 00	

The revenue of Ceylon is in round numbers R15,000,000, but the whole of this is not derived from taxation, land and timber sales, pearl fishery receipts, and the bulk of the railway receipts and harbour dues are not taxes but excluding these the balance derived from taxation is about R9,000,000. The cultivated area of Ceylon is (Ceylon Directory) about 3,000,000 acres, and of this tea occupies 200,000, therefore tea should pay for its fair share 1.5th of R9,000,000 or R600,000 and there is very little doubt that it really contributes at least three and perhaps four times that amount. It has been contended by some that the import duty does not fall upon the planter ; but obviously that person pays the tax who would be benefited by its removal. At present I am making a profit of 12½ cents (last year it was a loss) per bushel of rice, this would be converted into a profit of 41½ cents by the removal of the tax, and even if rice was issued at cost price and rates of pay not lowered we should benefit by the increased number of coolies who would flock over when what would practically amount to a rise of pay was given ; less coast advances would be needed and less flush lost through shortness of labour. It may also be contended that tolls are not a tax but payment for services rendered, viz., upkeep of roads. A moment's consideration will show that this is not the case. We are supposed to get services rendered for all taxation in the shape of such a Government, etc., and other blessings such as trial by jury etc., etc., and moreover if tolls are merely for the upkeep of the roads they are placed on they should be credited to the districts in which they are levied and any surplus over upkeep should be expended in either improving the roads of that district or in reducing toll there. Toll rents however seem to be paid into the general revenue, and the districts where they are collected get no benefit whatever from them. To make the thing still plainer, if the Government in lieu of tolls were to levy a land-tax from me of R3 per acre, I should be no loser nor would Government, the services would still be rendered, but it would then be seen that a tax was paid. Stamp duties will be generally admitted to be taxation and import duty on personal and coolies' consumption of dutiable articles and tolls thereon stand on the same footing as the import duty on rice.

It appears to be time for a revision of its taxation in the interest of the tea planter at any rate and direct taxation would be preferable to the present system as it would at all events open the eyes of all and sundry to the extortionate amount we have to pay at present. I do not see why we should dread a land tax. Government can hardly assess

more for the hillsides and ridges than for the alluvial valleys where the paddy fields are or the chena on identical land just outside the boundary of many tea estates. A land tax would also be fairer in the case of opening new land. At present, tea begins to pay tax through import duty the instant jungle is felled, whereas paddy though an annual crop does not pay for four years. This exemption would no doubt be extended to tea and other products.

The planting representative need not look further than his constituents if he wishes to redress unequal taxation. He might ascertain from the Government for instance on what principle and at what distance are tolls placed on public roads. At present in this neighbourhood there are on a stretch of road 28 miles in length 4 tolls, 2 of them in a distance of 12 miles. The effect of these combined with cost of transport raises the cost of salt 100 per cent, and other provisions are sold at greatly enhanced rates. These tolls therefore operate as a food tax. The cost of tolls on 80 or 90 miles of road is ½ cent per lb. of tea and 12½ cents per bushel of rice, or 25 per cent of the cost of transport in the one case and 16 per cent in the other. In no country that I am aware of are such high rates levied or at such frequent intervals. It is a severe tax on such comparatively valuable commodities as tea and coffee, but it absolutely stifles all vehicular traffic in low-priced native products such as straw, by-products of various palms and jungle produce which it would pay to send to Colombo were transport cheaper. At present carters prefer to return with empty carts if they cannot get a full load, as the extra toll on loaded carts will take all the hire of a half or quarter load. More than half the total toll receipts were collected in the Western Province for the year 1888. This cannot be fair on that province, as it can hardly be that half the expenditure takes place there. I believe if you can lay your hands on the figures that the railway would not be in it as a paying concern with the road from Pelmadulla to Colombo ; and surely roads at any rate were not intended as a means of revenue but to develop the country. We have to pay the ¼ cent Mr. Skrine objects to and do without a railway as well. What the Badulla planters pay as tolls for the long mileage used by them must be enormous—at least ½ cent per lb. tea. It is a matter the Badulla Association should take up ; districts without railways are sufficiently handicapped without being weighted with excessive tolls. If the Ceylon Government would follow the example of the English Government and do away with tolls it would be for the public advantage. The present system is wasteful, a large amount of the tolls going into the renter's pockets. If it is not possible to do away with tolls, they should be reduced to a reasonable amount. It becomes serious when they amount to 25 per cent of the total cost of transport. I see the pet province has no tolls and the Eastern practically none; why this favour? No toll receipts appear for 1888 for the N.-C. Province and only R900 for the Eastern ; what can be done in these provinces can surely be extended to the other portions of the island.—Yours truly,

B. B. B.

INDIGENOUS WOODS FOR TEA BOXES
A WARNING TO PLANTERS.

DEAR SIR,—With the growing expansion of tea cultivation, comes the great demand for tea-box wood. I have lately observed in some of my travels that the village carpenter has taken to prepare any sort of timber, no matter how inferior. Many must damage and destroy the tea, when used as they now, are in a green and unseasoned state. The

supply of suitable wood has already become exhausted in the native gardens in the Central Province.

There is no need to import tea-box wood into this island while we have so many quick-growing trees, and none can equal that excellent tree the *lunumidella*, *Melia dubia*. It loves heat and moisture and grows luxuriantly from sea-level to 2,000 feet, and in ten years can be utilized for tea chests.

I consider wild mango, *Mangifera zeylanica*, and the red cotton tree (katu-imbul), *Bombax Malabaricum*, may be used, but the wood should be cut for some time, as the resinous juices they contain are of a corrodent nature and would very soon destroy the lead lining of a tea chest. The following woods should be avoided; nevertheless it is difficult to reject them, as the carpenters mix them up with other woods:—Kekuna, *Canarium zeylanicum*.—Wood contains a resinous balsam, is used by the natives for burning after being mixed with paddy chaff, and the smoke given off is reputed to drive away snakes. The wood is worthless and readily attacked by insects. This tree is one of the most characteristic features of a village garden, its silvery white foliage add a pleasing contrast to our sylvan hamlets. It belongs to that Nat. Order *Burseraceæ* producing balsamiferous trees and shrubs.

Rukattana, *Alstonia scholaris*.—Boards of this wood are used by children in the Indian schools to write their lessons on, hence its name. The wood is very light and does not stand exposure for any length of time, is as bitter as gentian; in common use in Ceylon for coffin making. The bark is a powerful tonic.

Riti, *Antiaris innoxia*.—A stately evergreen tree with light-coloured shiny bark, common in our village forests up to 1,500 feet above sea-level: wood light and very inferior, rapidly decays when cut up. In the Madras Presidency the natives make bags from the bark by a very simple process. A branch is cut, corresponding to the length and diameter of the sack wanted. It is soaked a little, and then beaten with clubs until the inner bark separates from the wood. This done, the sack, formed of the bark, is turned inside out and pulled down until the wood is sawn off, with the exception of a small piece left to form the bottom of the sack, and which is carefully left untouched. The Sinhalese also form bags from the bark, but in a rude and simple way. The tree produces a small fruit like a fig, purple or crimson, pyriform, velvety and intensely bitter. Known as the upas tree of Java. The upas antiaris poison is prepared from the juice, which flows from incisions in the bark. Belongs to the Nat. Order *Urticaceæ*, containing figs and nettles and many valuable fibre plants.

CACAO CULTIVATION.

March 27th.

DEAR SIR,—After all that has been lately written in disparagement of cacao by disappointed planters, it is refreshing to see Mr. Holloway coming forward with advice and encouragement for all sceptics.

There can be no doubt that the variety of cacao which he so freely advertises is the very best for planters who know how to treat their soil and to grow shade properly, and who know the right time to prune their trees, but a large proportion of planters have still a good deal to learn; the majority, I believe, never prune at all.

In your issue of 21st instant (see page 739) you made mention of one fortunate proprietor whose crop last year "was not far off an average of 5 per cwt. per acre" a very fair yield.

Your recent correspondent "Eldorado" and other hostile critics, though correct in their arithmetic as to the average return (from 12,000 acres planted before 1885) being less than $1\frac{1}{2}$ cwt. per acre, evidently wrote under the impression that an acre in cultivation is necessarily in full bearing when six years old. But the only way to arrive at good results is to calculate, as Mr. Holloway has done, the crop given by the very finest trees, then allow say 300 good trees to an acre and write down one's acreage according to the number of good trees scattered over the whole estate. In this way, most estates will show returns "not far off an average of 5 cwt. per acre," and some even more than this, which will satisfy even "Eldorado," and the figures in your Directory will be brought down from 12,050 to about 3,000 as being under cacao cultivation.—Yours faithfully,

VINOIT VERITAS.

LOSS FROM INSECTS AND FUNGI IN THE UNITED STATES.—Professor T. Maynard states on the authority of the Entomological Division of the Department of Agriculture, that the loss to the farming interests, including all its branches, for the past year from insects and fungi amounts to \$400,000,000, say over £80,000,000.

PEPPER CULTIVATION IN PERAK is thus noticed in a report on the district of Kuala Kangsa:—

The Secretary to Government arrived here on the morning of the 3rd, and was engaged all day in Court. On the night of the 3rd I accompanied him to Chigar Galah, where we arrived early the next morning, and inspected the pepper estate of Syed Musa. On the whole, the estate appears to be doing well; but as is usually the case with plantations superintended by Malays, there is not sufficient attention paid to the tying up of the vines, and some portions of the estate are not kept so clean as they might be. Mr. Treacher proposed that an experienced Chinaman should be employed to supervise the work of the contractors, who are mostly Achinese. Syed Musa was pleased with the suggestion, and Mr. Lee Kong Lin, who accompanied us, undertook to secure the services of a man for this purpose. There are a number of smaller plantations at Chigar Galah, the owners of which have been supplied with decap and pepper cuttings by Syed Musa. The Secretary to Government visited several of these, and also a clearing about 9 acres in extent on the opposite bank of the river, belonging to Syed Abdulrahman. This land has been most judiciously selected both as regards aspect and soil; the latter being even more suitable for the cultivation of pepper than that of Syed Musa's estate.

The Government plantation at Tempurong, which is about 8 acres in extent, includes a large nursery which contains about 30,000 plants, and these can be supplied to planters here at a far more reasonable price than that which they have hitherto been paying for cuttings purchased from Ara Kuda and elsewhere. The Government plantation at Pandok, which was also visited by Mr. Treacher, is a failure, as the Malays and others interested in the cultivation of pepper always predicted it would be. The soil there is composed principally of bat guano, and, although for the first two or three years the pepper vines appeared to be thriving, they are now all dying off.

Great damage is being done to the pepper plantations by the buffaloes that are allowed by their owners to stray at night. In a few instances the former have been captured and the owners identified, but as a rule this is not possible, as the buffaloes come in herds, and any attempt to catch them only leads to further damage being done to the trees and vines.

About twenty years ago complaints of damage done to coffee estates in Ceylon by buffaloes were incessant. Now we never hear of damage done by these animals to tea or other culture.

COCOA.—That veteran planter Mr. Alfred Paine, of the Kururegale district, must be congratulated on the fine price he has recently obtained for his cocoa from Isabel estate. It has been sold locally at R65 per cwt., which I believe, is the highest price ever obtained in Colombo for this product.

COCOA CULTIVATION.—We learn from a planter whose crop last year was not far off an average of 5 cwt. per acre, that no product responds so well to bulky manure as cacao. Wherever cattle manure or town refuse and sewage can be readily obtained for a cacao field the return is sure to be satisfactory.

CINCHONA.—"Crab-Apple" writes:—A friend of mine who owns a large cinchona estate in Wanaad, last July and August shaved 100 acres of Ledger. Renewal at once set in, so fine and strong, that in the early part of February last he decided to coppice the same 100 acres. This work is now almost finished, and up to date most satisfactory results have been obtained. Over fifteen analyses have been taken off different portions of the estate, and in many cases the renewed has analysed more than the original bark, though in most cases about the same. As regards quantity of bark, the renewed is as thick, if not thicker than the original. The consignments of bark that have reached the London market have fetched good prices. As will be seen from the above, the experiment has proved satisfactory in every way. I believe this to be the first acreage of any scale that has been shaved, and I think clearly proves that shaving Ledger pays.—*Madras Times.*

INDIAN AGRICULTURE: EFFECTS OF HEMP AS GREEN MANURE.—Some very valuable experiments have been made at the Cawnpore Experimental Station, of which Dr. Voelcker has spoken with approval. From the latest report we quote as follows:—

lb.

Page 11, average for six years,	950
" 12, ditto	1,133
" 13, ditto	956
" 13, ditto	940
" 14, ditto	659 (average of 2 plots).
" 14, ditto	596 (ditto 6 do.)
" 14, ditto	614
" 15, ditto	586 (ditto 4 do.)

The yield of unmanured land in a series of years is one of the most interesting points on which information is being collected. There are a good many such plots on the farm. I give in the margin the average outturn of wheat per acre of all plots which have been without manure and under wheat for the past six years. In some of these plots the yield is possibly still affected by manure applied before the land was placed under the present series of experiments, and may be expected to decrease in future years. Taking a bushel of wheat at 61 lb., the general yield of unmanured land of the kind found on the Cawnpore Farm—a loam of average fertility cropped year after year and carefully watered and tilled—may be put at 10 to 13 bushels an acre. The American average for all the States of the Union is about 12 bushels. The English average is 30 bushels. The Cawnpore experiments conclusively show that 5 to 10 bushels can be easily added to the average yield by the application of R5 worth of farmyard manure or even by green-soiling with hemp at the cost of R3-8-0 per acre. This is putting the increase at a minimum. The six years' average yield of the plot manured with farmyard manure only in the "Rabi duplo series" is 27 bushels, and of the plot manured with *pouretie* 23 bushels. Thus we get the American average on our unmanured land and approximate to the English average on our manured. I am afraid that the American average is not unfrequent in many districts of these Provinces, especially

in those where canals enable the cultivator to subject the soil to a systematic process of exhaustion. As regards the comparative value of manures, the experience of the Cawnpore Farm is not favourable to artificial or extraordinary fertilizers. Bones, bone-superphosphate, gypsum, kainit, &c., are considerably more costly in this country than the common kinds of manure and so far as they have been tried they have not given commensurate results. Green-soiling with indigo or hemp might, however, be more commonly adopted by the Indian agriculturist than at present. The cost of sowing hemp and ploughing it in when green is put at R3-8-0 an acre. But this is chiefly made up of hire of labour and bullocks, and the cultivator can find both without actual expenditure of money. In districts where indigo is not a staple crop, the fields destined for wheat (unmixed) are almost invariably left fallow in the preceding kharif. To sow these with hemp instead of fallowing them would, according to the Cawnpore Farm Experiments, make the wheat crop heavier. Most of the produce of the farm is sold to the public for seed, the seed-grain being carefully cleaned and selected. Dr. Voelcker was of opinion that this branch should be developed, and some of the minor experiments abandoned. I am considering how effect can best be given to this suggestion. The demand for good wheat, cotton, barley, and maize seed is increasing, and in endeavouring to meet it the farm can be of practical utility.

THE MAGAZINE

OF

THE SCHOOL OF AGRICULTURE, COLOMBO.

Added as a Supplement monthly to the "TROPICAL AGRICULTURIST."

The following pages include the contents of the *Magazine of the School of Agriculture* for April:—

ARTESIAN WELLS.

THE most favourable condition which renders artesian wells possible is a basin-shaped arrangement of porous and impermeable strata.

The surface water flows along the line of dip down the porous strata till the latter become as it were surcharged like a sponge; so that if a boring were made down to a water-bearing stratum of this character, the water which had no means of rising through to the impermeable stratum above it, will owing to the hydraulic pressure gush out at the surface. The following examples are given by Prof. Geikie to show the great depth to which artesian wells may be sunk: at Grenelle (Paris) the water rises from a depth of 1,771 feet; at Neusalzwerk, near Minden, the depth is 2,394 feet; at Louisville in Kentucky, 2,086 feet; at St. Louis on the Missouri, 2,624 feet. The hydraulic pressure under which the water is forced to the surface is often very great. At Grenelle the fountain ascended at first 112 feet, at Louisville 170 feet. The continuity of the typical underground basin may be interrupted, and in many cases artesian wells merely tap underground waters which would otherwise find an outlet to the surface as junction springs.

The advantages of artesian wells are thus set forth by Mr. Tousher of Malmesbury, who undertakes to bore and drill artesian wells:—

1. Because they are bored to such a great depth, the depths of the deepest wells being insignificant. 2. Because they can be bored and

drilled through strata where it would be impossible to dig, for instance quicksand. 3. Because there is no necessity to stop at the first water obtained, as is the case in dug wells, but that if the first water should be brackish or impure, it can be completely shut off, and the boring proceeded with until the next water-bearing stratum is reached, and so on. 4. Because the water obtained is always pure, as the artesian well does not allow any contaminated water to come in, while the water in a dug well is always more or less impure, as, being drainage water, it will always permit decomposed matter to percolate into the well. 5. Because the water is always copious and unfailing, being drawn from the underground strata, while the water in a dug well is always directly dependent on the rainfall. 6. Because they are almost everlasting, not being liable to tumble in like a dug well. 7. Because there is no danger attached to them. 8. Because they are cheaper. 9. Because they can be bored from the bottom of any dug well, no matter how deep, and whether it contains water or not, and without in the least interfering with present arrangements; thus saving the expense of boring to the depth of any existing well at any place. Mr. Tousher as an interested witness to the advantages of artesian wells, it may be thought speaks too disparagingly of dug wells, but it must be admitted that his remarks are in the main well founded.

Mr. Henry Penning of the Geological Survey of England and Wales, writing on this subject, says that the water supply of a district is not by any means proportionate to its rainfall—the water-bearing beds being great distributors that equalise the supply. The supply to be obtained by boring down to a deep-seated spring, is, he says, practically inexhaustible, being rarely, if at all, affected by drought, and these springs form the only source on which can be placed a full reliance. Referring to the light which geology throws on the question of water-supply, Mr. Penning says “An improvement in the water-supply of a district is one of the practical results that may be expected to arise

from the working out of its geological structure—that is, from the knowledge obtained of its rocks and of their relation to each other. The phenomena of springs and the sources of supply to artesian wells are so entirely dependent on stratigraphical and physical features, that an acquaintance with their principals cannot fail to be of use to the student of field geology.

It follows that when all the condition of dip, permeability and continuity are known, it becomes a matter not of speculation but of certainty to estimate the depth at which water will be found, and the height to which it will rise in a well."

With rumours of a geological survey and of artesian wells, the despondent agriculturists of our drought-stricken districts may well gain a little courage!

OCCASIONAL NOTES.

A correspondent writes with reference to the yield of Arekanuts:—Now that attention has been called by you to the cultivation of arekanuts, and a question raised as to the income derivable from this product, it may be interesting to you and your readers to know that 50 cents per tree is by no means a high average—that is to say where it is cultivated as it should be. The safer valuation of 25 cents per tree, to which some well-informed people would incline, may be based on the experience gained by natives from the produce of their *arambas* or groves. But then these arambas are invariably planted so closely, that the plants do not get sufficient feeding ground and sunlight. The consequence is that they get attenuated, reaching a great height and yielding individually but a small crop. Let the plant stand 12 feet apart between the rows and far enough in the lines to enable the pluckers to go from one tree to another without descending and thus making the harvesting of the crop an expensive work, and it will be found that the plants in ordinarily favourable situations, will come into bearing so early as at 5 years, and that they will yield more than twice the crop obtained by the natives, who plant them among *jak*, *kitul* and other such garden products, along with which the areka has to share the enjoyment of sunlight and soil. I have counted up to 300 nuts in a bunch, though, I am told, a maximum of 500 may be reached. The price of arekanuts is about from 75 cents to a rupee per 1000, and you should not think it too much to expect from 500 to 1000 nuts to a whole year's crop. However, if you obtained only 25 cents per tree, still, with 600 or 700 trees to the acre, it will be no mean product.

The Kew Bulletin for February contains a note on Kath or Pale Cutch. This substance also known as Pale Catechu is prepared from *acacia catechu*, and is to be distinguished from cutch or catechu, and from gambier which is sometimes called Pale Cutchu. Pale cutch is the substance used all over India and in Ceylon for mixing with betel leaves &c. for chewing purposes, and is known in Sinhalese as *Caypoo*. Catechu is used in medicine, especially Veterinary medicine, as an astringent, and the catechu of Burmah (poor in catechin) is exported to Europe as a dye stuff.

Pale catechu or Kath when pure consists chiefly of catechin, a chrySTALLISING substance nearly insoluble in cold water, and which must not be brought in contact with iron. Its preparation is a long and tedious process, as the extract got from boiling the wood-shavings of *acacia catechu* has to be brought to a high degree of concentration and left to stand for a long time, till the catechu is got to chrySTALLISE out of the catechu tannin, with which it is found mixed. The preparation of the dark catechu which consists chiefly of catechu tannin, is a much simpler process, and is merely a boiling down of a watery extract of the wood of *A. Catechu* and *A. Suma*. Pale catechu or Kath and Gambier have been pointed out by Flückiger and Hanbury to agree in composition, both consisting mainly of catechin (*Catechucic acid*). As Pale catechu so closely agrees with gambier, which is now in great demand, it is surprising, thinks the Kew Bulletin, that it is not exported to Europe, where it would be readily accepted by the dyers as a substitute.

The word *Catechu* is considered by some writers to be a modern Latin derivative from the South Indian name *Kachu*, and that from South India the product was first exported; while others derive it from the Cochin Chinese word *Caycan*, which is no doubt connected with the Sinhalese *Caypoo*. The Sanscrit authors mention the drug, and Barbosa in 1514 notices what is in all probability is this drug under the name of *Cacho*.

It is interesting and sometimes amusing to read the opinions of old writers on Ceylon regarding the agricultural capabilities of the Island. Sir Samuel Baker, like the promoters of the late Model Farm at Colombo, committed a huge mistake when he attempted to start farming in Ceylon upon the lines he choose to work on, and in both cases the projects resulted in signal failures. No doubt Sir Samuel wrote with a prejudiced mind when he condemned in such general and emphatic terms the soils of Ceylon, for their extreme poverty. In his book entitled "Wanderings in Ceylon" there are, however, observations and suggestions which prove that the author had evidently carefully examined into the needs, and considered the means of improvement of the natives of the Island. He refers to Mr. Thurston's Industrial School in the Cinnamon Gardens of Colombo, on the site now occupied by the School of Agriculture, and suggests that the Government should develop the plan upon which that establishment was worked, so as to bring an agricultural and technical education within the reach of the masses, and specially advises that an improved system of cultivation should be introduced to the natives, and that new products should be brought to their notice. So far as the suggestions referring to agricultural education are concerned, Sir Samuel Baker's advice has been acted upon, while there is also a move to give effect to his suggestions regarding technical education. It is not of course to be considered that these results have been brought about by Sir Samuel Baker's work, but it must be admitted that the author had studied the condition and requirements of the people of Ceylon, at a time when few—the Government excluded—were sensible to the fact that there was a reform to be worked, which remained for Mr. H. W. Green to initiate.

The idea of having small tracts of land attached to schools about the country, so that each school may have its own experiments in agriculture, has been carried out to a considerable extent. The "narrow policy of Government" with regard to salt, which of late has been much discussed, is condemned by Sir Samuel Baker in strong terms, among other reasons for impeding the preparation of hides. The chief obstacle in the tanning industry in Ceylon is now however not so much the high rate of salt as the difficulty in procuring hides. Of the natives we are told that they never stint time and trouble where the prospect of money is safe; and with this remark we quite agree, though we were understood (wrongly) to think otherwise, from our remarks on native enterprise in a previous issue of this Magazine.

Dr. Trimen's Administration Report for 1890 is out early as usual, and is as full and interesting as previous reports. Under the heading of "Economic Plants" we find that the acquisition of the true gambier (*Uncaria Gambier*) has, after many failures, been at last accomplished. "It is clearly," says Dr. Trimen, "very fastidious and difficult to propagate, but it ought to succeed in our hottest and wettest districts. Naturally an extensive climber, it is in cultivation kept down by cutting so as to form a low bush of 5 or 6 feet. With Cubebs (*Piper Cubeba*), however, Dr. Trimen is unable to report any progress, and the plant "still remains a desideratum." There is also a note on Chinese ginger, which in our last issue, we reported as having been identified with *alpinia galanga*, the well-known "Kaluwala" of the Sinhalese. "It is a little difficult to believe," says Dr. Trimen, "that the 'preserved ginger' of commerce is the produce of the same plant, especially as the rhizome has not the appearance of the commercial article: and I cannot help suspecting the possibility of a mistake having been made when originally sending the plant to Kew." Since, however, the identification of the plant has been accepted as correct by the authorities at Kew, it is only to be supposed that by careful selection and cultivation the original *alpinia galanga* has to some degree been metamorphosed into the "preserved ginger" plant of China.

In the report of the Saidipet Experimental Farm for the year 1879, is a note on the poisonous qualities of the grain known as *Annu* in Sinhalese, and *Varagu* in Tamil. This is one of the fine grains cultivated in the chenas of Ceylon, the seeds of which are small, black and shiny. Sometimes the effect of eating this grain is followed by a feeling of giddiness and prostration—in fact all the symptoms of poisoning evince themselves. In the absence of proper treatment, in some instances, the result has been the death of the consumers. In the villages of Ceylon, however, the people have a very simple remedy derived from common herbs, which counteracts any evil results from eating *annu*. Mr Wilkins, the Botanical lecturer at the Madras School of Agriculture, says that the poisonous grain is not the product of any particular variety, but of plants that yield the healthy grain; and bad seeds may produce wholesome grain. He has not been able to discover anything in bad grain that can

account for its poisonous principles. A number of instances have been recorded in India of the bad effects of this grain on man and cattle. It is generally held that grain raised at the proper reason is wholesome, but that raised on the same ground as a second crop, and that raised on wet marshy ground, are both unwholesome. Dr. Bonavia's opinion is that after rain, when the ear is ripening, a fungus attacks it, and it is the fungus which does the mischief. This reminds one of the case of rye and other cereals and grasses, which are rendered unwholesome by reason of the attack of the fungus known as ergot (*Claviceps purpurea*) which has caused the death of many hundreds of people on the Continent, and innumerable cattle in England. Dr. Bonavia states that washing the grain well before cooking renders it harmless. Dr. Macree, late Chemical Examiner at Madras, did not think that the wholesome could be distinguished from the poisonous grain: but he observes that when a sample of bad grain was "placed in an air-tight chamber and exposed to the influence of air and water, some of the seeds germinated in three days, while a plentiful crop of what (MICROSCOPICALLY) appeared to be ordinary mould was developed." It will thus be seen that nothing certain appears to be known regarding the poisonous principle in *annu*, and that it is very desirable that further observation and experiment should be made so as to throw further light on the subject.

FURTHER NOTES ON GINGER.

By W. A. DE SILVA.

In my last contribution on ginger, I mentioned the method of cultivation of the true ginger, and its preparation for market for use in medicine and as a condiment. Ginger also finds its way to the market in the form of "essence of ginger," which is used largely in medicine. We also come across ginger in a preserved state. Preserved ginger is largely exported from the Chinese ports, and especially from Canton. In the January number of the Kew Bulletin, an account of the Chinese ginger plant is given, and it has been ascertained that the preserves are not manufactured from the true ginger, but from a rhizome obtained from another species of plant allied to the ginger. This has been accepted to be *Alpinia Galanga*, the *Kaluwala* of the Sinhalese. It has also been found out that Siam exports a species of ginger obtained from the rhizomes of a variety of *alpinia* known as *A. Zingiberina*, which is, however, not essentially distinct from *A. Galanga*. The rhizomes of the alpinias possess in addition to the characters of the true ginger an aromatic smell, and they are not so pungent as ginger. In Ceylon we find in addition to the *A. galanga* the supposed Chinese ginger, some other varieties of alpinia very similar to *A. galanga*: these are the *A. albughas*, *Sin. albugas*, *A. nutans*, *S. Rankiria*, and *A. Calcarata*, *S. Ketakiriya*. The rhizomes of all these possess the characters of the Chinese ginger, *A. galanga*.

Chinese ginger in a preserved state does not possess the characteristic aromatic taste or smell present in any of the alpinias. This may

evidently be owing to its being lost or modified when prepared into a preserve.

Anyhow it is certain that the Chinese preserved ginger is quite different from *Zingiber officinale*. When ordinary ginger is preserved it can never be made to possess the characters of the imported preserves. The taste, size, and texture of the rhizome always differ much, and the true ginger, when preserved, is found to be of a very pungent taste and of a harder texture than the Chinese preserve. If then the Chinese preserves are made from the *A. galanga*, the Sinhalese *kaluwala*, there is a fair prospect of opening a new industry in Ceylon, as the plant seems to thrive well in the southern parts of the island, as well as in Kalutara, so far as I have seen. The only use which *Kaluwala* is put to by the Sinhalese is that of chewing the pungent and aromatic flowers of the plant along with betel, these flowers resembling cardamoms in taste. The rhizome is only occasionally employed as a medicine. The following is said to be the method adopted in China in making preserves of ginger:—Soon after the rhizomes are dug out they are washed clean, and after the outer covering or the epidermis is scraped off, rewashed, and kept in water for twenty-four hours. They are then taken out and are spread on a board, the portions which are in any way discoloured or spoilt being removed. Then the whole is pricked with forks which are made specially for this purpose. After having undergone this operation, the ginger is washed again and exposed to the sun till the water is evaporated. Next the rhizomes thus prepared are mixed with sugar and boiled for fully two hours. They are then placed in earthenware pots for a few days, after which they are subjected to the same process of boiling with sugar for a second time. This being the final operation, they are packed in small vessels and sent to the market.

LAWS OF CEYLON RELATING TO AGRICULTURE.

Ordinance No. 23 of 1889.

II. An Ordinance relating to the Irrigation and Cultivation of Paddy Lands.

[This is a consolidation of all the previous Ordinances on the subject, together with some amendments.]

CHAPTER I.

"*Proprietor*" means owner of paddy lands, and includes the cultivator or person in actual possession of any such land.

"*Occupant*" includes a person having the charge, management or control of any land or premises.

"*District*" means any korale, pattu or village, or any other subdivision of a province, which may from time to time be defined by the Governor by Proclamation in the *Government Gazette*.

"*Grain tax*" includes the tax, duty or share due to Government in respect of grain grown in this Island under any of the following Ordinances:—No. 14 of 1840, No. 29 of 1865, and No. 11 of 1878.

For the purposes of Chapters VII. and VIII. "majority of proprietors" means a majority consisting of two-thirds at least of the proprietors present. Provided that such majority shall represent at least one-third of the acreage benefited by such irrigation works, and if they do not represent one-third, then the votes of the proprietors representing two-thirds of the acreage to be benefited shall constitute the majority.

CHAPTER II.

1. There shall be a Board, consisting of the Governor, the Surveyor-General, the Director of Public Works, and such other persons as the Governor shall from time to time appoint, of whom one at least shall be an unofficial member of the Legislative Council, to be styled the Central Irrigation Board of Ceylon. In the absence of the Governor, the senior official member present at any meeting of such Board shall preside thereat.

2. In each province there shall be a Board to be styled the Provincial Irrigation Board, consisting of the Government Agent as President, the Provincial Engineer of the province, and such other persons as the Governor may appoint.

3. The Colonial Treasurer shall pay annually as soon as may be after the first day of January, into the irrigation fund, a sum equivalent to one-fourth of the grain tax collected in the several provinces during the preceding year; such irrigation fund shall be vested in the Central Irrigation Board.

4. Moneys voted by the Legislative Council for irrigation works shall be paid into the Irrigation fund.

5. The Central Irrigation Board shall prepare an estimate of sums to be apportioned from the irrigation fund to the provinces. Estimated apportionment to be laid before the Legislative Council.

(a) Provided that a sum so apportioned to any province may, if necessary, be re-apportioned; sums so re-apportioned shall be included in the annual report of the Board.

(b) Provided also that sums not voted by the Legislative Council for specific purposes shall be apportioned or re-apportioned to each province.

6. Reports of Irrigation Boards shall be annually submitted to the Legislative Council.

7. All acts required to be done by the Irrigation Boards shall be done by a majority of the members of such Boards. The President shall have a casting vote.

CHAPTER III.

1. (a) The Governor in Executive Council may proclaim irrigation districts.

(b) The Government Agent shall call a public meeting or meetings (where more than one are required) for the purpose of determining whether this Ordinance shall be carried into operation with the aid of headmen or of Village Councils or of both.

2. Public notice of such meeting shall be given at least one month before the day fixed for the meeting, calling upon all proprietors within any district or division to attend in person or by proxy.

3. (a) Every meeting so convened shall be held at the time and place appointed, in the

presence of the Government Agent; every proprietor within such district or division for which the meeting has been called shall be entitled to vote.

(b.) The Government Agent shall explain to them the provisions of the Ordinance.

(c.) The proprietors at such meeting shall appoint a Committee of not more than twelve, nor less than three persons, to be associated with the Government Agent for the purpose of carrying out the provisions of this Ordinance, and for advising him in matters connected with the irrigation of the district.

(d.) Where more meetings than one are held, each division shall be allowed to appoint its proportion of the Committee to make up the number for the entire district. When any members of the Committee die, or leave the district, or refuse to act, the Government Agent may appoint others in their stead.

(e.) The questions and resolutions proposed at any meeting, and the number of votes given for and against the same, shall be recorded in the Minutes of such meeting, and shall be signed by the Government Agent. The said Minutes shall be deposited in the provincial or district Kacheheri, and copies thereof, certified by the Government Agent, shall be transmitted to the Colonial Secretary.

4. All questions as to the right of any person to vote shall be decided by the Government Agent. Such question and the decision thereon shall be entered in the Minutes.

5. A majority consisting of two-thirds at least shall decide all questions or resolutions passed at any meeting.

6. The Government Agent may make rules in districts where proprietors cannot publicly meet.

7. All acts committed contrary to the customs and rules, and all complaints relating to matters provided for by this Ordinance shall be investigated and dealt with in manner provided in Chapter IV. or Chapter VI. according to the nature of each case.

H. A. J.

(To be continued.)

THE GRAPE VINE.

(*Vitis Vinifera*.)

4. *Soil and Climate*.—The Vine will thrive best on light soils that have a dry bottom. In such as are rich and deep, it will grow luxuriantly and produce abundance of large fruit. In shallow dry gravelly soils, it will produce less fruit but of better flavour. It grows well in the north of the Island where the soil is generally shallow and dry and lies on calcareous rock. The red sandy soils of Jaffna called *Chempadu* would grow good grapes for wine-making. Retentive clays are the worst soils for the vine. As it wants a very dry soil, it will be advisable to drain the land well where it is not sufficiently dry by nature. The bramble has been found to correspond to a great extent to the vine; and therefore any soil where the former grows freely would be good for the latter. We are growing some vines on such a soil here at Happy Valley, by way of experiment; but as yet I cannot write

with much confidence about them, as the plants are still young.

A warm dry climate is best suited to the vine; and if we want to lay out a vineyard we ought to select a site freely exposed to the sun, especially to the morning sun. The dry hot districts of Jaffna in the north and Hambantota in the south will grow good grapes. As to the fitness of the former place there can be no doubt, as it has been practically proved by our Jaffna gardeners from the late Government Agent Mr. Dyke downwards. Grapes might also be grown with advantage in or near Chilaw, Puttalam, Mannar, Trincomalee, Batticaloa, and parts of Uva. There are indeed several other places in Ceylon where fairly good grapes can be grown for the table, by expert gardeners; Wahakotte, which I mentioned in the last instalment, being one of them. But of course where the requirements of climate and soil do not come up to the proper standard, no grapes suitable for making wine can be produced, as those grown in such places would be too deficient in saccharine matter.

5. *Propagation*.—There are at least four ways by which the Grape Vine is propagated, viz., by seed, layers, cuttings and grafting.

(1.) *By Seed*.—The vine may be propagated by seed produced by cross-fertilization for the sake of obtaining new varieties superior in the size of the bunch and berry, in flavour and delicacy, or in point of hardiness and productiveness. But as yet grape-culture in Ceylon has not advanced to such a degree of development as to call for propagation in this way.

(2.) *By Layers*.—By this method large showy plants can be procured that will soon come into bearing. Loudon recommends the following plan for propagation by layers:—"At the pruning season leave a shoot of strong wood, over and above what may be wanted for training, of a sufficient length to bend down to any convenient place where a pot can be placed to receive it as a layer; and also for training it during its growth. When the vine begins to push, displace all the buds from the shoot intended for laying, except the leading one. When this is grown to about 8 inches or one foot in length, bend it down to the pot and lay it so that the top joint whence the wood has sprung, may be fixed with a strong crook at about one inch under the surface of the mould. As soon as it begins to take root, which may be known by removing a little of the earth, begin to weaken its resources from the mother plant, by making an incision in the wood behind the pot. Deepen this incision by degrees, as fast as the young plant will bear it, until it be quite separated from the old one."

(3.) *By Cuttings*.—This is the most convenient method for us in Ceylon where, generally speaking, Viticulture is yet in its infancy. The advantages of propagating by cuttings are simplicity of operation, economy in labour, and economy in the wood or shoots to be propagated from. The cuttings should be one foot to 18 inches long, and should be planted sloping-wise so as to leave only two eyes above ground. They may be first set in a nursery or in baskets and shaded till they strike, and then planted out after they have grown sufficiently.

(4.) *By Grafting*.—Delicate vines of superior variety can be grafted on stocks of hardy kinds,

and thus the desirable qualities of both can be preserved. This is about the best use of this mode of propagation. 'Grafting by approach,' in which the complete separation of the scion from the parent is effected after the former has begun to draw sap from the stock, recommends itself as the surest method. The best time for grafting is when the vine breaks into leaf after pruning and the shoots have grown about two feet.

AGRICULTURAL LITERATURE AMONG THE ANCIENT INDIANS.

BY W. A. DE SILVA.

The Rishis and Pandits of India who flourished during the earlier ages cultivated many a branch of science met with in the present day. Astronomy, chemistry, planetology, medicine, &c., formed themes for many a volume. The ancient Hindus were great observers of nature, and no branch of Natural Science escaped their observation, and the phenomena of nature they tabulated and wrote treatises on, mostly in verse; this being more adapted for the system of learning (committing to memory) then in vogue.

Printing was an unknown art then, and copies of these great works were possessed by only a few, either pupils of, or descendants of, the authors. Copying was attended with great difficulty, and the language and style was such that a single omission or addition of a letter or syllable was sufficient to greatly alter the original ideas.

It must be admitted that there are a good many incongruities in the writings of these ancient philosophers; but while some of these may have occurred in the original works, there is no doubt that many must have crept in in the frequent process of transcribing the treatises.

Some of the observations on the cultivation and treatment of different products may appear absurd to the modern agriculturist, but there is on the other hand a good deal on the subject of Agriculture that quite corresponds with modern theories and practices.

I shall notice here some observations on gardening given in the Brihat Samhita, an ancient Sanscrit work by Varahamira, who is said to have lived in the fourth century of the Christian era.

Varahamira, in the introduction to his work says:—"Having examined the vast works that have proceeded from writers from the time of Brahma downwards, I purpose to write a brief work embodying the substance of the same. The task is a pleasing one to me." In this work he has devoted a chapter to Agriculture, and from the above passage it is clearly seen that Varahamira's work was not composed of original information, but was compiled from other ancient works.

In this work, the soil and its preliminary treatment is referred to as follows:—"Soft soil is congenial to the growth of all trees; such a soil should be selected for the garden, and the *Sesamum* plant (gingelly) should be first grown

in it; as soon as the plant begins to bear blossoms it must be cut down."

The first piece of advice given here, that of growing gingelly on the soil and destroying it just as it flowers would appear to be absurd to those who are unacquainted with scientific agriculture. But this is evidently intended to prove the necessity of manuring, and to show that green manure is useful in a soft soil, and besides points out the principles of green manuring, by advocating the growth of a pod-bearing, (in this case not leguminous) quick growing plant, with succulent leaves and stem, containing a good percentage of nitrogenous matter. The time of cutting down the plants is also rightly given,—“just as they begin to flower.” In fact no better plant adopted for green manuring, and no better method could be advocated.

Then follows two passages in which certain directions are given regarding the propagation of plants. The first gives the names of some of the principal trees which are grown from seeds; the second runs as follows:—"The jak, the asoka, plantain, jamba, breadfruit, pomegranate, vine, citron, &c., should be grown by planting either their roots after clipping them, or their branches smearing cowdung on the parts cut."

The above trees are more or less successfully grown by division or by cuttings, and the recommendation to smear cowdung on the parts cut is an excellent one, through the neglect of which many failures occur at the present day. It need not be cowdung, but any substance to prevent the rapid evaporation of the sap and the rotting of the parts cut that should be used.

Speaking of the best seasons for growing certain plants the author says:—"Trees that grow without branches shall be grown in Sisira season; and in the Hemanta shall be grown trees that grow without branches; in the Vasantha season shall be grown trees possessing good trunks. The year is divided into six seasons by the Indians, each consisting of two months, thus, the Sisira season extends from the middle of December to the middle of February; Hemantha, from October to December; and Vasantha from February to April."

Then the author proceeds to give the space that should be left between plants; this is of very great importance, seeing the neglect of this important operation among our native agriculturists, though they were taught by their ancient and honored philosophers to adopt a suitable plan. The passage runs as follows:—

"An interval of twenty cubits between trees is the best, one of sixteen is passable, and one of twelve is injurious."

"The trees that are planted very near each other get their branches interwoven as well as their roots, and such trees get choked and do not grow well."

The importance of irrigation and the desirability of watering trees whenever the soil is dry is forcibly laid down; and the names of some of the trees which thrive on wet soils is also given; among the list we find jamba, rattan, nauclea, pomegranate, vine, emberalla, jak, &c.

I shall reserve for my next a notice of the cause and treatment of plant diseases and of special manures and preparations which produce variations in fruiting, growing, &c.

BUILDING MATERIALS.

SECTION II. TIMBER (*continued*)

BY A FACTORY APPRENTICE.

It very rarely falls to the lot of the Architect to select timber whilst in a state of growth, but if such a need arises, he will, of course, choose healthy vigorous and flourishing trees. Preference should always be given to those in which the trunks are most smooth, since a swelling above the general surface is a sure sign of decay. That the condition of the roots of a tree is the best index to its soundness is well known, but yet dead branches, especially on the top, render it very suspicious. In felling trees the large branches should be first cut off, so that the tree may not be injured or strained in its fall, and the trunk sawed as close to the ground as possible. When felled, but not before, it has to be barked, trimmed of its branches, and left to season. Before, however, leaving it for this purpose, it is thought best by workmen to square it to prevent its tendency to split.

The pieces selected for building should possess straight grain, but there are pieces which are occasionally employed, for instance for knees and braces, wherein a curvilinear direction of the fibres is extremely desirable. It may be generally stated that in the case of two equal-sized and seasoned pieces the heavier is the piece to be preferred.

The boughs and branches are never so good as the body of the tree; the larger are stronger than the small limbs, and the wood of the heart stronger than all. When green, wood is not so strong as when thoroughly dry, which it rarely is till two or three years after it is felled. Timber that contains much sap is not only weaker but decays sooner. Timber is weakened by knots at which by experience it is found that fractures most frequently occur: and it is important to the Architect to recollect that he should always reject cross-grained pieces. The life of trees, like that of men, has been commonly divided into three stages: youth, maturity and old age. When a tree has arrived at a mature age the proportion of sap-wood is small and the heart-wood is nearly uniform, and is hard, compact and durable, and this is the proper stage for a tree to be felled. A tree when felled in infancy contains a great deal of sap-wood; when not felled till it is on the decline, that is, till it reaches old age, the wood is brittle and devoid of elasticity, tainted, discoloured and soon decays.

In order that timber may be durable, not only is it necessary that it should be felled during maturity, but due attention ought also to be paid to the proper season of the year for felling.

(*To be continued.*)

PADDY CULTIVATION IN THE NORTH.

SIR,—Will you allow me through the medium of your Magazine to make certain suggestions with regard to paddy cultivation in Jaffna?

It is generally known that paddy cultivation in that place has proved a total failure during the last three years, and I think we may safely

fer in that there is very little hope in the future of a successful crop there. The usual nature of the seasons seems to have changed, and there appears to be a tendency towards a lengthening out of the dry and a shortening of the wet season.

The average paddy crop in Jaffna is undoubtedly a poor one. True, there have been cases in which good crops of paddy have been reported, but the figures meant to denote high yields refer only to special cases, where a very small extent of land, on which more than the ordinary treatment and attention has been bestowed, is cultivated. I am led therefore to think, and that not without reason, that paddy cultivation in Jaffna cannot be a success. How then can Jaffna hold its ground? I say let it look to that which thrives in the North.

The fact that Jaffna has long been famous for its fruits and dry grains, such as peas, gingelly, chillies, varaku, kurakkan, maize, &c. cannot be denied. Grapes and mangoes, oranges and pomegranates are unrivalled for their quality. Good mangoes in Colombo are identified with Jaffna mangoes. Mr. Green, the indefatigable promoter of agricultural knowledge in the Island has in his Agricultural Primer rightly suggested the extension of fruit culture, as well as encouraged the cultivation of dhall in Ceylon. Jaffna ought to lead the way in carrying this advice out, especially as its soil suits the cultivation of fruits of superior quality and of leguminous plants.

The digging of wells in the usual way in the midst of every cultivator's land is essential to a place like Jaffna, to water his crops whenever the rain fails. I will not speak here of novel experiments such as the boring of artesian wells, which has engaged the public attention for some time past.

New implements of culture are not for the most part suitable to the Jaffna soil, which is of a shallow limy nature, but there is nevertheless room for improvement in Jaffna. I would suggest that the cultivators should cultivate paddy and dry grains alternately, and give more attention to the latter—that is to say they should practise a simple rotation of crops. A rotation is carried on there to some extent, but in no systematic manner, and I propose that dry grains be cultivated, in turn, throughout one whole year.

Hitherto dry grains were looked upon as something secondary, but in fact, they are of primary importance in Jaffna, and ought to be considered such, as the *dry* season is predominant there. The Jaffna farmer has hitherto considered himself to be the cultivator of paddy, and to cultivate it was his chief aim and ambition. Hereafter his chief object must be to engage himself in the cultivation of dry grains (which is sure to remunerate him amply) and not to waste his time, strength and capital in his vain endeavour to secure a few bushels of paddy each year. The dry season is sure to come every year, but the wet season, almost as a rule, disappoints him. Therefore, he ought to ponder over these facts and betake himself to a more extended cultivation of that species of grain which is suited to the conditions of soil and climate in this district. By doing this Jaffna will find itself in a better position than now, and by gradually dropping the cultivation of paddy, will in an indirect way, help to abolish the paddy-tax!

R. M. C.

GENERAL ITEMS.

Mr. T. W. Goonewardene, Agricultural Instructor at Kolonna, writes:—Kolonna is a small village situated fifteen miles to the east of Rakwana, and consisting of about sixty dwelling houses surrounded by hills on three sides. The average temperature may be fixed at 82°, and the rainfall, as calculated last year, 50.38. The small rainfall at present is no doubt partly traceable to the destruction of the forests for chena cultivation. The inhabitants depend mainly on kurakkan, and, to a smaller extent on paddy. They devote most of their time to chena cultivation, owing no doubt, for one reason, because it is less troublesome than paddy cultivation. Parangi and fever, whether due to the common diet of dry grain and elk's flesh or other causes, are very common among the people. Both clayey and sandy soils are found in the district, and these overlie a dolomitic limestone formation which is seen on the sides and bed of the river. The natives burn this limestone and prepare lime for washing their house walls. There was hardly any rain during January last, and the drought coupled with the prevalence of fever makes it hard to carry on any experimental cultivation on a large scale. There is also no tank to which we can look for water to irrigate the fields during the dry seasons. There are only two tanks in the korale, one near Maduwanwela Ratamahameyas' residence, the other at Hulandawa. The R. M. is doing much philanthropic work, and the poor and afflicted inhabitants owe much to him as well as to Dr. Vethecan. I have been engaged in preparing a piece of land for the cultivation of dhal, which I shall endeavour to popularise among the inhabitants as a nutritious food.

Mr. Juanis writes from Nildandabhinna. The weather at present (March 3rd) is very warm, there having been no rain for two weeks past. This sudden drought and heat is most inopportune, and not having been calculated on, is doing much harm to the young crops, especially those in hilly places where it is so difficult to water them by the hand. If there is no break in the weather before long, and the drought holds out for a month or two, the paddy crop must prove a total failure, and the people must look for bad times owing to short food supplies. The dhal and arrowroot I planted are holding out well, under adverse conditions.

Mr. Jayasuriya, head-teacher Walapane, sends a translation of a curious "disquisition on water" from the "Yoga-arnawa" of Meyrupada, an eminent and learned priest who lived in the reign of Prakrama Bahu III. A. D. 1267:—

Of all waters rain-water is the best—it is light, promotes appetite, destroys the three *dos* (viz., bile, phlegm and wind), and is an antidote for poison. The same when it enters into the earth, wells, &c. acquires different tastes and loses much of its virtue. The water of rivulets is tasteless, but it produces flatulency; that of lakes is sweet and light; that of tanks prevents both phlegm and flatulency, that of ponds promotes flatulency, that of pools is tasteless and induces hunger, that of waterfalls and rapids is light and destroys phlegm, that of wells

promotes hunger and flatulency, that of water-springs destroys bile, and that which proceeds from mountains, washing them in its course, as well as that contained in natural lakes, causes pulmonary diseases, affections of the head, boils in the necks, &c. River-water which flows eastward is light, and that which proceeds westward is heavy; the same if in a muddy locality is heavy, but in stony places is light. The water of a first shower of rain, by reason of its coming in contact with dry organic matter, and engendering worms and insects, produces coughs, cold, asthma and inflammations. Rain water should not be used during autumn, since it is said to fall on account of serpents. But above all, let not water teeming with animalculæ or filthy water, or water mixed with *sevel* (*Valisneria*) in stagnant pools, or water which has seen the light of neither the sun nor moon, be used.

The following answer is given to a correspondent to the Agricultural Journal of Cape Colony who puts the query, "Has the Banana seed, and can it be propagated from seed as well as from the tuber? Also at what age does it begin to bear?"—

Answer.—The Banana, like most plants cultivated from time immemorial, has altered enormously from the wild form. There are dozens of varieties; and the ones most prized are those absolutely without seeds. Obviously such plants can only be propagated by vegetative method, analogous to cuttings, suckers, layers, &c. The custom is to allow the stem of the year to ripen its fruit, then to cut it down a little above the ground. A little mulching of old banana leaves is heaped loosely at the base, and in a few weeks new shoots spring up from the side of the old stool. The largest of these shoots has been known to show bloom in the third month after appearance above ground. But if the major part of the old stool is cut away and the root mass or rhizome be transplanted, it will not show fruit till the tenth and eleventh month. Some varieties of Banana, however, have seed. Pinlayson, in his Siamese Journey, found examples of cultivated bananas with a few seeds, and mentions a wild sort full of seed, but deficient in pulp. (*Journal Voyage to Siam*, London, 8vo., 1826, p. 56.) Meyer describes the "Plantano de Pepita," in the Island of Luzon, which though propagated as usual by shoots from the rhizome, is full of fertile seed, and is good eating.

Practically, at the Cape and Natal, shoots are the only mode of propagation. Even if seeds were obtained the result would be unsatisfactory, as the seedlings would be sure to "throw back," or revert to the wild state, more or less. This custom of using seedlings of orchard trees for fruiting, instead of for stocks to graft on, is ruinous to the character of Cape fruit, and accounts for our mostly tasteless apples, our leathery peaches, and thick-skinned oranges. I have known a banana shoot bear in the third year, but it is mostly a question of climate.

An excellent remedy for hoven in cattle is said to be carbonate of soda. The soda—one ounce—must be given in a bottle of warm water and slowly poured down the throat. This is recommended even for horses,

TEA AND COFFEE IN CEYLON.

UPS AND DOWNS—CONTRADICTORY EXPERIENCES—
FARMING VICISSITUDES IN ENGLAND.

LAST mail brought us the following pertinent criticism and enquiries and interesting notes from a Ceylon proprietor now at home. They will be read with attention by planters, especially the in-

formation given about farms in England:—

“The *Ceylon Observer* of the 5th Feb. has been my study today, and I am much struck with the conflicting accounts of the tea and coffee industries. Why should the proprietors of Brae group part with their apparently valuable property for £4,500, when the Yatiyantota Company can pay 25 per cent dividend? Unless I am much mistaken Mr. Hugh Fraser was specially complimented in your columns of the *Observer* on his good fortunes in Brae? * Again in Haputale bug is reported to be disappearing and some quite phenomenal crops are reported—thousands of bushels in fact. Accounts from Madulsima however show that bug is *very* bad on the small acreage of coffee left. A similar report comes from Udapussellawa. † Wilson and Smithett have just sent me a sample of some ——— (Uva) peaberry which made 136s per cwt. This is 9s. over the highest price, which ——— (Uva) coffee ever made, when comparatively healthy. From what my manager says, however, I cannot think that coffee will ever pay for money bestowed upon it. A crop is a mere chance.

“Cinchona seems to have become like a broken reed—and no wonder, when quinine is quoted at 11d per oz.! I believe chemists still charge from

* True, and Brae in tea has done well and promised to do better; but Mr. Fraser had absentee partners who wished to realize, we believe.—Ed. *T. A.*

† True again: Haputale coffee is wonderfully free from bug, while it is very prevalent beyond the patawas on Udapussellawa coffee at present.—Ed. *T. A.*

3s 6d to 5s. When do you think that we shall have a railway into the heart of Uva? Is it not nearly 20 years since the first agitation? Enough to break stout hearts.”

[Yes indeed: our first Memorial was in 1872, but our correspondent will be glad to hear that the line—not merely to Haputale, but to Bandarawala with a new and fairly level road to Passara—should be open by September 1892.—Ed. *T. A.*]

“What very poor prices, they seem for estates in tea compared to the prices paid for coffee estates in our prosperous days, such as Monaragala £70,000, Wallaha £27,000, old Sylvakande £15,000, Alice Holt Group £75,000, Ceylon Plantations Co. Group £50,000, Doomoo £14,000, Forest Hill ditto, Yapame £18,000, and jungle at R280 per acre!

“All I can say is that these vicissitudes are not peculiar to Ceylon. The finest grazing land in England can be bought at about £30 to £40 per acre—very often 20 years purchase on the reduced rents—and land in Essex is at this present moment abandoned. It is like a jungle, and homesteads and cottages are falling into ruins.

“I have just been over a farm of 88 acres in this county which let at £150 and £130, and the rent is now £60 per annum. The outgoings are about £30 p. a. The craze is laying down land to pasture to escape expenses, and over a great deal of this land one can “whip a mouse” at all seasons.

“Farmers and peasantry are being rapidly ruined, and the ‘Deserted Village’ is no poetic imagination.”

BAD TEA SENT FROM AMERICA TO AUSTRALIA.

A telegram in an Australian paper, dated Melbourne, March 5, runs:—

Two hundred and fifty chests of bad tea per “Tsinan” have been returned from Sydney. The tea was shipped in the United States and was recently condemned in Melbourne. It is understood that the United States Consul will prevent the tea from being landed in the United States.

A GERMAN inventor proposes to make boots with stone soles. He mixes with a waterproof glue a suitable quantity of clean quartz sand, which is spread on the thin leather sole employed as a foundation. These quartz soles are said to be flexible and almost indestructible, while they enable the wearer to walk safely over slippery roads.—Ex.—*Indiarubber Journal.*

THE AMSTERDAM CINCHONA AUCTIONS.

AMSTERDAM, Feb. 26th.

The following are the analyses of the cinchona bark offered here today:—The manufacturing bark contained about 9 tons sulphate of quinine, or 3.86 per cent., on the average; about 1½ tons contained 0.1 per cent. sulphate of quinine; 20 tons, 1.2; 42 tons, 2.3; 65 tons, 3.4; 60 tons, 4.5; 19 tons, 5.6; 8½ tons, 6.7; 9 tons, 7.8; 2 tons, 8.9; 2 cwt., 10.11; 1½ ton, 12.13 per cent. Of the total quantity offered 2,385 packages were disposed of at a decline in prices, the unit averaging barely seven cents, or not quite 1¼d. per lb. The following was the range of prices: Manufacturing barks in quills, broken quills, and chips, 8 to 91 cents (1¼d. to 1s. 4½d. per lb.); ditto root, 15 to 50 cents (2¼d. to 9d. per lb.); druggists' bark in quills, broken quills, and chips, 14 to 140 cents (2¼d. to 2s 1d. per lb.); ditto root 12 to 13 cents (2¼d. per lb.) The principal buyers were the Auerbach and Brunswick factories.—*Chemist and Druggist.*

COFFEE IN NEW CALEDONIA.

The *Fiji Times*, in advocating the revival of the coffee enterprise in Fiji, notices its success and probable extension in the French convict settlement of New Caledonia. We quote as follows:—

Another matter, which was almost abruptly abandoned before it had received a fair trial on anything like a comprehensive scale, also might well come to the fore. That is—Coffee. Notwithstanding the effects of the disease to which it is subject, there can be no doubt that it can be made a highly profitable production. Fiji need not look far for assurance in this respect. Her near neighbour, New Caledonia, is making a success of it. From a recent number of the *Times*, we learn that "in an official report upon the condition of that colony the Governor states that agriculture, which has hitherto been of only secondary importance, seems to be entering upon a period of rapid development under the influence of the fresh means of action afforded it by the immigration from the New Hebrides, and New Caledonia will produce in this year (1890) 400 tons of coffee, while it is expected that in four years' time the production will exceed 1,000 tons * * * The Governor reports that what New Caledonia is most deficient in is labour, but he adds that the work done by the convicts, especially at the Thio penitentiary, is much more satisfactory than that of the convicts in Guiana, while the men who have served their time and who choose to work can always find employment at wages of from 4s. to 5s. a day, while at piecework they in many cases earn 10s. a day."

It has been proved beyond question that this colony can produce coffee in perfection. Machinery is here, and skilled knowledge. Yet coffee ceases to count among the exports and home consumption has become a thing of the past, simply because the industry has been given up. It is puzzling to arrive at a comprehension of why this should be. Of course there is the ready answer that it "does not pay." But why should that be the case. If New Caledonia can grow at a profit why cannot Fiji do the same. That the French settlement is doing this may be gathered from the expectations entertained of progressive production. An anticipated increase at the rate of 150 tons per annum is by no means despicable; while at the same time it warrants the belief that no oversanguine estimate has been made. It means a lot of money, however, and this colony is not so superabundantly supplied with that evil of life, but that she can cheerfully bear a heavier burden.

So far as labour is concerned, no reason exist why Fiji shall not be reckoned as on a par with New Caledonia. If growers there can afford to pay reasonable wages and find a fair margin of profit, why should not similar conditions prevail here. Soil is at least as fruitful and climate quite as favorable. In fact, it would be hard to state wherein this place is not at least equally well-off with her neighbour in those constituents.*

* So far as the *Fiji Journalist*,—but not a word is said as to whether leaf disease has reached New Caledonia. Its absence would make all the difference in the world.—*Ed. T., 4.*

PORTSWOOD TEAS AND LOCAL SALES

The proprietor of Portswood is not inclined further to support local Tea Sales. His experience is not favourable as may be seen from the following extract which we venture to make from a letter before us, not however, written for the printer:—

"You know that some of us have often been asked to sell our teas locally. I have done it twice or three times and each time with a loss. At a recent sale in Coolemb 86 66 and 57 cents were bid for Portswood teas—all were left unsold, being considerably under my values—but since the sale, they have been sold privately by the Brokers at R1, 72 and 62 cents and these prices are 1 to 17 cents under the average net price I received in London on 17th Feb. last. Why therefore should I continue to sacrifice the estate interests?"

THE TUTICORIN PEARL FISHERY OF 1890.

Pearl-oysters require rest; and after one fishing a pearl-bank is left in undisputed possession of the young oysters for a certain number of years, to enable them to grow and to settle down on the bed. Following the wisdom which teaches that some years' rest to the beds should be insured after each fishing, the officers and authorities who had the reviewing of the Pearl Fishery Report for the past year have allowed themselves sufficient rest and have proceeded in a leisurely manner to bring into perfection the pearl of a G. O., which now lies on our table. The first report of Captain Baker, the Superintendent of Pearl Fisheries, is dated the 20th of March last year, and his second report the 15th of May the same year. The Acting Collector of Tinnevely submits his narrative of the Pearl Fishery to the Commissioners of Land Revenue on the 16th June, and the Commissioners submit the same with a review thereon to Government on the 22nd August. The Government deals with the Pearl Fishery on the 19th January of the present year, and the whole proceedings, after enjoying a comfortable rest in the Government office like the oyster on the recently fished up bank, come to us now.

The fishery, as appears from the report, was commenced on the 27th January, 1890, and lasted until the 8th March, when it had to be closed, as the divers went over to Ceylon. It was recommenced on the 23rd April, but it had to be closed again on the 4th May on account of a panic among the divers, two of whom had been bitten by sharks. The number of days during which the fishery was conducted was 40 and the Government's share of the takes amounted to 1,204,816 oysters. The price at which they were sold ranged from R16 to R36 per 1,000. The total amount realized was R24,701-5-10. To this amount has to be added R359-12-0, being the value of loose pearls and the sale-proceeds of the materials of the temporary buildings erected for the fishery. The charges amounted to R17,257-11-5, so that the net profit to Government was only R7,803-4-5. This is a very disappointing result, especially when compared with the net profit of R158,483 which was obtained during the fishery of 1889. The cause of these poor results as explained at length by Captain Baker are chiefly competition by Ceylon, the panic caused by the appearance of sharks, and the extremely low prices. The two last are to be regretted, but could not be avoided, say the Commissioners of Land Revenue. As regards the competition between the Madras and Ceylon fisheries, the Madras Government agrees with the Board of Revenue that effort should be made to come to some amicable arrangement. It is, of course, open to either side to bid for the services of the divers by the offer of better terms, but the Government declares that it would be most averse to entering upon any such system of rivalry, which in the end could not fail to be very disadvantageous to both Governments. This Government has accordingly decided to ask the Government of Ceylon whether it will consent to any arrangement under which the interests of both fisheries will be safeguarded. The questions of clandestine opening of oysters

and of clandestine fishing of the banks were also raised in the papers received by Government. There appear to be three sources of danger to be guarded against—(1) Poaching on the banks by a foreign vessel; (2) Poaching on the banks by a British vessel; and (3) Pilfering of pearls by the boats' crews whilst conveying the shells from the banks to the shore. The first, the Government observes, is a remote danger and may be disregarded. The second may possibly have some foundation of reality. So long ago 1883 the belief was expressed that the banks were extensively poached but there is nothing on record to show to what extent such poaching was prevalent. Before taking any action in the matter, the Madras Government has resolved to address the Governments of Ceylon and Western Australia in order to obtain full particulars regarding the pearl-fishery laws in those colonies. In the latter country it is said that "the fishing takes place in the main outside the 3-mile limit, and the colonial jurisdiction is not supposed to extend so far." With regard to the third difficulty the Bank of Revenue considers that when once the oysters have been raised to the surface and placed on British vessels by persons employed for that purpose by Government, they become the property of Government, and that if the pearls are then abstracted, taken ashore, and sold, the offence is one of simple theft. In this view of the matter the Government is inclined to agree, and in any case by diminishing the value of the produce to be shared between themselves and the Government, the divers are guilty of cheating. The provisions of the Penal Code, the Government considers, are therefore sufficient to meet the case.—*Madras Times*, March 10.

THE W. P. A., in its usual go-ahead manner, has offered a prize of R200 for the best essay on tea cultivation, of practical local value. The point on which it requires particular and reliable detailed information is the best manner in which a factory on the Joint-Stock Principle can be worked. Essays are to be sent to Mr. Hockin of Vayitri, S. Wynaad, before 1st June.—*Madras Times*, March 18.

WYNAAD PLANTING NOTES, March 12th.—Last month the rain came down heavily, measuring in some places, as much as two inches, though the fall was very partial, and from what I hear, I fear was insufficient in some parts. The Vythery and Sultan's Battery districts were especially favoured; and the result has been a very fine and healthy blossom which, to all appearance, has set satisfactorily. A great quantity of backward spike is now maturing, and we shall soon be crying out for more rain to bring out our second blossom. So far crop prospects are exceedingly favourable, but so many ills is coffee heir to, that we cannot feel sure of our future, until much later in the season. The heat is very great here now, and the drought is severely affecting the locals; wells are being dug in the paddy flats, and in some of the parties the people are actually suffering from want of sufficient water to drink. This, of course, is also a bad thing for the new clearings, and a great number of young plants will be destroyed. In spite of the heat and dryness (attributed to the failure of the North-East monsoon), our old coffee is looking remarkably well, and throwing out quite a flush of young leaves. Two of our community, each on his own account, are working hard at experiments for the destruction of leaf disease. Both seem hopeful on the subject, and even should they fail, are deserving of our gratitude for their praiseworthy efforts on our behalf. Wynaad is not particularly lively just now, but the "submerged tenth," of us who *can't* get away even to the hill tops, contrive to meet once a week or so for tennis, and general sociability, and it is certainly pleasant to catch the cheerful drifts of conversation.—"Glad to hear you had such a splendid blossom"—"never saw anything like my spike," and so on. It feels like getting one's head above water once again. I hope that my next will be a further record of things, and that I may be able to report that another good rainfall has brought out a second blossom, nearly if not quite equal to the first.—*Madras Times*, March 18.

THE CULTIVATION OF PADDY has been shown to be an unremunerative concern. Not only so, but in a congested place like Jaffna where everything depends upon the periodical rains the chances of success are few and far between. Then let our young men launch themselves into other pursuits. Nothing enriches a people or a nation so much as successful commerce. But if trade or commerce is to be successfully pursued, our young men should fully realise the power of association and the value of mutual confidence as the chief conditions of success on any large scale.—*Com.*

PLANT DISEASES.—Professor Plowright's lectures at the Royal College of Surgeons have been delivered this week. The first was devoted to generalities, and to the effect of fungi in producing over-growth (hypertrophy), from irritation or wasting (atrophy), by depriving the plant of its natural food, and appropriating it to its own use. Various illustrations were given. The second lecture was devoted to the Potato disease. As we shall be in a position to publish these lectures with numerous illustrations, we forbear from further comment at present.—*Gardeners' Chronicle*.

WYNAAD PLANTERS' ASSOCIATION.—From proceedings of a general meeting held at Vayitri Jubilee Hall, 4th March. Present—Messrs. Atzenwiler, Batty, Boosey, W. F. Brown, Chanier, Hockin, Lamb, McCabe, Powell, Ramsay, Rosling, Taylor, Trollope, Walker, Winterbotham and J. F. Jowitz, Acting Honorary Secy. Mr. Hockin in the chair. *Leaf Disease*.—Read letter from the Honorary Secretary to C. E. P. Veruede, Esq. in reply to his offer to come to Wynaad. Also Honorary Secretary's letter to Dr. McCabe thanking him for his Essay. Likewise letter from the Honorary Secretary to the Chief Secretary to Government, Madras, asking the Madras Government to be good enough to forward an application on the Association's behalf to the Government of India for the services of Surgeon Major Barclay on the special duty of further investigating Hemileia Vastatrix. Read also a letter from Mr. Murray together with an extract from the "Detroit Free Press" on the Washington Bureau of Vegetable Pathology. Resolved that Mr. Murray be thanked for the interesting article, and that the Honorary Secretary communicate with Professor Galloway in charge of the Bureau, bringing to his notice the disease our coffee is suffering from, and solicit his aid.

LIQUORICE.—In *A Modern Apostle: Alexander N. Somerville, D. D.*, by George Smith, C. I. E. LTD., there is an interesting account of the manufacture of liquorice as witnessed by Dr. Somerville at Sokia, near Smyrna. In his (Dr. Somerville's) own words—"The juice is extracted by machinery, here and in America; for the firm (Messrs. MacAndrew and Forbes) has a factory there, and exports from Asia Minor a large quantity of the root. Only a trifling amount now is employed for medicinal purposes; it is principally used for combining with Tobacco leaf to make 'Cavendish,' which is much in vogue with sailors. The whole valley of the Meander for above 100 miles is more or less over-spread with diggers, men and women, extracting the roots from the ground, stacking them, putting them into bags, and sending them on to various stations on camels. I was led to understand that this gives employment to nearly 100,000 persons. Indeed, the business has an important influence throughout the district, by teaching the people habits of industry..... We went over the factory, connected with which are Scotchmen, Circassians, Turks, people from the Isle of Patmos, and Scala Nuova, near Ephesus. The manufacture of liquorice paste is accomplished by grinding down the root between ponderous mill-stones. James, observing in the yard some seventeen of the stones formerly used, and detecting in them a resemblance to the drums of colossal pillars, inquired whether they had not been taken from some antique structure, and elicited the information that the worshippers in the temple of Artemis, at Magnesia, in the days of Themistocles, had not been unfamiliar with them when occupying a very different position."—*ATHENEUM—Gardeners' Chronicle*.

CINCHONA CULTIVATION IN JAVA.

Mr. van Romunde's report on the Government cinchona enterprise in Java for the fourth quarter of 1890 states that the weather during the quarter was very abnormal. October and the first half of November being very wet; the second half of November being very dry with low temperature at night and frost in some parts; and December being characterized by alternate rain and drought. The drought in the latter part of November caused considerable damage to the young plants; but the loss can be made good by means of the large number of well-grown plants in the nurseries. The older plantations showed remarkably good growth during the later months; and the prospects for the crop of 1891 are therefore very favourable. The crop of 1890 amounted to 459,000 half kilograms of bark, of which by the end of December 364,123 pounds had been forwarded to Tandjong Priok. Though a considerable decrease in production has been experienced during the past year, this is certainly not to be ascribed to a diminution of the stock of bark in the plantations, but is found in the sparing to the utmost of the trees, specially of the ledgerianas after it was seen that very densely grown plantations were not attacked, at least not appreciably, by *Helopeltis antonii* or by caterpillars, which have caused such devastation of late years. The amount of bark in the plantations has therefore very largely increased during the past year, in spite of the unfavorable weather of 1890. On 2nd October, 6th November, and 11th December, sales of the bark of 1889 were held in Amsterdam, the unit prices obtained being respectively 9, 8 and 8 cents per half kilo. In November and December cinchona seed was sold by public auction, the gross amount realized being f1,027 and f792. In consequence of the small amount of dry weather in 1889 the supply of ledgeriana seed was very small, and the prices realized therefore far exceeded the minimum prices fixed by the Government. For one lot indeed so much as f2 per gram was paid. The total number of plants in the Government plantations at the end of 1890 was 3,489,800, made up as follows:—in the nurseries 920,000, viz., 510,000 ledgeriana (including 10,000 grafts) and 410,000 suceirubra; in the open 2,569,800, viz., 1,905,000 ledgeriana (including 265,000 grafts and cuttings, but exclusive of the more or less 3,000 original ledgerianas), 2,400 calisaya and basskarliana, 605,000 suceirubra and caloptera, 55,900 officinalis, and 1,500 lancifolia (among these about 1,000 *O. pitayensis*).

REVIEW OF CINCHONA BARK AT
AMSTERDAM FOR THE YEAR 1890.

(Report by a Dutch Broker.)

Amsterdam, Dec. 1890.

The past year has been one of great importance for the Amsterdam cinchona market, in the struggle for precedence with London as market of the world; our market may be looked upon as the victor.

Much has been contributed to this result by the energetic leadership of the founders of our cinchona establishment, who from the beginning, have taken care that everything could be done to the bark received here, which would tend to promote a favourable sale. The untiring energy with which growers are made acquainted with possible improvements and economy in their productions, has been attended with marked result.

Both buyers and sellers have become convinced that our market offers advantages which are not to be found elsewhere. Each package can be inspected and

sampled three weeks before every sale, and of every parcel an analysis is made and published by non-interested analysis. In addition to this the charges to all parties interested have been calculated on a very low scale and are very much less than in London or elsewhere.

From the subjoined tables it will be sufficiently clear how much the trade in this article has increased here. When taking into consideration the average strength of the Java bark and that of the barks offered in London, it will be clearly seen, from a comparison of the turn-over of both markets, in which direction our market is progressing.

At the end of the year our stock in first hand only consisted of about 2,000 packages, being for the greater part arrivals which came too late for the December sales, and partly lots left over from previous sales. This quantity does not comprise the Government barks intended for the public sales in 1891. The stock in second hand is not worth mentioning at least as far as the factory barks are concerned, whilst the stock of pharmaceutical barks is if anything smaller than at the beginning of the year. Notwithstanding the important increase in the arrivals, we yet find here a stock too small to be of any importance, whilst the stock in London is continually decreasing. It appears therefore that so far the demand for quinine has kept pace with the increased productions. Whether this demand owes its origin to an increased consumption (as many think) or whether it is attributable to an increase in the number of speculative buyers, it is difficult to say. So much, however, is certain that in the first case, the low basis which cinchona bark has reached would be perfectly unjustifiable, and the position would have to be attributed to abnormal relations and influences which interfere with the natural course of events.

FACTORY BARKS.—The handling and packing in Java now leaves very little to be desired, and the arrivals this year were again in both respects much better than formerly. Occasionally parcels were met with, which had been insufficiently cleared of wood and fibres which causes distrust amongst the buyers. Bales insufficiently filled are now very much the exception. In Java the importance has been well understood of carefully mixing the barks before putting them in the bales, by which process the bales of every parcel show equal quality. Shippers whose marks have been treated with special care in this respect, will have experienced the advantages of this mode of treatment.

In January the market was very firm and in the first public sale everything was sold at an average unit of about 10 cents, quinine was sold in that month at, from 1s 2½d to 1s 4½d per oz. (f. 25½ to 28 per kilo.) This favourable tendency continued until shortly before the March auction, when quinine dropped to 1s 1½d (f. 23½), and the unit after having reached + 10½ ct. in the February sales dropped to + 9½ ct. In the May sales a slow market was experienced with falling tendency and the average price realised was only 9½ ct.

In June and July larger transactions took place in quinine at lower prices (12d f 21) and the two sales only realized + 8½ ct. and 8½ ct. respectively per unit. Before the August sales an improvement set in which caused the average unit to rise to + 9½ ct. but in the October sales under the influence of low offers of quinine for forward delivery, the value again fell to a unit of about 9½ ct. The November sales the largest of the year were held at a bad time. The financial situation was unfavorable, general distrust and want of activity was experienced, all of which led to a drop and quinine was offered at 11½d (f. 26½). In this sale not more than 8c. per unit could be made, at which price 703 packages were taken out whilst 409 packages had been withdrawn before the sale. On the same day however the greater part of the barks taken out were sold privately at secret prices.

In December the tendency became if possible still more unfavorable; quinine was even offered at 11½d, but the low price brought apparently an increased demand. In the last sale of the year everything could be disposed of, at an average unit of 7½ ct. and after this

sale the tendency of the article has slightly improved. PHARMACOLOGICAL BARK.—*Succirubra* was freely offered but it must be observed that there were many parcels amongst them, which were bought by the factories as "fine dust" with a relatively high percentage of sulphate of quinine, and which therefore ought to rank as factory barks.

QUILLS.—Fine, silver-grey, quills well covered with moss fetched continually firm prices and larger shipments of these would undoubtedly be welcome. The highest price was paid for a parcel of officinalis stem bark quills, only 25 centimetres in length, but of a beautiful typical appearance and well grown over being f. 1.15 per $\frac{1}{2}$ kilo. Inferior qualities will no doubt have frequently given disappointment to growers when sold here. When the bark is dark and smooth without moss or silvercoat it does not pay to make it into quill shape; it is more advantageous to grind these barks to dust. In the case of fine but thin bark of good colour, which it is desired to ship as quills it is advisable to pay less attention to obtaining long quills, but to roll them well (not too broad, but straight pieces, well assorted and convenient for packing in cases). The result obtained by a few shippers with produce of only average intrinsic value but which had been prepared with great knowledge and care, has proved the great advantage that can be derived in this way.

BROKEN QUILLS AND BOLD DUST.—*Succirubra*, in bold thick pieces, coated with moss and little dust always finds ready buyers at relatively high prices. Except from the Government plantations, where very old trees are found, very few parcels of the desired quality appear on the market. Thinner younger bark, of good colour and free from dust, such as private growers can also furnish also finds buyers however at comparatively good prices. C. Schukkratt, on the contrary remains low in price. H. A. VAN OVERZEE, JR., Broker.

AN ACTION ABOUT CINCHONA BARK.

A PLANTER COMPLAINS OF HIS COLOMBO AGENTS FOR HOLDING HIS BARK CONTRARY TO INSTRUCTIONS.

Baker and Hall v. E. P. Wilmot.

(D. O. Colombo No. 1,027.)

This was an appeal from the judgment of Mr. J. Grenier, Acting District Judge of Colombo.

Mr. Wendt (Mr. Dornhorst with him) appeared in support of the defendant's appeal.

The Attorney-General (Mr. Brown with him) for the plaintiffs, respondents.

Mr. Dornhorst replied, and the Court took time to consider its judgment.

On 4th March 1891 the following judgments were delivered:—

DIAS, J.—The defendant in this case is an estate owner, and the plaintiffs are Colombo merchants. It was agreed between the parties that the defendant should forward to the plaintiffs at Colombo his cinchona bark, and that the plaintiffs should cure, prepare and ship it to their agents in London for sale; that the plaintiffs should draw on their agents against the bark, and the proceeds of the drafts should be paid over to the defendant, and if the bark when sold in London should fail to realise sufficient to cover the drafts, then the defendant should make good to the plaintiffs the deficiency, with the usual mercantile charges. Accordingly, from 26th Dec. 1887 to 10th April 1888 cinchona bark was sent by defendant to the plaintiffs who shipped it to London, for sale, which resulted in a deficiency of Rs. 2,109-93, of which the defendant paid plaintiffs Rs. 1,500, leaving a balance of Rs. 740-93 in favour of the plaintiffs, and this action is brought to recover that amount with interest. The contract as it is set out in the libel is not denied, but the defendant adds another condition to it, which is that the plaintiffs should not sell the bark for any price less than 3d per unit of sulphate of quinine in such bark, the unit being one per cent of the weight of the bark. The defendant says that till Nov. 1888

the plaintiffs held in London 23,765 lb of the defendant's bark, and that in December 1887 and Jan. 1888 the market price for such bark was 3d per unit, when it was the plaintiffs' duty to sell, but they did not and sold in Oct. 1888, when the market price had fallen to 2d per unit—that if the bark had been sold in Dec. 1887 and Jan. 1888 it would have fetched £508 13s 3d, the plaintiff's claim would be less by Rs. 2,788-48, and the difference in favour of the plaintiffs would then be Rs. 748-02, which the defendant brings into court. There is also a claim in reconvention by the defendant, which in the view I take of the case need not be noticed. In the replication the plaintiffs denied the new contract set up by defendant, and they also denied that in Dec. 1887 and Jan. 1888 bark like the defendant's was worth 3d per unit.

Two questions arise for consideration, viz. (1) whether the plaintiffs were expressly prohibited by defendant from selling below the 3d., and (2) whether the market price of cinchona like the defendant's in Dec. 1887 and Jan. 1888 was 3d per unit. The correspondence between the parties has been summarised by the District Judge, and the result arrived at by him is that the defendant gave the plaintiffs a discretion as to the price, and this finding I think is fully borne out by the letters. On the second question the evidence is all on one side. It appears that by a mere accident the price of cinchona in the London market on the 6th December 1887 had reached the figure 3d, but when we come to consider the circumstances under which public sales of cinchona bark are held in London, the plaintiffs cannot be expected to foresee that on a particular day in the month of December Cinchona bark would realise 3d per unit. In a carefully considered judgment the District Judge gave plaintiffs judgment, and I am not prepared to interfere with it. Affirmed.

CLARENCE, J.—I think that the Judgment of the Court below is right. The evidence does not sustain defendant's averment that there was an agreement not to sell for less than 3d per unit. The letter of defendant, to which plaintiffs' letter of October 4th 1887 was the reply, is not before us, and all that appears is that defendant wished to get not less than 3d per unit, and plaintiffs then assented to let their London Agent hold the bark for the present, in hopes of the market reaching that price. The market afterwards about December 1887 momentarily touched 3d and then drooped. Plaintiffs, with defendant's approval, held on till October 1888, and then in despair of any improvement in the market sold for about 2nd. Nor do I think that the evidence discloses any breach of duty on plaintiff's part in selling under 3d. It is, I consider, sufficiently shewn that the rise in December 1887 was a sudden and unexpected rise of merely momentary duration and that, having regard to the time required for preparing lots for sale, no negligence can be imputed to plaintiffs in not having seized this momentary rise. Nor, indeed, am I satisfied that defendant's bark, if thrown on the market at that moment, would have commanded the full 3d rate. I agree that this appeal fails and should be dismissed with costs.—Local "Examiner."

SALE OF ESTATES.—The sale and purchase of estates in Ceylon goes on merrily, and hardly a week passes but we have to record properties changing hands, sometimes in the island, though often the purchasers are home capitalists the safety of Ceylon estates as a profitable investment having apparently at last become evident to investors at home. We hear for instance that a Syndicate at home is now in treaty for the purchase of the properties of Mr. F. M. Corbet which led to the now famous litigation with the Ceylon Company, while a telegram was received yesterday by Messrs. E. G. Harding & Co., to the effect that the estates in Rakwana of Mr. C. Shand—Barra, Rangelwelle, and Springwood—have been sold to a Syndicate, the names of whom were not mentioned, while the price is also unknown, but Messrs. E. G. Harding & Co., who have been appointed by wire to look after the interests of the purchasers, will know soon by mail.—Local "Times."

MEMORANDUM ON THE PRODUCTION AND DISTRIBUTION OF SILVER.

As it is now practically certain that no fresh Silver Legislation will be enacted by the present Congress, and as the new House of Representatives is not likely to be called together (unless for special business) till the 4th December next, our friends who are interested in Indian Exchange may like to see the following estimate of the Statistical Position of Silver:—

The following therefore is our Estimate for the current year's Distribution, assuming as in Table I that the total production is taken at 145,000,000 ounces viz:—

Table III.		Ounces.	
PRODUCTION OF SILVER (in ounces.)			
Table I	United States	Rest of the World	Total
1887 ...	41,230,000	54,917,375	96,177,375
1888 ...	45,780,000	64,292,140	110,072,140
1889 ...	50,000,000	75,988,671	125,988,671
Estimates	1890 ...	53,000,000	136,000,000
	1891 ...	57,000,000	145,000,000

The estimates for 1890 and 1891 are, of course, to some extent guesswork, but it will be seen that the ratio of increase has been put very considerably below that of the preceding years, though the stimulus to production afforded by the higher prices recently current would seem to justify very much larger estimates. For instance a Daiziel telegram from New York to *The Times* yesterday estimates the United States production for 1891 at 65 million ounces, against our estimate above of only 57 millions.

DISPOSITION OF SILVER.

The following figures are (approximately) summarized from the Report of the United States Treasury to Congress in December 1889, and refer to the previous year (1888).

Table II.	Ounces
United States Coinage and Certificates ...	26,000,000
Arts and Manufactures (for all the World, Soetbeer's Estimate) ...	16,000,000
Subsidiary Coinage, Europe and S. America ...	17,000,000
Sundries (unaccounted for) ...	6,000,000
China, India, and the East ...	45,000,000
Total for 1888 (as per Table I)...	110,000,000

PRESENT POSITION.

No more recent figures than the above as to the Distribution of Silver are obtainable, but we think it may be fairly assumed that the Consumption for Arts, Manufactures, Subsidiary Coinage and Sundries (unaccounted for) will be no more now than it was in 1888, looking to the rise in price. The purchases by the United States Treasury have however increased from 26 million to 54 million ounces, in consequence of last year's legislation.

United States Treasury Purchases...	54,000,000
Arts, Manufactures, Subsidiary Coinage and Sundries (unaccounted for) as in 1888...	39,000,000
Leaving for consumption by India and the East ...	52,000,000
	145,000,000

From the above it would seem that India and the East will have to absorb (even on the extremely moderate Estimate of production given in Table I) 52,000,000 ounces in 1891 against 45,000,000 in 1888, although Silver and the Eastern Exchanges are now higher than they were then. Moreover there is now a large accumulated Stock of Silver in the United States estimated at about 15 million ounces, which must also be disposed of. These considerations seem to indicate that Silver and Exchange must come down considerably in order to admit of the additional absorption.

On the other hand it must be borne in mind that the new House of Representatives which meets in

December next is very differently constituted to the present one; they are largely pledged in favour of Silver Legislation, and the expectation that they will pass some strong enactment in favour of Silver is likely to sustain the price of it speculatively.

The following figures show the shipment of Gold and Silver from Europe to India and the amount of Council Bills for the last 5 years:—

Table IV.	GOLD	SILVER	COUNCIL BILLS.*	
			£	Rs.
1886 ...	819,204	7,044,477	10,292,692	13,53,25,369
1887 ...	1,984,739	6,577,748	12,136,279	16,70,03,150
1888 ...	1,308,232	5,854,533	15,353,557	21,81,23,993
1889 ...	2,103,381	8,189,210	14,262,859	20,89,91,221
1890 ...	3,283,375	8,825,771	15,474,496	22,41,86,638

£9,498,931 £35,924,739 £67,524,903 Rs.95,36,30,371

* For the Financial Year, viz.:—1st April—31st March.

The steadily increasing shipments of Gold to India constitute a noteworthy feature, as tending to decrease her balance of trade and consequent ability to absorb Silver.

ARBUTHNOT, LATHAM & Co.

33, Great St. Helen's, London, 26th Feb. 1891.

PINEAPPLE FIBRE IN THE PHILIPPINES.

Mr. F. W. van Eedeu, director of the Colonial Museum sends us the following for publication. Mr. P. K. A. Meerkamp van Embden, our Consul at Manila who sent us some fine samples of Pineapple fibre last year, which was prepared at Scron, now furnishes us with an account of the mode of its preparation. The Ananas which was introduced here from Mexico about 300 years ago, is named in Spanish "Piña" (pronounced "Pienya") and has no other name in the native languages or dialects of the Philippines.

The plant bears fruit generally in the second year, sometimes in the third year, shortly before this takes place, the leaves which, by that time have attained their full growth, frequently a metre in length are cut, and their preparation begins immediately.

Should the fruits be once formed, the quantity of the leaves deteriorates.

The preparation is simple to the last degree, the leaves are worked one by one, being laid on a smooth wooden plank, and scraped with a little earthen pan or dish until the fibre on one side of the leaf becomes exposed and can be carefully drawn out. The leaf is then turned over, in order that the fibre may be detached in the same way from the opposite side.

For removing the pulpy matter from the leaves a piece of coarse china pottery is commonly used, as good well made pottery would be too smooth. The fibre from the under side of the leaf is of finer quality and therefore of more value than that from the upper side. There now remains nothing more to be done than to wash the fibre and to bleach it in the sun until it becomes sufficiently white, though the color always has a yellow tinge.

Before being woven the ends of the threads are tied together, the knot is so carefully made, that it requires very close examination to discover it. Occasionally the ends of the fibres are united by means of starch, but this practice cannot be recommended, and is but little used because the fibres thus joined are liable to loose.—Translated from the *Indische Mercur* of the 21st February 1891, by J. D. Y.

[NOTE BY TRANSLATOR.—It is from this fibre that the beautifully fine "grasscloth" is made. The Ananas grows so well in Ceylon and most tropical countries that it seems strange that the Philippines seem to retain a natural monopoly of the very fine "grass-cloth." It used to be brought to Ceylon but I have not seen it for many years. It is a pity the Consul Meerkamp van Embden has not given any particulars as to the kind of Ananas which furnishes the fine fibre. Can you tell your readers whether it grows in Ceylon or not, every variety that has been introduced into this island seems to flourish wonderfully well?]

CEYLON TEA IN AMERICA.

We venture to take the following extract from a letter of Mr. R. E. Pineo, under date, New York, 23rd February:—

"Although I have not rushed into print I yet feel very keenly how misunderstood and how little appreciated in Ceylon my efforts here have been. It has not been easy work to get Mr. May to help us in our great cause, but I feel encouraged by what he is doing and am delighted that you appreciate and understand him through his manly, straightforward, honest letters that cannot but convince you how strong and conservative he is. We are making slow, but I think sure, progress; and, in time, I hope our work will be better known and appreciated by our friends in Ceylon.

"Our work is being honestly performed, and through us pure Ceylon tea is becoming known. We are getting agents, but as we are very particular about securing the right men our progress may be thought slow."

Mr. Elwood May's last letter to Ceylon, we may tell Mr. Pineo, certainly did not create a favourable impression as regards manliness!

THE CINNAMON TRADE.

The news we published on March 17th of the quarterly Cinnamon Sales held in London last month, was not very cheering to Proprietors. The supplementary information contained in our commercial columns yesterday, was not calculated to lighten anxiety. It will be seen from the prices realised, that some of the finest Marks, which always commanded top prices, fetched about the lowest prices. The explanation is, not that there has been any falling off in the quality of the spice turned out by the crack Estates, but that the higher qualities had to be bought in. Looking at the Sale Lists received on Tuesday, we find that of more than half the catalogue which failed to find buyers, the better part was fine Cinnamon. Thus, the only quality of the A. S. G. P. (Golua Pokuna) Mark which was sold, was No. 4. Of Firsts 28 Bales, of Seconds 41 Bales, of Thirds 46 Bales, and some even of Fourths had to be bought in. So with the higher grades of F. S. W. S. (Wester Seaton) and F. S. K. (Kimboolpitiya)—they found no buyers. Some part of these Marks was, we believe, sold subsequently at a decline of 2d. a lb. These Marks had long commanded 1s. 7d. to 1s. 8d. for their highest qualities—prices low enough, when far coarser Quills of the same classification fetched about double those prices, so late as 15 to 20 years ago. The highest price last month was fetched by the J. D. S. R. Mark; and that was obtained after the sale. The conclusion seems inevitable, from a study of the results of the last and the preceding sale (at which, too, a large quantity of the best Cinnamon had to be bought in) that buyers have decided on a maximum of 1s. 2d. to 1s. 3d. a lb. Unless, therefore, the manufacturers of fancy quills are prepared to reduce their prices by almost one-third, they must hold their stocks. The more important question, however, has reference to the future—Will Estates continue to manufacture Cinnamon of a quality for which there is no demand commensurate with the cost of preparation? There should be only one answer to the question.

When dealing, about a fortnight ago, with the note of warning sounded by a Voyagoda correspondent against fine cutting, as injurious to the productiveness of Estates, the thought occurred to us, that the need of manufacturing quills of extraordinary thinness might cease by a falling off in the demand for them. We had not forgotten that at the November Sales the finest spice had been neglected; but, in view of the strong demand that there had been a few quarters before for fine qualities—medium and coarse sorts having shown a decline!—we hesitated to discuss a contingency which did not seem imminent. But the news brought Thursday points to the proba-

bility that buyers have noted the continued overproduction of the spice, and have also, perhaps, discovered that bark of coarser make might serve their purpose almost as well as fine quills. Whether this feeling is temporary, or is likely to be established permanently, it is impossible to say with certainty; but experience with the downward tendency of prices for a long time past, and the ready market found for Chips, justifies the fear that growers must be prepared for a further fall. In these circumstances, it would be absurd to continue the manufacture of over-fine Quills, to the detriment of Estates. We have no faith, however, in combination; and fine manufacturers, we fear, will continue to depress the prices for medium makes on one side, just as Chips have done from another. It is not easy to see a remedy, to avoid, on the one hand, the Scylla of deterioration of Estates, and on the other the Charybdis of over-production. One point seems clear, that extra-payment for extra fine quills should cease. If an arrangement be practicable, limiting 30 quills to the lb., the fall in price may be made good by an increased outturn, and by the revival of Estates.—Local "Examiner."

POLISHING WOOD.

The method of polishing wood with charcoal, now much used by French cabinet makers, is thus described in a Paris technical journal:—All the world now knows of those articles of furniture of a beautiful dead black colour, with sharp, clear-cut edges and a smooth surface, the wood of which seems to have the density of ebony. Viewing them side by side with furniture rendered black by paint and varnish, the difference is sensible that the considerable margin of price separating the two kinds explains itself. The operations are much longer and more minute in this mode of charcoal polishing, which respects every detail in carving, while paint and varnish will clog up the holes and widen the ridges. In the first process they employ only carefully selected woods of a close and compact grain, then cover them with a coat of camphor dissolved in water, and almost immediately afterwards with another coat, composed chiefly of sulphate of iron and nutgall. The two compositions, in blending, penetrate the wood and give it an indelible tinge, and at the same time render it impervious to the attacks of insects. When these two coats are dry, they rub the surface of the wood first with a very hard brush of conch grass (*chien dent*), and then with charcoal of substances as light and friable as possible, because if a single hard grain remained in the charcoal this alone would scratch the surface, which they wish, on the contrary, to render perfectly smooth. The flat parts are rubbed with natural stick charcoal; the indented portions and crovices with charcoal powder. Alternately with the charcoal the workman also rubs his piece of furniture with flannel soaked in linseed oil and the essence of turpentine. These pouncings repeated several times cause the charcoal powder and the oil to penetrate into the wood; giving the article of furniture a beautiful colour, also a perfect polish which has none of the flaws of ordinary varnish.—*Ceylon Advertiser.*

ANOTHER PAPER MILL FOR BENGAL.—A Calcutta paper says that a paper manufactory under the auspices of several respectable zemindars of Behar is to be started at Patna under competent European supervision, and with this view arrangements have just been completed in Calcutta to import the necessary plants and machinery from England. The services of a competent foreman are also to be imported from home, and a certain well-known paper manufacturer of England has been addressed on the subject. It is anticipated that the venture will succeed, as Behar possesses an abundance of the raw materials suited to the manufacture of paper.—*Pioneer*, March 8th.

PRESERVING HEMP ROPES.—In order to insure greater strength in ropes used for scaffolding purposes, particularly in localities where the atmosphere is destructive of hemp fibre, such ropes should be dipped, when dry, into a bath containing 20 grains of sulphate of copper per litre of water, and kept in this solution some four days, afterward being dried; the ropes will thus have absorbed a certain quantity of sulphate of copper, which will preserve them for some time both from the attacks of animal parasites and from rot. The copper salt may be fixed in the fibres by a coating of tar or by soapy water and in order to do this the rope is passed through a bath of boiled tar, hot, drawing it through a timble to press back the excess of tar, and suspending it afterward on a staging to dry and harden. In a second method the rope is soaked in a solution of 100 grams of soap per litre of water.—*Indian Engineer.*

DARJEELING.—We have had a tolerably good fall of rain here, which has been pretty generally distributed throughout the district, and which it hardly needs to be said has done a very great deal of good in every way, more especially to crops of all kinds. This rain was, of course, exactly what all tea-planters were needing after such a long-continued drought as we have had; and I notice that everything has been freshened up by it. Snow fell at the same time all along the crests of the Singalela Range as low down as Tonglool, and, indeed, as I write, the snow has not even yet been entirely melted on the crest of Phalut. I notice that large consignments of "shooks" for tea boxes are arriving by the D.-H. Railway. Most, if not all, tea estates in the district are now-a-days obliged to import their box planking just as they have all along been obliged to import tea lead, solder and other stores required for manufacture, as the restrictions of the Forest Department are so great that it is cheaper to import box-wood than to obtain it locally. It is here that the metal boxes must tell in the long run, and judging from the brokers' reports these metal boxes have answered the purpose very well wherever they have been used.—*Indian Planters' Gazette*, March 4th.

THE DANGERS OF SUGAR CULTIVATION AND MANUFACTURE IN CUBA.—There being no sugar cultivation of much consequence in Ceylon, (the enterprise having proved a failure), we do not often quote articles referring to the sweet cane. But there is much of interest and value in exchanges which reach us. For instance, in the *Louisiana Planter*, just to hand, there is a letter from Havana, disclosing the special risks of the pursuit from fire on the field and steam in the factory. We quote as follows:—

We have, this week, to report a long series of sad events, consisting in several large cane fires, which seem to have commenced this year earlier than customary, and two terrible boiler explosions, which, besides inflicting heavy losses to the owners of the plantations on which they occurred, have also caused the death of several men and wounded a larger number. The plantations on which fires took place are: La Rosita, Alfonso XII, 160,000 arrobes; La Gabriel, at Nueva Paz, 150,000 arrobes; San Juan, at Roque, 100,000 arrobes; Mercedes, at Palmillos, 50,000 arrobes; colonias, Sangre de Dios, at Nueva Paz, 40,000, and San Ramon, at Jaguoy Grande, 50,000 forming a total of 550,000 arrobes, equivalent to about 7,375 tons of cane that was burned, the greater part of which may as yet be converted into sugar, provided that it does not rain before it can be ground. By a strange coincidence, both estates on which a boiler exploded are called Morceditas, on the first one, situated at Melena del Sur, part of the sugar house and machinery department were torn to pieces and the death of six men and severe wounds to a great number were to be deplored, whilst on the second, situated at Banoa, the damage was limited to the unroofing and part of the walls of the engine house tumbling over. With the exception of the fire on estate Morcedos, which was intentionally set, all the others seem to have taken place through carelessness.

THE SEA ISLAND COTTON OF TAHITI is a beautiful silky fibre, but difficult to manipulate. We learn, however, that M. Raoul, a French colonist of Tahiti, has succeeded in growing a hybrid variety, obtained by crossing the sea island cotton plant with the wild cotton shrub of Guadaloupe. The journals of Tahiti give a glowing account of the fibre and the richness of the yield.—*Globe.*

BELLEVUE AND SINNEGODDE COCONUT ESTATES.—The information we published, that Mr. Charles Byrde is the purchaser of these estates, was derived from a source that should have been well informed, but it is probable that the purchase was on behalf of Mr. F. W. Byrde who had recently disposed of a Kelani Valley property of his. A correspondent writes: "It will be instructive to know that there was keen competition for these estates. The offers were as under—

R15,000 by J. P. de Vos.

R17,000 by H. J. C. Pereira.

R20,000 by F. W. Byrde per Messrs. Rogers & Co. R20,000 being the highest offer made, the sale was concluded in favour of Mr. Byrde—at the rate of almost R100 per acre."

PATENTS IN HOLLAND.—A good many years ago says the *Journal of Useful Inventions*, the Minister from Holland, at London, was consulted in respect to some proposed reforms in the patent system there. He replied there were no patent laws in Holland, and none were required, the arts in that country had passed beyond the period of discovery, and hence the improvements made by individuals could not fairly become personal property. This is the substance but not the words of the story, and it contains a tolerably large suggestion, supposing the Dutch Minister to have been sincere in his views. A much better explanation, however, would be to say that the Dutch have so nearly abandoned the arts that a patent law there would amount to little more than a tax in the interest of foreign inventors. Looking at Holland of our day, it is hard to imagine that 300 years ago it was a kind of centre in Europe of skilled industry, including millwrighting, and so on. The want of fuel, water power, iron, and timber, has nearly put an end to such industry there, and to patents too.—*Electrical Trades Journal.*

THE GARTMORE FANCY TEA.—"The sale of a pound of Ceylon tea in Mincing Lane for £10-12-6 beats even the highest of the recent high records. The Gartmore Estate has achieved the costly honour of obtaining for a small lot of tea this extravagant price. A plantation which should be so reckless as to send to Mincing Lane fifty boxes of tea of equal value would not long escape bankruptcy. The method employed to achieve the result is even more wasteful than the process which the famous Soyer recommended for producing a juicy mutton chop—to skewer three chops together side by side and burn the two outer ones to cinders so as to obtain in the middle chop some share of the juice and flavour of its calcined mates. In plucking tea the practice is to pick the three top leaves of every tender branchlet; on plantations where quantity is in more demand than quality the topmost five are taken. The smallest, the most delicate in flavour of the three, or the five as the case may be, is the topmost, which is also the youngest and the least in size. By picking out this the rest lose that flavour which is necessary to impart the bouquet to the whole and sink into the lowest and almost unsaleable class of teas. The tiny leaf is so light and fills so small a space that a great number is required to make up even a pound or two. Nothing so wasteful of the gifts of nature has been devised by the wit of man since Roman epicures made ragouts of the tongues of nightingales, or drowned valuable slaves in fish ponds in order to procure lamprey of the finest flavour.—*Bombay Gazette.*

NITRATE OF SODA.

The transition from nitrogen-absorbing plants about which I wrote recently, is natural to nitrogen in its concentrated form as derived from the nitrates or saltpetre of Chile, the supplies of which may be rendered uncertain by the

WRETCHED CIVIL WAR

which has arrested the previously satisfactory progress of this leading South American Republic, although Peru and Bolivia also export nitrate of soda. There is an interesting article on the chief article of Chilian commerce,—the mainstay of its revenue, in truth,—in the latest number of the "Agricultural Gazette of New South Wales." Mr. Anderson, the Director of Agriculture of the above colony, believes that this valuable fertilizer has been formed by the decomposition of sea-weed and other organic matter:—

The nitrogen of which has become nitric acid by the process of nitrification, which acid has eventually formed nitrate of soda or Chili saltpetre. In its crude state it contains from 27 to 65 per cent. of the nitrate mixed with common salt, sulphate of soda, gypsum, and other impurities. After purification the commercial article is supposed to contain 95 per cent. pure nitrate of soda, or—in the language of analysis—it has a refraction not exceeding 5 per cent. The exports from Chile rose from 729 tons in 1878 to 1,000,000 of tons in 1889, mainly from the discovery that the nitrate added so largely to the saccharine matter in beetroots. The results were the

ENORMOUS INCREASE OF EXPORTS

I have mentioned and the sinking of the prices of nitrate from £16 to £9 per ton and of beet sugar from 15s to 11s per cwt. To quote again:—

The maerial value of nitrate of soda is due to the 15.75 per cent. of nitrogen which this salt contains. It is extremely soluble, and therefore be used only on growing crops which can utilise it, and not allow it to be washed out of the soil into the drains.

Reckoning sulphate of ammonia, which contains 20 per cent. of nitrogen, at its Sydney price of £13 a ton, nitrate of soda is worth £10 5s a ton, and is therefore well worth experimenting with at anything under that price.

There is considerable rivalry between this salt and sulphate of ammonia as the two chief sources of nitrogen amongst artificial manures, but it is now generally admitted that on dry soils and on light loamy soils the former is to be preferred, on heavy clayland and wet soils, the latter. The nitrate has been proved to be of great value to all straw growing plants, especially wheat and barley, peas, vetches, lupiner, clover, buck wheat, rape, sugar-beet, potatoes, celery, onions and linseed; with maize and tobacco the ammonia salt does better. Dr. Voelcker has shown at Woburn that 1½ cwt. of nitrate of soda gave £1 8s 6d worth of wheat and 12s 6d worth of straw. With barley and potatoes also the results are very satisfactory.

Many farmers argue that nitrate of soda exhausts the soil, and therefore leaves it in a poor state for the succeeding crop. It will be at once seen that the larger it makes the crop the greater is the quality of mineral matter it must take out of the soil; but which is more valuable—the increased yield of grain and straw, or the few pounds of potash and phosphoric acid?

For example, 1 cwt. of nitrate of soda may increase a crop of oats by 3 cwt. of grain and 5 cwt. of straw, which will remove from the soil about 4 lb. of phosphoric acid and 11 lb. of potash; but the increase in the crop is worth about 25s., while the mineral matter can be replaced by 20 lb. of superphosphate and 1 cwt. of kaintit for 4s 6d.

This points to the expediency of using nitrate of soda with some form of phosphoric acid, such as bone-dust or superphosphate of lime (which must be dry when mixed with the nitrate, or decomposition may

ensue), and some source potash of such as the sulphate or kaintit.

It is very valuable in enabling crops to resist the attacks of small parasites such as the beet-fly, turnip-fly, and fungi, owing, probably, to the rapid development of chlorophyll in the leaves by which the plants are placed beyond the destructive influence of those parasitic pests.

We cannot help thinking of the probable

GOOD EFFECT ON RICE

of an application of nitrate as we read:—

On a good mineral soil, 1½ cwt. of nitrate of soda has been found to increase the yield of wheat from 27 bushels and 1 ton of straw, to 41 bushels of grain and 1½ tons of straw, For vegetable gardens and fruit orchards applications of this substance seem specially valuable:—

For the market gardener who wishes to raise immense crops of early vegetables, this manure has proved a great boon. Instead of applying 75 to 100 tons of stable manure per acre, and working the same in with great toil, he now applies 250 lb. of nitrate of soda and 500 lb. of superphosphate in early spring before drilling in the seed, and again 250 lb. of nitrate when the plants are a few inches high, and yet another similar dressing in three or four weeks. The results in promoting great growth and early maturity are surprising. Why? First, because this amount of nitrate of soda really contains more nitrogen than 25 tons of average stable manure would supply, and it contains the nitrogen in a form—nitric acid—at once available, whereas the nitrogen of the dung has to be changed into nitric acid for the use of the plant by the presence of lime or carbonate of lime or potash in the soil, and the slow process of nitrification—a process that depends on minute living organisms (bacteria) producing a ferment in the soil, and must have a proper proportion of moisture with a temperature ranging from 54° F. to 98° F. It can hence be readily understood how nitrate of soda acts so wonderfully in a drying cold spring, where dung or sulphate of ammonia may refuse to act. Hence also may be deduced the wisdom of applying dung in the autumn and the nitrate as a valuable supplement in the early spring. For early cabbages, cauliflowers, onions and celery, its value has been proved. With regard to fruit, it is of great service in promoting the formation of sugar and early maturity. A dose of ½ lb. will often recover a sickly lemon or mandarin tree.

The article from which I have been quoting is followed by one on the cultivation of *Coffea arabica* in certain parts of New South Wales, where it grows well and is singularly free from disease. No doubt tea and coffee, like sugar, could be grown in many parts of Australia, but the

HIGH WAGES OF LABOUR

place an insuperable bar to profitable cultivation of such plants in competition with places where comparatively low priced labour is plentiful.

"TIMEHRI."—The December 1890 number of this journal of the Royal Agricultural and Commercial Society of British Guiana has the following contents:—Papers.—The Post Office in British Guiana before 1860, by James Rodway, F.R.S.; Fireflies, by Lady Blake, Jamaica; Statute Law Revision, by Dr. J. W. Carrington, C.M.G., Q.C.; The Necessity of Pure Air for Health, by E. D. Rowland, M.B., C.M., Edin.; Notes on the Geological Reports of British Guiana, by the Editor; On Parasites, by A. T. Ozzard, M.R.C.S.; England; Contracts with Cane Cutters, by A. R. Gilzean; Notes on Scale and other Parasitical Insects, by R. Ward; On the Upper Berbice River, by the Editor; The Barbados Sugar Cane Experiments, by J. B. Harrison, M.A., F.G.S., F.C.S., &c. Occasional Notes.—Gold and Diamonds in British Guiana; Rice growing in British Guiana; Dried ripe Bananas; Scale Insects; Young Aboma. Reports of Society's Meetings, from July to December, 1890. List of Popular Science Lectures.

THE NEW TEA DRIERS:—THE MAN AND THE MACHINE.

The production of tea in Ceylon has now attained such dimensions that every improvement in the machinery or its manufacture must be of high importance to planters. The two or three inventors who are coining fortunes out of their patents can have by no means exhausted the possibilities of invention, and this truth they prove themselves by continually making so-called "improvements" to what were declared to be "perfect" machines only the year before. But this is a dodge common to most patentees, as profitable to themselves as its object is transparent and irritating, if—being satisfied with the original type,—you are unable to get its worn-out parts renewed because they have been "improved" out of existence. It is high time, therefore, that we had some more permanently perfect machine, more up to the work it is declared able to perform than as 50 is to 200. Concerning this fact I will tell a good story later on. Not having been able to be present at the public trial of Sharpe's new Drier, at Hangran Oya, and I was invited to a private view a day or two ago, and I then made the acquaintance of the inventor and his machine at the same time, and I now propose to give you some account of both in a free and easy manner. Owing to the inevitable "accidents" that always happen, that public trial was almost a failure. With the impetuosity characteristic of youth, these big men—Messrs. Philips and Sharpe (6 feet 4, and 4 feet 6 respectively)—hurried on the "trial day,"—a month too soon—with the inevitable result—partial failure. The machine itself is no failure, but its public exhibition was, and that without anybody being to blame, because Mr. Sharpe "wanted to get away," and the jobbing engineers failed to produce an essential part "till the very last moment," thus rendering anything like preparation impossible. The consequence was that the "report" sent to the *Observer* was the poorest stuff that ever flowed from the facile pen of that ready writer, while the other fellow who reported for the "Independent" got fits for his pains from the outraged inventor. I predict that those who avail themselves of a private view a month hence will form a more favourable opinion, and be forced to admit that a new Drier of great durability and capability has come quietly into the country, and has come to stay.

Personally, Mr. Sharpe is a genuine and interesting specimen of the British Working Engineer, to whom an intricate piece of machinery is as familiar and dear as his playthings are to a schoolboy. It is a gain to Ceylon to have such men amongst us occasionally, and unless Mr. Sharpe's interests are very extensive elsewhere, he would do well to settle in Ceylon, where there is plenty of room for competition in his line by really competent men. Anyone troubled with obstinate machinery refusing to do its fair amount of work would do well to invite Mr. Sharpe to take a look round his factory. Here's a case in point:—Mr. Sharpe paid a visit to one of our largest factories, chokefull of all sorts of rollers, driers, packers, sorters, turbines, engines and the rest, with miles of belting whirling in every direction as might be expected in a factory where they turn out 5,000 lb. made tea a day, more or less. The manager, whom we will call Mr. Ponsoby, gave Mr. S. *carte blanche* to check the work done by any machine he liked. He fixed on the latest brand new "Horizontal Blower"—"Tea seed in at one end, and 300 lb. an hour of sorted tea packed in fancy canisters out at the other end," sort of Drier. Instead of 300 lb. he found it doing 50 lb. an hour (!) and almost bursting its boiler at that. Mr. P. thought there must be some mistake, but testing it again along with Mr. S. no more could be got out of it. "Fancy that," said Mr. P., "what 's to be done?" "Ah," said Mr. Sharpe, "What indeed? All the world knows by this time, that you can make good tea, but you can't be expected to know everything about machinery. I see there the fault lies plain enough." "Do you? What is it?" ["Well," said Sharpe, scratching his head, "I am at heavy expences coming to Ceylon. Everybody has got his own business, and that's mine. Any other

machine I can test for you?" "Oh, bother any other machine," said Mr. P., "tell me what 's the matter with the 'Horizontal Blower,' and name your own fee." "Well, thank you, sir, R100 please." "Call some coolies and masons"; and without touching the machine itself, Mr. Sharpe doubled its output on the spot. Before going further let me confess that the words enclosed within brackets are my own wicked invention all the rest being true. In point of fact, Mr. Sharpe most liberally did the job for nothing without a hint at a fee.

Perhaps *this* hint to the wealthy proprietors of that estate will not be thrown away—if Mr. Sharpe himself will forgive me for saying so—on the principle that the labourer is worthy of his hire. Such is Mr. Sharpe.

As for the Drier itself, he is still working at it, exercising such patience as the absence of his big shops and appliances at Lincoln render necessary.

Externally, apart from the inevitable furnace, it is a steel cylinder standing on the floor level 7 ft. or 8 ft. high, by 6½ ft. in diameter. Within revolve horizontally four trays, their centres being fixed to and turned by a vertical shaft, their circumferences being supported on a narrow fixed rail, on which they travel. Each of these rails has a "cut-out" part, at the proper place, which drops and raises sections of the trays, rapidly, one after the other, till in the course of one revolution each tray has discharged its contents on to the one below it, the tea being automatically delivered outside, from the bottom tray. At the trial only three trays were in operation, I am told, doing 60 lb. an hour. The construction of a fourth tray is that which is engaging Mr. Sharpe's attention now. All future machines of this size (the smallest size made) will have four trays, and the output be guaranteed at nearer 100 lb. an hour than a maund. So says Mr. Sharpe. The trays are not wire gauze, but thick sheets of galvanized perforated iron. Instead of its vital parts wanting renewing every year, I think it likely that, once put up, a machine will see the estate itself change hands before its own parts call for change.

R. W. J.

DR. GOEBEL, a well-known botanic scientist, has gone out to Demerara for the purpose of making a careful study of that curious pink flower, or rather lily, which is peculiar to the watercourses in that region. The plant, it will be remembered, excited some interest at the Colonial and Indian Exhibition in Kensington in 1886. It belongs to the order of Podostemaceæ, and generally it grows under the water, where beds of the plant can be seen. In the dry season, when the river shrinks and the plant is exposed, it takes advantage of the opportunity to flower and fruit. After the fashion of sea-weeds, it adheres to rocks by a disc-like root, and it holds its ground in the most violent rapids.—*Colonies and India.*

CEYLON TEA FOR AUSTRALIA.—Australian buyers are again suggesting that our teas for their market should be packed in 40 lb. packages, in place of the ordinary 50 to 60 lb. half chests. Dealers in the Southern Colonies are accustomed to the smaller boxes and no doubt prices slightly higher—1 or 2 cents per lb.—would be paid for tea in such packages. It might be worth the while of planters who look to sales in the local market to try some breaks in 40 lb. boxes. The danger would be that buyers for the English market would not compete.—Since writing the foregoing the following extract from a letter for "the Colonies" has reached us:—

"We would suggest to growers, who, we are sure, are anxious to meet the demands of the Colonial trade, that they pack a fair proportion of half-chests weighing from 40 to 45 lb. net. We feel sure that growers would obtain a higher price at the sales for good breaks (80 to 100 half-chests), medium to good medium, Pekoe souchongs and pekoes."

COCONUT BEETLES.

Mr. Hale of Tampin sends the following notes to the Journal of the R. A. S. about the coconut beetles, which seem worth recording:—

"The natives here (Tampin) have the following names for this insect in the larval stage *Lembelah* and *Kelematah*. The latter means "that which tickles the eye (sight being understood), and the former is probably derived from it." Kelemata, originally Gelemata, may, he thinks, be derived in the following way:—"Malay women are generally slightly hysterical, and seeing a lump of these larvæ wriggling about in a vessel would make a Malay woman squirm (I can find no better word) and would give her a feeling of being tickled which she would so express. The large millipede I have known to cause the same sensation to Malay men who are particularly nervous." This suggestion seems quite a possible one for the derivation. One may compare Forbes's account of his throwing a woman into a state of *latah*, by flicking a caterpillar upon her, and I have known a syce unable to look at a death's head caterpillar which I was carrying without violent shuddering and horror."

Mr. Hale adds:—"The larvæ are very much relished by Malays, and I myself ate several of them and found them particularly sweet and nice, having a flavour like a fried filbert. The way to cook them is to put them alive into a pan over a slow fire and fry them until they are crisp. In the process of cooking they exude a quantity of a clear sweet nutty-flavoured oil (100 larvæ will yield about half a pint). This is believed by Malay women to be a most excellent hair-oil, and is much used by them for that purpose to encourage the growth of girl's hair. The perfect insect is called Kumbang Jenti, Kumbang Kalapa and Buang, but all of these names are applied indifferently to other large beetles."

Mr. Ridley says, in the same publication, "Towards the end of last year, on examining the contents of a pitcher of the common pitcher plant *Nepenthes ampullacea*, (Jack) which was growing in the jungles in the Botanic Gardens, I was surprised to find there larvæ of one of the mosquitoes living and apparently thriving in the water of the pitcher. Carefully cutting off the pitcher and keeping it in a bottle, I succeeded in two or three days, in rearing two of the larvæ to maturity. The mosquito larvæ are not very particular as to the water they live in is known to every one who has ever watched them, but it is certainly very remarkable to find them living and thriving in the *Nepenthes*, which is so speedily fatal to any other insect which chances to fall in."—*S. F. Press*, March 11th.

MR. H. F. BLANFORD ON CEYLON,
(From the Hills.)

Mr. Blanford, in his "Elementary Geography of India, Burma and Ceylon," traces the Taprobane of the Macedonians, to "copper water." We have heard of the copper-coloured palms of Wijaya's soldiers who fell to the earth on landing in our island, but the copper water is new to us. We have always felt a strong inclination to believe in the botanical origin of the name, from the Tamana tree, whence Tamankaduwa, the forest of Tamana trees. It is interesting to be reminded that the area of Ceylon is three-fourths that of Ireland. In saying that all the Ceylon rivers save the Mahaweliganga are mere mountain torrents, Mr. Blanford is scarcely correct. The Walawe, the Kelani and the Mahaoya are good-sized rivers, the Kelani, indeed, being navigable for large-sized boats for some thirty miles from the sea. The Mahaweliganga is described as rising under Pidurutalagala, the reference being to the Nanuoya, which with many other affluents forms the Kotmalemanga, and joins the Adam's Peak branch at Pasbage, below Nawalapitiya. But the Agraoya which rises under Kirigalpotta and the Dambagastalawa which flows down the

Elk Plains from Totapala, and which unite below the Agram, are really the chief sources of our greatest river, the Agraoya being the farthest from the sea. As a matter of fact the actual sources of the Mahaweliganga can be seen on the great table-land of Horton Plains, 7,000 feet above sea-level. Besides not knowing that our mountain railway has been now for some years extended from Nawalapitiya to Nanuoya and is being extended across our mountain system into Uva, Mr. Blanford was ignorant of the fact that Sir Arthur Gordon had added two further Provinces, those of Uva and Sabaragamuwa, to the seven enumerated in the geography. Kandy is not quite 1,700 feet above sea-level, instead of 2,000, although the mountains immediately surrounding the mountain capital rise to altitudes of over 4,000 feet. In the case of Badulla the altitude is represented by the curious combination of four figures 2, or 2,222 feet above sea-level. Cinna-mon, no doubt, grows wild in our forests, but it is the cultivated spice which has been for many years exclusively exported. The price has fallen so low that it would not now pay to collect "Korle cinnamon." With the exceptions noticed the brief account of our island is correct. Our climate, and especially that of our mountain sanatorium, Nuwara Eliya, is fully dealt with in the same author's able and interesting work on the "Climates and Weather of India, Burma and Ceylon." But with the one sanatorium of Ceylon, as yet (for the lofty and extensive table-land known as Horton Plains, 7,000 feet above sea-level, richer in soil than Nuwara Eliya, must surely be opened up and settled as the railway traffic begins daily to pass its base)—with our one mountain health resort and the thirteen scattered over India, from south to north, I must deal in a subsequent communication.

INDIAN PLANTING NOTES.

DHUDHUR ALI, March 2.—Rainfall this week 1.42' total to date 2.25. Thermometer highest 75, lowest 57. Rain has changed the appearance of the whole country about here, and there is a perceptible change in the climate warning us of the hot weather's approach. In the Garden. "Hoeing" and "Tipping" are about the only works going on.

CHARALI, March 3.—Weather seasonable. We have had several welcome showers of rain. Early pruned bushes almost ready for tipping. The D. M. R. were inspected at Tezporo on the 25th ultimo when all the Bishnauth Division turned up except one man. The station officials don't seem to take much interest in volunteering as everyone of them cleared out to the Mofussil.

NAGRAKATA, March 6.—We are having very seasonable weather and the expected rain fell in heavy showers on the 5th instant. Rainfall up to date 1.04 against 1.15 last year.

DARJEELING, March 7th.—Yesterday was a nasty cold day with $\frac{3}{4}$ inch in rain. Clearer today. With sun, leaf should commence to come on strong. Cold weather works finished on most gardens; and all manufacturing houses ready for the commencement of plucking.—*Indian Planter's Gazette*.

TEA EXHIBITS AT THE AGRI-HORTICULTURAL SHOW AT MADRAS.

We have been favoured by the Honorary Secretary of the Agri-Horticultural Gardens with a copy of the Calcutta Tea Broker's Report on the teas exhibited at this show.

WOODCORE ESTATE—Valuation 1s 3d per lb. Leafy and small broken Pekoe, fair tip, brisk, rather light, little flavory.

KODANAAD ESTATE, Kotagiri.—(2 exhibits) No. 1. Valuation 1s 2d per lb. Small close black Pekoe leaf, fair tip, rather brisk, light.

No. 2. Valuation 11d per lb. Dark Pekoe kind, rather broken, fair tip, fair strength, rather coarse, poor quality.

GLENDALE ESTATE, Ooonoor.—(2 exhibits) No. 1. Valuation 1s 6d per lb. Rather bold, curly Pekoe leaf, fair trip, brisk, good flavor, light.

No. 2. Valuation 2s 2d to 2s 4d per lb. Small Pekoe leaf, good tip, little full brisk, good flavor.

TERRAMIA ESTATE, Ooonoor.—1s 5d per lb. Curly dark Pekoe kind, rather broken, mixed with ends, little flavory, liquor wants pungency.

PARRY & Co., South Wynaad.—Valuation 10d per lb. Dark mixed Pekoe leaf, rather stalky, mixed with ends, thin, poor quality.

Glendale estate obtained the gold medal, and Woodcote estate the silver medal.—*Madras Times*, March 7.

THE DEMORALIZED QUININE MARKET IN AMERICA.

The action of one of the manufacturers in reducing the price on small packages of quinine to a figure very close to the quotation for bulk has completely unsettled the market without apparently causing the increase in the demand usually following closely upon such a radical change. There seems to be nothing in the position warranting such a decided departure from ordinary practices, and the explanation given in our market report last week, that the step was instigated by the recent publication of the views of a former manufacturer, accompanied by an offer to sell small packages at unusual low prices, appears in the absence of more definite reasons to have furnished the incentive for the move. Since the break was announced with as much publicity as the parties making the announcement could command, it has been met by most of the agents of the foreign makers and that fact has resulted in a further decline. The price first named on five ounce packages by the domestic manufacturer referred to was twenty-five cents not, but the subsequent competition impelled him to offer an extra inducement to jobbers by allowing them a discount of five per cent. One of the foreign brands is now offered at twenty-four cents, less one per cent for cash and it has been intimated that some sellers might accept even less. The fact that buyers have not responded with any degree of alacrity to the flattering propositions made by the sellers has robbed the situation of some of its importance. The apathy of the jobbers is probably due to their knowledge that retailers, under the existing condition can do almost if not quite as well as they and that they therefore have no inducement to buy more than they need to fill current orders.

The market for bulk goods in spite of circumstances that should contribute to a weak feeling is fairly steady. At the same time speculative interest is almost entirely withheld and were it not for the brisk consuming demand caused by the presence of the grip and malarial diseases in the South and West, the market would present a dull appearance. Many are disposed to believe that the present war of rates is only a temporary matter and that it will be followed by a very decided reaction during the spring if not sooner.—*New York Drug Reporter*, Feb. 4th.

D. MORRIS, M A., F.L.S.

(From the *Jamaica Gleaner*, with a portrait.)

Mr. D. Morris, so favourably known and esteemed in Jamaica, was another of the prominent personages who arrived yesterday in the packet from Barbados. Mr. Morris is on a special tour of the West Indies for the purpose of encouraging the agricultural industries in these islands and increasing the usefulness of the several botanical stations. He has visited most of our sister islands and has delivered addresses to large audiences in each, stirring up their interest in the industries peculiar to the island they live in. Here also no doubt we shall see and here a good deal of

one at Jamaica's warmest friends. It may not be amiss to give a few brief details of the career of Mr. Morris. Mr. Morris is a native of Swansea, South Wales, and was educated at Obeltenham, and Royal School of Mines, London; was senior moderator and first gold Medallist, and took natural science honors at Trinity College, Dublin, receiving the degree of B. A., in 1876 and M. A., in 1880. He was appointed by the Earl of Carnarvon, assistant to Dr. G. H. K. Thwaites F. R. S., C. M. G. at the Royal Botanical Gardens, Ceylon, in 1877. He was next placed on special duty, in the Coffee Leaf Disease Inquiry, in that island in 1879 and publicly received the thanks of the "Planters' Association of Ceylon" for services in connection therewith, as also special commendation from Sir Michael Hicks-Beach, and an honorarium equal to one year's salary. Appointed Director of Public Gardens and Plantations in Jamaica in 1879. He was engaged on a special mission to Grenada and Trinidad to report on the cultivation of cacao in 1882 and in the same year he visited and reported on the economic resources of the colony of British Honduras. He was appointed Chairman of the Jamaica Committee of the Amsterdam Exhibition in 1883 and in the same year he visited and reported on the resources of the island of Helena at the request of Lord Derby, and was appointed a member of the Government Committee on Fibre Plants. In 1884 he prepared a report on "Planting Enterprise in the West Indies" which was presented to both Houses of Parliament and in the same year 1883 he was Chairman of the Institute of Jamaica. In the following year he went as Commissioner for Jamaica to the World's Exposition at New Orleans where he was instrumental in getting the quarantine restriction removed against Jamaica. He was appointed in 1886 Assistant Director of the Royal Gardens at Kew and left the island amid the regrets of all who knew him. He has since done good work at Kew and this year he has come out to the West Indies on the mission referred to. Mr. Morris is author of "The Colony of British Honduras" "The Agricultural Resources of the island of St. Helena," "Cacao, how to grow and how to cure it," "The Mongoose on Sugar Estates in the West Indies," "The history and cultivation of Liberian Coffee" and numerous other works treating on the distribution and cultivation of economic plants in the West India Islands.

THE CONSUMPTION OF SUGAR.

Uncle Sam has a sweet tooth. It has been suspected for some time; now there are figures to show it. The latest statistics reveal the fact that the United States consumes more sugar than any other nation in the world. Year by year the human family has been developing its taste for sweet things, the consumption of sugar of various kinds having steadily grown faster than the race has multiplied. And year by year the States and territories making up this hustling "Yankee nation," have in their use of sugar been as steadily gaining on the average consumption *per capita*, until now our 62,500,000 are found to have beaten the record, not only in the total amount consumed as a country, but probably in the average per inhabitant as well. It seems that we used about 50 lb each, last year, or, to be more exact, near 3,100,000,000 lb in all. The rest of the world consumed nearly 10,000,000 lb. It will doubtless be news to a great many people in the United States to learn that of this vast quantity of sugar consumed by the different nations, over 60 per cent is made from beets. It is only a few years since beet sugar was first brought into the market, but from the time of its introduction the quantity of it used has steadily gained on that of cane sugar. In 1884 and 1885 the quantity of each was about equal; the season of 1885-6 placed beet sugar in the lead, and each year's work has given it a little advantage, until now the world consumes 7,700,000,000 lb of sugar made from beet, as against 5,011,000,000 lb of sugar made from cane. The relative quantity of the two kinds consumed in the United States at present is not in the same proportion; beet sugar being less than one-fifth of the whole amount. But there are strong indications of a

very rapid change in this respect. For instance, we import four-fifths of all the sugar we use; the amount of cane sugar imported last year was no larger than that of the year before, while the importation of beet sugar was nearly four times greater than it was the previous year. This was an exceptional increase, to be sure, but the growth has been steady for some years past; and when to these significant facts are added the successful commencement of beet sugar making and the tremendous interest now being taken in the possibilities of the industry, it will be seen that the probabilities are altogether in favor of both the production and consumption of beet sugar in this country soon exceeding that of sugar made from cane. The position of beet sugar among European products is thus stated in a pamphlet issued by the Oxnard Beet Sugar Co., of Grand Island, Neb.: "Beet sugar paid the Prussian war debt in France, and has done more to make the people wealthy than any other thing. Last year Germany produced 1,220,000 tons of beet sugar—more than any other nation. Austria followed with 730,000 tons, France with 700,000 tons, Russia 480,000 tons, Belgium with 195,000 tons, Holland 60,000 tons. Total production 3,445,000 against 2,761,457 tons in 1888, and 2,451,900 tons in 1887. This is the most successful agriculture in Europe. It will soon make the farmers of Nebraska who raise sugar beets rich and stimulate all other interests."

[The above is from the "Sugar Bowl," published in New Orleans. In the same paper occurs the following paragraph on the very exceptional riches in saccharine matter of sugar cane grown in Louisiana:—

As a SUGAR COUNTRY.—*Louisiana Equals the Tropics.*—Judge O. B. Sansum, a native of the West India island of Bermuda, we believe, where he was reared as a sugar planter, is enthusiastic over the future of sugar in Louisiana. He says last season we grew richer cane than he ever heard of in that country, and he thinks we can compete with the world in sugar production. To prove this, he shows an analysis of cane which he grew on the pine lands of Tangipahoa, which polarized 16 1/2 per cent in sugar! Not only the pine lands, but also many other sections last year made cane nearly as rich in sucrose.

—Ed. T. A.]

BARK AND DRUG REPORT.

(From the *Chemist and Druggist*.)

LONDON, Feb. 26th.

CINCHONA.—Tuesday's bark sales offered a fairly extensive supply, distributed as follows:—

	Packages	Packages
Ceylon bark	956 of which	655 were sold
East Indian bark	1,526 do	1,293 do
Java bark	65 do	40 do
South American bark	183 do	56 do
Total	2,731 do	1,954 do

The assortment was a poor one, and the auctions were altogether lacking in spirit, large piles being bought in at nominal prices because the limits fixed for them could not be obtained. On the whole the market was decidedly castor, and the unit price can scarcely be said to have averaged 1 1/2d per lb.

The following are the quantities purchased by the principal buyers:—

	Lbs.
Agents for the Brunswick work	154,370
Agents for the Mannheim and Amsterdam works	119,284
Agents for the Auerbach works	41,782
Messrs. Howards & Sons	33,838
Agents for the French, Italian, &c., works	34,075
Agents for the Frankfurt o/M. and Stuttgart works	29,008
Sundry druggists	37,018
Total quantity sold	468,375
Bought in or withdrawn	158,943

Total quantity offered 625,318
 QUININE.—Business has been very quiet this week, and the market closes weak and lower. A few days ago

5,000 oz. second-hand German bulk were reported sold at 10 1/2d per oz., and today there are further sellers at that price, but no one ventures to buy.

LONDON, March 12th.

ANNATTO.—Bright Ceylon seed is reported to have been sold privately to some extent at the rate of 2 1/2d per lb.

CINCHONA.—The supply of bark offered at Tuesday's auctions was exceedingly small. The catalogues comprised:—

	Packages	Packages
Ceylon bark	575 of which	561 were sold
East Indian bark	587 do	475 do
Java Bark	3 do	— do
South American bark	360 do	248 do
Total	1,525 do	1,285 do

The assortment was a poor one, and does not call for any special observation. A quiet tone prevailed, and there was no quotable change in the prices. The unit remains at about 1 1/2d per lb. Fine bright *Succirubra* chips and shavings for druggists are scarce and realise comparatively high prices, with good competition.

The following are the quantities purchased by the principal buyers:—

	Lbs.
Agents for the Brunswick works	166,380
" Mannheim and Amsterdam works	145,117
" Frankfurt o/M and Stuttgart works	21,468
" American and Italian works	22,042
" Auerbach works	20,265
Messrs. Howard & Sons	18,099
Mr. Thomas Whiffen	1,780
Sundry druggists	19,690

Total quantity sold	288,033
Bought in or withdrawn	52,829

Total quantity offered 340,862

JAVA CINCHONA.—Three cases good druggists' stem quills were bought in at 1s per lb.

SOUTH AMERICAN CINCHONA.—Of 243 packages cultivated Bolivian Calisaya, 215 packages were sold (27,180 lb.) at 7 1/2d per lb. for fair broken quill; 5d to 5 1/2d for quilly chips, and 1 1/2d per lb. for very common twigs. Twenty-nine bales damaged Pitayo, and 4 bales ditto soft Colombian, via Hamburg, sold at 2d per lb. A parcel of 75 bales damaged Cartagena, also via Hamburg, is held for 6d per lb. The next Amsterdam sale will take place on April 2nd. The shipments from Java continue large, the steamer "Sumatra" which left Batavia on January 29th, carried about 75 tons of bark. The exports of cinchona from Java are given as follows by Messrs. Böhlinger & Sons:—From July 1st, 1890 to February 27th, 1891, about 2,400,000 kilos; from July 1st, 1889 to March 1st, 1890, 1,758,000 kilos. On the other hand the arrivals by rail in Colombo show a considerable decline, the figures being: January 1st to February 23rd, 1889, 575 tons; same period 1890, 415 tons; January 1st to March 1st, 1891, 250 tons.

The arrivals from southern India this week have been very heavy, the S. S. "Stentor," which arrived on March 5th, alone brought 1,729 packages from Calicut and 459 from Bcyperc.

ESSENTIAL OILS.—Citronella without business, at 3 1/2d to 3 3/4 per oz. Lomon grass also quiet at 1 1/2d to 1 3/4 per oz.

IMPORTATION OF UNSOUND TEA.

The Collector of Customs having been requested by the Colonial Treasurer to report on the statements of a deputation to the effect that unsound tea condemned in Melbourne was being imported into Sydney, forwarded to the Government Analyst six samples of the questionable tea, and asked for a report, the three points to be determined being—(1) Whether the tea was of the following standard—30 per cent. of extract, 3 per cent. of soluble ash, calculated on the dry tea 212 degrees Fahrenheit, or more than 8 per cent. of total ash. (2) Whether the tea represented by the samples contained any ingredient injurious to the health of possible consumers. And (3) Whether the tea was unfit for human consumption. To these questions the Government Analyst replied as follows: Government Laboratory, Sydney, 25th February, 1891.—Sir,—I have the honour to submit the result of my analyses of the samples of tea, which are

found to be as follows:—

Per-centage of Mineral Ash.	Per-centage of Extract.	Per-centage of Soluble Ash.	Per-centage of Theine.	Per-centage of Insoluble Ash.
6.20	27.88	3.03	0.69	63.50
6.23	23.20	3.23	1.37	67.95
6.56	36.10	3.62	1.55	64.28
6.07	29.80	3.25	1.40	65.54
6.18	25.76	3.47	0.81	67.16
5.87	27.30	3.07	0.88	69.05

In reply to the request contained in your letter the above results will, I think, answer your first question as regards quality. The sample third on the list passes the standard for genuine teas. To the second question,—viz., as to whether the tea represented by these samples contains any ingredient injurious to the health of possible consumers,—I am able to answer in the negative. With reference to the third and final question,—as to whether these teas are fit or unfit for human consumption,—I am of opinion that they are fit for human consumption, one of them passing the standard adopted by different Governments and institutions. In the Public Health Bill now awaiting the attention of the Legislature definite standards are provided under which five out of the six teas would have been condemned as unfit for human consumption. The fact, however, remains that all the samples are of very inferior quality. I am, &c. William M. Hamlett, F.I.A., F.O.S., Government Analyst." On this report the Colonial Treasurer has expressed the opinion that in the present state of the law it is not possible to prohibit the importation of the tea in question, which, with the exception of one sample, is found to be of lower quality than the standard adopted by any other colony. He, however, regards the report of the Government Analyst as satisfactory evidence that the tea does not contain any ingredient injurious to the health of possible consumers, and that it cannot be considered unfit for consumption. The adoption of a standard regulating the quality of imported tea will be considered when the proposed Public Health Bill is introduced.—*Sydney Mail*.

TEA PLANTING IN UVA.

The Haputale and Madulsima Companies, on the principle of "Hobson's Choice" we fancy, are following the many examples set them by estates originally opened for the cultivation of coffee and cinchona and are now going largely in for tea. Mr. George A. Dick and Mr. Arthur Scovell (two good men and true—most experienced and reliable planters) have recently joined the Ceylon Board of management, a fact which argued well for the future success of the two Companies in question. "It is a long lane that has no turning" and we heartily and trustfully anticipate a good time coming for both the Haputale and Madulsima, as for other Uva Planting Companies.

LARGE PURCHASES OF ESTATE PROPERTY.

The Ceylon and Oriental Investment Corporation, Limited, have just acquired the group of lowcountry estates comprising about 1,500 acres,—about one-third in tea—belonging to Mr. Jeronis Pieris. There are five estates (Wilton, Moraliya, Pathragalla, Northupana and Decgalla) situated in the Awisawella and Kalutara districts, all of them more or less planted up with tea. The negotiations were finally closed yesterday afternoon by Mr. J. Huntley Thring, and Mr. E. G. Harding on behalf of the Company, and Mr. W. H. Davies on behalf of the seller. Mr. Thring, the Managing Director of the Corporation, returns to England per S. S. "Kaiser-i-Hind," after a successful business trip through the planting districts.

TRINIDAD SUGAR PLANTERS AND THE MCKINLEY BILL.

Last month a majority of the Trinidad sugar planters called on the American consul, Hon. Wm. Pierce, and read an address correcting the impression that their immigration tax is an "export duty in disguise," depriving them of the benefits of free entry of their sugar in the United States. Their address is interesting. It cites that when, 45 years ago, slavery was abolished there, the sugar industry would have been extinguished but for the act permitting introduction of East Indian immigrants, on a ten year contract—five years' indenture to the planters who employ them, at an indenture fee of £5 per head and an immigration tax on their produce; the second five years they being free to hire where they please. They stated:—As a result, there are now 70,000 East Indians in Trinidad, in a total population of 200,000, and, as a further result, the exports of the colony have increased in a most remarkable and satisfactory manner.

Mr. Pierce promised to lay their views before our Government. During the interview he spoke of our recent legislation as follows:—The sugar producers of the United States had expended more or less money in the way of sugar estate improvements, upon the idea that the sugar industry was being protected by a heavy import duty. For the Government to have thus encouraged them to make those improvements and then to greatly diminish the value of the same by taking off the custom house duty on imported sugar, would be unjust, if some way had not been found to compensate them for their loss, and their bounty, which is only to last till 1905, was doubtless intended as such compensation.—*Farm Journal*.

THE INDISCRIMINATE PLANTING OF TREES IN OOTACAMUND.

[The conclusion of the discussion on alleged excessive tree planting in Ootacamund contains the commonsense of the matter. It is evidently a minute by the chief Government officer of the district, in his capacity of Chairman of the Municipality.—Ed. T. A.]

Notes on the influence exercised by trees on climate by Dr. Balfour, printed at page 416. Madras Journal 1849-50. In this reference is made to the fact that the climate of Canara became drier, the seasons more uncertain and the land less fertile, since the tract was denuded of forest and Dr. Balfour adds "I have also understood that effects of a similar kind have been experienced at the Nilgiri Hills." The whole of the notes is very interesting and a summary of the beneficial results of trees are given at pages 445. The notes were highly commended by Minutes of Consolation dated 8th September 1843. No. 931. *The atmosphere by Flammarion* page 280 and 281. There the advantage of trees in point of temperature is fully explained. There are other books and papers in which the planting of trees is highly commended, and there is not a word in them pointing to any disadvantage in a place like Ootacamund. Ootacamund is located in an extensive valley which permits of the free course of the winds and which is sufficiently inclined to allow of good natural drainage from every part of it," page 48 of the District Manual.

"The climate * * * for the greater portion of the year is decidedly salubrious. The air is pure and bracing, and has a sensible affect in exhilarating the spirits and increasing the disposition to exercise." Same book—page 48.

The area of the Municipal town is nearly 12 square miles. The excessive planting complained of is not apparent to any one who looks around. On the other hand, the portions on the East and West seem to be markedly bare. The direction of the winds is chiefly from the West and North (page 49 of the Manual.)

The existing plantations have been formed first for shelter and in later years for profit; but they are by no

means excessive, regarded either in point of sanitation or local requirements. The complaint has been as reported by Dr. Balfour, that Ooty has become drier than it was 15 or 20 years ago and this change is attributed to deforestation. As to the 2nd conclusion of the Sub-Committee vide para (8), it appears clear that the Municipal Council can take action under the present sections of the Act in regards to Acacia Wattle, and undergrowth containing decayed vegetation and noxious matter. Otherwise, no interference can be exercised, nor is it necessary or expedient to ask for power to do so, as however unrightly such growth may be it is a source of profit and living to several people in the town. The poor people use it for fuel and Wattle has a commercial value as tanning material, although no one has availed himself of the advantage: As to conclusion 3, (vide para 8), the Sub-Committee has not proved by statistics the evil said to have resulted from trees and undergrowth and what evils are feared in the future. The law reports to which I carefully referred make this particularly clear. You cannot restrict the number of trees growing in existing plantations without fully compensating the owners, nor can you restrict future planting in private land without very seriously interfering with private rights. This must be demonstrated before Government can be induced to legislate in the direction pointed out. The Sub-Committee's proposals involves a serious interference with private rights and vested interests, calculated to depreciate the property very considerably. It is a maxim of law that "A legislative enactment ought to be prospective, not retrospective, in its operation." "The laws are adapted to those cases which most frequently occur." There is no wrong without a remedy." "In law the immediate, not the remote, cause of any event is regarded." "Enjoy your own property in such a manner as not to injure that of another person." If Government takes into consideration the amendment of the law as recommended, the restriction in regard to past plantations can only be enforced on payment of compensation to the owners concerned as explained by the above maxim the analogy of section 168 (3) of the present Municipal Act.

I would recommend the Council to pass a resolution in general terms to the effect that after fully considering the vegetation existing within Municipal limits it considers that existing plantations cannot be interfered with without interfering with private rights to an unwarrantable extent as it is not prepared to compensate owners for the value of all trees to be cut out of existing plantations.

II. That as regard Wattle, it will endeavour to effectually deal with this pest by the continuous issue of notices to clear.

III. That it appoints a standing Sub-Committee to watch vegetation and to report instances of noxious vegetation for want of notices to clear. The members of the Sub-Committee in fact to divide the inspection of the town among them. I don't think this is asking too much, as with one or two exceptions the Commissioners don't do very much inspection. That as regards future plantations, the Government be requested to obtain the opinion of the Advocate General as to the competence of the Council to pass and of the Government to sanction, the passing of a bye-law prohibiting the planting of any tree except purely ornamental trees without the sanction of the Council previously obtained. The question bristles with legal difficulties and is eminently one for the Advocate General to advise.

It has just occurred to me that the Council might very fairly ask the Government to help in reducing the timber area within Municipal limits by closing their depot. Purchasers would thus be driven to private producers of firewood and private plantations would be reduced in area.—S. I. Observer.

MIDDLING PLANTATION COFFEE is quoted by Reuter at 109s 6d per cwt., but sales have been effected by Colombo firms within the past few weeks at as high a figure as 115s per cwt. delivered cost and freight at Trieste, while it has exchanged hands locally at R72 per cwt.

CEYLON COCOA.

By DR. A. J. H. CRESPI.

One of the most curious features of modern commercial activity is that Nature is, as it were, compelled to improve on her own earlier efforts. Supposing that some much-prized plant is found to do well in a particular region with a climate of given warmth and under certain recognised conditions: the next thing is to find out a region where those conditions are still better, and to introduce the plant there. This seems to have been done with the cacao tree in Ceylon, and cocoa superlative excellence has for many years been manufactured from cacao beans imported from that beautiful island. Some brands of Ceylon cocoa have been recently commanding very high prices; this shows what a magnificent field exists in Ceylon for cocoa culture, and that the quality of the cocoa from that island is far above the average of West Indian varieties. The principal peculiarity of the Ceylon brand is its delicate flavour and rich aroma; although when prepared for use its price is not very high, and quite within reach of most incomes. We confidently predict that as it becomes more generally known, it will be sold in still larger quantities, and so open up a fresh and most important branch of trade to British enterprise.

Messrs. J. S. Fry and Sons, the well-known makers, whose house was founded in 1728, were not slow to recognise the peculiarly delicious flavour of Ceylon cocoa, and they have accordingly added another luxury to our household beverages in the form of Ceylon chocolate, a speciality that is being much appreciated by connoisseurs. While on the subject of Ceylon cocoa, we have just been favoured with some of the most recent statistics relating to the consumption of cocoa in England. Although a great authority gives the average consumption as five ounces per head, it is now ascertained to amount to eight, or to be more precise, in 1889 it reached 18,464,164 pounds. This is not a large total after all, but marks progress. In 1820, duty was only paid on 267,000 pounds; in 1875, on 9,900,000 pounds. In other words, the consumption has doubled in fourteen years, and should the present rate of progress continue another fourteen or fifteen years, the trade will reach, for the first time, very respectable dimensions.

Considering its fragrance and nutritive properties (for all preparations of cocoa are a true food, and valuable as tissue restorers and force producers), perhaps the small consumption is surprising. For our part we prefer well-prepared cocoa to all other beverages, while indigestion, which is so frequently caused, or at any rate, aggravated by the too liberal use of hot tea, does not follow cocoa. The cocoa trade is in a healthy and active state, and the wants of the general public are not likely to be neglected as long as so many leading English firms busily engaged ministering to the national needs.

One of the best uses to which Ceylon chocolate can be put is to eat it when on bicycling or pedestrian excursions. We have it most convenient, and we believe that cyclists, who are often at a great loss for a portable and palatable food which they can eat without dismounting, will more and more trust to chocolate as their sheet-anchor. Long before our attention had been directed to the subject by a circular we were reading the other day, we had found out the value of dry and satisfying food when many miles from home and pressed for time.

—Hardwicke's Science Gossip.

ECHOES OF SCIENCE.

According to a paper read by Professor Maisch at the Philadelphia College of Pharmacy, the camphor tree is being cultivated on an extensive scale in Florida. It grows rapidly there, and seems to flourish in any kind of soil. Professor Maisch estimates that in ten years there will be more camphor than orange groves in that State. The quality of the gum obtained is more like that of Japan than China, the odour of saffrol being quite sensible.

An American contemporary records the blood-poisoning of several greenhouse workmen through contact with a plant known as the Chinese primrose (*Primula obconica*). It is a native of Central China, and was first cultivated from the seed in England about ten years ago, when it created some stir owing to the beauty of his winter blossom. It has, however, the property of irritating and even of poisoning the skin of some people who touch it, producing an inflammation resembling eczema. The sting of the leaves will sometimes last for several days.

Quite recently Mr. W. H. Weed, of the United States Geological Survey, has proved that plants of a low grade are important agents in the production of travertine, tulas, and sinters, hitherto believed to be the effect of inorganic chemistry. The abundance of algae in hot springs has often been observed, but passed over as a curiosity of biological science, in spite of the well-known fact that certain water-plants extract carbonate of lime from its solution. Some years ago the present writer drew attention to the fact that most of the "coral sand" on a certain West Indian island is really the calcareous skeleton of a sea-weed, and not, as was imagined, the debris of rock coral. Cohn, a German naturalist, has shown that vegetation is an agent in the production of travertine in the Carlbad springs.—*Globe*.

TEA: FINE PLUCKING AND HIGH AVERAGES.

(From a correspondent.)

I think there can be little doubt Alnwick and Portswood pluck fine, though they do not admit it. The samples at the Exhibition in Nuwara Eliya looked so. If according to Wilson, Smithett & Co's, account, Portswood only made 20,000 to 30,000* lb. last year there is no wonder the average was high. You will find wherever they make quantity the average will go down, or I am very much mistaken. Generally speaking, it will never pay to make fine teas unless you could make a large quantity and that would be impossible.

NUWARA ELIYA EXHIBITION AND TEA PRIZES.

A planting correspondent writes:—

"In giving the prizes at Nuwara Eliya for Ceylon teas of breaks to be sold,—that is, the samples were supposed to be of breaks to be sold,—"Alnwick" received the gold medal, and Portswood the silver medal, the teas from the latter having averaged 1s 4d all round for 1890, the estate never having EVEN BEEN ONCE below the first average out of all the monthly sales during the year. Alnwick for the same period was at 1s 1½d—see Wilson & Smithett's Circular (Ceylon Tea Memoranda for 1890) published in March 1891:—

"Alnwick 56,000 lb. average 1s 1½d.
Portswood 45,000 lb. (sold some locally) 1s 4d."
The Portswood teas sent to the Show, I believe, were drawn from the bulked tea by Mr. William Mitchell junr. in the Portswood tea factory."

* No—the return for Portswood is 45,000 lb., and extent in tea being 240 acres, but all will not be in full bearing. Alnwick is down for 56,000 lb. at an average of 1s 1½d last year, the *Directory* showing 235 acres in tea.—*Ed. T. A.*

PORTSWOOD TEA AND LOCAL SALES.

The rates at which the Portswood teas were actually sold after last sale—R1, 72 and 62 cents—are so good and (as the Brokers tell us) so fully covered the reserve rates, that we think the proprietor is scarcely justified in grumbling about local sales. No doubt Mr. Grinlinton has got higher rates at home; but has he made full allowance for the different state of the market at different dates? So far from casting reflection on "local sales," we think the splendid prices realized here for Portswood teas last week, is about the strongest encouragement to sell teas locally that we have yet seen. As a matter of fact, the sale in London in February took place at a particularly good time, while a sale here at the end of March with the prospect of what the market may be towards May is a rather different matter. At any rate, we can only say: "Well done the Colombo market and the Colombo Brokers that got such splendid prices for Portswood teas last week."

CEYLON TEA.—The *Times* reports that a consignment of Tea from Ceylon, recently sold at Mincing Lane, was, in the opinion of experts, the finest Tea ever grown. It was ultimately sold for no less a sum than 87s. a pound; and again changed hands at £5 10s.—a price never before approached in the Tea trade. Bravo, Ceylon! Honour to the memory of the botanists in India, whose labours and discoveries more than half a century ago rendered such things possible.—*Gardeners' Chronicle*.

"KEW BULLETIN."—The January number comprises articles on the West African Bass Fibre, the produce of a Palm, *Raphia vinifera*. Chinese ginger, the preserved ginger of commerce, is, it appears, not a ginger at all, but the produce of *Alpinia galanga*, which is said never to flower in China but which has been obliging enough to do so at the Hong Kong Botanic Garden, as well as at Dominica. The remainder of the number is taken up with correspondence relating to the production of seed in the sugar-cane, and the consequent possibilities of new varieties being originated.—*Gardeners' Chronicle*.

CLOSE PLANTING OF VINES.—That the practice of planting the Vine much closer together than 3½ to 4 feet is not always a failure, is shown in a photograph of a viney with Vines in bearing (not suitable for reproduction), sent us by Mr. Richardson, gardener, Wood House, Staunsted, Essex. The house is 50 feet long, and contains twenty-one canes of Back Alicante and Lady Dowae's Seedling, planted at 2 feet apart. The crop seems, from the view taken in October, to have been a heavy one. In the long run we think that close planting would end in inferior crops for very obvious reasons. The weakening of the Vines would commence and go on with the exhaustion of the border, the yearly lessening size of the foliage, and the size of the annual wood.—*Gardeners' Chronicle*.

MORE ABOUT THE GARTMORE TEA.—The following is from the *Sunday Times* published in London:—

"Tea at £10 12s. 6d. a Pound!—A small lot of Ceylon tea from the Gartmore estate realised this ridiculously inflated price at a public auction at the Mincing Lane sale rooms. The tea is said to possess extraordinary qualities in liquor, and to be composed almost entirely of small 'golden tips,' which are the extreme ends of the small succulent shoots of the plant, and the preparation of such tea is of course most costly. I should like to know something more about the 'extraordinary qualities' of this two hundred-and-twelve shillings-and-sixpence a pound tea when it is in liquor? Does it waken snakes? Will it make goats dance? Will it make to see comets, or feel like the Grand Turk? Well, the worth of anything is just as much as it will bring. It is a pity, nevertheless, that Sardanapalus and Cleopatra are deceased. They would perhaps have liked to invest in a small lot of 'golden tips' at £10 12s. 6d. per pound for their five o'clock teas."

CEYLON TEA IN 1890.

MESSRS. WILSON, SMITHET & Co.'s REVIEW.

We give on page 766 the full text of this extremely valuable series of notes and statistics for the course of London sales of Ceylon Teas for last year, together with general statistics as to total imports, consumption and stocks of all teas in the United Kingdom. While Portswood estate heads the list with the highest average price of any Ceylon estates teas, K. A. W. has the honour of sending the largest quantity (568,000 lb.) from any Ceylon factory with the good average of 10½d. The leading position in price as regards districts of Bogawantalawa and the Nuwara Eliya neighbourhood, reminds us of the remark credited to Mr. Arthur Thomson that our highest-grown teas when shipped in sufficient quantity to keep up a regular supply, might well be marked "Ceylon-Darjeelings" to attract the special attention of buyers of fine teas. Has any shipper done this with high-grown teas and with what result, we should like to know. Kintyre green teas are referred to with commendation, and it is gratifying to see that both Russia and America are expected to be good customers of Ceylon teas in 1891. What is said about the size of bushes again merits careful attention. Dimbula of all districts sent the largest quantity of tea—5,700,000 lb.—at an average of 11½d in 1890. It is very remarkable to note how the consumption of China teas in the United Kingdom had fallen from 106,310,000 lb. in 1885 to 57,500,000 lb. last year; while that of India and Ceylon had risen from 68,890,000 lb. to 136,500,000 lb. in the same period.

From Messrs. Geo. White & Co.'s Annual India, Ceylon and Java Tea Report, date 20th March, 1891, received today, we quote as follows:—

CEYLON.—When writing last year, we were able to chronicle a marked expansion in the Ceylon trade. Further decided progress has since then being made, the result being an increase in both imports and deliveries of about seven million lb. for the eight months ending 28th February last, the consumption having no doubt been stimulated to some extent by the reduction in duty. This is satisfactory, as it proves the steady and increasing demand existing for these growths, which also no doubt prevented the fluctuation in value seen in former years—the lowest monthly average during 1890 being 10d and the highest 11½d, whereas, in 1889, the range was from 9d to 1s 1½d; the 545,000 packages sold during 1890, and 433,000 packages in 1889, having however, realised about the same price, viz., rather under 11d per lb. After Christmas, demand further improved in consequence of the statistical position, which was strengthened by the loss of the S. S. "Nepaul" and "Hong Kong;" but later on, owing to heavier arrivals and quiet country trade, there was less disposition to purchase. On the whole, quality has been desirable, there being a much smaller proportion of over-fired and sour Teas, though few ever really choice flavoured parcels, perhaps due to rather coarser plucking on some of the gardens. During the season, several little lots of "Golden Tips" have been sold, one at 30s. 6d., another at 87s., both of which were re-sold at large profits; and a third was knocked down at £10. 12s. 6d. per lb., after some very spirited bidding between two of the largest advertising firms.

FINE TEA.

There is both profit and satisfaction in handling fine tea. It makes trade. Customers, as soon as their attention is directed to the matter, will discover that there are pronounced differences in flavour and come to appreciate the delicate fragrance of a fine leaf, instead

of, as now, being satisfied with any sort of an infusion so long as it is warm. It is not likely that a grocer will sell fine tea unless he is himself a lover of the beverage and can discriminate as to body and flavor, and last of all style. People will soon learn that a high-priced tea is very little more expensive than a cheap tea. The Ceylon factors impress upon their customers that their "money can go as far in \$1 25 tea as in a 50-cent tea; that is good tea can be cheap." Then, consumers need to learn the art of making tea and acquire the habit of steeping it at the table.—*American Grocer.*

THE MICA INDUSTRY.

With the extraordinary growth of the electrica industry in the United States for a number of years past there has been created a new and steady demand for mica, which, curiously, has failed to stimulate the mica mining industry in this country; the most important mines, indeed, show a decided decrease in producing during this time, and the business is now in a depressed condition. In the construction of dynamos, electric motors and some other electrical appliances, mica is a very important element, valued on account of its flexibility and excellent insulating qualities. For this purpose, however, there is a decided preference for foreign mica, the Canadian "amber mica" being generally used.

Mica is employed in dynamos and electric motors, mainly in building up the armatures, strips of various dimensions, but unusually about one inch wide, and from four to eight inches long, being used.

The foreign mica is considered preferable to that of North Carolina for this purpose in that while the latter can be split into thin sheets, it is by no means so tough, which is an important requisite. Such mica may perhaps be found in the United States, but up to the present time there is no doubt that some imported micas have proved more suitable for this purpose than the usual domestic grades.

Hitherto the most important, in fact, almost the only important use for mica has been in stoves, and the demands, and consequently prices of the article for this purpose have been such that mica mining was carried on at considerable profit.

The chief mines in the country are in New Hampshire and North Carolina, but principally in the latter State, these producing an excellent quality of the mineral. Several years ago changes were made in the patterns of stoves whereby smaller and correspondingly less expensive sheets of mica were used, and the lower prices resulting depressed the industry greatly, especially in North Carolina, where many mines were closed. The total value of the product in the United States decreased from 363,525 dols. in 1884, to 70,000 dols. in 1880. During the same time the imports of mica, which, prior to 1884, had been of but trifling importance, increased from 23,284 dols. to 57,541 dols.—*Engineering and Mining Journal.*

SILVER.—I note that the Mount Zeehan Tasmanian Silver and Lead Mining Company has received a letter stating that lodes have been now found of 8 feet and more, and, as some 3 feet was before about the limit, it is clear that the value of this mine is infinitely greater than many supposed. I am of opinion that Mount Zeehan will be but one of the many coming examples of the enormous mining wealth latent in Tasmania.—*"Anglo-Australian"* in *E. Mail.*

TALKING OF TEA reminds me that Her Majesty always has her tea from a quaint, old-fashioned shop in Pall Mall. It costs, I believe, five and fourpence a pound, and is called "Earl Grey's mixture," from having been recommended to the Queen by that nobleman. It is said that Her Majesty's five predecessors have patronised the same tea. It says a great deal for this mixture that amidst so much degeneration in the tea that there is now, it should have held its own so long.—*Cor., A. F. Press.*

WILSON, SMITHETT & Co.'s CEYLON TEA
MEMORANDA FOR 1890.

London, March 1891.

The amount of Ceylon Tea brought to auction in London between January 1st and December 31st, 1890, was about 30 per cent in excess of the supply in 1889, and, it is satisfactory to note, realised the same average price as was recorded for that year, viz., 10½d per lb., and only ¾d per lb. less than in 1888, when the Imports were less than half those of the year under review.

The event of the year has undoubtedly been the reduction of the Tea Duty from 6d to 4d per lb. When in the early spring rumours were afloat as to the intention of the Chancellor of the Exchequer to partly utilise his surplus in thus relieving taxation the idea that Tea would be one of the articles touched was not generally credited; it was argued that if once reduced the old duty could never be re-imposed unless under most pressing circumstances, and that the reduction itself would give no relief to the poorest class of consumers who buy their tea in penny worths. The eventual decision of Mr. Goschen has, however, been gratefully acknowledged by a large section of tea-drinkers, and so far as India and Ceylon producers are concerned the boon was conferred at a most opportune time. The rise in silver, precluding any invasion of the market by low-class China leaf, the impetus given to the home consumption shown by the increase of 8,400,000 lbs. in 1890 over that of the two previous years, operated entirely to the benefit of British-grown teas. The silver question itself threatened at one time to be of grave import to the industry, but the crisis once past it may reasonably be questioned whether the danger was not after all a blessing in disguise.

In taking a retrospect of the course of the market during 1890 we are chiefly struck with the comparatively uniform range of prices ruling throughout the twelve months; the average never sank to the low level it touched in the spring of 1889, whilst it failed to reach the high average attained in the autumn of that year. The fears of the trade as to any prospective over-supply were effectually allayed by the rise in silver, whereby the exports from China were considerably curtailed; and on the other hand, in the autumn, when the strong statistical position of the trade as a whole might have led us to expect a more important advance in values, a check was imposed by the wave of commercial depression caused by financial troubles, which at one time threatened to overwhelm the credit of the country.

Early in the year we enjoyed a very firm market for the lowest grades for price, but the better qualities soon commenced to recede in value, and the average price of 11½d for the first week in January was reduced to 11d at the end of the month. In February a generally dull tone supervened, and operations were conducted in a very hand-to-mouth manner. At the earliest sales in March the market became very flat, and the quality of the offerings at this period was not calculated to counteract the downward tendency; the average price gradually declined, and one week was as low as 9½d per lb. This low range attracted attention for a while, and some slight improvement took place; good Broken Pekoes and Pekoes, which showed the greatest depression, were more enquired for, and sold at enhanced values. A temporary flatness soon followed; in view of the possible reduction in the duty country buyers deemed it expedient to clear as little as possible, and dealers consequently also refrained from going into stock to an extent. After Easter, as the time for the disclosure of the Budget proposals approached, the chief buyers began to take advantage of the heavier sales to extend their operations in view of heavy clearing orders in the near future; finest qualities rose slightly in value, but the lowest grades were chiefly affected, medium qualities, for the time, being disregarded, and the average price for several weeks fluctuated from 10½d to 10½d per lb.

The reduction of the duty, in due course, was accepted very quietly, but if it did not cause any marked advance in prices, it was no doubt an important factor in preventing any decline at this usually depressed period. Throughout June and July a steady tone prevailed, the best teas were well supported, and indeed the fluctuations were principally effected by the quality of the offerings. On the 1st July the first New Season's Chinas were offered, and, with the exception of several of the finest lines which commanded very full rates for export, sold at a low range. In August, the generally poor quality of Indian and China directed more attention to Ceylon—more especially to the fine teas. In September the improvement became more accentuated, and the average price gradually rose to 1s ¾d—the highest rate recorded in the year. In October the low rates ruling for ordinary Indian Pekoes unfavourably affected the corresponding grade of Ceylon leaf; but a good all-round demand prevailed, the finest invoices being strongly competed for. After the first week in November the market began to show signs of weakness and irregularity, particularly for the more undesirable sorts; common Souchongs declined ¾d per lb., and the weekly average gradually receded, and at the closing sale of December stood at 11d per lb.

The issue of our Annual Circular has again been unavoidably delayed by the heavy amount of work entailed in summarising the results obtained by most of the chief estates in Ceylon, numbering over 450. It is quite possible, that, for reasons advanced on previous occasions, some slight miscalculation may be discovered; we can, however, confidently recommend our statistics as substantially correct for all intents and purposes, and we trust, that all those whom our circular reaches will prove it so for themselves, and regard it as of some practical interest and value. We can only once more congratulate Planters and all concerned on the highly satisfactory state of the industry, and confide our researches to their favourable consideration and study. It will be remembered that whereas last year only five names appeared in the first group of estates aggregating over 200,000 lbs. seventeen are to be found this year, two of which, Mariawatte and the Kadawella group, have contributed over half-a-million lb. each. The fine teas of the New Dimbula Co., with a yield of 209,000 lbs., head the list with an average of 1s 1½d against 1s 1d per lb. last year closely followed by Wallaha with an output of more than double that quantity. In several other cases last year's average has not been maintained, but in many instances this is to be traced to rather freer plucking, and we doubt whether many more satisfactory results can be quoted than the average of 1s 0½d per lb. for Chapelton with a yield of 450 lbs. an acre. In the second group Labukelle has given 15,000 lb. less tea, but has more than compensated by an increase of 2½d per lb. in the average price realised; the fine delicate flavour teas of this garden have sold largely for Russian account throughout the year. The next estate in the list—Kotiyagalla—whose Pekoes also have again found marked favour in the same market, has with an increased yield of 16,000 lbs., averaged 2½d per lb. more than in 1889. Kirkoswald sending 43,000 lb. more has maintained the same average. Glendevon with an increase of 20,000 lb., is only a ¾d per lb. behind, and Invery at a like small expense has increased its yield by about 70 per cent. In the third group Mooloya with a stationary yield has advanced 1d per lb.

The Highest average of all is that of Portswood viz. — 1s 4d, against 1s 4½d per lb. last year; perhaps no estate has so well maintained its distinctive character as this well-known mark.

Bogawantalawa and the country round about Nuwara-Eliya head the Districts with an average of 1s 0½d, or 1½d above the average realised by the Ceylon Tea sold on the London Market; but the case of Dimbula will perhaps be considered the most satisfactory; the yield from this fine district we estimated last year at 3,800,000 lb., this year we put it at 5,700,000 lbs., with the same average, viz., 11½d. Amongst the

remaining districts the most noticeable is a rise of 3d per lb. in the productive Kelani Valley.

During the past year the demand for Ceylon Tea on the Continent has developed considerably; a comparatively large business was done, principally with Russia, and we confidently look forward to a still greater distribution in this direction in the coming season. Several large lines of good useful Pekoe Souchongs have sold in the United States and in Canada, and we may also reasonably look forward to extended competition from this quarter in the future. The Ceylon Tea Co. in New York, founded at the close of last year, will doubtless prove a valuable medium for prosecuting this desirable enterprise.

Early in the spring of 1890 some especially fine Green Teas from Kiutye estate, attracted much attention and commanded very high prices; they did not, however, find a ready market in the country, and subsequent consignments were disposed of at much lower but still at satisfactory rates. The demand for this class of tea is restricted to a very small area at home and prices obtainable in America are not such as to encourage their manufacture on any large scale. The example of the above estate was followed by several others, but the quality of the teas was of a very inferior kind. Several small consignments designated Oologs met with very languid competition, being dry and malty and totally lacking the distinctive character of the Formosa type.

The size of the breaks from many estates was much more satisfactory last year, and it is to be hoped their example will be more universally followed in the coming season. Much irregularity in prices will be saved if care is taken in this respect especially in the large proportion of medium qualities. In times of heavy supply the large lines will always secure the most attention, except in cases of tea of particularly fine quality, when their marked superiority naturally compels competition. The surprise experienced at the varying prices sometimes realised for different marks, actually counterparts are one of the other, is almost always assignable to this cause.

WEEKLY PUBLIC AUCTIONS OF CEYLON TEA

SUMMARY OF CEYLON TEA SOLD AT PUBLIC AUCTION in London between January 1st and December 1890, estimated quantity in lb. and averaged prices realised:—

Average price for the Year 10 3/4d per lb., against 10 3/4d in 1889, and 11 1/4d in 1888.

The initial letters following the estate names refer to the mean elevation, as follows:—

L (low) sea level up to 1,000 feet—H M (high medium) 2,500 to 3,500 feet—H H (highest) above 5,000 feet—M (medium) 1,000 to 2,500 feet—H (high) 3,500 to 5,000 feet.

THE REPORTS FROM DELI, the tobacco country on the north-east coast of Sumatra, are still very favourable for the tobacco cultivation, and it is expected that the present crop will be the largest one ever harvested in Deli.—*Colonies and India.*

NEW STEAM FUEL FOR LOCOMOTIVES.—It is stated that a substitute for coal in the raising of steam purposes is now being successfully carried out on one of the leading lines of railway, and that two eminent London engineers have patented a system by which a ton of residual oil costing £3 10s may be made to create 8,000-horse power for a space of one hour, and generally to do twenty times the work of coal. It is also stated that the experiments made by the Great Eastern Railway have turned out most successful, and that Mr. Holden, the locomotive superintendent of the line, has patented an injector in connection with the fluid, and that it is now being used on about a dozen locomotive engines as an auxiliary to coal. The fluid, it is stated, is tar, to which is added some green oil from tar works, and the cost is three half-pence per gallon. Each engine uses about 12lb. of coal and one gallon, or 11 lb. of fluid fuel per train mile, as against 34 lb. of coal. The relative cost, it appears, is rather less than coal at the present price of both, but the value of the injector, it is asserted, is seen especially on gradients, when steam can be got up instantly by touching a tap at the hand of the driver.—*Railway News.* [All this ought to be good news for many Ceylon tea planters looking to the future.—Ed. T. A.]

LIBERIAN COFFEE in and in the neighbourhood of Colombo is all out in a splendid blossom at present, the beauty and fragrance of which are very attractive to bipeds as well as bees. Many of the trees are at the same time, laden with fruit in all stages from green to dark purple as well as with the snowy white blossom. If the native villagers took to cultivating this tree as they do coconuts, they certainly should never be at a loss for a supply of coffee for their own needs.

A REMEDY FOR MALARIA.—Mr. G. Yeates Hunter, late Brigade Surgeon of the Bombay Army, writing to the *Financial News*, says:—"There would seem to me to be little cause for surprise at the reduction in the price of quinine, when it is borne in mind that the Indian kreet is now generally admitted to be, in many respects, superior to quinine. To my knowledge halviva—a preparation of kreet—answers admirably in controlling fever, and also in repairing the mischief wrought by quinine in that large number of patients who suffer from its ill-effects, evidenced by head symptoms, general malaise, intense irritability, &c. After more than 20 years' experience in India of the comparative value of quinine and kreet, I believe that the latter will be more and more recognised by the medical profession as the safest and best remedy against malaria.—*Pioneer.*

THE SEASONS FOR FELLING TREES FOR TIMBER AND FIREWOOD are thus indicated in the *Indian Forester* :—

On the season in which trees are felled depend the technical properties of the wood, and even the possibility of carrying out the work, for labour may not be available in sufficient quantity and at reasonable cost throughout the year, and malaria or heavy rain or snow may be a bar to all operations.

To prevent cracks timber should be allowed to season slowly. Hence it should be felled in damp and cool (if possible, even cold) weather. Where there is a true winter, felling in winter also preserves the wood from fermentation of the sap, from infection by fungus spores, and from the attacks of insects. With regard to durability alone, the theoretically best time for felling occurs when the trees contain their minimum of reserve materials that is to say, generally just after the new flush of leaves is out. But this season can be observed only when it does not coincide with the appearance of new seedlings, which the felling and export operations are bound to destroy; or with the season of heavy rains, during which the ground would be soft and muddy and the advance growth, if there is any, full of tender and easily-injured shoots. It may of course be observed in coupes that are to be clear-felled and then re-stocked artificially. For the safety of young growth the best time for felling is the season of repose, when the plants are least fragile and possess their greatest recuperative power; but on the higher ranges of the Himalayas the snow lies too heavy for felling to take place then without risk to human life, and, as export must take place during the following summer, most of the trees have to be cut in spring, while the seedlings are only just sprouting or coming up from seed. As regards firewood, we know that the quicker it dries, the better it is; also that it is heavier the more full it is of reserve materials. Hence in felling for firewood, the best time of the year, provided sylvicultural exigencies do not bar it, is when dry, warm weather prevails; and if this coincides with the season of repose, so much the better. The time for felling coppice is limited, by purely sylvicultural considerations, to this season, the only exception being when bark for tanning is the chief produce sought, in which case the felling must be effected during the first three or four weeks of the season of vegetation, unless the trees are barked standing, or this period falls within the rainy season. In the case of charcoal-making the charcoal-burners must have a sufficiently long spell of fairly dry weather in which to complete their work. Cleanings and early thinnings in which the poles are cut as they are selected, must, of course be effected while the forest is in full leaf

THE QUININE RING.—The sequel to the recent efforts of the American quinine manufacturers to establish a quinine combination is given as follows in the last report of Messrs. Schoellkopf, Hartford and MacLagan, of New York:—"There can be no doubt we are in for an era of cheap quinine in the States, for a fierce war of prices is raging here, and is likely to grow worse. The representative of an American factory, having failed signally in his recent attempt to beguile the European makers into some sort of combination or arrangement, persuaded his people to enter on an aggressive course to coerce the recalcitrant German factory (supposed to be the Brunswick) to come to terms. The outcome is anxiously watched, but the fight is expected to be a long one, especially, as it is generally believed here that our manufacturers can supplement their output by using the ammunition of their enemies in the battle without any great loss to themselves. Meanwhile the large Philadelphia maker looks on, and keeps his price up. One good effect this quarrel will have—it will relieve the European market of considerable surplus stock.—*Chemist and Druggist*, March 21.

THE TEA TRADE BETWEEN CHINA AND TIBET.—In "Through Eastern Tibet and Central China," by Mr. Woodville Rockhill, in the *Century* for March, the following occurs:—

The road was covered with long files of heavily loaded porters trudging slowly on to Ta-chien-lu, and in every tea-house their huge loads were placed on benches while the frugal coolies refreshed themselves with a cup of tea or a bowl of bean-curd and a chunk of corn-bread. Most of them were carrying tea from Ya-chou or some neighbouring town, about one hundred and fifty miles away, to be taken later, on yaks or mules, into Tibet. They were of all ages, and I was surprised to see among them not a few women and small children. The packages of tea, each about four feet long, six inches broad, and three to four thick, and weighing from seventeen to twenty-three pounds, are placed horizontally one above the other, the upper ones projecting so as to come over the porter's head. They are held tightly together by coir ropes and little bamboo stakes; straps, also of plaited coir ropes, pass over the porter's shoulders, while a little string fastened to the top of the load helps to balance the huge structure, which it requires more knack than strength to carry, for its weight must bear on all the back and only slightly on the shoulders. In their hands the porters carry a short crutch which they place under the load when they wish to rest without removing it from their backs. The average load is nine packages, or from 190 to 200 pounds, but I passed a number of men carrying seventeen packages, and one had twenty-one. A man, I was told, had a few years ago brought an iron safe weighing four hundred pounds for Mgr. Biet from Ya-chou to Ta-chien-lu in twenty-two days. Old or decrepit people commonly travel along this road borne on the backs of porters. Many of the women porters carried seven packages of tea, nearly two hundred pounds, and children of five and six trudging on behind their parents with one or two. The price paid for this work is twenty tael cents (about twenty-five cents) a package, and it takes about seventeen days to make the trip from Ya-chou. So far as my knowledge goes there are no porters in any other part of the world who carry such weights as these Ya-chou tea-coolies; and, strange as it may appear, they are not very muscular, and over half of them are confirmed opium smokers.

There is an illustration, showing some of these tea carriers with their loads on their backs. The Bhutias of Darjiling are also noted for their carrying powers, taking enormous loads of tea lead and other heavy material on their backs up to Darjiling from the foot of the mountains. There is a story, similar to that related above, of an iron safe being carried up to Darjiling on the back of a Bhutia.

THE PRODUCTS AND MANUFACTURES of the coconut palm are thus noticed in "Notes by the Way" in the *Jamaica Gleaner*:—

The original design of a coconut trophy has been partly carried out by the manager who has arranged the coconuts in their various stages round the base of the tree in the Jamaica court, and shown the coir and the fibre beside it, while ranged round the sides of the interior are useful household articles manufactured from the fibre, the latter being exhibited by a London firm. I recommend my readers to see this instructive exhibit.

CARDAMOMS.—Cardamoms grow wild in the Ceylon jungles, but about fifteen years ago they began to be cultivated in several districts of the island by European planters. The results of the venture turned out unexpectedly profitable, the yield having occasionally been as high as 400 lb. per acre. Until a few years ago cardamoms were propagated only from the rhizomes, or bulbs, but since then it has been shown that they can be successfully grown from seed. Until not very many years ago cardamoms were imported exclusively from the Indian mainland, and a considerable quantity, including some of very fine quality, are still drawn from that country; but since the cultivation has been taken up in Ceylon that island has altogether eclipsed the Indian exports. Indian cardamoms are usually imported in large cases, containing from 1½ to 2 cwt. and the Ceylon variety in boxes usually varying from 40 to 80 lb. in weight. The average crops in Ceylon during the last few years have been about 300,000 lb.—*Chemist and Druggist*.

INJURIOUS INSECTS IN 1890.*—The 14th annual report on the ravages of injurious insects amongst our farm and garden crops, which Miss E. A. Ormerod, the able entomologist to the Royal Agricultural Society, issued last week, is a most satisfactory publication. When *The Times* called attention to the first very small report issued in 1877 the subject of economic entomology was almost unknown, whereas now it is recognized as an integral portion of agricultural teaching at the whole of our leading educational institutions. That all this has been brought about from the initiative work by Miss Ormerod must not only be gratifying to that lady, but should be matter of satisfaction to agriculturists and gardeners. The present pamphlet does not differ in form from those that have preceded it. In all 26 distinct attacks by injurious insects and eelworms are fully described and illustrated. This means—as was stated in the history of "British Agriculture in 1890," which appeared in *The Times* a few weeks ago—that last year was an average one so far as insect damage was concerned. Nearly all our common crop pests were present, but only a few really did any serious damage. There is, therefore, no need to refer to these at length. The chief lessons of the year are as to the use of more effective insecticides, such as "Paris Green." The use of these has been considered somewhat dangerous owing to their poisonous character, but with a fuller knowledge of the strength necessary to destroy attack Miss Ormerod thinks the time has come when they may be safely recommended for more general use. In one case a correspondent reports that he last year sprayed his trees ten times with Paris Green (2oz. to 20 gallons of water) with good effect. Although his fowls had a free run all over the field none were injured. In the use of these poisons, however, it is strongly recommended that farm animals should never be allowed to pasture or feed under trees that are being, or have recently been, so sprayed. The chapter dealing with this subject is very interesting, and may be said to exhaust the subject.—*London Times*.

* "Report of Observations of Injurious Insects and Common Farm Pests during the year 1890, with methods of Prevention and Remedy." Fourth report. By Eleanor A. Ormerod, F. R. Met. Soc., &c. London: Simpkin, Marshall, Hamilton, Kent, and Co. (Limited). 1891.

CEYLON UPCOUNTRY PLANTING REPORT.

CEYLON PRODUCTS IN THE MARKETS OF THE WORLD—
JAVA VERSUS CEYLON KAPOK IN AUSTRALIA—CEYLON
METHOD OF PACKING AND FREIGHTS—RAILWAY RECEIPTS
FOR TEA BOXES—A SHORT SINHALESE HARVEST—COFFEE
CROPS—FLUSH OF TEA—COOLIES.

April 2nd.

It is not often that a Ceylon product has to take a second place in the markets of the world. We are so much accustomed to a front seat, that we have begun to look upon it as a right, and if not awarded, inquire the reason why. It is our pride, more than our pocket that is offended when even one of our minor products runs with the neck, instead of leading as we hold that all Ceylon things should do.

One of those minor products which does no credit to the name of Ceylon is Kapok—the tree cotton. It grows well enough, and ought to do well enough, but in the Australian markets it is a drug and cannot get a buyer, if kapok from Java can be had at the time. Now the Java kapok is, I understand, exactly the same as our own, and the reason why it is readily bought up, at from 8d to 9d a lb., while Ceylon kapok is hard to move even when offered at 5d to 6d is simply a matter of preparation. Java kapok reaches the Australian markets packed in mat bags, thoroughly teased out, and free from seeds, whereas the Ceylon article has been subjected to hydraulic pressure, has been very imperfectly cleaned—not only seeds but even the core remaining, and the cotton often in little lumps.

There is no doubt that by the Ceylon method, of having the cotton heavily pressed, there will be a considerable saving in freight, but upholsterers and especially mattress-makers dislike it. It breaks the spring of the cotton fibre, and a mattress made of the Ceylon kapok is heavy and solid, whereas a Java kapok one is light and elastic. A gentleman who has just come up from the Australian Colonies, and to whom I am indebted for the above information, was most emphatic on the positive dislike which existed among buyers of kapok, to any of it coming from Ceylon. It was simply because freight from Java was not always to be got, and as a consequence the market was sometimes wholly devoid of the Java article that the kapok of Ceylon got an innings at all. Now this is not a hard matter to remedy. To have the kapok wholly free from seeds, or any other impurity, well teased, and looser packed is all that is wanted. What is not wanted is what goes down at present, an imperfectly cleaned and slovenly prepared product, and which is rendered less valuable still, in that it arrives pretty nearly as hard as a concrete block and bound with hoop iron.

As I said at the beginning, Ceylon takes unkindly to a back seat in any matter, and as regards kapok—for which there is a good demand in Australia—there is no earthly reason why growers of it here should not get the top price going. The difference in freight would be very much more than met by getting the advance in price, and then the comfort of having an article that would sell.

The Ceylon Government Railway is about as irresponsible as it can possibly make itself, and its regulations and by-laws are the astonishment and envy of the managers of home lines. But the tide still runs in the direction of even greater security and if a motto were wanted for that branch of the Government, the historic one of "I'll make siccar" might well be adopted. Railway receipts are seldom clean, and if you are despatching tea, let your boxes be what they may, there is some remark about them, testifying to the argus-eyed vigilance of our carrying Company. We are now pretty well

accustomed to the "one plank loose" or "some nails coming out," or other matter of this kind and the whole thing ending in nothing. It always reminds me of a mate's receipt I once saw. Bar iron was being shipped, but while the number of bars were right enough, there was the saving clause of "very rusty" written across the document! The other day I got a receipt back from the railway; there were no planks loose this time nor nails coming out, but, two of the tea chests were "stained with cow dung"? Was there ever such perfection as that? This official deserves and I trust will be promoted. Just contrast his precision, with the loose way things are often done on board ship. Three elephants were once shipped at Calcutta, or at least were supposed to be shipped. All the receipt that could be got out of the ship however was for two, with the clause "one in dispute," added. I never heard if the other elephant was found.

The Sinhalese harvest just being reaped, is I hear, a short one in some districts—as much as a third behind last season it is said. If the villagers have not a sufficient rice harvest, if they but come to the tea estates, and work steadily, they will earn a harvest of rupees instead. What tea flushes we have been having, and how pushed all have been to keep up with them! A wonderful season certainly.

Coffee, too, in many places is looking very well; I was hunting the other day for a specimen of leaf-disease and could not find one. There is a fine crop, too, set and a promise of more. But there is the experience of the past of what a fair deceiver coffee is, and while it is legitimate enough to chronicle the present prosperous appearance of things, and rejoice therein, still there is so much between this and the harvest.

The unusual push on estates at this season has made the value of Ramasami rise again, and the recommendation of the Planter's Association in the matter of advances is pretty much disregarded. Those who have fairly and honourably tried to act on the suggestion have found their labour force falling off and have had to do the next best thing, join in the scramble.

This is very much to be regretted, but it was not wholly unforeseen. Every year makes the need of coolies more and more evident, and yet it is wonderful how we manage to scrape through. The Tamil nation met our wants when there was the big run on coffee, although there was many a fearful Jeremiah with his roll of the coming woe, who foresaw nothing but disaster, and I have no doubt that history will repeat itself, and with our increasing outturn of tea there will come an increasing influx of Tamil labourers to meet our wants. Any how it would make one uncomfortable to believe otherwise.

PEPERCORN.

A SUBSTITUTE FOR COAL: THE FIRST LIQUID-FUEL EXPRESS LOG MO- TIVE IN THE WORLD.

[We are indebted to a correspondent who writes:—"I send you copy of the *Daily Graphic* with the account of a run on a Liquid-Fuel Express Train. As the matter bears on estate firing, I thought you would like to see same."—We give nearly all the report as of special interest to planters and others who may be longing for an economical fuel.—Ed.—T. A.]

A RUN ON A LIQUID FUEL EXPRESS.

(BY OUR SPECIAL COMMISSIONER.)

It was the box-seat that did it. Had we something corresponding to the box-seat on our fast engine, where for an extra fee, one could face the wind and the rain, the sunshine and the mist,

we would discover that trains are no less interesting and picturesque than ever the old lumbering dead and gone stage coaches were; for there is beauty in an engine—leaving on one side the smoking, puffing, evil-breathed metropolitan or suburban engines—the beauty of strength and speed. Had not Dickens and Hazlitt and other literary giants of that day told us in their best of the joys of the ride on the stage coach, and hid from us its many discomforts, we would have seen less of romance in it than we do now.

ENGINE 759.

At any rate, I found much to admire in Engine 759 as she ran up the line at Ipswich station, coming to a stand after her steam from Yarmouth. She is practically the only express engine fed by liquid fuel. There are other liquid fuel engines, many in Russia, a few in the United States, and in South America, but none are entitled to be called "express" engines, engines which do long runs at a high speed. Engine 759 is now some eighteen months old, and she is in the pink of condition. She differs from the ordinary engine in appearance by having on the tender, instead of some tons of coal, an iron tank, and in her cab one to the manner educated would have noticed a few more taps and handles and levers than usual.

A REFUSE OF VALUE.

I had travelled down with two officials of the Great Eastern Railway Locomotive Department at Stratford, and was told of one of those mechanical revolutions, of which this century has seen so many. The story is a curious one. The railway company have at Stratford gas works where they make from shale oil the gas which is burned in their trains. In the making of this gas refuse in the form of thin tar is given off, and this having been run into some stream at Stratford, the authorities came down on the company for river pollution. That it was possible to further pollute any stream at Stratford was a surprise to me. However, the company had to get rid of their refuse in some way, and it occurred to Mr. James Holden, the Locomotive Superintendent, that the best he could do with it was to burn it. He hit on a plan of burning it under the stationary boilers used for making the gas, and suddenly, from a mere refuse, this by-product had become valuable. Little did he know. Mr. Holden went on to invent a system by which the refuse could be used as fuel on locomotives, and at once effected a revolution in the fueling of engines.

SOLID AND LIQUID FUEL.

There were great difficulties to be got over. In this country it would be of little use designing a system which would render engines useless for solid fuel, or one such a nature that the parts are complicated and easily thrown out of action. It has, further, to be under the ready control of the driver. Another and chief difficulty is the blast. All these points have been fairly met. Dealing with the blast first, I must explain that when burning liquid fuel the blast required is much softer than when burning coal alone. A greater quantity of air must pass through the body of the fire when coal is used. Means were found to enlarge and reduce the blast pipe, and thus fit the engine for either coal or liquid fuel. Accompanying this is a sketch of the engine, with the front removed to show the blast pipe. The diameter there shown is 6in., and it is that diameter which is "on" when the liquid is being burned; but when coal alone is being used, the fireman touches a lever, the ring above comes down, and,

being conical, reduces the blast pipe to 5in. diameter. When the large diameter is in use there is less wear and tear of fire-box and tubes, and less back pressure on the cylinders, and the engine in consequence works more freely. It will be seen that this arrangement of enlarging the blast pipe, which has been invented in connection with this system, is of high value.

HOW THE FIRE IS FED.

To explain thoroughly the ingenious arrangement of Mr. Holden's apparatus would require much technical detail. How it is done is simply this:—The liquid fuel is conducted from the tank through pipes to the "injectors." These (two in number) are placed below the footboard in front of openings provided in the fire-box. Coming from the boiler are steam pipes, all easily regulated by the bunch of handles shown in the sketch. The steam passes through these pipes to the injectors, there meeting the oil and driving the atomized fuel into the fire-box. But before combustion takes place the stream of pulverised liquid is met by still another gush of steam known as the ring jet, which induces a strong current of air, and the fuel is thrown into the fire as a fine spray, charged too with abundant oxygen for rapid combustion. Then there are other cunning contrivances—a lever which regulates or stops the flow of fuel to the furnace, a handle which, turned, sends a jet of steam through a coil in the tank to warm it in cold weather or liquefy it when it is thick, and various other matters, all tending to great economy in working and in fuel. As to the relative value of the system with that of solid fuel, that also is important. One pound of the fuel is equal to 2 lb. of coal, which means that, as with a pound of coal 8lb. of water can be evaporated, a pound of liquid fuel will evaporate 16 lb. of water. The fuel costs 25s a ton; coal to do the same work (two tons) costs 35s—a big saving alone. Of ten engines of the same class, one using liquid fuel requires per engine-mile (which includes standing in sheds, sidings, &c.), 11 lb. liquid and 12 lb. solid fuel. The others require 34 lb. solid fuel per engine-mile. The weight on the tender is reduced by a couple of tons, and the saving all round is something like 50 per cent. The gentleman who has had this department of the Stratford Works in hand from the first, tells me that the fuel used to cost them $\frac{3}{4}$ a gallon. They are now paying 1d a gallon for it. They add to it a refuse oil obtained from the Backton Gas Works, a creosote or green oil left over after tar distillation, which costs from $1\frac{1}{2}$ d to 2d a gallon, and brings up the cost of the fuel to about three halfpence per gallon.

THE START.

But all this time Engine 759 has been standing waiting the signal to be gone. Here is her official description:—Driving wheels, four coupled, 7ft. diameter; cylinders, 18in. by 24in., weight, in working order, 40 tons. Our times were:—Ipswich 4.22; Liverpool Street, 6 o'clock—nearly seventy miles to be done in an hour and twenty-eight minutes. A few yards away rose the tree-clothed hill, crowned with a pretty red-brick house, which serves to make Ipswich Station one of the most striking in the Eastern Counties. Even the tunnel, with which it has been pierced, hardly disfigured it, and on such a day—sunshiny, warm, and blue sky—after a spell of London fog it was enough to suggest the still far-off spring. I climbed into the cab of Engine 759, and saw the fuel pipes at rest. The fire was a dull glow, for it is one of the benefits arising from the use of liquid fuel that none of it is wasted when the engine is

at a standstill, and no steam generated only to be blown away in a shrieking howl from the safety valve. Driver Dennison was oiling the human machine which is his, as he turned to welcome us aboard. Bob, the fireman, was oiling Engine 759, and we had the engine to ourselves for a moment. Its weight saved it. But time was now up. The "board" fell, somewhere in the rear of the train the guard whistled, and with a sharp toot and then a long call from the whistle, we were on our way up the tunnel. Bob had pulled the fuel lever and touched the steam cocks, and as he threw in three or four shovelful of coals, showed us the fire-box suddenly become a raging furnace of white flame. Yet as we came into the daylight the smoke stack gave no sign of smoke. A long line of steam trailed behind us, and it was pointed out that even when she was being coaled no smoke came from the engine funnel. Here is the smoke nuisance solved, so far as railways are concerned, thought I. We had now settled down for the run. We were going up hill—something like one in 110, I believe—and the load, seventeen coaches, was a heavy one. Another coach and we would have had to come on with a pilot, as is the case with this train all the summer months.

* * *

AT TOP SPEED.

A little steam was blowing off and we seemed to whistle under archways and station roofs in our speed. Away as far as I could see as I leaned out of the cab, were a number of platelayers, their day's work done, going home. They were on the up line, and when there was still a long distance between us and them the driver pulled the whistle cord. They stepped aside with pleasing promptness, and almost at once I caught a glimpse of their brown upturned faces as we powdered past. "We did that bit at over sixty," said my mentor. Only "Surfaceman" could sing the praises of such an exhilarating whirl of life inspiring haste as that! Yet one had time for contrasts. In the height of our fastest pace a country church with its white headstones, each with its wreaths and flowers of remembrance, was for a moment in sight. Who could have failed to think that for all our rattle and rush and roar, for all our "ever toiling up the climbing wave," there was the terminus? Still even there it may be pleasant to think we have been one of the first to do seventy miles in an hour and a-half on a liquid fuel express. We were nearing the end. A murky haze ahead and the lessening of the distance between the stations betokened an approach to London, whose lights were now beginning to show. Away down in the country there was an impression of stillness. The stations, the roads, the fields looked quiet. We were the only noisy object in sight. Even the woodman as we passed stopped his chopping to gaze at us in the still of the evening air.

ALMOST HOME.

Now people appeared thickly on the stations. The roads had become streets, and wore brisk with traffic. We went by suburban trains laden with folk. London was around us. We had had a clear run. Only once did a signal stand out against us, and at once the fuel was shut off and the train began to slow. But it was only for a moment. Even in the crowded ways about the suburbs our course was indicated by green lights, and only outside Liverpool Street itself did the red show. We came to a full stop, shut off steam and fuel, and waited. The effect of shutting off the fuel was wonderful, reducing the fire at once to merely a bright glow. "She's down,"

said Bob, as the signal dropped and we glided into Liverpool Street ahead of time, with the black of the fire bars showing in the box—engine-men will appreciate that after an express run—and no steam being wasted at the valve. It only remains for me to add that the system has already begun to affect the coal supply. Mr. Holden's agents, Taite and Carlton, are fitting it up on South American engines, and there it means all difference between very cheap liquid fuel at their own doors and English coal imported at £3 per ton.—*Daily Graphic*, March 4th.

THE ANCIENT CINNAMON REGION.

At the meeting of the Royal Geographical Society on Monday last, an interesting paper was read by Dr. H. Schlichter, on "Ptolemy's Topography of Eastern Equatorial Africa." The object of the author was to show that Claudius Ptolemy, one of the most famous of ancient geographers, who flourished at Alexandria about 150 B.C., knew and mapped out the position not only of the coast of Africa as far, and even farther, south as Zanzibar, but also, with tolerable accuracy, indicated the position of the great lakes of Eastern Equatorial Africa. In how far Ptolemy's topography was correct need not now be inquired into; but, in the course of the discussion it was pointed out that Ptolemy placed the "cinnamon country" of the ancients (*Regio cinnamomifera*) to the south-east of the Victoria Nyanza, whereas the country known to the ancients as the myrrh and cinnamon region was placed by them along the south coast of the Gulf of Aden, and the littoral south of Cape Guardafui. In connection with this statement it may be pointed out that there is evidence for the assumption that the cinnamon known to the ancients was the Chinese cassia; while it is practically certain that long after Ceylon was visited by European trading-vessels no cinnamon was produced in that island. The question whether in classic times cinnamon, or cassia, really did grow in Eastern Africa has frequently occupied the attention of pharmacologists; but the balance of opinion appears to incline to the belief that the cassia of China, along with other products of the far East, were carried to the ports on the Red Sea and the north-east coast of Africa by Indian traders, and there taken possession of by the Phœnicians (and after the decay of Tyre by the Egyptians), who carried them further towards Alexandria and other Mediterranean ports, but were, of course, careful not to divulge the trade secret of the origin of the valuable spice. In modern times neither cinnamon nor cassia has been produced anywhere in Africa on a commercial scale.—*Chemist and Druggist*.

[And yet, cinnamon is almost the only product left to us to which we thought we could safely apply the term "indigenous": we have the wild cinnamon tree in our jungles. We shall want to hear what Dr. Trimen has to say in answer to Dr. Schlichter.—Ed. T. J.]

OPALS of a finer quality than those of Mexico have been discovered near Moscow, in the State of Washington, U. S., close to the Idaho Railway. They were found by some labourers while digging a well in a wheat field, the mother rock being a basalt wacke. Opal is an amorphous hydrated silice, and is deposited from water. The finest specimens of the gem or precious opal come from Hungary, but those of Mexico are very fine. The fire opal of Zimapau, in Mexico, is transparent and of a deep red, being coloured by oxide of iron. Small veins of opal have been found in several parts of the United States.—*Globe*.

THE JAMAICA EXHIBITION:
WHY NOT A COSMOPOLITAN EXHIBITION IN CEYLON?

PRODUCTS OF JAMAICA.

From a description of the Jamaica Court, some interesting extracts must be taken:—

In the centre of the Court as already stated shoots up a palm tree whose spreading branches arch overhead and add to the picturesque effect of the building. At the base of this tree are two tropical plants in tubs, one is the pepper plant the other is a fine specimen of the pine apple—*Ananassa Sativa*. At the four corners of the Court are bananas in tubs, coffee plants in berry, palms, crotons, large barrels of raw coffee berries and a small barrel of cocoa berries. Barrels of sugar are placed at the other corners.

COFFEE.—The specimens of coffee are arranged on shelves, on the east side of the court on the exterior. They are the first objects one sees on entering the hall and looking to the west. The different coffee parishes are well represented. In the centre is a fine exhibit sent by Capt. G. G. Taylor, from his Moy Hall Estate in the Blue Mountains. This coffee is grown at an elevation above 4,000 feet and competent judges state that some of the samples here shown are equal to the finest coffee produced any where. In connection with this exhibit we may mention that Capt. Taylor exhibits in the same court a painting of his Coffee Plantation works, and also one of his Coffee Fields at Moy Hall. These are very characteristic views, giving one a true idea of what mountain scenery in Jamaica is. There are also fine samples from Whitefield Hall, Cold Spring (John McLean), and from the various parishes. From St. Catherine for instance there are samples from the estate of Mr. Thomas Kemp, Mr. Thorp, &c. From Manchester from Mr. Wyman, Mr. Elder and Mrs. Martin. St. Andrew from Messrs. Henderson, McClaverty and Thorp. Clarendon from Messrs. Young, Welsh, Waddell and Logan. St. Mary from Mr. Walker, and a specimen of Liberian coffee from Mr. Jenoure, Portland.

RICE &c.—In the corresponding division on the opposite side are exhibits of pimento, nutmegs, and cinnamon. There is also an interesting exhibit of rice from Dr. Calder's fields in Westmoreland, and one from Portland, sent by Mr. Thomas Briscoe.

COCOA AND KOLA.—On the eastern shelves is arranged a pretty exhibit of cocoa. The seeds are contained in bottles on either side and in the centre are a lot of fine pods, mixed with specimens of the prepared cocoa from different exhibitors. Specimens of Kola beans are also shown with the powder.

Tea seems to have been exhibited only by the Botanical Department. The negroes of Jamaica, although more advanced than those of Hayti, have not, it appears, yet abandoned their savage and degrading superstition of the Obeah; as the following paragraph shows:—

The article in the "Victoria Quarterly" on Obeahism by Inspector Thomas is one of the most scathing that has ever appeared in that generally very mild journal. Inspector Thomas has had exceptional opportunities for studying the superstition and what comes from his pen is sure to be trustworthy. The picture he draws of the degrading belief is a sad and disgraceful one, and it is in the hope that his article will assist in stamping it out that the Inspector has penned it. It will be published in pamphlet form and sold at the Exhibition, where the Inspector has also an exhibit of some of the articles taken from the practisers of the vile art.

The Christian Church as presented in its state-supported form could not, in days of slavery, have been instrumental in superseding such superstitions by a purer faith, as witness the utterances of a candid clergyman regarding the now happily disestablished Church of England:—

Churchmen are not the only men who will wish to have the book. Nonconformist will buy it, read it, and learn from it. And they will be pleased to find that

they have in the writer of the sketch of the history of the Church of England in Jamaica one who writes without fear, favour or affection out of place. The exclusive spirit that wounds, because it ignores the Christian work of other people, Mr. Ellis does not cherish. If he does, it is not in his book. There is the ring of honesty in what he says of this other work, and it occurs again and again, so that the acknowledgment is full. On the other hand Mr. Ellis touches frankly on the shortcomings and the blots on the early Church of England in Jamaica. He is as plainspoken on these, as on the good work done by the Nonconformist missionaries. In this way and following the thread of his narrative, the reader gets a very fair outline of the history of Christian progress in Jamaica, and he learns that that progress is real, and better still is assured.

Mr. Ellis gives his readers some curious glimpses of the clergy in the olden times. One of his mildest censures is the following:—"Nor, as we shall presently see, were the character and attainments of some of the clergy, licensed by Bishops of London, calculated to give the laity of Jamaica much confidence in the tact and judgment of the prelates who selected these clergy and licensed them for their sacred duties." In the early part of the 18th century the Jamaica Church was, he says, "regarded as little more than a respectable and ornamental adjunct of the State, the survival of a harmless home institution, which would cease to be tolerated if it showed any great signs of energy or activity. At best it represented the religion of the white settlers, and cannot claim in any real sense to have been a missionary church to the black labourers * * * few traces are to be found of any marked efforts on the part of the church to raise the moral tone of the slaves, to ameliorate their distressful position or to instruct them in the elements of religious truth." Referring to the circumstances that must have hemmed in any clergyman disposed to be active, Mr. Ellis observes, "As subsequent events prove, and as no doubt the plagues anticipated, the inculcation of Christian truths should not fail to produce feeling of disaffection, and a consciousness of humiliation and ill-treatment in the minds of the African bondsmen. 'The truth shall make you free,' and those who were opposed to freedom were at any rate consistent in withholding the truth. It is easier to find fault than it is to make allowance, and if the Jamaica clergy of the eighteenth century deserve their share of blame, they are at least entitled to a large and charitable allowance in view of the difficult and unusual circumstances under which they laboured." A contemporary writer is quoted as saying of the clergy of that time that the majority of them were "of a character so vile that I do not care to mention it; for, except a few, they are generally the most finished of debauchees." Mr. Ellis then remarks, "The same writer adds that many of the churches were seldom opened, a fact which only a sham sentiment can regret. There is a sort of pleasure in giving these disreputable clergy credit for the possession of that amount of grace and of good feeling which was sufficient to prompt them to keep their shameless persons outside the doors of the houses of God."

Some startling information is given in reference to the administration of the Sacraments of the church. "As an instance," says Mr. Ellis, "of how little care the legislature took in the religious condition of the slaves at this time, we may mention that the fee, fixed by law, for administering the Sacrament of Holy Baptism to a slave was £1 3s 9d, a sum large enough to be prohibitory." Even in this century things were in a strange condition. In 1816 when Mr. Monk Lewis was on a visit to the island to look after his properties, the following incident occurred. "One day during this visit a slave wished one of his children to be baptised, and, as there was no clergyman within many miles, Mr. Lewis undertook to administer the Sacrament. The ceremony took place in the dining room, Mr. Lewis signing the child's forehead with the sign of the cross, and offering an *ex tempore* prayer. This was followed by the baptismal party giving three

cheers for Mr. Lewis, who concluded the ceremony by distributing Madeira among the congregation." In the same year the baptismal fee for a slave was fixed by statute at two shillings and six pence. Between 1821 and 1824 one clergyman baptized 12,000 slaves at half-a-crown a head.

Dr. Wolcott (Peter Pindar) was, for a time, one of the exemplary clergy referred to. Some of the *Observer* readers may be as ignorant as we were until we read the literature of the Jamaica Exhibition, that, amongst Queen Victoria's titles, in addition to Empress of India is "Supreme Lady of Jamaica." We notice that the working of the railway by the American company to which it was so unwisely sold by Government is described as most unsatisfactory. A fatal accident is reported in the paper before us. Amongst the distinguished personages present at the landing of Prince George was Major Knollys, C. M. G., Inspector-General of Police, who came to Ceylon as Sir Arthur Gordon's A. D. C. The report states that

The photo-artist of "Harper's Magazine", the "Illustrated American" and "Frank Leslie's Newspaper" was busy during the interval of waiting taking photographs with the camera.

If we quote a notice of the opening ceremony at the tail-end of this communication, it is due to the arrangement of the matter in the three sheets of the special edition of the *Gleaner*. From its report we learn that

The ceremony which took place in the Exhibition Building was certainly one of the prettiest from a spectacular point of view that has ever been performed in our island. For never before has such a handsome building graced our town and seldom has such a galaxy of distinguished men and women been gathered together on so interesting and important an occasion as this when our first International Exhibition was opened by His Royal Highness Prince George of Wales. Truly our Royal visitor received a welcome worthy of the grandson of the Queen—a welcome which every one could see was the source of deep gratification to him.

His Royal Highness then stood in the centre of the dais, the Governor on his right and Lady Blake on his left, the Vice-Admiral Watson being next to her. Lady Blake was attired in a dress made in an English School of Art and designed by a Baroness. It was trimmed with Orchids and leaves embossed on light Canary Satin with Chaneille trimming, each end of which alternated with balls of Canary and Heliotrope. Her Bonnet, was of light canary velvet with Heliotrope Orchids and aigrette.

From the address by the Commissioners to Prince George, we take a few paragraphs:—

The original suggestion from which this Exhibition took its rise was, by collecting and displaying samples of the Agricultural, Industrial and Commercial products of the Island, to arouse and foster a spirit of enterprise and emulation among the inhabitants of Jamaica, and at the same time to disseminate among the people of other countries a more extensive knowledge of the resources and capabilities of the colony.

The spontaneous and liberal manner in which funds for carrying out the enterprise were guaranteed by the people of the colony and those interested in its welfare and the ready response with which the invitation to take part in the Exhibition was met by the Mother Country, and the sister colonies—notably by Canada—and by many Foreign states led to the enlargement of the original scheme and has resulted in an Exhibition on a larger scale, and of a more general and comprehensive character than that at first contemplated by its originators.

Every effort has been made to render the Jamaican Exhibits a complete and representative collection of the agricultural, mineral and industrial products of the Island and we would venture respectfully to express a hope that, as such, they will be found by Your Royal Highness to possess features of novelty and interest.

The Prince made a suitable reply; and after a prayer by the Bishop, during which a canary poured out its song, and after Sir Henry Blake had presented a golden key to the Prince as a fitting emblem of a golden future for Jamaica, Prince George declared the Exhibition open. The address from the city was enclosed in a casket made from 120 ounces of silver. When we left Britain for Ceylon in August 1837, there were not more than 200 miles of railway completed, and the first experiments in telegraph were being conducted by Wheatstone. Deeply interesting is the progress of telegraphy in the interval, as narrated in connection with exhibits of the appliances of the art:—

Of Historical Telegraph Apparatus there are Cooke and Wheatstone's 4 needle Telegraph 1833, Cooke and Wheatstone's Double Needle Telegraph 1844, First Train Signalling Instrument 1840 used on the Blackwall Railway between Limehouse and Stepney. Specimen first Telegraph Line 1837 between Buxton and Camden Town. Double needle small pattern, Highton's single needle Telegraph 1848 Wheatstone's Type Printer 1841. Varley's Horizontal Relay 1856. Wheeley 1855; set of wire joints 1842, to 1851 Switch or commutator 1857. Preece's Semaphore 1860. Bain's Chemical Telegraph 1850. Morse Embosser 1853, Universal Switch 1860. Specimen of first submarine cable Dover and Calais 1850.

Mr. Wilson informed us that this cable was of solid copper wire insulated with Gutta Percha there being no outer protection whatever, the consequences were that the Gutta Percha almost immediately chafed through and the undertaking failed. To make the cable sink to the bottom weights were attached during the laying at about every 100 yards.

In 1851 another effort was made to carry the Telegraph Line across the Channel, which was successful. This cable is now working, that is to say portions of it, for in the many repairs it has been subject to fresh cable has been put in, to replace the old.

Mr. Wilson also informed us there is today over 100,000 miles of Submarine Telegraph Cables in operation. The general portion is owned by English companies, and all are manufactured and laid by English firms.

Mr. Wilson said, to give some idea of the employment of labour throughout the world brought about by the varied applications of electricity the following is about the number of persons employed. Land Telegraphs, 180,000 persons. Telephone Companies 30,000 persons. Electric Lightning Companies 100,000 persons. Submarine Cable Manufacture (Mainly British) 5,000 persons. Submarine Cable Company (Mainly British) 6,000.

Mr. Wilson informed us that at the present day the Telegraph systems throughout the world possess about 1,800,000 miles of wire. Russia claims 154,000, France 170,000, Germany 180,000, the United Kingdom 240,000, India and Colonies 200,000 and the United States 600,000. Traffic carried over such Lines—United States 70,000,000 messages per annum, United Kingdom 45,000,000, Colonies and India 12,000,000, France and her Colonies 32,000,000, Germany 18,000,000.

Mr. Wilson told us all Englishmen should be proud that the first specification of patent taken out in any country for telegraph apparatus was granted to Cooke and Wheatstone in 1837.

It was not till 1845 that public interest was really attracted towards the Telegraph—Fame and success are infrequently due to a mere accident and this was the case with the Telegraph. A murder was committed at Slough and the murderer escaped by the first train to London. The telegraph was set to work and the carriage occupied by Fawell—that was the man's name—was arrested much to his surprise he not having taken into calculation the new element which had been used against him.

We fear we have extracted too freely, but we think the interest of the matter will more than atone for its

length, especially to readers who favour the idea that Ceylon, no less than Jamaica, ought to have an Exhibition of her own: not merely a collection of local exhibits, but a cosmopolitan and comparative show to which all the countries in the world should be invited to contribute. If such an Exhibition is deemed feasible, and if it is to precede the great World Show at Chicago, there is clearly no time to be lost in making the necessary preparations and arrangements. Money will be required, and may we suggest that to no better or more reproductive object could the proceeds of the pearl fishery now in progress be devoted? The responsibility of cordially accepting or coldly rejecting the idea rests with Sir Arthur Havelock.

BURNT EARTH.

This material is very useful to the cultivator who has a cold or stiff soil to deal with, as it promotes the drainage, and is especially useful where liquid manure is applied, the noxious substances inimical to plant life being eliminated, and the soil made much warmer and richer in potash, lime, phosphoric acid, carbon, &c., ingredients which increase greatly the fertility of the land. Burnt earth dressing will prevent the cracking of the surface during dry weather by rendering it less adhesive, and therefore not so liable to cake. We use a large quantity of it here for mixing in the Vine and Peach borders, for Roses, &c., under glass, and outside for herbaceous plants, and it is found to be useful for all of these; in fact, I have not the least doubt that it would prove beneficial to all kinds of plants here, and also wherever the soil is stiff and cold. If used in the proportion of one part burnt earth to six parts soil, and well mixed, it makes a great difference at once in the working of the latter, and is, in fact, the best thing that can be applied for the purpose; other materials that are often used for keeping soils open, such as sand, coal-ashes, lime rubbish, &c., do not give such good results, because they tend to impoverish instead of enriching the soil. A good instance of its utility is to be seen here at the present time; the borders are being renewed in our large Peach-house, because they were not properly made when the house was built, and some four years ago I had a quantity of burnt earth worked in amongst the roots of the trees on the coldest side of the house. These trees now lift with a nice lot of fibrous roots; the soil comes away cleanly, and in good condition. The soil of the opposite border, which has not been treated in the same manner, has become sour in many places, and the tree-roots have not many fibrous roots.

I have not had the opportunity of trying its effects on light soils, but imagine that it would benefit them also if used in a smaller quantity; it would certainly improve any that might be overcharged with nitrogen through excessive manuring, &c., and during dry weather it acts as a reservoir for moisture when placed beneath the surface.

The best time of year for preparing it is during a spell of warm, dry weather, everything burning freely when dry, and earth being no exception to the rule; but it is possible to burn it under any circumstances by using a larger quantity of fuel.

In this, as in all other operations, very much depends upon getting a good start. We generally get some large tree-roots, or "butts," which have been sawn off, or some large logs cut into lengths of 3 to 4 feet, and a small quantity of sticks and straw to get a good body of fire as quickly as possible. The small stuff soon burns out, but when the larger pieces get well alight, some bush prunings, &c., are thrown on it in order to keep the soil from settling down too close to the large logs, and as soon as the fire burns partly through this covering, some soil may be put on. This should be done gradually at first, so as not to overload the fire; but when all the fire has had one good covering of soil, and the fire is seen to be making its way through it, some

coal-dust should be scattered all over, and another lot of soil put on; after this is burnt through, the heap should be ready to "draw" by opening out the middle, so as to spread the fire, and get a good base of ashes. This is best done by what is called a "muck drag" in this part—an iron tool with two or three prongs about 9 inches long, shaped like a Canterbury hoe; after the fire is well open out, another old log should be put in the centre to keep a body of fire going on, some more garden refuse placed over this, and then more soil added.

The heap by this time should be a large one, and in dry weather will burn almost anything with little further assistance; but if the soil is wet and the weather rainy, some coal dust or old pieces of timber should be added occasionally so as to keep the fire well alight. The best soil for burning is a rather light loam from a pasture, cut in turves about 4 inches thick, but this is not easily obtained by many persons, and the best that can be had must therefore suffice; clayey soils will not do, as they burn too lumpy and require screening afterwards, and very sandy soils would most likely run down too fine to be of much benefit; old fruit borders that have got sour or worn out will answer well for burning, and refuse from the potting benches, if free from crocks, burnings of fruit trees, &c., make first-rate ashes if burned up in this manner, but this is properly speaking charred refuse, and does not come under the heading of burnt earth.—W. H. DIVERS, Ketton Hall, Stamford.—*Gardeners' Chronicle*.

COCONUTS AND CINNAMON.

VEYANGODA, 28th February.

With very nearly $4\frac{1}{2}$ inches of rain February, one of our driest months, all anxiety with regard to the effects of the drought is at an end. Under ordinary circumstances, the drought will practically be at an end in March, for in April we have the fitful showers which are associated with that month. A heavy fall of 2.53 inches on the night of the 12th instant was particularly welcome to all forms of vegetation, and to cattle. The latter have not, as is usual at this time of the year, suffered from want of pasturage.

The prospects of coconuts are bright for the year. The effects of three consecutive years of liberal rainfall are now apparent in good crops. Prices both for the raw nuts and for copra are good. The former is kept up by the demands of the local Desiccating Factory, where prices ranging from R34.50 to R35.50 are paid according to quality of nuts. There seems to be no end to the extension of the works here. Buildings seem to be cropping up all over the grounds to supply the orders that pour in from all quarters of the globe.

The cinnamon season 1890-91, that will end in March, will belong remembered as one of the most unfavourable on record. Both the S. W. and N. E. seasons were unfavourable for continuous peeling. Harvesting was carried on by fits and starts, whenever rain fell. With any other product, one would have been safe to predict a diminution of crop as a result of unfavorable seasons. This is impossible with cinnamon, the output of which mysteriously increases when circumstances point to a decrease. It is safe, however, to say that the vast majority of cultivated Estates in the principal Cinnamon districts of the Western Province have secured little more than an half of their annual crops. With the rain we had this month many Estates have resumed peeling. The possibilities of continuing the work are dependent on the weather, which, if appearances are to be relied on, will prove favourable. Last night we had all the indications of an imminent shower in low rumbling thunder and flashes of lightning, which seemed nearer and nearer as the night wore on. They ended in nothing, however, here, but may I think be safely regarded as a precursor of what we may expect in a day or two. With a diminished crop, the contemplation of lower prices at the last sales is not over pleasant to proprietors. The hopes ex-

pressed of a rise in prices "next time" are the usual buoys that keep those engaged in agricultural pursuits from despondency.

The necessity of supplying certain demands often threatens an industry. The suicidal inclination to meet them is fostered by high prices. The encouraging prices paid for fine Tea stimulate fine picking, in spite of its having been shewn by a competent chemist that it is a great strain on the bushes. Not only the prices realised, but the reputation an Estate and its Manager acquire, promotes a pernicious practice. The reference to Tea is only to exemplify what is being done with another product with which I am more immediately concerned. Those who are in a position to compare cinnamon estates as they were 20, or even 15, years ago with their present condition, cannot fail to be impressed with the evils of fine cutting. It is not to be supposed, however, that the difference in appearance is mainly due to the difference in the height of the bushes. No, the growth is decidedly weaker now than then. The bushes are less healthy. Those whose accounts of crop cover the period I have named will, I am sure, find, on reference to them, that the difference in quantity will range from 20 to 40 % between then and now. The mischief is that the decline has been so gradual as to be hardly perceptible. For 2 or 3 years the yield is kept at the old average by forced cuttings. Then the inevitable, that crop has decreased, is faced, and a lower figure is accepted as the annual yield. It is attempted to keep up to this lower figure by a system of forced cuttings for a few years, with a like experience—a lowering of the estimate of yield in a few years—till now, as I said before, the difference in yield, though imperceptibly, has declined materially. The growth of wood, as before stated, is not as healthy now as it was before. The sticks are stunted. This, however, is not to be wondered at, and is the natural result of shoots from immature stools. Where I wonder is this system of fine cutting to end? I see no end to it, however, as long as the demand for fine cinnamon lasts. The manufacture of cinnamon is becoming a fine art. The older generation of peelers is quite out of it, and the "quilling" is entirely in the hands of young men and boys. The improvement in the make of the quills will be best understood when one circumstance is mentioned. About a dozen years ago, and after the craze for manufacturing fine quills had set in, a Manager of a crack Estate drew special attention to a parcel of exceptionally fine cinnamon of "superiors" which averaged 19 quills to the lb. Now 40 quills to the lb of the same quality of cinnamon is thought to be nothing unusual! I warn proprietors, however, to look carefully into the question of fine cutting, and to decide whether it is to their interest to persist in it.—Local "Examiner."

TEA AND COFFEE SUBSTITUTES.

(Continued from page 732.)

COMPOSITE.

44. *Helichrysum quinerve*, Lessing.—A sample of the dried leaves of this plant were shown in the Cape of Good Hope Court of the Colonial Exhibition, 1886, as Bushman tea, and said to be used as a substitute for China tea.

45. *Turchonanthus camphoratus*, Linn.—A shrub, 6 to 8 feet high, native of the Cape of Good Hope, were it is known as Dugga. When fresh, the leaves have a peculiar camphor-like smell, hence the specific name; they are infused in the form of tea, and are supposed to have medicinal effects. They are also chewed by the Mahomedans, and smoked by the Hottentots. There is a sample of the leaves of this plant in the Kew Museum.

VACCINIACEÆ.

46. *Vaccinium arctostaphylos*, Linn.—Under the names of Thé de Bel Dagh, Trebizond tea, and Broussa tea, the dried leaves of this plant have been variously known. It was noticed in the *Pharmaceutical Journal* for January 17, 1885, pp. 573-4, and March 21, 1885, pp. 771-2. In 1817, Mr. George Maw brought for the Kew Museum from Asia Minor a small

sample of a native tea obtained at Broussa in Anatolia, where it was sold for about 8d. per pound. In a report by Her Majesty's Consul "On the Town and Port of Samsoun, and on the Circassian Colony in the District," contained in the *Commercial Reports from Her Majesty's Consuls*, 1884, part 1, p. 147, reference is made to the production of a native tea which considerably interfered with the import of China tea into the country. The *Vaccinium* tea is in appearance very like coarsely-prepared black Indian or China tea, and has a similar aroma—so much so, indeed, that the Customs authorities demanded duty upon the samples sent to Kew by Her Majesty's Consul; the taste of the infusion, however, has no resemblance to true tea. Upon submitting samples of the Trebizond tea for the opinion of a well-known firm of tea brokers, they remarked that common China tea showed a better value in every respect, so that the admixture of the Trebizond tea could hardly reduce the cost, while it would certainly not improve the flavour.

The following further notes on this subject are gathered from a memorandum by H. M. Vice-Consul at Samsoun. The tea in question became a commercial article so recently as 1880. At first its consumption was limited to the country, and particularly to those districts in which Circassian colonies had been founded. It is manufactured by Circassian planters in the neighbourhood of Amassia, Tokat, and Horek, all in the province of Roum, at a short distance from the forest, which clothes the mountain chain called Beldagh, and on which the plant which furnishes the tea in question grows in great abundance. The manufacture is carried on in the houses of the Circassian colonists who undertake this industry, and who appear to be pretty numerous. There are several gatherings of the tea; that which yields the best quality takes place in May. About 5,000 ocques (an ocque equals 2½ lb.) are manufactured annually, but this quantity could be considerably augmented if there were occasion for it. The tea is sold on the spot at about 5 piastres per ocque. The cost of transport to Samsoun might amount to about 1 piastre, which brings the price per ocque to 6 piastres in that town.

The consumption is almost limited to the requirements of the vilayets of Sivaz (Roum) and Angora (Anatolia). It is to the town bearing the last-mentioned name that the greater part of the crop is sent. In 1881 a consignment was sent to France, but the transaction was not a profitable one. Some further consignments to Constantinople also do not appear to have been successful.

47. *Vaccinium hispidulum*, L.—A sample of the twigs of this plant is shown in the Kew Museum, under the name of Anise tea, from St. Pierre and Miquelon.

48. *Agapetes saligna*, Hook. f.—Described as a large epiphytic shrub of the Sikkim hills, at an elevation of from 1,000 to 5,000 feet. The leaves are said by Hooker to be used as a substitute for tea.

ERICACEÆ.

49. *Ledunpalustre*, L.—An erect, small-leaved bushy shrub. Native of Canada and Labrador, where the leaves are used as tea under the name of Labrador tea.

50. *Ledum latifolium*, L.—The Cree Indians in the Hudson's Bay territory use the flowering tops of this plant as tea; they are gathered when in full flower, and dried, when they have an odour between that of Tansy and Camomile. The leaves are esteemed pectoral and tonic, and are said to have been used as a substitute for tea during the war of Independence. It is called Karkar-pukwa, or Country tea.

51. *Kalmia angustifolia*, L.—The twigs, with the leaves and flowers, are known by the Cree Indians in the Hudson's Bay territory as Bitter tea; the infusion is used more as a medicine than as a beverage.

52. *Gaultheria procumbens*, L.—A small, creeping, shrubby plant, native of shady woods in mountainous districts in Southern Canada and the Northern United States; it is known as Mountain Tea, Jersey Tea,

or Tea-berry. The leaves have a pleasant aromatic flavour, and an infusion is used in some parts of North America as a substitute for China tea, under the name of Mountain or Salvador tea.

STYRACÆÆ.

53. *Symplocos Alstonia*, L'Her.—A small tree of New Granada, described as having the habit of the tea plant. The leaves, which are of a pale green colour, are employed as tea on account of their slight astringency. It is known as tea of Santa Fé.

LOGANIACEÆ.

53A. *Gærtnera vaginata*, Lam.—The seeds of this plant were introduced to notice under the name of *Mussaenda borbonica*, but were identified at Kew in 1889 as those of *Gærtnera vaginata*. The interest at first attached to the seeds was on account of their use as a substitute for coffee. It was made the subject of an article in the *Kew Bulletin* for December, 1889, from which the following notes are taken:—The plant is a native of Réunion, and in a letter from the Consul to the Foreign Office, it is described as a shrub found in the forests, but not plentiful, bearing fruit only at the extreme ends of the branches. "The berry, when gathered, is peeled, and then much resembles the coffee berry, though smaller. In fragrance, it is inferior to coffee, and in colour to chicory. The yield is far less than that of the coffee tree, and the picking more expensive, that is to say, about 1s. the pound. It is much doubted, by reason of its inferiority, that *Mussaenda* could ever compete with coffee and chicory, even if it were cultivated." From an examination made by Professor Dunstan, of the Pharmaceutical Society, it was proved that the seeds contain no caffeine, and that in consequence it cannot be regarded as a proper substitute for coffee. The result of Professor Dunstan's examination is printed in the *Pharmaceutical Journal* for November 16, 1889, p. 381. A sample of the seeds is contained in the Kew Museum.

BORAGINÆÆ.

54. *Lithospermum officinale*, L.—The Gromwell of our hedges and copses is found also in other parts of Europe, and in the Basse Pyrenées; the plant is used as a substitute for tea, under the name of Thé de Montagne. A sample of this tea is contained in the Kew Museum.

SCROPHULARINÆÆ.

55. *Veronica officinalis*, L.—A native of this country and of other parts of Europe, as well as in North America. The leaves, which are astringent and bitter, are made into tea in Sweden and some parts of Germany, and used medicinally as a stimulant under the name of Thé d'Europe. Simon Paulli contended that this tea was identical with the true tea of China. A sample is contained in the Kew Museum.

56. *V. Allioni*, Villars.—A glabrous procumbent plant, native of Switzerland, Southern France, Italy, &c. A sample of the dried leaves in the Kew Museum is labelled "Thé de Mont Cenis, used as a beverage on Mont Cenis."

57. *Capraia biflora*, L.—It is known as the West Indian Tea plant, Lunan says, according to Long and Barham, the leaves not only resemble those of tea, but make an equally agreeable decoction, which is also recommended as an excellent febrifuge. The plant is very common everywhere in the Savannas.

Barham, writing of the plant says: "A Frenchman, captain of a ship, affirmed to me as we were walking about the town of St. Jago de la Vega, and observing this plant growing so plentifully, that it was the same as the tea plant of China that he had used in the part of the world many years, had seen large fields of it, and the manner of cultivating it, and all the difference was that the Chinese plant was larger, which he ascribed to such care and cutting of it, and had no doubt but the Jamaica plant if it were set in rich ground and attended with equal care would improve in size." Barham further mentions the fact of "a gentleman who never drunk any other than West Indian tea, and that although he could not coil up the leaves so dexterously as they do in China, yet he performed this operation

tolerably well, and every person whom he regaled with it extolled it as the very best green tea they ever drank in their lives. It is certainly unknown to what perfection it might be brought if reclaimed from its wild state, and cultivated in the rich soil of gardens, and it well deserves the experiments of the curious." The plant is a shrub widely distributed in the West Indian Islands, extending into Mexico, Brazil, Peru, as well as in Tropical Africa.—JOHN R. JACKSON, Museum, Kew.—*Gardeners' Chronicle*.

EEL WORMS AND ROOT GALLS.—The *Agricultural Gazette* of New South Wales for August, 1890, contains an elaborate account by Mr. N. A. Cobb of the eel worm (*Tylenchus arenarius*) which is causing great mischief to root-crops in New South Wales. A synopsis of the known species is given. When established, cure is impracticable; but prevention may do something by ridding the soil of the worms, or by putting such obstacle in their way as to render their ravages bearable. This may be done by the use of some chemical—preferably a fertiliser—which will destroy the larvæ before they have entered the roots; by the selection of some varieties not subject to the attacks of the creature; by trapping the worms and destroying them. To trap and destroy enemies numbered by the million, and hidden away under ground, might seem impracticable; nevertheless, a plan based on the life history of the creature has been successfully adopted in the case of Beetroot. Strubell, who obtained a prize from the University of Leipzig for an investigation into the nature of the disease affecting the Beetroot, observed that the larvæ, after entering the roots, did not become mature till after an interval of five or six weeks. Whereupon Professor Kuhn recommended that the plant should be pulled at the end of four weeks, when the creatures would die, and leaves no progeny in the shape of eggs. By thus sacrificing two or three crops of seedling plants, the pest is so diminished that a crop of roots can be successfully raised. Gas lime applied to the soil would probably be efficacious. These pests are becoming more frequent, or are sooner observed than heretofore, not only in outdoor crops, but in the case of pot plants.—*Gardeners' Chronicle*.

A FEW OLD SIMPLES.—To allay hæmorrhage, a toad, well dried in the sun and put into a bag, was hung round the neck by a string sufficiently low to touch the region of the heart; and a preparation of garlic and honey smeared on the person was said to act as a charm against the bites of dogs and reptiles, or the sting of numerous insects, likewise effecting their cure. Toothache could be charmed away by a few leaves of the "shepherd's purse," placed in the sole of the shoe on the reverse side of the body to that in which the tooth was aching. An excellent recipe for weak or sore eyes was the expressed juice of the calyx of the red honeysuckle; provided always that the flowers were gathered by eeling, repeating nine paternosters in honour of the Trinity, nine more "to greet Our L-dye," and a creed. Rest and sleep were required after application. Another prescription for the eyes much in favour with the Anglo-Saxons was a paste made of the strawberry-plant and pepper, diluted with sweet wine. Children were passed through the split stem of a tree for the cure of the rickets, but the fracture must be afterwards bound up sufficiently tightly to ensure cohesion. For ague a very well-salted herring, split open, was applied, as hot as possible, to the sides of the feet. It might also be mitigated by the habit of wearing round the neck of an emerald—a gem equally potent in epilepsy. Precious stones were accredited with marvellous powers over the moral qualities and affections, as well as physical diseases:—hence the origin of their being set in rings and worn. The teeth of old age were fixed firmly in the gums by an infusion of powdered jet; while water in which the beryl had been steeped afforded a valuable wash for strengthening the eyes, besides ensuring the mutual love of a wedded couple.—*Hospital*.

CEYLON TEA AND THE NEW FRENCH TARIFF.

Mr. Mundella, the President of the Board of Trade, may justifiably be credited with the desire to see that all sections of British industry receive careful safeguarding when the terms of the proposed new French tariff have to be discussed between the respective Governments of Great Britain and France. It is questionable, however, whether any possible reduction of the present duty on teas imported into France would be beneficial in inducing its people to make such a change in their habits and tastes as to take to the use of tea instead of the present national beverage of coffee. We believe the existing rate of duty to amount at present to a little over one franc, or tenpence, the pound, and though comparatively high, this can scarcely be said to be a prohibitory tax. Of course tenpence strongly contrasts with the British rate at the figure (fourpence) to which the English duty has lately been reduced.

No doubt it would be a great thing for all growers of tea if the consumption in France and on the Continent of Europe generally, could be increased; but, as we have said, the item of duty upon the article is not the most important matter. A recent London Letter told us that a family in the South of France had been paying no less than seven shillings the pound for all the tea consumed by the household. Of such a price, the item of duty makes up but a small proportion. The question therefore must naturally present itself whether so excessive a rate of cost may not be due to want of commercial activity in introducing the article. At the rate at which Ceylon tea could be imported into France—notwithstanding the existing high rate of duty—the retailer who vends tea at seven shillings the pound must be demanding a profit of something like three hundred per cent! If competition cannot be induced so as to greatly lower such a tax upon would-be tea drinkers, it is easy to see that there can be but little chance of the consumption of tea extending in France. It might, it seems to us, have a different result if really good tea was sold, as it might well be and with a satisfactory profit to the vendor, at something between three shillings and four shillings the pound. But even at such a rate there must yet remain a disadvantageous comparison between the cost of the coffee so freely imported into France and that of the tea which we desire to see largely supplant the former article.

So far as we are aware, the effort to introduce Indian tea to the Parisians has not as yet been marked by any great success. When that effort was first made, the hope was entertained that its effects would radiate from the capital as a centre throughout the provinces of the Republic; but this is scarcely likely to follow unless some further effort is made to reduce the prices at which tea seems still to be retailed in the localities the more removed from Paris itself. We could scarcely recommend such localities as a field at present open for direct attack by our own tea agencies. Our efforts are now quite sufficiently widely directed to occupy our attention for a good many years to come. But in spite of that fact, it may be as well that our distributors should bear in mind the disadvantages which are tending to restrain the French people from acquiring a taste for tea drinking. That restraint will be strengthened should the existing duty be, under the new proposed tariff, increased appreciably, and to the prevention of this we trust the President had by our London Association with the President of the Board of Trade may materially contribute.

THE CEYLON LABOUR SUPPLY FROM SOUTHERN INDIA.

Like nearly all other large employers, Mr. H. L. Forbes, the Managing Director of the Scottish Ceylon Tea Company, felt during his recent visit to the island, that the labour supply was the most ticklish question in connection with the future of the Tea industry in Ceylon. We impressed on him in leaving, the advantage of learning all he could from a fellow-voyager, Mr. C. H. Greswell, a gentleman who, while knowing the Ceylon planting districts, had spent the last ten years in the centre of the labour supply districts in Southern India, as Resident Engineer on the South of India Railway. Both gentlemen travelled home by the P. & O. S. S. "Khedive" and the result is that we have the following interesting information from Aden, which we have no doubt will receive due attention from the Committee of the Planters' Association. In the first place Mr. Forbes writes:—

S. S. "Khedive," Gulf of Aden, March 26th.—We have had a fine run so far and hope to be at Aden tomorrow. It has been fairly cool till today which is very muggy and hot. With Mr. Greswell I have had several chats about labour supply, and enclosed is the result. All danger, apparently, of distress in Southern India has been wiped away by late rain. Undoubtedly what we looked upon as our own supply of labor has now also to serve other countries: the Cape largely. This is a very serious question and one which the P. A. should take up without less of time; as if the migration to Burma, the Cape, etc. is to increase, our already too meagre supply will further naturally decrease. We must not allow other countries to become more liked than our own.

Mr. Greswell's letter is as follows:—

S. S. "Khe live," March 25th.
To the Editor "Tropical Agriculturist."

DEAR SIR,—Mr. Forbes has asked me for a few lines to enclose in his letter to you on the important question of the Labour Supply for the Ceylon tea estates. On leaving India I was not aware that any difficulty had been experienced by owners and managers of estates in obtaining coolies in sufficient numbers from the out districts in S. India. At one time owing to the partial failure of the N.-E. monsoon distress was predicted and Collectors of Districts were ordered by the Madras Government to submit special reports on the then existing state of affairs. These on the whole were favourable, and the rain which fell early in February removed all cause for anxiety. I am not in a position to explain why the Ceylon planters should find it difficult to obtain labour now that confidence has been restored in the island and coolies are again paid regularly. Undoubtedly a great many emigrate to Burma and S. Africa and these countries afford a splendid opening for the industrious Tamil where in a few years he makes a small fortune. As an instance of this I may mention that only a few weeks ago I saw a batch of coolies alight at the Mayavaram station in the Tanjore District, and one of these had a large cash chest with him containing he said no less than 6,000 rupees. I asked him how he had managed to amass so much money. He replied that about 5 years ago he went to South Africa where the Government had given him a grant of land for supplying the men engaged in the Diamond Fields with vegetables and poultry; and he added he was now proceeding to his native village to buy land. According to the census returns the population of the Trichinopoly District has increased 95,000 during the last 10 years. The returns from S. Arcot, Tanjore, Madura and Tinnevely Districts have yet to be published; but assuming their increase is in the same ratio, the question one naturally asks is what becomes of this (what may be termed) surplus population? As far as I have been able to observe the area of land now under cultivation between Villupuram and Nogapatam, a distance of 165 miles much the same as it was eight years ago and yet,

It is not always easy to procure cool labour, in fact during January and February last on account of the harvest all works in connection with the S. I. Railway were more or less at a standstill for want of labour; and during the early part of last month when heavy rain fell the ryots were paying as much as 1s a day to their coolies for harvesting the ground-nuts which were beginning to sprout and had to be gathered in with as little delay as possible. On the other hand during the slack season which extends from March to July there is an abundant supply of labour, and it is then that a push is made with all Government and Railway Works. In July when the rains come down in flood, cultivation is resumed and the coolies return to the fields. If I had known before leaving India that the labour question was such an important one I would have inquired more fully into it and furnished you with details relating to the emigration of Tamils to other countries; as it is, I fear you will find the above remarks of little interest. On my return from leave to S. India, I will however endeavour to ascertain the cause of the falling-off in the labour supply to Ceylon from the districts I have already referred to.—Yours faithfully,

C. H. GRESWELL,

Resident Engineer, South India Railway.

We are much obliged to Mr. Gresswell and shall be glad to have his further reports by-and-by. Clearly, however, there is to be no surplus of Tamil labour this year.

DR. TRIMEN'S TRIP TO THE STRAITS AND JAVA.

The M. M. S. S. "Natal" brought back Dr. and Miss Trimen after a pleasant trip extending over six weeks to the Straits Settlements and Java. Dr. Trimen has not fallen in love with the climate of Singapore which he considers hotter and more trying than that of Colombo. He was met by old friends in Sir J. F. Dickson and Mr. Trotter (Auditor-General) and very kindly received at Queen's House by Sir Clementi and Lady Smith. He also made excursions to Johore—where he met Mr. Turing Mackenzie, not over-satisfied with the progress of planting, and Mr. John Milne—and to Malacca, where he met a brother of our Auditor-General, Mr. O'Brien who is now Postmaster-General at the Straits. He also met Sir F. Weld, who looks the courtly old English squire and who, we regret to say, had returned from Pahang—which he came out to explore on behalf of an English Company, with an attack of "liver" which had quite laid him aside in Singapore when the "Natal" left. Sir F. Weld in his day has been one of the greatest of Australian and New Zealand explorers and bushmen, but he is too old now to presume on such work especially in tropical jungle.

The more important part of Dr. Trimen's trip was of course to Java. Here our Director of Botanic Gardens found a great contrast in many respects to Ceylon—the rich volcanic soil, the rather slovenly style of cultivation on plantations, the very happy contented appearance of the Javanese, the permanent location and easy-going ways of the Dutch, and above all the splendidly-equipped Buitenzorg Government Gardens, where the scientific staff includes no less than twelve Europeans, all graduates and "Doctors" and all busy in their several departments. The division of the 24 hours into two days and two nights is rigidly carried out almost everywhere in Java, so that when Dr. Trimen called at the Gardens after luncheon about 2 p. m., no one of the staff could be found! The siesta between 1 and 4 is a universal custom, while, to compensate, excursions are common after dinner

up to midnight or 1 a. m., gardens and bands of music being then utilised as in English Colonies from 5 to 7 p. m. Anything will grow at Buitenzorg with the minimum of trouble, owing to the rich soil and moist climate; the Gardens are on a very extensive, luxuriant scale, though perhaps less attractive than our own at Peradeniya.

Dr. Trimen was not impressed with what he saw of tea in Java; up to 3,500 feet above sea-level the tea gardens seemed of poor jāt and careless management as compared with Ceylon. He was not able to get away to the great cinchonagrowing region, but he found this article generally as little esteemed in Java as with ourselves of late years. The boom in Java at present seems to be in Liberian coffee which is being freely planted, and will apparently supersede the Arabian variety. Dr. Trimen saw little or no disease on it and the growth and crop are reported as satisfactory. He was told by English merchants in Batavia that proper preparation (a good drying of the beans) does away with the slight bitterness complained of, and now they get as good prices as for the best of the ordinary coffee. This was confirmed at Singapore: the Liberian variety is also as greatly in favour in Johore, &c.

When at Singapore, Dr. Trimen took the opportunity of seeing gambier prepared by the Chinese; he was able to follow the operations though a little puzzled as to how the final coagulation took place. Dr. Trimen has brought back some cubeb plants with him, but he has also discovered that already he has plants of the West Java variety growing in the Peradeniya Gardens.—Dr. and Miss Trimen return, we are glad to say, in good health, much pleased with their trip.

STEALING OF CACAO FRUIT FROM YATTAWATTA ESTATE.

P. C. MATALE, No. 5,843.

Sinuratam Palle Kanakapulle, complainant, v. Sinna Tambi accused. The charge here was that on or about the 7th day of February 1891 at Yattawatta, the accused was found in possession of about 8 lb of the unripe fruit of the cacao tree, of the value of Rs, without being able to give a satisfactory account of his possession thereof, and thereby committed an offence punishable under Section 368 of the Ceylon Penal Code and the 2nd clause of the Ordinance No. 22 of 1886.

The accused was found guilty and was sentenced to four months' rigorous imprisonment and to receive 15 lashes. In his judgment the Magistrate narrated the circumstances of the case and added that thefts of cacao had been increasing of late to a very large extent. He did not therefore consider he would be doing his duty, if, in every case where it was clear that accused persons had been guilty of the offence of having unripe estate produce in their possession for which they add give no satisfactory account, he did not inflict a punishment that would deter others from indulging in similar offences. In this case he said Mr. Martin had proved that small thefts from his estate had been committed for some days before accused was caught. Since accused's capture Mr. Martin had not noticed any thefts.

MESSRS. GEO. WHITE & Co.'s Annual Tea Memoranda—already referred to in our columns—will be found reproduced so far as several of its more generally interesting paragraphs, on page 784. What is said about 'prospects,' 'additional outlets,' 'manufacture,' 'style of package,' 'bulking and packing,' 'marking' and 'analysis of crop' deserves the consideration of all practical tea planters.

BARK AND DRUG REPORT.

(From the *Chemist and Druggist*.)

London, March 21st.

ANNATTO SEED.—The market is well, in fact almost over-supplied with seed. Two parcels, together with 175 bags from Ceylon and the East, were offered today, and 77 of these sold at 2d to 2½d per lb. for fair to good bright.

ESSENTIAL OILS.—Citronella oil was bought in at ¾d per oz., and Lemongrass at 1½d per oz.

QUININE was reported rather firmer during the week, and yesterday it was even said that there were buyers at 10d, but no sellers under 10½d per oz. for second-hand German bulk. The B & S agents say that 1s per oz. is their lowest price. Nevertheless, at today's drug auctions the article touched the lowest price yet recorded, 1,000 oz of the Auerbach brand selling at 9½d per oz.; 2,000 oz Brunswick at 10d to 10½d; and 4,000 oz Whiffen at 1s 1½d per oz. There has been very little business done privately this week.

A FIRMER QUININE MARKET

in our last market review shows that the article was beginning to recover from the great and sudden break that had occurred the week before on the strength of most depressing news from London, and since that time further progress in the line of improvement has been made. As the decline in the first instance began in London so has the reaction been caused by reports emanating from that market. It is difficult to ascertain what caused the break unless it be the decline in the price of bark at the recent public sale in London, but as there has been in the past, even a greater decline in the unit price of bark without effect upon the quinine market, this explanation is hardly satisfactory. In view of the fact that the effort recently made to bring the manufacturers of the world into accord on the question of regulating prices and production failed because, as it is reported, one manufacturer refused to lend assistance to the scheme, it has been intimated that the late extreme depression was the result of a bear movement inaugurated and continued for the purpose of compelling the recalcitrant manufacturer to co-operate in a measure designed for the general good. There is no evidence that the manufacturers have yet come together and unanimously adopted a plan to place the quinine market on a substantial basis, while it is a fact that the market has recovered somewhat, therefore the cause of the improvement will have to be sought in some other direction. The facts seem to be that the average speculative holder of quinine is seized with a panicky feeling whenever the article begins to show evidences of unusual weakness from any cause whatever, and at once hastens to unload, thus increasing the weak tone of the market and quickening the downward movement. More confident buyers then step in, and after the pressure to sell has been relieved, the inevitable reaction occurs. This is an experience often repeated in the quinine market, and in the absence of any better explanation seems to fit the conditions recently prevailing in the quinine market.—*New York Oil and Drug Reporter*, Feb. 25th.

WILD FLOWERS OF CEYLON.

Nanuoya, April 6th.

Through Miss Martin's courtesy I am now able to send you the list of 54 of our hill wild flowers, portraits of which that lady exhibited at the Nuwara Eliya Show. The names have been carefully copied so as to render the task of the compositor and proof reader easy, while a careful comparison has been made with Dr. Trimen's list by Mr. A. M. Ferguson, junior, who has added Trimen's numbers in nearly every case, with native and other names, where given or known. With regard to the suggestion of publishing a work after the model of Miss Anne Pratt's "Wild Flowers of Britain," Miss Martin very reasonably doubts if sufficient encouragement could be calculated on for so expensive a venture. In any

case, should publication be ultimately decided on, the lady artist feels that she must add very considerably to her present collection. She deems it probable that she will not have exhausted the hill country wild flowers (especially if she goes into orchids and ferns) under three years. This shows how rich our mountain region is in wild flowers. Meantime the advance list of those drawn, coloured and exhibited by Miss Martin is as follows:—

MISS MARTIN'S EXHIBIT OF WILD FLOWERS.

- 1 Coleus inflatus, 623.
- 2 Sopubia tiffida, 558.
- 3 Utricularia rosea, 563.
- 4 Eriocaulon quinqueangulare. (Kok-mota), 907.
- 5 Sida carpinifolia, 87.
- 6 Campbellia cytinioides, 561.
- 7 Christonia subcaulis, 562.
- 8 Burmannia pusilla, 767.
- 9 Balanophora indica, 687.
- 10 Euonymus revolutus, 164.
- 11 Vaccinium Leschenaultii, 443.
- 12 Strobilanthes Hookeri, 586, (*nilu*).
- 13 Parochetus communis, 209.
- 14 Smithia blanda, 217.
- 15 Gentiana quadrifaria, 517. (Gentian.)
- 16 Utricularia, 563.
- 17 Exacum Walkeri, 512.
- 18 Do. macranthum, 512.
- 19 Swertia zeylanica, 518.
- 20 Senecio zeylanicus, 433.
- 21 Emilia zeylanica,
- 22 Do. sonchifolia. (Kadu-para) } 431.
- 23 Pedicularis zeylanica, 559.
- 24 Hapenaria arietata } 822.
- 25 Do. spiralis } 822.
- 26 Satyrium nepalense.
- 27 Do. do. var. white } 823.
- 28 Spirauthes australis, 810.
- 29 Liparis Wightiana, 771.
- 30 Kingia Notouiana. (Diyaniilla), 568.
- 31 Impatiens Walkeri
- 32 Do. bipartita } 118. (Balsams.)
- 33 Do. acutis } 118. (Balsams.)
- 34 Do. macrophylla } 118. (Balsams.)
- 35 Valeriana Moonii, 400. (Harebell).
- 36 Wahlenbergia gracilis, 440.
- 37 Pachystoma speciosum. (Daffodil orchid.) 777.
- 38 Barleria Arnottiana, 589.
- 39 Oxalis Carniculata. (Hin-embul-embiliya), 116.
- 40 Trifolium minus, p. 22. (Trefoil.)
- 41 Cynoglossum furcatum. (Bu-kattu-henda), 528. (Forget-me-not.)
- 42 Vernonia setigera, } 402.
- 43 Do. Wightiana, } 402.
- 44 Sonerila hirsutula, 302.
- 45 Osbeckia rubicunda.
- 46 Do. cupularis.
- 47 Hygrophila spinosa. (Katu-ikira S., Nirmulli T.), 580.
- 48 Commelina, 864
- 49 Phaius bicolor, 779. (Large ground orchid, A. M. HF. Jr.)
- 50 ibiscus angulosus, var. grandifloras. (Kapu-kinissa), 93.
- 51 Crotalaria semperflorens, 208.
- 52 Scutellaria, 629. (Skullcap.)
- 52 Hypericum, 69. (St. John's Wort.)
- 54 Aselepias curassavica.

TOBACCO DISEASE.—In his note on the above subject, Dr. Cooke seems to have fallen into error when he says that *Peronospora hyoscyami* is "confined apparently" to *Hyoscyamus*. He does not tell us what species of Tobacco he refers to under the Tobacco of Australia. *Peronospora hyoscyami* has, according to Professor W. G. Farlow, badly attacked for the last four years *Nicotiana glauca* in Mexico and California, and great fears have been entertained in America of the pest spreading to the Tobacco-growing districts of Virginia.—W. G. S.—*Gardeners' Chronicle*.

CEYLON TEA MEMORANDA.

(From Messrs. Geo. White & Co.'s Review for 1890.)

PROSPECTS.—There is little probability that the causes which brought about smaller supplies than expected both from India and China in the season now closing, will be again in operation this year. We must therefore, in the ordinary course of events, be prepared for larger crops from India and Ceylon, while the better prices realised for China Congou throughout, and the high rates paid by Russian buyers at the northern ports for fine teas suitable to their requirements, will no doubt induce the Chinese to pick and manufacture considerably more. It must not be forgotten that in 1890 almost the whole of the second crop and part of the first was destroyed by wet and unfavourable weather, while the high rate of exchange also helped to curtail shipments. Fortunately, to meet this probable larger supply, our requirements have become greater, and show a slight tendency still to expand; but as the estimate of China given overleaf will most likely be exceeded, there will be a surplus, and prices current in 1890-91 must not be looked for.

ADDITIONAL OUTLETS.—A though the consumption of Tea in the United Kingdom has risen to rather over 5 lb. per head of population in 1890, against 4½ lb. per head in 1880, it would appear that the present consuming power of this country will not suffice to counterbalance the annually increasing output. It is therefore all the more important that every effort should be made to further foster the Trade in British-grown Tea with our Colonies, Europe and America. It is gratifying to note that shipments to Australasia have shown considerable development, the export from Calcutta 1st April, 1890, to 31st January, 1891, being 4,279,000 lb., against 3,156,000 lb. in 1889-90, and from Colombo 2,448,000 lb. against 1,076,000 lb. To America direct shipments from Calcutta are disappointing, as they have fallen from 174,000 lb. to 106,000 lb. in the same period, but from Colombo they have quadrupled, being 172,500 lb. against 42,600 lb. proving that the persistent efforts to push the Trade there have been rewarded.

As regards the Continent of Europe export figures from Calcutta and Colombo are not much guide, the great portion of the Trade being done from here. Considerable attention has been given to the promotion of business in both India and Ceylon Tea in Russia. The Government there is inclined to assist the introduction of these growths, and to prove the interest taken in the question one of the largest Russian buyers in Hankow called at Colombo on his way to China and is reported to have visited several Tea gardens.

MANUFACTURE.—Heavy shipments being expected from all the producing countries, it behoves British planters to use every endeavour to prevent the market being flooded with mediocre Teas of poor liquor. They will therefore probably find that by plucking a little finer than usual they will make much better Tea, and in the long run show a more satisfactory result financially, as the enhanced prices obtained will more than recoup them even should the total output be smaller.

Garden managers are much more independent of the weather than formerly, owing to the introduction of withering machines, such as "Blackman's." Manufacture and the use of patent dryers are also now so much better understood, that it is quite exceptional to come across over-fired, scorched, or sour invoices, which were noticeable in former years, and the few that are seen generally result from some exceptional cause. In the early part of the season many of the Assams had a peculiar musty flavour, attributed by some to the Tea having been packed too hot into damp or not thoroughly seasoned chests.

The requirements of the Trade vary from time to time, but thick rich liquoring parcels with a bright infused leaf, which cream over when cold, are always in request, especially for Ireland. Pungent Teas of good flavour, with a greenish infused leaf, have also been in demand for some time past. Ceylons with these characteristics have occasionally sold at high rates, but unless fine quality can be secured this style of fermentation is dangerous. It must be remembered, however, that a fancy article is liable to meet

with capricious sales, as in the case of Ceylon greens. The first arrivals of these were particularly choice, and brought exceptional prices, but they did not appear to meet the public taste generally, and later shipments were very difficult of sale. Teas with good leaf are likely to be in favour, being used more freely by the large blenders than Broken Pekoes, which have been somewhat neglected unless possessing exceptional strength. Leafy kinds are also taken for export, and the demand is gradually increasing. Many gardens now send large breaks of 200 packages or more, which as a rule meet with spirited competition, especially in the case of Pekoe Souchongs which are suitable for the terminal market. Planters would probably find it worth their while to bear this in mind, and instead of making so many breaks to go in for three leading ones—viz., one first-class Broken Pekoe, Pekoe, and Pekoe Souchong, instead of say, two Broken Pekoes and two Pekoes—any remaining might be classified as Broken Tea or Pekoe fanniage, and occasionally an odd package or two of dust.

STYLE OF PACKAGE.—For the Home Trade full chests are ordinary suitable, though many buyers prefer half-chests, especially for export. Leafy kinds, for self-drinking, often sell well in boxes, but to avoid the 1-lb. draft they should be under 23 lb. gross.

BULKING AND PACKING.—A large quantity of factory-bulked Tea has come to hand, and as more care has been displayed in filling the chests, so as to avoid crushing the leaf when treading in the last few pounds and thus altering its colour, they have been in favour with the Trade; while exporters prefer them, as they can re-ship them without the leads being cut. The tares must not, however, vary more than 2 lb. in each break, otherwise every package is turned out by the Customs authorities for separate tare. By attention to the scale on which the warehouse charges are at present based, a considerable saving may often be effected; as, for example, chests weighing 199 lb. gross, are not charged more than those of 160 lb. Half chests weighing 89 lb. gross, not more than those of 80 lb. Boxes weighing 28 lb. gross not more than 17 lb.

MARKING.—We would again point out the objection which exists to marking either weight or tare on the packages, the name of garden, description of tea and chest number being all that is necessary.

ANALYSIS OF CROP.—The India crop of 1890 has, taken as a whole, been good, though from time to time quality has shown considerable fluctuations. Some of the Darjeelings have been of exceptionally fine flavour, while other invoices from the same garden have been much inferior, no doubt due to climatic influence. This has also been more or less the case with the Assams, but generally the quality improved as the season advanced. Dooras at times have been desirable and chiefly of a useful quality. Cachars and Sylhes were of ordinary character at first, though later shipments shewed some improvement. Kangras and Kumaons have throughout the season been disappointing in the cup, with the exception of a few invoices of each mark, they evidently, like the Darjeelings, having been affected by the inclement weather. Although some of the Travancores have been of good strength and flavour, the average of many gardens is low. The appearance of the dry leaf might often be improved, and no doubt this will be remedied as the output increases. Not so much variation in the quality of Ceylons has been noticeable as in former years; the crop, though a very useful one, has been rather deficient in choice parcels. The general result should be satisfactory to garden proprietors, as although during a great portion of the season exchange has been high, they have not, as in the case of India, suffered from a diminution in output through the early setting in of cold weather. The rise in the price of silver also acted as a salutary check on the shipment of common China Congons. As previously noted, the general quality of Javas has shewn a distinct improvement in consequence of the plants raised from Assam seed becoming more developed, so that in many cases they are similar, to Teas of India growth. Although the total average price is still rather low, that obtained for the produce of several estates is very good, ranging from 10s. to 1s. 1d. per lb.

COCONUT VERSUS PALMIRAH.

European planters and native planters too who more readily copy the faults of their European guides than follow their virtues, cut down the palmirah to make room for the coconut. This is a senseless procedure. First because no other tree that grows high can ever injure the coconut trees, unless it shuts out air and light. On the contrary it protects the coconut trees from the effects of the frequent droughts to which the Pachchillapalli district is liable, if its leaves or branches are lopped off from time to time, when they show a tendency to obstruct air and light. The palmirah and the margosa are more conducive to the growth, preservation and fructification of the coconut trees than inimical to them. Secondly, because sixteen palmirah trees can very well stand in the space occupied by one coconut plant. Rejecting eight of these as male trees, we have 600 female trees per acre. Each female tree yields on an average 6 cents per annum, *i. e.*, R36 per acre. We get these R36 per acre without sowing, transplanting, fencing, watering, watching, digging, manuring, picking, peeling, drying, weighing, carting etc., all which have to be done in order to get something out of the coconut and this something, after deducting all expenses, can never exceed R20 per acre in this district.

If we take into account the interest of the capital laid out in the purchase of the coconut estate, the R20 will come down to R10. But if we take into account the interest of the money laid out in the raising of the coconut trees, the industry will be found to entail a dead loss of R30 or 40 per acre per annum. There is not a single estate in this district, but has changed four or five hands, the last purchaser paying not more than one-fifth or one-sixth of the original cost of planting up the estate with coconut.

If the palmirah be utilised for treacle, the male trees will also become available and the income per acre will be raised to R72 per annum.

It is usually said that the palmirah takes a long time to bear. If the a tention paid to the coconut be paid to the palmirah, it will come into bearing at the same age at which the coconut does, *i. e.*, 20 years. People say that the coconut tree bears at so early an age as 4. This is true in exceptional cases. But I will not alter my limit of 20 years, unless one who has actually planted a coconut estate demonstrates to me that its income covered its own current working expenses before its 20th year. I won't ask him to include the interest of the capital laid out in the purchase of the land or in the various operations from the time the trees were planted to the time of their coming into full bearing. If these were included, no coconut estate would be found paying in this district.

The average age of the coconut tree is 60 years, that of the palmirah is over 100. When the latter dies through accident or exhaustion, the trunk is worth from 25 cents to one rupee, if not more. When the former dies, you require at least 5 cents to cut it down or burn it.

The palmirah cannot be choked out of existence by any foreign vegetation, but the coconut can be and always is. The palmirah sows itself, but the coconut does and cannot. The palmirah like the coconut has many enemies, such as cattle, beetle, drought, lightning, cyclones etc., but the palmirah withstands them much better than the coconut. It is a pity that the pioneers of planting did not plant palmirahs rather than coconuts in this peninsula.—*Com.*—Jaffna "Patriot."

DEATH OF THE VICTORIA REGIA AT THE GORDON GARDENS.

Our morning contemporary has the following:—

DEATH OF THE "VICTORIA REGIA."—This beautiful aquatic plant, which was brought from Madras and placed in the lower fountain basin in the Gordon Gardens, appeared to thrive at first. Afterwards, however, it seemed to be affected by sun and wind, and its large round leaves curled up. A cadjan screen was put up on one side, but that accomplished nothing, for at last the *Victoria regia* has died, and the remains have been removed.

With reference to the above a correspondent writes to us:—"I annex an extract from 'Firminger's Manual of Gardening' which may account for the demise of this plant, if no other cause has been discovered. I have not been to look at the plant myself for some time." The extract is as follows:—

"*V. regia*.—The plant is found not to exist more than two years, when its place must be supplied by a fresh one raised from seed, which in the vicinity of Calcutta it bears abundantly. If the seeds have to be conveyed to a long distance, it has been found that they will only retain their vitality by being kept in phials of pure water. . . . The seeds are sometimes very long in germinating." ("Firminger's Manual of Gardening for Bengal and Upper India," 4th Ed., Part IV, page 449.)

BIOGRAPHICAL INDEX OF BRITISH AND IRISH BOTANISTS.—From the list of those published in the *Journal of Botany* for January, we extract the following as being interesting to horticulturists:—

"THWAITES, GEORGE HENRY KENDRICK (1811-1882): b. Bristol, 1811; d. Kandy, Ceylon, Sept. 11. 1882. Ph.D. F.L.S., 1854. F.R.S. C.M.G., 1878. Local Sec. Bot. Soc. Lond., 1839. Lectured at Bristol, 1846. Superintendent, Peradeniya Bot. Gard., 1849; Director, 1857-1880. Contrib. Bristol list to Top. Bot. and to 'Phytol.' from 1841. 'Enumeratio Pl. Zeylanicæ,' 1858-64. Described *Dasygloia amorphosa* for Eng. Bot. (2941). Pritz 318; Jacks. 612; R. S. C. v. 989; Proc. Linn. Soc. 1882-83, 43; Gard. Chron. 1874, 438, with portr.; 1882, ii., 505; 'Athenæum,' 1882, 500. Portr. Kew. *Thwaitesia*, Montagne. *Kendrickia*, Hook f. —*Gardeners' Chronicle*.

THE GINSENG TRADE IN CANADA.—Ginseng, the root of *Panax quinquefolia*, var. *Selinseeng*, is well known as a valuable medicinal product of China, Manchuria, and Corea. A kind of Ginseng, *P. quinquefolia* proper, is also grown in America, and the root exported thence to China, but this industry has of late years much declined. Under the title, however, of "The Revival of an Old Canadian Industry," our contemporary the *Chemist and Druggist* has the following:—"Ginseng, the drug par excellence of Chinese *Materia Medica*, was formerly extensively collected and dried in Canada. It was one of the first articles of commerce exported from Canada after the Peace of Utrecht, and for a time considered hardly less important than the fur trade. This plant was discovered growing near Lachine, by the Jesuit Lafitan, in 1716. He had learned of its value as a medicine in China, and a Company was formed for its export to China, Tartary, and Japan. When first introduced, the price at Quebec was from 30 to 40 dollars (or cents) per lb, and anyone was permitted to sell the plant. But in 1751, the Company obtained a monopoly, and excluded all others from the trade. The price rose to 12 livres, and at one period even to 33 livres per lb. As the demand for the plant increased, the care with which it was obtained and prepared was relaxed. It was gathered out of season, and dried imperfectly before it was ripe. Under these circumstances Canadian Ginseng soon lost its reputation in China, but during the time when the drug realised high values, agriculture was neglected altogether in some localities, the entire attention of the inhabitants being given to the collection of Ginseng, with the result that in some parts of Canada the plant entirely disappeared. When the trade was at its maximum in 1752, the value exported was about 500,000 livres per annum, but two years later it had sunk to 33,000 livres. The Company then ceased to purchase the plant, and the trade entirely disappeared. All that remained of it was a proverb among the people, when speaking of some matter having failed, that it had come to nothing as the ginseng, *C'est tombe le Ginseng*. It is a strange fact, that the word Ginseng has the same meaning both in the Chinese and Iroquois languages. At present Ginseng gathering is again becoming a large industry in Canada, the root being collected for sale to the Chinese in the United States."—*Gardeners' Chronicle*.

COCOA AND ITS CULTIVATION, AND THE PREPARATION OF CHOCOLATE.

The cocoa tree is very common in the warm regions of America, but since the conquest it has been cultivated in Mexico, in Guatemala, and Nicaragua. Under the kingship of Montezuma, the Spaniards transported this tree to the Canaries, to the littoral of Venezuela, to the Antilles. The cocoa tree requires a rich soil, deep and damp. Nothing suits it better than a grubbed-up forest. All the plantations are similar; shady localities, at a short distance from the sea or on the banks of rivers. When a piece of land is selected as fit for the cultivation, a commencement is made by assuring a system of shade. If it is to be grubbed up, the trees which have been stripped are left standing, or else there are planted some shrubs of rapid growth, such, for instance, as the *Erythrina umbrosa* (bonana tree.) To the South of the Equator, in the province of Guayaquil, the planting is done directly by seeds, while in Venezuela they are planted out as seedlings, in the latter case every precaution being taken to protect the young plant against the sun's rays. The seeds germinate in eight or ten days; in the second year the cocoa tree reaches a height of about a yard, and it is then that it is topped. The tree generally flowers at the age of about thirty months, when climatic conditions are favourable. There are few plants, the flowers of which are so small, and especially so disproportionate to the size of the fruit. The flowers do not appear separately, but in bouquets, on the same stem, at all elevations, on the mother branches, and even on the ligneous roots running along the surface of the soil. A gentleman, who has lately studied the question, in his researches on the constitution of the cocoa berry and on the composition of chocolate, gives some interesting particulars as to the distances which separate the trees and the care brought to bear on their cultivation. From the fall of the flowers to maturity nearly four months elapses. The fruit, or *cabosse*, is divided into five lobes; its weight varies from 300 to 500 grammes. The seeds which are taken from the fruit are exposed to the heat of the sun; during the night they are raked into a heap under a shed. An active fermentation soon set in, which would be hurtful were it allowed to increase. From 100 kilogrammes of fresh seeds our authority has seen 45 to 50 kilogrammes of dry and vendable cocoa extracted on a hacienda in Aragua. A cocoa tree which has attained the age of seven to eight years annually furnishes an average of 0 kilo. 72. At Gigante, in Upper Magdalena, the yield is about 2 kilos. The cocoa is decorticated by the application of moderate heat; the shell having become weak, it is then removed by the winnowing. In torrefication the berry acquires, like that of coffee, an odour, due to a low proportion of a volatile principle. This is the aroma perceived in chocolate. The cocoa berries are rich in nutritive principles. Independently of a strong dose of fatty matter, they also contain azoted substances, similar to albumen and caseine, theobromine and compounds of ternary composition, these elements necessarily varying in quantity according to the place of growth. Numerous analyses have been made at the Conservatoire of Arts and Sciences. The following is the result of an examination of cocoa, coming from Trinidad:—Butter, starch, theobromine, asparagine, albumen, gum giving mucic acid-tartaric acid free and combined, soluble cellulose, and matters of an indeterminato nature. As is well known, decorticated cocoa slightly roasted, and separated from the seeds, is the basis of chocolate. In the products of French factories, there have been found in chocolate from 55 to 59 per cent of sugar; in Spanish products, 40 to 53 per cent. In chocolates honestly prepared only cocoa and sugar should be present, too large a quantity of the latter weakening the quality. Thus, the gentleman from whom quotations have already been given, when about to start on a long journey in America, procured a preparation of 80 parts of

cocoa and 20 parts of sugar, a composition represented by:—

	Parts.
Sugar	20
Butter	10
Albumen	41
Phosphates	3
Other matters	26
	100

This was a useful addition to the ration which consisted of meat dried in the air (tassajo), maize biscuits, or cassava cakes. The Mexicans made a paste with cocoa which they called chocolate, in which they mixed a little maize. Up to the sixteenth century travellers differed widely in their opinions as to chocolate. Acosta considered from a prejudiced point of view. On the other hand, Cortes probably exaggerated the value when he pretended that by drinking a cup one could march throughout the whole day without taking any other nourishment. In France, the new drink had its partisans and its detractors. Madame de Sévigné, in a letter to her daughter said "I have wished to reconcile myself with chocolate: I take it in the afternoon to digest my dinner, with a view to supping well, and I take it to nourish myself, and in order to fast till the evening; it has brought about the effects I wished; that is why I find it pleasant; it acts according to the intention."

Chocolate in its small volume contains a large portion of alimentary matters. Humboldt says that it has been truly remarked that in Africa rice, gum, and shea butter aid men traversing the desert; and in the New World, he adds, chocolate and maize flour render accessible to him the plateaux of the Andes and the vast forest. By the addition of albumen, fat, of the congeners of sugars, and the presence of phosphates, cocoa recalls the composition of milk, the type according to Prout, of every nutritive regimen. Having arrived at a certain stage of civilisation, man frequently adopted into his food plants which acted on his organism in the manner of fermented drinks. Like wine taken in proper quantities, these aliments favoured digestion, improved the memory, exalted the imagination, and developed a feeling of well-being without giving place to a hurtful reaction so often the case in the abuse of alcoholic drinks.

It is a curious fact that human races, separated by the greatest distances and never having had any communication the one with the other, prepare, with certain vegetables, exciting drinks, such, for instance, as tea in China, coffee in Arabia, cocoa in Peru, mate in Paraguay, cocoa in Mexico, utilising either the leaves or the seeds of plant of which the seeds of plants of the botanical species have no analogy, but which, despite this difference of natural source, exercise a similar action on the nervous system and on digestion. The reason is that there are in these different plants substances possessing the constitution of alkaloids, and endowed with similar properties; that is, caffeine in the leaves of tea plant, of maté and in coffee, cocaine in the leaves of coca; and theobromine in the berries of the cocoa tree. Thus the Chinaman, the Arab, the Peruvian, the Paraguayan Indian, the Inca, and the Aztec were under the influence of a similar agent when they had taken their habitual drink.—*Indian Grocer*.

[This is the first time we have heard of the "*The Indian Grocer*"?—Ed. T. A.]

COFFEE IN BRAZIL.—The following communication, addressed to the *Jornal do Commercio* of this city, was published in that paper on the 5th instant:—"I have seen in the *Jornal do Commercio* an item taken from the *Rio Novense*, of Rio Novo, in regard to the coffee crop of that municipal district. From the observations I have made of the heavy flowering in the north of S. Paulo, I can assure you that the trees will not produce more than half the crop that flowering seems to promise."—*Rio News*, Feb. 10th.

KOLA: WHAT IS IT?

By THOMAS CHRISTY, F.I.S.

Having been consulted by several gentlemen who are manufacturers as to the best way of administering kola and introducing it amongst workmen, I thought it would interest you if I furnished you with a copy of my reply.

It is well known that intoxication or drunkenness may be produced from several causes, one may be the craving for drink from overwork, or from indigestion, or from pain; and in old times it used to arise from sitting in the public-house for want of something better to do; but in the present age of newspapers and the advance in education, a very large number of people who used to drink for want of something better to do now have not this excuse, therefore it is easier to attack the causes enumerated. It has been found that kola has an extraordinary effect on beer and spirits, and large bottling establishments, where the "ends" of the casks have been drawn down as low as it was thought safe, the thick residue has been emptied into large casks, and a small quantity of kola stirred round, and in quite a short time it has cleared the beer to such an extent that nearly the whole quantity could be bottled off without in any way impairing its keeping qualities.

At the Linnean Society we had the evidence put before us from gentlemen living in the West Indies of what they had repeatedly witnessed, viz., that men who are insensibly intoxicated are by the use of kola restored in a very short space of time to sobriety; a bad headache, produced perhaps by new spirit, is acted on in a very short space of time, but what is of more importance is this, that the craving for drink is at first suspended, then stops, and a more healthy state of the system follows; bodily exercise is enjoyed, and the mind appears bright.

No more than the owner of a mill or factory regrets the loss of the assistance of his manager or best workmen from intemperance, and to my knowledge the most happy results have ensued from kola in some form or another being used. When the head of a family brightens up he infuses a healthy tone to all around him.

In the year 1520 cocoa was introduced, and it got better known about 1659. I do not propose to go into the merits of this fruit. Suffice it to say it contains about 50 per cent. of butter, which has to be extracted or thrown down by the addition of starch before it can be used as a beverage, or it would produce indigestion.

With tea the relief to a weary body is very temporary, and for a brain-worker the tannin sorely troubles those who use it as the most convenient form of stimulant.

Coffee, pure and of good quality, well made, is one of the greatest rarities, and few things are more adulterated before it reaches the consumer. Kola is consumed by a large number of the African tribes, and reports sent home lately to the British Government showed that those labourers who took it as food could do double as much work in one day as those who did not. The reports in the Press have been so ample that I only desire to quote instances that have come lately to my knowledge. I am very proud of having been the introducer of this valuable food, and my reticence on the subject will be appreciated. Many of the most wonderful records of cycling against time have been chronicled as largely due to the use of kola. The riders say that though the exertion of the body was at the utmost stretch, still the head and brain were clear and the physical powers were strengthened. Even a small quantity of kola had a magical effect; it appeared to be as much a tonic as an anodyne to the brain, and whereas only a few minutes before the whole of the machine was as laborious to work as the treadmill itself, the efforts of the rider were made pleasurable exercise, and the desired speed was attained with less exertion and the happiest results, so that "beating the record" seemed an easy matter. There was no sense of lassitude or prostration, but instead a cheerful feeling pervaded

the system; a healthy appetite was created for food, and what was more important, it was digested with a satisfaction seldom experienced before.

During the late examinations many ladies felt the usual anxiety to surpass the "lords of creation," and in London they also had to endure the thick atmosphere from the fog so trying to delicate organisations. I recommended fathers who were in despair when their daughters declared that they must give in, to try kola, but of course without giving any details as to what it was.

In certain cases they took it for breakfast, and then again in the form of chocolate for lunch. The result was a success, and aided by the assistance to the bodily and mental powers thus given, the highest positions were gained, without the recurrence of headache or nervousness.

For working people kola is prepared in the form of chocolate, so that it can be carried in the pocket and a small piece broken off and eaten when the feeling of hunger, thirst, or weariness occurs. It acts in a few minutes. A teaspoonful of kolatina at breakfast, in hot water or milk, or even alone, is sufficient for a breakfast, but the effect lasts for several hours.

Many people who know of this preparation employ the pure kola nut, ground to a fine powder. This they boil with milk, but it is an acquired taste.

In the early part of this year a coloured doctor informed me that the men carrying goods for sale go away from the coast for journeys of 24 hours; all they depend upon are kola nuts and water, and they bring back loads of goods that they have taken in barter.

In Western Africa kola nuts have even taken the place or rather fill the place of a currency in some parts, and are very highly esteemed by the natives.

I give the following letter from Mr. A. E. Floyer, F. L. S., an intrepid traveller:—"I think there can be no doubt that kola chocolate is a genuine good thing. I have used it a great deal lately, and I think the following test (which I am about to say, was in some points involuntary) conclusive. I went into the hills on the morning of the 9th with my shikarri; we did ten hours' very severe climbing, much of it anxious work, in the dark; we slept on the rocks, and the next day ten hours' more very severe climbing, and at last got out of the mountains. It is no exaggeration to say that we arrived at the camp in capital spirits, though very leg weary. During these two days we had divided between us four biscuits, three oranges, and three tablets of kola chocolate; practically nothing but kola. It seems to have no ill effects, nor interferes with ordinary stomach arrangements or with sleep. Half a cake at 10 a.m. and the same at 3 p.m., and you can wait till midnight before you lunch, and have a good appetite when you get it.

I am confident that its extraordinary properties have only to be generally known to be recognised by all classes of the community, and more particularly by persons whose occupations are such as to involve constant and sustained employment of their vital powers.—*Cheshire County News.*

INSECTICIDES.

The following notes by Dr. J. C. Neal, the entomologist to the State Agricultural College, Florida, U. S. A., will be found of interest:—

Nothing has been done in practical entomology that has shown better results than the use of emulsions containing kerosene or insoluble poison held in suspension, and their application to infected plants in a fine spray by various atomisers and spray pumps. With one of these machines, an insecticide can be brought into contact with the insect, and its feeding ground thoroughly impregnated with poison. It is needless that the spray be very fine, and that it be applied with force to reach every infected part, or the hiding-places of insects. For cases like infected buildings, as chicken-houses, that are usually very difficult to keep clear of mites and tick-fleas, the spray of carbolic whitewash, tobacco, kerosene, oil of Tansy, &c., is easily applied.

I append a few formulas that have been tried and found to be valuable:—

I.—SOLUTIONS.

1. Tobacco, 1 lb.; boiling water, 3 gallons; strain when cool. Very effective when used as a spray against flea-beetles, lice, aphides (plant-lice), and ticks.

2. Quassia-chips, 1 lb.; boiling water 3 gallons. This very bitter solution is good for prevention rather than cure. Apply as a spray to Rose bushes, and to kill plant-lice.

3. Pyrethrum; 1 oz. of the "Buhach" powder added to 2 gallons of cold water for Cabbage, Beets, Tobacco, or any plant used for food, as this is not poisonous.

4. London Purple, Paris Green; actively poisonous. Use 1 lb. of the poison to 200 gallons of water or other solutions. Dissolve a little flour paste in the water to make it sticky. Stir frequently. Applied to trees, it is a sure cure for all insect plagues.

5. Bordeaux Mixture.—This, while primarily a fungicide, has some good qualities as an insecticide. It is prepared thus:—1 lb. sulphate of copper, dissolve in 1 gallon of hot water in one vessel; in another, 1 lb. rock lime is slaked in 1½ gallon cold water, and, when cool, pour into the copper solution and strain; add 2 gallons of water, and it is ready for use. (Cook).

6. To this, add London Purple, 1 lb. to 200 gallons of the Bordeaux Mixture. This sprayed over non-bearing Grape vines or Tomato vines not in bloom, &c., will prevent rot, and insect life as well.

7. Soap.—1 lb. resin soap to 1 gallon hot water. This, used as a spray, is often a valuable remedy for the attacks of small and soft insects; in fact it can be used to advantage for soft scales, when they are few. It should be often used to get the best effect.

8. Water in which tar has been placed acquires some value as an insecticide.

II. EMULSIONS.

1. Stronger Emulsion of Kerosene.—4 lb. soap, dissolve in 1 gallon hot (boiling) water; remove from the fire, and add 2 gallons kerosene while hot. Churn with a spray-pump violently till the oil is emulsified; add 27 gallons cold water for use.

2. Weaker emulsion (Cook).—1 lb. soap dissolve in 2 gallons hot water as before, but add only ½ gallon kerosene, and dilute till 8 gallons are made. Adding ¾ pint spirits turpentine to No. 1, increased its stability (Tracy). Allowing even 40 gallons of water to be added to 1 gallon of the emulsion, and sprayed on Tomato worms, it was very effective, and did not injure the plant in the least.

3. Emulsion 1.—Adding 2 oz. of balsam of Fir with the kerosene makes an emulsion that adheres better to the surface of the leaves, and is slightly superior to No. 1 for the armoured scales.

4. Using emulsion 2, only substituting the same quantity crude carbolic acid for kerosene, is especially valuable for Oak and Pear insects.

5. The same formula, using oil of Tansy or Sassafras 1 oz. in place of the ½ gallon kerosene, is efficacious for roaches, mites, ticks, bed-bugs, and pests.

III. ARSENICAL, RESINOUS, AND OTHER COMPOUNDS, FOR SPRAYING.

1. To kerosene emulsion No. 1 add 1 oz. London Purple, and mix well. Highly recommended.

2. Resin compound.—Caustic soda, 1 lb.; resin, 8 lb.; to make 32 gallons compound. Dissolve the soda in 1 gallon boiling water; take out half; add the resin slowly to the remainder and boil, stirring rapidly; when dissolved, add slowly the part taken out. Dilute till it will pass readily through a thin cloth, which should be always done. Dilute before using, to 32 gallons. This alone is very valuable against most scales, but the addition of 2 oz. London Purple makes assurance doubly sure, against even the dreaded Icerya.

3. White arsenic, ½ lb.; sal soda, ¾ lb.; water ½ gallon; boil till a solution is made, then dilute to a gallon. One quart of this to 50 gallons resin compound—use on Peach, Pear, and Plum, either after fruit is gathered or just as bloom has fallen.

IV. POWDERS.

1. While slaking 1 peck fresh lime, add 1 quart of kerosene, sift out lumps; apply lightly to Cucumbers, Melons, and Tomatos, for beetles and squash-bugs.

2. 50 lb. land plaster, mix 1 pint crude carbolic acid; sprinkle over leaves and Vines for aphides and beetles.

3. Pyrethrum.—This, the powdered flowers of the Pyrethrum, when fresh, is especially valuable if sprinkled on infested leaves, or in boxes, drawers, &c. House flies and mosquitos are easily subdued by closing up the room tightly and slowly burning in it a spoonful of the powder. It is slightly narcotic, but not at all dangerous to human life. For infested Cabbage, Lettuce, Celery, and the like, or Tobacco, it is the best insecticide we have, involving no danger if eaten.

4. Tobacco.—This insidious narcotic is valuable in the destruction of plant-lice, mites, &c. Applied either as a powder or by its fumes it often is quite beneficial.

Bisulphide of carbon, like chloroform, is highly volatile, but its vapour, unlike that of chloroform, is very explosive. Bins and corn cribs can be easily rid of ants, weevil, rats, mice, beetles, &c., if the room be made air-tight, and occasionally filled from the top with the vapour of bisulphide of carbon.

This is the only way in which our farmers ever will keep Corn, Peas, &c., from insect attacks.—*Gardeners' Chronicle*.

Mr. T. S. ANDERSON, of the Gartmore Estate, inserts this advertisement in the Ceylon papers: "Not having sufficient tea from which to supply the great demand in the London Market for Golden Tips, I undertake under certain conditions and for a Fee of £125, to show Planters how to prepare the same. The Tea, so prepared, will be guaranteed to be equal to the sample of Gartmore Tea, sold in Mincing Lane for £10 12 6 per lb, and the manufacture to cost not more than 25 cents extra per lb." This is all very well, but can Mr. Anderson tell us (1) to what extent the value of the rest of the leaf is depreciated by plucking golden tips; (2) what demand there is in London for tea at £10-12-6 per lb. It is all very well paying a fee of £125, spoiling the bulk of your tea, increasing the cost of manufacture by 4 annas to find that when it arrives in the London Market 2s or 2s 6d per lb. is the outside it will realize, which will probably be the result should any large consignments of Golden Tips be made.—*Madras Times*.

The ARTIFICIAL MANURES, &c. (ADULTERATION) BILL, which was introduced into the House of Commons and read a first time in November, but which has just been issued in a revised form, has for its object the better prevention of frauds in the manufacture and sale of artificial manures and other preparations for agricultural purposes. This it proposes to attain by making it compulsory, in all sales in quantities of not less than one hundredweight of artificial manure or feeding stuffs, for the seller to deliver to the purchaser a guaranteed analysis of the article sold, and by making misrepresentation in this certificate punishable by summary process. In order to facilitate the carrying out of the law, the Bill provides for the appointment by every County Council of "one or more persons possessing competent knowledge, skill and experience as analysts of artificial manures and feeding stuffs within such county," from whom purchasers will be entitled to obtain an analysis on payment of a fee of 5s. All appointments of these analysts would be subject to the approval of the Board of Agriculture, which may require to be supplied with satisfactory proof of competence; but the only other limitation is that no person shall be appointed as analyst who is engaged directly or indirectly in the trade or manufacture of the substances he may be called upon to examine. The Board of Agriculture would also be empowered to authorise a County Council for a specified time to appoint inspectors to obtain and deal with samples of manures and food-stuffs offered for sale in a manner corresponding to the provisions of the Sale of Food and Drugs Act.—*Gardeners' Chronicle*.

QUININE AND JAVA CINCHONA.

The market value of quinine has now declined to a point unprecedented even in the history of the Fallen Drug. Yet in Mincing Lane there are still many who, more noticeable than the Bourbon kings, appear to have learnt nothing, and forgotten all of its previous commercial history. Every other man one meets, no matter how ludicrously his forecasts have been falsified in the past, still clings to his own pet theory on the subject of the future of the quinine market, and the number of those who, with "Athena's wisest son," are frank enough to admit "all that they know is, nothing can be done," seems scarcely greater than that of the just men in the Cities of the Plain.

A favourite assertion just at present is that the price of quinine fluctuates altogether independently of the movements of cinchona bark, that, in fact, the two articles now revolve in different spheres. We are no adherents to that theory. On the contrary, we have more than once stated our view that the natural causes which have operated to depress both cinchona bark and its derivatives have been assisted by the unwise contracts made by certain Java planters with Continental quinine manufacturers of a speculative turn of mind. Full particulars of these contracts were published in this journal last year, and their substantial accuracy stands unchallenged. A variety of minor causes, such as the condition of the money market, the avowed, if unintelligible, policy of at least one of the English manufacturers to depress quinine, and so forth, have accentuated the state of limpness from which that drug is now suffering, but we see no reason to alter our opinion that the primary cause of the depreciation of quinine lies in the excess of the bark supply, and that a curtailment of the production of cinchona must precede any lasting improvement in the quinine market. So far as Ceylon is concerned the output of bark is already visibly dwindling away, and will continue to lose importance year by year as a factor in the calculations of the quinine dealer. The official export figures, which we quote below, are eloquent on this point:—

CEYLON EXPORTS.

1886	1887	1888	1889	1890
lb.	lb.	lb.	lb.	lb.
14,675,663	12,805,003	12,482,817	9,455,641	8,779,140

The displacement of Ceylon by Java, as the centre of cinchona production, is now as much an accomplished fact as the dethronement of Chinese by Ceylon and Indian teas in the British markets. Until 1890 it seemed doubtful whether Java would ever gain the mastery of the cinchona market. But in that year 4½ million ounces of quinine in the bark were sold by public auction in Amsterdam against 4 million ounces disposed of at the cinchona sales in London. That fact marks the commencement of the era of a Dutch supremacy in the cinchona market. There is no use whatever blunking it, however unpalatable it may be to London importers and brokers; and if the recognition of it should lead to the exercise of greater care and discrimination by the Ceylon planters, and the modernisation of London sale methods, our present loss may prove our future gain. We are induced to make these observations *apropos* of the annual report of the Soekaboemi (Java) Agricultural Association, just published. From this report, which is compiled with the greatest possible care, and forms a valuable guide to those interested in the progress of cinchona, it appears that the total crop of Java cinchona, for manufacturing purposes, in 1890 was 3 million kilos. The estimated crop for 1891 is 3½ million kilos. The average equivalent of sulphate of quinine in the bark was 3.94 per cent. last year, and is estimated at 4.07 per cent. for 1891. The total quinine yield of the Java manufacturer's bark of 1890 was 120,000 kilos, fully one-half of the world's estimated consumption. This year it will be 140,000 kilos., or about four-sevenths of the world's estimated consumption for 1891. We have tested two former estimates published by the Association in 1890 and 1889, and in each case found them to be somewhat below the actual yield. There is therefore no reason to believe that the estimated

figures for 1891 are exaggerated. There are now 114 known cinchona plantations in Java—in 1889 there were 115—and of these only 30 neglected to send full particulars of their cultivation to the secretary of the Association. Fifteen plantations will yield no crop at all this year, mostly because the trees are as yet too young, and only four or five are reported to have been "abandoned" or "uprooted." The facts are that, in spite of four or five seasons of starvation prices, the number of cinchona plantations in Java has not lessened. In 1888 there were 10,622 bouws (1 bouw = 1½ acre) under cinchona in Java, in 1890 there were 18,126 bouws. Another fact worthy of consideration is the existence of a tendency to a decline in productivity in the larger plantations. Thus, the nine largest estates on the island, including the Government plantations, yielded a crop of 1,168,156 kilos. bark in 1890, but they only estimate their output for 1891 at 912,000 kilos. The Government plantations produced only 240,000 kilos. bark last year, instead of an estimated yield of 300,000 kilos. This yield included 95,000 kilos. pharmaceutical bark. But the reduced output was not owing to natural causes so much as to partial compliance with the desire of the private planters that the Government gardens should temporarily cease to put forth their full strength, and thus help them to tide over a bad season. The result of this accommodation on the part of the Government is that they will have to get rid of their surplus in 1891 and the succeeding years. Hence their output for 1891 is estimated at 212,000 kilos. manufacturing, and 150,000 kilos. pharmaceutical bark. Two other possible portents of things to come lie in the facts that nearly all the medium-sized plantations in the western cinchona districts of Java are anticipating a considerable increase in their output, and that the figures denoting their area under cinchona cultivation point to a further decided increase in the near future. Take, for instance, the nine principal plantations alluded to above. They are among the oldest in the island, and their bark is the best known in the markets. Their total area under cinchona covers 3,687 bouws, and their yield of dry bark in 1890 has been about 317 kilos. bark per bouw. Now select nine other typical plantations from among the large number of those which have not yet attained their full producing power. These nine plantations cover an aggregate of 3,747 bouws. In 1890 they produced 46,400 kilos. bark or about 124 kilos. per bouw. In 1891 they are estimated to produce 536,000 kilos., or 143 kilos. per bouw. When they shall have attained the ripeness and producing power (317 kilos. per bouw) of the nine most fully matured estates in the island, they ought to produce 1,187,799 kilos. These figures do not look as if the supply of bark from Java is about to dwindle away. Yet, in spite of the tale they tell, a number of Mincing Lane people affect to treat the Java bark-production as a factor of no account in the quinine market. There is room in the drug market for an "Ancient Mariner," who stoppeth some of these, and for his hearers' own ultimate benefit, if not present delectation, keeps dining into their ears the true moral of the story from the islands of the East.—*Chemist and Druggist*.

LIBERIAN COFFEE IN THE STRAITS.

The statement we append will be read with interest by those planters and proprietors who are now turning their attention to the cultivation of this product. The Native States of the Malay Peninsula which have been opened up to coffee cultivation by European enterprise—principally through planters of Ceylon experience—are situated on the Western slopes of the mountain chain which traverses the entire Peninsular from North to South, forming as it were a "backbone," rising from 2,000 to 4,000 ft. in height, but decreasing on proceeding to the South. The surface is well watered, and very heavily timbered. The coffee, solely Liberian, is planted on the slopes of the main range, and on isolated hills, of which there are a vast number studded over the country. Estate bungalows are constructed entirely of timber obtained on the spot, and roofed in with *attaps*, the plaited fronds of a palm which grows in several varieties. The timber

felled and burnt off in opening up an estate would be of immense value could it but be got to the coast for export. The state of Johore extends from the territory of Malacca to the Southern shores of the Peninsula, and is separated from the island of Singapore by a narrow strip of water. Like the other States it is a British Protectorate, and the Sultan, an enlightened Malay nobleman, offers every encouragement to European enterprise. Sungei Ujong is situated North of Malacca and South of Selangor, and contains several very flourishing estates, notably those belonging to Messrs. Hill and Rathborne, a large and flourishing firm of planters and contractors, who have done much towards opening up the Peninsula to European enterprise, both in the matter of planting experiment and making roads. The State of Perak is North again of Selangor, and adjoins Siamese territory. Both Perak and Selangor are promising fields for the planter. The soil on the hills and plains is most fertile, water is plentiful, and the rainfall abundant. Both States are flourishing mining centres, and are being rapidly opened up with railways. The great want throughout the States is proper labour, which has to be imported. The Chinese are unsuited for coffee work and are very expensive, and the Indian labour, which is now being largely imported, though to a certain degree successful, is, as yet, far from being satisfactory. The yield per acre is simply wonderful if it can only be kept up, but it must not be forgotten that it is the result of virgin soil and soil very rich at that. The elevation of Weld's Hill estates, by the way, is, we understand, about 1,500 feet. A railway runs from Klang on the coast into the heart of the Selangor planting district, with good cart roads branching in all directions so that as the good effects of the virgin soil wear off, fertilisers can be applied at little cost so far as transport, usually about the heaviest item in the expense of manuring, is concerned.

REMARKS.

Crop was lost in 1884, 1885, 1886 and 1887 from want of labour.

The Crop on Weld's Hill was thrown back by heavy pruning and unsuitable weather for ripening.

The Crops for 91 will not decrease these averages. —*Madras Times.*

THE COMING TEA SEASON.

On the verge of another tea season in China we may fitly look at the position of tea in that country, and its prospects here. A feature of the season now drawing to a close is that, owing to the decreased imports, the larger part of the diminished export from China has gone into use. Another feature is that the wholesale dealers are much opposed to hold stocks of any kinds, so that it has almost become a matter of compulsion for the merchants to hold their importations until the buyers actually require the tea for consumption. For these two causes the coming season will require an unusual amount of care on the part of buyers in China, and also from the fact the stock of tea in this country of all kinds will be reduced to an unusually small quantity—say to about sixteen millions of China tea, which is considerably lower than it has been for very many years, or perhaps has ever been before; and, if the export from the East does not exceed that of last year there ought to be a fair chance of a good outturn; at the same time, if the quantity shipped is in excess of requirements, it will lead to a dragging market. The coming season will also require an unusual amount of care on the part of shippers, because the export having become now so diminished buyers may take a sanguine view of the prospect, and operate more freely than the actual requirements of the trade on this side would warrant. On no account must buyers overlook the fact that they have very strong antagonistic competitors in Indian and Ceylon teas, and it is daily becoming more apparent that China teas are losing their former monopoly of this market, owing to the depreciation in the quality of the various growths imported during the last few years; and in order to compete successfully with its rivals it is extremely necessary for all connected with the China trade to impress upon the grower the necessity of paying greater attention to the manufacture of his produce, and emulate the choice quality which brought tea grown in China so much into public favour. But of this later.

It is in the matter of preparation that we must look for good prospects in Chinese tea, and more particularly would we impress on Foochow dealers to give strict orders as to its manipulation. The slovenly way that they have been frequently prepared and sent forward has done much to account for the great annual decrease which is shown in the export figures. It has been rumoured that a few wealthy natives intend to purchase machinery for preparing tea, and set up an establishment for that purpose in one of the districts around Foochow. How much truth there is in the rumour we are unable to state, but we sincerely hope, both in the interests of the native and European, that the growers and dealers will not go on till they finally extinguish the trade ere seeking, and putting in force, remedies to arrest the decline. They may assure themselves that if they will only make good quality tea that they will be able to make better way against their rivals. China tea cannot and will not be completely driven out; for, given similar quality and price, there still remains a considerable section of the population who will always take it in preference to its rivals. The hardest foes that it has to meet consist of the prejudice against new methods and machinery for the better preparation; but in this way a Chinaman's pocket is being affected, and it may suffice to make him move. But he must move without delay. Foochow only requires a few more seasons of declining exports, at the rate of the last few years, to lose its trade altogether. The North is suffering, but not to the same extent. These better means of growth and preparation, so sorely needed, are even of greater importance than the imposts levied on the article by the Government, which likewise assist to strangle the trade and fetter its competition with the free article in India and Ceylon. Up to two seasons ago China could possibly afford to look on calmly at the diminished export to England, as Russia took what was over. Not so this last season, however, and we trust that now the figures have so materially altered, her foreign advisers will point out to her the double course of less taxation and greater care in preparation. Important as both these matters are, there is no doubt that the second is the more vital.—*L. and C. Express, March 27.*

NOTES ON PRODUCE AND FINANCE.

AMERICAN TASTE IN TEA.—The Philadelphia correspondent of the *Grocer* writes *apropos* of tea:—“Cheapness, not quality, is the main consideration. It is incomprehensible—the taste of the American for the bitter, acrid-flavoured Japan tea. More than half the quantity used comes from Japan. We need not look for an increased consumption here until importers bring higher grades of tea, and that will not be done until the retail dealers know more about tea than they now do, and until some pains are taken to educate consumers up to an appreciation of body and flavor.”

THAT REMARKABLE TEA.—As a climax to the advertisement obtained by the Mazawatte Tea Company over their purchase of tea at £12 10s 6d per lb., the company invited a number of people to taste the tea on Tuesday. That the infusion of these precious leaves produced a liquid of delicate flavour it is needless to say, but it is equally true that the palato of an expert is required in order to properly appreciate the beauties of this most expensive of luxuries. It is only necessary to say that some of those present declared that the parcel of tea was cheap at the price which was paid for it. The Mazawatte Company have refused to part with their purchase on any consideration.

CEYLON COCOA.—The chairman of the Ceylon Land and Produce Company, writing on the subject of Ceylon cocoa, says:—“It is curious to note that since the year 1887 the price of good red Trinidad cocoa has been gradually declining, from 78s. and 89s. to 66s. and 72s. per cwt., whereas that from Ceylon has been gradually rising from 70s. and 80s. in 1887 to 100s. and 133s. 6d. per cwt. for good red at present. There is no doubt that the beautiful pale chocolate colour it possesses, and its fine mild flavour have been the two principal factors in its being so much appreciated, and its taking the place which the Caracas variety held at one time. With regard to the extension of this product in Ceylon, you are, of course, aware that there is only a limited area where it can be grown successfully; furthermore, it takes from seven to ten years to come into full bearing, so that the present possessors of cocoa estates are very fortunate in getting the current very high prices, and which are likely to rule for some time to come. My company keeps up nearly 1,000 acres.” Messrs. Frys, of Bristol, have made a speciality of Ceylon cocoa, manufacturing from it a fine quality of chocolate and chocolate creams. Specimens were exhibited at the Health Exhibition.—*H. & C. Mail.*

VEGETABLE PRODUCTS IN MALAGA.—In a report of the British Consul at Malaga, dated October 13, 1890, it is stated that the Cork, or Corkwood, as it is generally termed in commerce, which is produced in the province of Malaga, and more especially in the districts of Cortes and Gaucia, in the hill country of Ronda, is perhaps the finest and the best in the world, and is, therefore, eagerly sought and paid for at high prices. The Cork is stripped off the trees every ten years, that being the time required for it to attain the thickness sufficient for the purposes to which it is destined. Last year's production was a short one, as the turn for stripping fell to only a limited number of the plantations. The Vice-Consul at Garruelia says that attention has been paid in that district to the growing of scent-producing plants, and some plantations of the lemon-scented Geranium have been made successfully in Vera and in the Cabrera hills, where an experimental establishment for the extraction of the essential oils has been put up. The climate is specially suited to the growing of such plants as those just mentioned, as well as Heliotrope, Gardenia, Lavender, &c., and wherever irrigation can be obtained, very large profits can be made in this way. Rosemary, Thyme, and a kind of Lavender (*Lavandula Stœchas*) grow wild upon the hills in considerable quantities. The Eucalyptus has been introduced for some years, and grows with marvellous rapidity wherever it can obtain moisture. It is sufficiently matured for use in timbering mines at seven years, and if successive plantations of seven sections, say, were made each year, they would begin to yield large returns from year to year after the first seven.—*Gardeners' Chronicle.*

A CHEAP COMPLETE FERTILIZER.—A mixture of acid phosphate, cotton seed meal, and kaint will make a complete fertilizer and of moderate cost, if used in the following proportions to form a ton:

1,200 pounds acid phosphate.
600 pounds cotton seed meal.
200 pounds kaint.

The acid phosphate should run 11 per cent. available phosphoric acid, the kaint should contain 12 per cent. potash, and the meal should contain 8 to 9 per cent. ammonia. This mixture will yield 8 per cent. of phosphoric acid, 1.98 per cent. of potash and 1.08 per cent. of ammonia, which is but a little lower than the average commercial fertilizer selling for \$25 and \$30 per ton. The ingredients and mixing of the formula should cost not more than \$19 per ton, and possibly less, if the ingredients are carefully purchased. You may have to mash up some lumps in the kaint, but both acid phosphate and meal are always in fine condition for mixing. By mixing with bees on a smooth floor the whole may be rapidly and easily mixed.—H. B. Battle, North Carolina Experimental Station Raleigh.—*Florida Agriculturist.*

WHITE PEPPER FOR BLACK.—We mentioned some time ago that a patent had been applied for for converting black pepper into white. The inventor is a Mr. Dunderdale, of Liverpool. The process requires a special apparatus, but, apart from that, the way in which it is done is this:—A liquor of soda ash is made—10 lb. to 1 cwt. of pepper. The pepper is stirred about in the hot alkaline liquor and left to stand until, on trying a sample, it is found that the colouring matter is dissolved off, or nearly so. The liquor which is of an almost inky-black colour, is now run off, and can be utilised for dyeing purposes. To the partially-bleached pepper is added a solution consisting of 84 lb. of chloride of lime to 250 gallons of water. When the seed has been sufficiently bleached this solution is run off and fresh water passed through to wash the pepper, after which the latter can be taken out and dried. It then closely resembles ordinary white pepper. The coloured solution, after being allowed to stand to remove all dirt, is decanted and treated with hydrochloric acid to precipitate the colouring matter, which may be sold for dyeing purposes. [We take this from *Discovery*, which seems to be unaware that black and white pepper are from the same plant.]—*Chemist and Druggist.*

GOVERNMENT RESERVATIONS.—It will be seen by the report of the proceedings of the Committee of the Ceylon Planters' Association that the planters of other districts are endeavouring to obtain from Government the same concessions as regards reserves along the streams passing through their estates that have been accorded to the planters of Udupus-e-lawa. An admission of failure in the object for which these strips of land were reserved having virtually being made in the one case, it may be supposed there will be but little difficulty met with in the case of Ambagamuwa. We are under the impression, however, that the reservations in the one district differs from those in the other to a considerable extent. In Udupus-e-lawa there was a reservation on both sides of the tavalam road that runs through the estates for miles; then there was a reservation along the cart road; and reservations along the course of streams. These different reservations intersected the estates and intersected each other in all directions, and proved extremely vexatious to everybody and the decision of the Government to allow them to be purchased by the estate proprietors has proved very satisfactory. We are not aware of any such network of reservations in Ambagamuwa, but do not for a moment doubt that those along the streams are in their way as vexatious as those in Udupus-e-lawa; but the planters have not quite so strong a plea for their acquisition. That they are utterly useless for the purpose for which they are made we concede, but whether the Government will regard it in that light is quite a different matter.—*Local Times.*

"CEYLON AND ITS GEMS."

We should like to know where the "Roving Correspondent" of the *Times of India* whose letter will be found below got his information in respect of the more important part of the information he tenders to his readers. He says that a safe and reliable estimate makes the annual export of gems from Ceylon in value about £10,000; and this, of course, means the annual gathering from the gempits, as very few of the actual finds are permanently retained in the island. The correspondent referred to quite understands that the Customs' returns cannot be at all depended on for the export of precious stones, so many being taken away—like the pearls from our present Fishery—on the persons of the owners, to India especially. In fact the large proportion of our sapphires, cat's-eyes, rubies &c. find their way out of the island without being reported; and we cannot help thinking that the estimate of £10,000 or £100,000 a year is far below the mark.

One test we have which it is surprising the correspondent and editor of the Bombay paper did not apply for themselves. The letter mentions—correctly enough we believe—that before the recent more stringent legislative restrictions, as many as 20,000 natives found employment or were connected with the gemming industry. Certainly this number is not above the mark, if the Kakvana district and province of Sabaragamuwa are considered, and also the Galle, Weligama and Matara districts in the South. Now, without counting the middleman's and exporter's profits, is it likely that 20,000 people, engaged for the greater part of the year in gem digging or hunting, are content with an average return of *five rupees per head per annum*? The idea is absurd. Our contemporary of the *Times of India* ought to have said that not £10,000 or £100,000, but £100,000 or £1,000,000 must, at the lowest, represent the annual find and export of gems from Ceylon, to entice and keep 20,000 Sinhalese more or less engaged in the digging and washing industry, apart from the host of relations, tamby pedlars, jewellers and other middlemen who make a livelihood out of gem selling and buying.

(By A ROVING CORRESPONDENT.)

Tradition has it that the gemming industry was first established by a peculiar people called "Mookars," who were probably a race of Malabarese. They were under the control and guidance of a woman, called Mookery, and their efforts were so successful that within a short space of time they accumulated a large quantity of treasure, with which they loaded a ship and departed from the Island. But they were not destined to reap the fruits of their toil, for, having incurred the anger of an evil demon, their ship was, by his influence, totally wrecked, and the treasures were washed ashore and deposited anew in various directions. To this the natives attribute the fact that gems are occasionally found in the most unlikely places.

The most valuable gems found in Ceylon, and particularly in the Sabaragamuwa District, are the ruby, the sapphire, and the cat's-eye—this last much prized by Asiatics and especially by the Malays. Stones of little value, such as garnet, moonstone, tourmaline, topaz, spinel and amethyst are to be had in abundance. The zircon, in rich shades of brown, violet and green, with its members the grayish white and white jargoon, and the red hyacinth, is found in greater quantities than in any other country. It is here that the unwary globe-trotter has to be on his guard, as with the desire of becoming the envied possessor of a fine diamond or ruby, he not unfrequently becomes the prey of the designing "Tamby" or Moor-man, who palms off as a diamond of the purest water a valueless zircon, or as a ruby a worthless

spinel, garnet, hyacinth or even quartz. It may be noted that a true ruby will scratch any of these counterfeits. Notwithstanding this abundance it is not possible owing to the system under which the industry has been worked to fix with any degree of accuracy the annual value of the gems unearthed. The Customs' registers are not reliable, for out of the many valuable gems found, some are retained in the island, and others are purchased for nominal sums by private persons and speculators, the real values of which are not, if ever known until they are disposed of in Europe or to some of the wealthy princes in India. A rough calculation, however, based on the best available data, gives the value of the precious stones found at about £10,000 annually.

The ruby is of most value, and has at times secured the highest prices. Rejecting as a traveller's tale the assertion of Marco Polo, that he saw a Ceylon ruby the size of a man's arm it may be interesting to recall what is related of another Ceylon ruby, in connection with the part played unwittingly, in the rise of a family that was of note in a subsequent period in the history of the Dutch Republic. A "Chetty" physician became the owner of a large ruby, said to have been the size of a small curry-stuff grinding stone. Cutting it into pieces, and retaining the larger portions, he presented the Dutch Governor of Colombo, Imhoff, with eighteen buttons set with the smaller pieces. Imhoff, not unmindful of gratitude, promptly exalted the donor to the proud position of first Malabar Mudaliyar of the Gate, a title of honour still retained, and about equivalent to a Lord Lieutenancy of a county in England. This rise in rank however stirring into restless action the dormant energies of the Chetty the Governor was at last glad to get rid of his protégé by transforming him into a dignitary learned in the law and presenting him with a seat as Judge of the Supreme Court in Java. This gentleman was grandfather to Dr. Quint Ondaatjee alluded to in Allison's "History of Europe," as the "Great Democratic Leader" &c. Whatever, however the value attached to the Ceylon rubies in the past or the present it should be noted that really valuable ones have ever been scarce and they cannot vie in comparison with some Burmese specimens.

Two of the latter were sent to London in 1875, weighing 37 and 47 1-16 carats. These were reduced after recutting by Mr. J. M. Forbes to 32 5-16 and 39 9-16 carats, respectively, and the former of them was sold for £10,000. What became of them eventually it would be interesting to ascertain, as possibly no single regalia in Europe contains two such fine rubies. Originally they belonged to the King of Burma, but impemperiousness and the chronic state of "hardup-ness" prevailing at that court led to their disposal. This was not an easy matter to achieve, for the people were proud of their possession, and resented the idea of their being sent out of the country. Strategy and military force were brought into play, and with a strong guard and amidst intense excitement they were conveyed to the vessel that was to bear them away to their destination.

In Ceylon, while really valuable rubies are rare, and sapphires common, the converse prevails in Pegu. Still of the sapphires a few splendid specimens have been unearthed, and mention might be made of one in the collection that was sent by the Colony to the Paris Exhibition in 1855, which was valued at £5,000. Notwithstanding the hardness of its nature, the sapphire can be beautifully engraved and in the Cabinet of Strossi in Rome, may be seen one, with the profile of Hercules, the work of Ceneis.

The cat's-eye, too, is occasionally of some value, as instance the one that was in the collection of the last King of Kandy, which sold in London in 1820 for more than £400. This specimen measured two inches in diameter.

Though tradition speaks of the "Mookars" as the pioneers of the gemming industry in Ceylon, it is silent as to their methods of work. How far it resembled the practice adopted by the natives at the present time

of which an account is here furnished, cannot be known. The sites selected for prospecting are either the beds of streams or the dry land in their vicinity, and as the gemmer needs but few appliances, he is not handicapped by much initial outlay. These appliances consist of a few crowbars, a few mamotees, a long iron sounding rod, "Illankora," and a close basket made of split bamboo reeds.

Thus equipped, the gemmer, if the site selected is the bed of a stream, commences operations in the dry season (December to March), when the water is low and sluggish. He first clears the sand away, and from time to time uses the sounding rod to see whether the gravel or "illan," hence the name of the rod, is accessible. In getting to this "illan," the matrix in which the gems are found, his efforts are sometimes retarded by impedimenta in the form of blocks of rocks, and invariably by a sort of crust, called "Cabook" which has to be penetrated, as it is commonly under this crust that the "illan" lies. On reaching this stage, and when the gravel is exposed, the coolies, who have hitherto been assisting the gemmers, are promptly sent away, as none but the initiated and those vitally interested in the success of the undertaking, are allowed to be present at the further development of the search. The gravel is now scooped out by means of the mamotees, and is deposited in the wicker basket, held under water with the feet. The basket thus scoured, the "illan" in it is rotated with a quick motion, by which means the clay is dissolved and the lighter particles of stones, and, from time to time, the larger ones, if after due inspection they are worthless, are thrown out. The whole is thus reduced to what is termed "naboca," a thin heavy sand, mostly composed of particles of precious stones, which on careful security are secured.

Much similar to this is the process when the site for search is on dry land near a stream, the season for work being the same. Here the earth is removed to the level of the water, and when it becomes soft, the sounding rod is brought into requisition. So deftly is this used in the hands of an experienced worker, that he is seldom misled as to whether the "illan" is within practicable depth. The result being satisfactory, an anxious moment ensues, for the gemmer has to guard, with redoubled vigour, against an influx of water. The soft sand being removed, the "illan" is readily come upon, should there be no "cabook" to break through, and, by means of the crowbar, it is detached and heaped up for washing, either in the pit itself, if there is not much water in it, or in the adjacent shallow stream. To facilitate labour, the whole of the pit is not gemmed at once. Only one-half of the earth is removed, a flight of steps being constructed in the other half to expedite the removal of the earth and the baling out of the water. This half being exhausted, room is afforded for the earth on its removal from the remaining half, which is then in its turn operated on. The "illan" on being heaped up undergoes the process already described.

Simple and primitive as the process of gemming appears, it is in the majority of instances disappointing in the extreme, when the tangible benefits derived are compared with the great amount of labour involved. The sites and directions in which gems are imbedded are very uncertain and quite unknown, and though in some cases pits are workable in a few days, in others, days, months and sometimes years lapse before the matrix which contains these precious stones is discovered. But the reward of this may not be here, for the matrix may not yield a sufficiency of gems, even of the smallest value, to show a profit or even to cover the expenses. From enquiries the writer has instituted, it may be taken as substantiated, that of every ten pits sunk but one is found to pay. That, notwithstanding these facts, the industry should have been engaged in by the poorer class of natives, shows how hard a struggle for life they had to encounter.

During the reign of the Kandyan Kings when caste prevailed and was rigidly observed, for once a barber always a barber was the rule, the inhabitants of certain villages were exclusively set apart for gemming pur-

poses. A body of hereditary gem men, with two headmen, also hereditary, to superintend the establishment was thus formed. This practice died out on the advent of the more enlightened and liberal British Government, and the gemming industry became open to all sorts and conditions of men.

For the past fifty years, the industry has been pursued by a number of poor people whose sole subsistence depended in very great measure on any little find. Others again, mostly agriculturists, resorted to gemming to eke out what the cultivation of "paddy" did not always afford them, so as to save themselves from absolute starvation. While so affording relief, a system of joint-stockery on a small scale, between expert gemmers and landowners, introducing speculation into it, gradually crept in. In course of time the attention of European speculators, forming themselves into companies, was drawn to it, leading to the investment of larger capital.

Up to the time of the formation of these European companies, the natives were unrestricted in their efforts at gemming, the only places they were not allowed to exploit without licenses being Crown waste lands. The advent of European capital caused the Government to step in, in the early part of last year, with the enactment of an ordinance, that with one fell swoop did away with all the privileges hitherto enjoyed by the indigenous population. The features of this ordinance may be briefly summarised. It enacts that a fee of R5 is payable for a license for every pit opened in *whatever locality*, the number of men employed on each pit being fixed, for each of whom a sum of 75 cents., or 12 annas, for a term of three months is due. A specially hard feature lies herein, for if the number of persons when the license is issued should be 26, and 27 happen at any one time to be employed, the license can be cancelled by Government, and each extra man so employed may be fined R50, or in default undergo six months' imprisonment.

That this is a most unreasonable clause should be apparent to the most unthinking mind, and its execution has had the effect of preventing the poor people to the number of 20,000 from in any way devoting their attention to gemming. It not infrequently happens that with a sudden influx of water into the pit an increased strength of labour is absolutely necessary for baling purposes if all the efforts already put forth are not to be frustrated. As has been shown, any excess of labour involves a heavy penalty, unless it has been duly applied for and a fresh license obtained, a matter involving a delay of, say, four days, if not more, as a number of formalities have to be undergone, including the drawing up of a report as to the altered circumstances of the pit, by the village headman, an *unpaid* native official.

The ordinance appears to have been drafted on the assumption that the Crown, as successors to the Kandyan Kings, has a prerogative right to gems, *even on private lands*. That such a right was ever exercised by those sovereigns is doubtful, and is not clearly established. It is at all events remarkable that the claim now put forth should have been lost sight of for a long period of years, and that it should now only engage attention.

But not content with these rights, the Government goes further and seeks to establish similar ones on lands which it itself previously sold *expressly as gem lands* for high and fancy prices. These lands were sold outright to the present owners, and that they should be called upon to render to Government a share of the gems found is opposed to every sense of political morality.

Another objection to the ordinance, and a potent one too, as it involves a clear breach of faith, is that the tax is enforced on lands belonging to Buddhist temples, and on the villages of Kandyan Chiefs, who assisted the British power in taking the Kandyan provinces, whereas by law these lands were declared *free* of all tax.

That the ordinance is felt as an extreme hardship by the people, leading them to transmit a temperately worded memorial to the Secretary of State for the Colonies, detailing their grievances, is not to be wondered

at, and sympathy cannot but be felt for them in their attempts to gain redress. The ordinance as it stands has practically killed the native industry, and leaves it for the present in the hands of the European speculators who have come on the scene. The *raison d'être* of it really appears to be, that if capital can be invested freely by foreigners, there must be something enormous to be made out of the industry, and so the Government thinks fit to have a share. But the question remains to be solved whether the introduction of European capital, aided by the most improved appliances and the latest methods for working gem mines, will develop into a remunerative business. There is nothing in the past to warrant such a belief, and when it is remembered that gemming has been openly carried out for years, openly and immediately under the eye of shrewd British business men, its success, handicapped as it is by an initial tax of 10 per cent, under the newer auspices, is, to say the least, highly problematic.

Ratnapura and Rakwana are the places where the best gems are found, though along the road I remarked several excavations where gemming had been conducted. Some very pretty moonstones were shown me, which however were of little value. From Pal-madale to Rakwana is a distance of sixteen miles up among the mountains. At one side is a deep valley heavily timbered and matted with luxuriant creepers. I noticed some curious orchids, with strange pendulous flowers, hanging from the angles of branches: their stems were covered with fungi of the most gaudy colours—bright red, yellow, and purple. The scarlet shoots of the iron wood tree seemed like flowers in their blood-red hue. Part of the hill side was literally a blaze of crimson, looking as if the wood was strewn with vermilion. This wood abounds with game, wild boar, elk, red deer, black faced monkeys; and the whirr of copper wings indicated flocks of parrots without number. Rakwana is a mining village, consisting of one long street, and looking absurdly small owing to the presence of some massive iron wood trees and tall palms which dwarf the little huts at their base. No more than 250 families reside here under the shadow of a big brown mountain with huge irregular spurs. Down the side of this mountain trickled a stream which fell over a rough bed of stones in a succession of small cataracts, until it got down to the valley when it slipped along in a placid stream. It looked like a frayed string of braid lacing the side of the huge mountain. One side of the hill was covered with matted jungle and the other placed under cultivation. The view higher up among the glens was inexpressibly fine. The twin wooden shanty of the planter stood out on the hill side, while the green tufts of tea hardly showed on the red brown earth. Down in the valley, the hills appeared like miniature hay cocks, under an amethyst sky of the loveliest blue. The beauty of this scene viewed from the glen where the evening operations take place was lovely, and pathetic in its loveliness. The plaintive note of a bulbul, who is supposed to have a passion for the rose and regrets seeing it plucked, communicated a feeling of sadness to my mind as I looked down from those lofty peaks into the distant valley. There is not a dog hole of the European continent that I have not visited, yet a finer view than the one before me I never witnessed.

The miners are an improvident lot, tunnel diggers getting an average of £2 and a half a day. I had a talk with Mr. Bradley, the Superintendent of the Ceylon Gem Company, and was courteously led round its pits by Mr. J. H. Smart, his assistant, a pleasant, genial, and highly informed gentleman. Here I heard a great deal more of gemmers and their hard lives than I can insert in this article. I trust, however, I have given my readers some idea of gemming in Ceylon to enable them to form a conjecture whether they will find it worth their while to invest their money in such lottery concerns.

Above, we publish a lively and entertaining paper upon "Ceylon and its Gems." Our "Roaming Correspondent" seems to have studied the question with some care, but it is startling to learn that according to

the best available data the value of the precious stones found in the island does not exceed £10,000 annually. The introduction of the new ordinance or tax has, we are told, killed the mining industry altogether, so far as the natives are concerned, and left it for the present in the hands of European speculators. The question, says our correspondent, remains to be solved whether the introduction of European capital, aided by the most improved appliances and the latest methods for working gem mines, will develop into a remunerative business. "There is," he adds, "nothing in the past to warrant such a belief, and when it is remembered that gemming has been openly carried out for years, openly and immediately under the eye of shrewd British business men, its success, handicapped as it is by an initial tax of 10 per cent., under the newer auspices, is, to say the least, highly problematic." None of our Indian readers are however, at all likely to put their money into the gemming industry of Ceylon, while the grievances of the native miners may be safely left to local public opinion. It is of much more interest to read the words of wholesome warning addressed by our writer to travellers anxious to invest in diamonds or rubies, and to learn what manner of inferior stones are often palmed off instead of them. The safest stones to buy in Ceylon are sapphires and cat's-eyes, but even with regard to these the assistance of an expert is desirable. Considering the thriving business done all the year round at Colombo, and especially with Australian passengers, it is at once a surprise and a warning to learn that the annual value of the gems found on the spot is not more than £10,000. What, we wonder, is the value of the annual sales?—*Times of India.*

LIBERIAN COFFEE AT THE STRAITS.—As already mentioned, Dr. Trimen has returned from Java and the Straits confirmed in the conviction that we in Ceylon have been too hasty in discarding Liberian coffee. In this connection we call attention to a statement and figures in our *Tropical Agriculturist* showing crops in the Malaya peninsula (Selangore and Sungei Ujong) averaging from 8 to 1½ cwt. per acre, returns handsome enough to induce a wide extension of planting. Ceylon has, of course, a far poorer soil, but there are parts of the Western and Southern provinces especially where Liberian coffee might well be planted, by the natives especially, with advantage.

KAORIANA, April 13th.—No shock of earthquake has been felt in this neighbourhood, but thunder-storms and occasionally heavy gusts of wind have been experienced. The north-east is bent upon going out with some bluster. From the 6th to the 10th there was rain in the evenings; the total fall being 2.28 inches. The mornings are delightful but the days are close and very trying. Growth of vegetation has been rapid for the last two months which will much benefit the cinnamon bushes, and permit of work being begun for the new season (1st May) early. I was much pleased to see Mr. Gladwin's letter, in Saturday's *Observer* on the increase of opium consumption in Ceylon. I have been greatly surprised at the number of opium-eaters I have come across in this locality, and from inquiry I find that opium-eating is becoming common among the Sinhalese. The usual reason given for its use is to relieve aches and pains; and when once taken to, the unfortunate victim has not the courage to give it up. Fortunately in this connection most of the people are too poor to indulge to any serious extent. As in the case of arrack I think the Government is greatly to blame, when, for the sake of a paltry increase to the revenue, it gives encouragement to the extended use of this drug—a boon to humanity when under medical control, but a fearful curse when it can be sold to the ignorant and confiding in the bazaars. These poor people imagine they have found a panacea for their ills, and find when too late that they have only added another and a worse one to the list.

A CUPPING INSTRUMENT FOR SNAKE BITE.

[From a number of the *Cape Agricultural Journal*, we take the following very valuable, commonsense information on the use of a cupping instrument for snake bite. Speedily and effectually applied so as to retract the poisoned blood, no better remedy could be used. In the recent case of poor Bosanquet, in Florida, his companion bravely did his best by sucking the wound. But the venom had got into the circulation through the veins in the *inside* of the foot. Had the bite been on the outside the sucking might have been effectual.—Ed. T. A.]

Snake poison is now ascertained to be a definite chemical compound, perfectly stable and indestructible, except by anhydrous sulphuric acid, permanganate of potash, and partially by carbolic acid, in fact, by those few substances which decompose and destroy any organic chemical. Ammonia has no effect upon it; for when the poison is mixed with ammonia and injected into the bodies of animal, it retains its energy unimpaired, but it is certain, from South African experience, that ammonia, especially taken internally, probably as a nerve stimulant, counteracts its effects:

There are two kinds of snake poison, the celluline of the cobras, and the viperine of the vipers or adders. The former is chiefly a nerve poison, and produces paralysis, especially of the respiratory nerves. It kills by causing carbonic acid poisoning, which is accompanied by convulsions. The viperine venom is both a nerve and a blood poison, the latter action being often the more dangerous of the two. The puff-adder is our best known viper.

As snake poison is of this stable and indestructible character, according to the dictates of common sense the first consideration is to get it out of the body, whatever the value of antidotes may be. Dr. Wall, who at the instance of the Indian Government carried out the experiments of Sir Joseph Fayrer to more definite results, is of opinion that nothing will save life in persons bitten by Indian snakes, except making a cut across the side of the bite, and dissecting out the subcutaneous tissues in which the venom is lodged a sixth of an inch or more beneath the surface. Our South African snakes are not quite so venomous, and no one but a skilled surgeon would venture on such cutting and carving. Another plan, therefore, seemed desirable. A good many cases have occurred where life has been saved by sucking out the venom with the mouth. This suction, however, is feeble, and is also highly dangerous if there happens to be any skin wound in the gums or mouth. The proper thing would be a strong cupping instrument. The ordinary cupping instrument is unsuitable, from the glasses being too wide in the mouth. It is also too dear for common use. That of S. Maw & Son, London, is 22s. to the trade, and would be at least 30s. retail price. It seemed to me that nothing would serve but an instrument prepared expressly for snake-bite, and sold at about half a guinea. I accordingly induced Mr. William Hume a well-known scientific instrument maker, Lothian Street, Edinburgh, to prepare such an instrument, giving him an exact description of what was wanted. He produced one which is thoroughly effective. The barrel is of brass, about five inches long by $\frac{7}{8}$ inch wide, with double valves and a bell-shaped glass $\frac{5}{8}$ inch wide at the mouth, and enlarged above so as to hold an ounce of blood. The suction is powerful. A larger glass may also be had at an extra charge, with the mouth an inch and a half wide, for animals. The instrument is sold in Edinburgh at 10s. 6d., What with Customs

duty, carriage, and commission it could hardly be sold for less than 15s. in this country, unless an importer were to order six dozen, in which case there would be a reduction of 20 per cent. Still, the price is very moderate, considering that snake-bite antidotes are sold at from 8s. 6d. to 12s. 6d., and are suspected of not keeping.

Treatment of Snake bite.—The thing to be done immediately, on a person being bitten, is to cut off the circulation from the part so as to prevent the venom from being absorbed. The best thing is an india-rubber band or rope, similar to Esmarch's bandage, either solid or tubular, and strong but flexible. This should be wound firmly and a number of times round the limb at the part next above the bite. As this band fits itself to depressions in the bone, it is far more effective than whip-cord even were it made so tight as to cut into the flesh. A soft reim is the next best, but anything, even a handkerchief, should be used in an emergency. The next thing is to probe the two fang punctures with a sharp penknife or lancet. Scarifying is a mistake. It merely removes the superficial blood, while the venom remains lodged in the tissues. The proper thing is to open up the punctures so as to get down to the venom, and secure that it and the envenomed blood is sucked out. The probing being done, the mouth of the cupping glass should be moistened and pressed down firmly over the wound so as to allow no air to get in at the edge of the glass, and the piston worked up and down. The flesh will be sucked in, and the glass will soon be filled with blood. This may be repeated. If the cupping is performed before the poison has gone into circulation, there is every reason to expect that life will be saved. Even if all the poison is not removed, life may be saved, for snake poison does not kill unless it goes above a certain proportion to the entire quantity of blood in the body. The antidote, which should be administered internally at the first, may now be applied to the wound after washing it with Condy's fluid (a solution of permanganate of potash), if it is at hand. * * *

[Then follows a notice of an antidote in the shape of tincture of a herb, the red or wild Dagga, *Leonotis leonurus*, but ammonia alone is probably best.—Ed. T. A.]

Directions for using the Cupping Instrument.—The instrument should be kept in a place known to all the household, and ready for immediate use. To keep it in perfect order, it should be examined periodically. In testing it, apply it to the chin or any fleshy part. If it does not work that may be from want of oiling the piston, or because the valves are wrong. The oil, should be sweet or olive oil, or else an animal oil, quite free from acid, so as not to corrode the brass. As oil dries up, the oiling requires to be repeated now and again.

To reach the valves, unscrew the milled edge at the lower end of the syringe for the one valve, and screw off the bottom plate of the piston for the other, using if necessary the two small holes to keep the upper part firm. The valves may require simply to be wiped from oil or dirt. If a valve requires renewal, that is a very simple matter. It is a strip of oiled silk (the umbrella article, or that sold by druggists will do) put over a small hole, with its ends tied over a groove in the brass by means of a thread. The packing of the piston can also be easily renewed. It consists of a round piece of leather, steeped in sweet-oil, with a hole in the middle through which the screw of the bottom piston plate passes, and the sides are then folded up—an arrangement easily understood on inspection. The instrument, which is a substantial article, is practically indestructible, and as they are all made exactly alike, glasses and other parts could be replaced for that matter.

The sample instrument in my possession was shown to Sir J. Gordon Sprigg, and as he approved of it, he gave an order home for six dozen. They have probably come by this time, and may be at the disposal of the Colonial Secretary. The intention, I suppose, was to place them in the hands of magistrates or other public officers, so that they might be seen by farmers and others in the rural districts, besides being used. No farm-house should be without a cupping instrument for snake-bite: puff-adders and other snakes are so numerous, and there are so many children, servants, cattle, horses and dogs liable to be bitten. The cupping glass will also be serviceable for the sting of the scorpion, the bite of the tarantula, the stings of wasps, and if applied at the moment, for poisonous blood or matter getting into a scratch.—ANDREW SMITH,

NOTE.—The cupping instruments have come, and a set will be sent on application to any Civil Commissioner or qualified medical practitioner. I may add that it has for a long time been my habit, in travelling, to carry, in my pocket, a small glass funnel for use in sucking the puncture in case of a snake bite. This, of course, does not act so powerfully as a cupping instrument, but has the advantage of being small enough to be easily carried in one's pocket.—EDITOR.—*Agricultural Journal*.

POULTRY NOTES.

Change the straw or hay in the nest boxes frequently.

In shipping fowls give them plenty of room, but make the coops as light as possible. Express companies have no souls and rates are high, and all we can do is to protest and pay.

It is only necessary to examine a chicken's crop to ascertain that a good variety of food as well as bones or gravel is essential, and ordinarily a good supply of a variety of food will be found much better than any kind of medicine.

Bran is excellent for poultry, but the hens care but little for it unless scalded. To make it "stick," and a handful of luseed meal to every point of bran. The two substances are an excellent combination, and will greatly aid the hens in producing eggs.

Do not be tempted to keep a cock that is not a thoroughbred, or that is related to the hens, no matter how promising he may seem. Change the cocks every year, and the flock will gradually improve in vigor, resulting in a greater number of healthy chicks, as well as an increase in the supply of eggs.

The coarse grain so universally fed to poultry is both expensive and unprofitable; being swallowed hurriedly and often in unwise quantities, it frequently produces indigestion or other serious disorders. A mixture of four parts of wheat bran to one of meal is what I feed, with signal success and satisfaction to both laying hens and growing chicks.—*Florida Agriculturist*.

ORCHID HUNTING

appears to be a fine adventurous sport—not so exciting, perhaps, as Waterton's snaring of the caymans with baited hooks in the great rivers of Brazil, but getting on that way. Unfortunately, the most prized of our orchids are reported to be rapidly disappearing from their native places. According to the "Journal des Orchidées," in the environs of Pacho (Ecuador), where hundreds of thousands of specimens of the *Odontoglossum Alexandro* have been collected, only a few plants are now left. In other places where it once flourished, it has entirely vanished. Though not in the true sense of the word a parasite, this beautiful plant prefers to grow upon the trunks of trees, which the natives dread to climb on account of the scorpions and stinging ants. Hence the practice is to fell the huge tree, with the frequent result that no orchid is found. The hunters, it is stated, separate into parties of five or ten, and dis-

appear for a fortnight in the dense South American forest, relying for food in great part upon their guns, and sleeping at night in hammocks. When sufficient specimens have been collected they are cleaned, wiped dry, placed carefully in crates on the backs of mules, and thus carried to the point of embarkation—Honda—on the river Magdalena. The journey occupies at least five days, even if the party are lucky enough to escape the frequent tropical rains which convert peaceful brooks into raging torrents. Sometimes it is found necessary to throw temporary bridges over these suddenly swollen water-courses and to carry the crates across by hand, while the mules, relieved of their burdens, swim across as they best can. The withering torrid heat is the greatest difficulty.—*Public Opinion*.

PADDY AND DRY GRAIN CROPS IN CEYLON.—From the Abstract of Sea-ports Reports for March 1891, published in the latest *Gazette*, we learn that in the Colombo district the condition of the paddy crops was good generally, with the exception of portions of Siyane Korale West, where recent rains had done some damage. It is also stated that "there is no distress or want of food anywhere, and the health of the district is on the whole good." In other parts of the Western Province also the prospects were favorable. In the Central Province, on the other hand, the paddy crops in the Kandy district were reported as generally poor; while the kurakkan crop, where cultivated, was only fair. In the Matale district, however, the paddy crops, where they were in existence, were "much benefited by recent unexpected rains." In the Nuwara Eliya district paddy and kurakkan were only fair or poor, owing to poverty of soil and drought, except in Kotmale, where the paddy crop was good. With regard to the Northern Province, the report from Jaffna on the paddy crop was:—"Reaping throughout district completed. Crop on the whole good, though there has been failure in some villages as already reported." And on kurakkan:—"Good crop expected owing to benefit by rain." It was also added:—"Tobacco in some places out—prospects of a very good crop." From the other districts of this province the reports were not very satisfactory; the dry grain crops seem to have been better than the paddy. In the Southern Province good showers had fallen, and the prospects generally were favorable. From the Batticaloa district of the Eastern Province it was reported:—"Prospects of grain crops most favorable. Harvesting of early munmari proceeding, and very extensive cultivation for kallawellamai in progress. The new paddy one rupee per bushel. Supplies of vegetables and Indian corn abundant, and cheap. Indian corn 75 cents per bushel. Manioc unsaleable though offered at 50 cts. per cwt. Plenty of water in tank, and rain at intervals." In the Trincomalee district progress was slow on account of cattle murrain. In the North-Western Province rains had fallen, but too late to do much good, except in the Wann and Chilaw. The tobacco crops in the latter division were excellent. From the North-Central Province the report was: "Partially distributed rain filled some tanks in east, west, and south of Nuwarakalawiya. Maha crop nil owing to drought, except in Kalpe korale and a few villages of Nuwaragam palata. Chenas partially revived by recent rain. Kurakkan crop generally middling. Abnormal rainfall in Tamankaduwa. Maha crop, where cultivated late, good. Chenas average half crop, and being reaped. Drinking water bad, and scarce in many villages." In the Badulla district of the Province of Uva the kurakkan and Indian corn crops were fair except in Buttala, where excessive drought had made the hen poor. In the Province of Sabaragamuwa the crops and prospects were generally good.

THE JAMAICA EXHIBITION :

WHY NOT A COSMOPOLITAN EXHIBITION IN CEYLON?

(From the Hills.)

It is surely curious that while it is now about a week since the special illustrated edition of the *Jamaica Gleaner* reached here, with a full account of the opening of the Exhibition at Kingston by Prince George of Wales, as the representative of his royal father, the Prince of Wales, no notice of the event has as yet been taken by the English press, judging from the negative evidence of extracts in the *Tropical Agriculturist* at any rate. You are,

no doubt, waiting for the promised account by Mr. Wm. Sabonadière, the only mention of whose name in connection with the ceremonies and festivities is the statement that, at a grand fancy ball given by Sir Henry and Lady Blake, he appeared in the character so dear to juveniles, of Santa Claus. The Governor himself appeared as Columbus, the discoverer of the Caribbean Island, while Lady Blake personated Queen Isabella, to whom the great navigator wrote such a glowing although not an exaggerated account of the beauty and natural resources of his discovery. At the ball the Governor is described as specially seeking out a lady, Miss Espeut, who, he understood, appeared as Jamaica. Some of the portraits given by the *Gleaner* are fearful and wonderful. For the males it does not so much matter, but we hope less than justice is done to the accomplished Lady Blake. She is sister of the Duchess of St. Albans and daughter of the late Mr. Bernal Osborne, famed for his caustic wit, which was so irrepresible, that, when he took office, he could not refrain from using it at the expense of his colleagues, and so had to resign. Jamaica has to thank the snobbishness of the Queensland democracy, who protested against a Governor who began life in the Irish Constabulary, for being at present ruled by one of the ablest and most active men amongst the list of Colonial Governors. He has worked incessantly to make the Exhibition a success, not only as a spectacle, but as a means of making the colony and its productions better known and so increasing its commerce. The only unpleasant incident we see noticed is in connection with another exemplification of the fact that democracy can degenerate into snobbishness. Mr. Blaine, who does the offensive policy of the United States, pretended that his country had been slighted because not specially invited to take part in the Exhibition. Sir Henry Blake showed that precisely the same invitation went to the United States as to all other countries. But this does not content the blatant Blaine, whose every effort is directed, by means of tariff distinctions, to force Canada and the West India Islands into "the Union." Although Sir Henry Blake is not himself a lord, and was, therefore, unacceptable to the Queenslanders, his Private Secretary is Lord George Fitzgerald, brother of the Duke of Leinster. The *Gleaner* describes the Exhibition as "a splendid success which will inaugurate a new era of advancement and prosperity for Jamaica." There is room for improvement, for the journalist states:—"In manufactures and even handicrafts our people are very children. In agriculture we are little further advanced than we were two hundred years ago. Literature, Science and Art are unmeaning words to 999 out of every thousand amongst us." It is added:—

One good at least, if none other, the exhibition should do and that is to give the lie to those unworthy sons and residents who are perpetually deerying everything of home growth, believing in nothing that is "creole" and taking a strange pride in uttering their loud contempt of everything Jamaican. The motto of these people has always been that nothing good could ever come out of Jamaica. They have preached it from pulpit and from press, they have dinned it into the ears of foreigners, taking as strong a delight in shewing up the weak points of the people and the country as some people do in harping on their own maladies or as a Neapolitan beggar in displaying his festering sores. The Exhibition will prove these people to be miserable carpers. It will show our own people what can be done in Jamaica by persistent energy, by united effort. It will nerve many to other achievements longed for for many a day but locked on as almost hopeless of attainment in Jamaica. If a great World's fair is possible in Jamaica, why not docks in Kingston Harbour? Why not a seawall on the harbour front? Why not nicely paved streets with commodious sidewalks? Why not a thorough system of drainage? Why not central factories? Why not smiling vineyards? Why not a network of railways over the Island? Why not in short a thousand and one things that we have been slumberously content to do without, while the great nations of the earth have for years past looked upon them as necessities of life?

Now if a World's Exhibition has been a splendid success in little Jamaica with only 600,000 of population, and most of them only emerged from slavery, surely the question arises and ought to be answered, why Ceylon, with her three millions of population, her central position in the eastern world, and her grand harbour, the resort of mail and merchant ships, with passengers and tourists from all parts of the world, should not attempt an Exhibition of her own, inviting all the countries and peoples of the world to take part in it? Will the glory of having initiated, matured and carried to a successful issue so great and so undoubtedly beneficial a design fall to Sir Arthur Havelock? Will our Governor do for Ceylon what Sir Henry Blake has done for the tropical island of the western hemisphere? There is more good work to be done and more of legitimate fame to be earned in carrying out such a design than in tampering with sources of revenue, prescriptive in their nature and, however objectionable in the light of western ideas, quite consonant with eastern customs and eastern notions.

The Ceylon Exhibition, if carried out, could so precede the great World's Show at Chicago that most of the exhibits might be transported to the western world, after having done duty here. The effect on our staple product of asking all the world to come and see it in the place of its origin cannot but largely help the efforts that are made to render it acceptable by sending specimens to the various countries of the world. Submitting the idea to readers of the *Tropical Agriculturist* from the Governor and Lieutenant-Governor downwards, we proceed to notice a few further points of interest connected with the Jamaica Exhibition. The only qualification noticed in connection with the opening of the Exhibition is the comparative failure of the electric light contractors to illuminate the building fully at night. Besides the great domed building, there are 23 acres of grounds laid out with tropical and other plants. Canada, which is competing with the United States for the trade of the West Indian Islands, occupies a commanding position in the collection of exhibits. A trophy of the finest woods of Quebec, in the form of a castellated wall, had to be erected in the grounds, as it was too large for the interior of the building. Admiral Watson and the officers of the British Fleet which accompanied Prince George added greatly to the effect of the show (the warships were

illuminated at night); while Major-General Clive, Justice and the officers of the Army, Militia and Volunteers were not behindhand. Limited as space in the *Tropical Agriculturist* is, we must make room for the following editorial remarks:—

When the public look at the diagram exhibited by the Jamaica Institute, showing the cane lands cultivated in 1790, the chief of the so-called "palmy days" of old, and turn to the companion diagram showing the cane lands cultivated today, they will see some reason for writing of a new Jamaica. Whether a better or a worse is not the question. When they turn to another diagram showing the extent of the small holdings at this date, and remember how few they were a century ago, they will be still more convinced that the Jamaica of today is a very different thing from what it was. When they turn again from these things to the educational and other statistics that indicate material, intellectual, and moral advancement, they will have before them proofs of a change amounting to a revolution that has not been all the circumstances considered, anywhere exceeded within the same number of years. It would be easy to point out in history many great and remarkable changes, but those who try will find it hard to point out one that exceeds in interest what has been effected here. It took that master lawgiver Moses more than his own life-time to build up a nation out of the oppressed Israelites. He did, however, good and lasting work. He made a people as enduring as granite. The modern lawgiver, the British Parliament and Executive, instructed by the British People, did a similar creative work, when during fifty years previous to emancipation they abolished the Slave Trade and watched jealously and carefully over the rights of the slaves, and when for the fifty years that followed they watched with equal care over the interests of the emancipated people. The result is the strong, growing new Jamaica that has made an Exhibition possible here, and is going to make it a success. This newness, with its assured continuance, is the great fact that should attract the attention of our more thoughtful visitors.

There is another new thing connected with Jamaica. The character of its scenery is not new. So far from that, it is as old as the hills. But the recognition of it and of the character of the climate is new. As Sir Walter Scott was said to have discovered Scotland in respect to scenery, so recent travellers have been discovering the truth, of the Governor's words, that Jamaica is one of the loveliest islands in the world.

What is anticipated for Jamaica might well be realized in the case of Ceylon, in the resort of visitors who desire to escape from depressing cold to genial warmth:—

If those who have eyes to see and natures fitting them to enjoy what is beautiful in scenery will in twos or threes make a leisurely journey from Kingston to Lucrea via Ewarton and by way either of the interior or the coast road, they will see in this month of January what will astonish them if they come from cold and leafless England or Canada. To transport in a day or in fourteen days a dozen Englishmen or Canadians to St. Ann's, Trelawny, St. James, or Hanover as they now are, would be a great surprise to people who think of us as sweltering under tropical heat, surrounded by parched fields, and hardly able to bear up under the burdens of existence. They find themselves in a garden, driving along main roads as smooth and pleasant as any in the world, where the scars made by pickaxe or shovel are soon healed, and nature all round wears a robe of riches and most varied green, and where the forms as well as the colours of plant life are strikingly attractive and beautiful. When they thought of what they had left behind of the cold and the nakedness of the land, of the struggle in the part of thousands to keep up the fire in the "living stones" which every animal's body is, they might well think that they had come to winter in paradise. The thought would be literally correct. Some of our present visitors will, when they go home, say so, and come back often and send others.

CEYLON PLANTERS' AMERICAN TEA COMPANY.

TRANSFERENCE OF BUSINESS.

THE TRADE WITH AMERICA.

At noon of April 9th, a meeting of the Ceylon Planters' American Tea Co., Ltd. was held in the registered offices of the Company (Darloy, Butler & Co.'s) 9, Queen Street, Fort, Colombo. Mr. L. H. Kelly presided, and the others present were the Hon. J. J. Grinlinton, Messrs. V. A. Julius, A. H. Thompson, E. B. Creasy, H. Whitham, J. F. Headrick and W. W. Mitchell, by his attorney Mr. J. F. Headrick. Mr. Grinlinton had proxies from Messrs. G. Koss, Le Vallon, Pussellawa, and James Westland, Gammadua, Rattofa. After the approval of the minutes of the previous meeting,

Mr. KELLY explained that at the last general meeting it was decided by the shareholders present that the best course they could adopt was to accept the arrangement which had been made by the Hon. Mr. Grinlinton on behalf of the Ceylon Planters' American Tea Co. with the new Company in America—the Ceylon Planters' Tea Co. It was thought most advisable that they should hand over their old Company to this new Company who were prepared to undertake it. That was the feeling of the shareholders at the last meeting, and it was then left to the directors to arrange all the preliminaries. The directors had done so, and this meeting had been called to endorse their action, to declare the winding up of the old Company and hand it over to the new Company. The shareholders were perfectly well aware of the reasons which had necessitated this step, and he could only hope with his brother directors that the step which the shareholders had taken was a wise one and would not only lead to the furthering and pushing of Ceylon tea in America, but also turn out a profitable speculation for those who are interested in it. (Hear, hear.) After reading the formal resolutions which it was necessary to pass, Mr. Kelly proceeded to say that the directors this morning went through the list of defaulters and had decided to forfeit the shares of those who had not paid up. Where, however, the slightest doubt might exist in the case—for instance, of men absent from the country—the directors had arranged to give these men a certain amount of time because being absent it was just possible that the notices had not reached them. With regard to the arrangement made by Mr. Grinlinton that interest at 9 per cent should be paid up to 1st October 1890, the directors had arranged that the interest should be paid at once, and would be paid forthwith. In answer to a question he said the only difference in the name of the new Company compared with the old was that the word "American" was left out.

It was then unanimously agreed on the motion of Mr. CREASY seconded by Mr. JULIUS:—"That the Ceylon Planters' American Tea Co. Ltd. be wound up voluntarily."

Mr. THOMPSON moved and Mr. WHITHAM seconded:—"That Messrs. J. J. Grinlinton and James F. Headrick be appointed liquidators of the Company, and that their remuneration be at Rs500 each."

Mr. KELLY pointed out that the offices of the Managing Director and Agents and Secretaries would cease as soon as the Company ceased to exist, but a very large amount of work would remain to be done in the way of settling matters generally, and remuneration to the gentlemen who did it was a matter of course. They could not expect them to undertake the work of winding up the Company and all the trouble connected therewith, without giving them remuneration.

The resolution was adopted unanimously, as was also the following one, which was proposed by Mr. CREASY and seconded by Mr. THOMPSON:—“That the assets of the Ceylon Planters' American Tea Company, Ltd., be transferred by the liquidators so appointed to the Ceylon Planters' Tea Company in terms of the agreement of the 15th Sept. 1890.”

The Hon. Mr. GRINLINTON suggested that the quantity of tea sent out might be mentioned.

Mr. KELLY said that since the Ceylon Planters' American Tea Co. had been set on foot and working it was satisfactory to feel that they had been doing something at any rate towards advertising Ceylon tea in America. From the date they commenced sending out tea up to the present moment they had sent 70,146 lb.; and although that might appear a small amount for so large a Continent, it must still bear some fruit. It was quite evident that 70,146 lb. of tea sent to America must make Ceylon tea known to a very much greater extent than it was before, and they could only express the hope that it would do so. Direct information had not been received from the American Tea Co., but indirect information which he had, rather from London sources than here, was that the Company in America were extending their agencies considerably and hoped to do a very good business in Ceylon tea.

The Hon. Mr. GRINLINTON added that the figures quoted by Mr. Kelly showed only the quantity of tea that was sent direct from Ceylon and did not include the quantity sent from the London agents of the Company of which they had no record at present.

Mr. CREASY believed it was in the power of the directors to have enforced the calls on the shares that had now been forfeited.

Mr. KELLY said he would leave Mr. Julius to speak as to that.

Mr. JULIUS said that notwithstanding the forfeiture of the shares it would be seen by the articles of association that the shareholders were still liable. In section 33 it was stated—“Any shareholder whose shares have been so declared forfeited shall notwithstanding, be liable to pay, and shall forthwith pay to the Company all calls, instalments, interest and expenses owing upon or in respect of such shares at the time of the forfeiture, together with interest thereon from the time of forfeiture until payment at 9 per cent per annum; and the directors may enforce the payment thereof if they think fit.”

Mr. CREASY queried:—But the Company being now at an end they will not now be liable?

The CHAIRMAN:—Oh! yes.

Mr. CREASY:—Although the Company is now dissolved?

Mr. WHITHAM:—The liquidators have power to enforce it.

The Hon. Mr. GRINLINTON:—But would it be judicious? Might not the forfeiture of shares be absolutely sufficient punishment? He did not know any Company—and he had known a good many in Ceylon—having a case in which they sued a shareholder for the balance of his shares; they had contented themselves with the forfeiture of the shares. It was a question for their consideration, however, and as one of the liquidators he should be glad to hear their views on the subject, but if it were left to the liquidators they should try to recover as much of the money outstanding as they could recover.

Mr. CREASY remarked that much inconvenience was caused by people putting down their names and not paying up.

The Hon. Mr. GRINLINTON:—I agree with you.

It is not at all right, and I am sorry to see that so many persons who ought to have known better should do so.

Mr. KELLY did not think it would be advisable to go to extreme measures. They did not give up their powers until the meeting confirming the present meeting, so that it would still rest with them in any case where they thought it necessary or advisable to push matters to the extreme.

Acting upon the suggestion of the Hon. Mr. Grinlinton, Mr. Kelly intimated that it was intended to hold a general meeting to confirm what had been done at this meeting on Thursday, 28th May, at one o'clock, when he trusted there would be a larger number present than there was today.

This was all the business, and the meeting separated after according a vote of thanks to Mr. Kelly for presiding, on the motion of Mr. Thompson.

SALE OF FORESTLAND.

Mr. E. John sold on April 9th all that allotment of land No. 6, at one time forming part of Mooloyakelle estate in Upper Heyaheta, in extent 180½ acres, of which 27 are planted with tea, for Rs12,100 to Mr. J.G. Wardrop who bought on account of Mr. R. J. d'Esterre who owns the adjoining property.

CROWN FOREST AND CHENA LAND FOR SALE.

Some 17 lots from 17 to 186 acres each in Bambarabotuwa division of the Province of Sabaragamuwa are to be sold early in June. Full particulars will no doubt be advertised in good time; and as tea land is so much in demand, an advertisement with details should appear in our “Overland” papers for home capitalists to see.

LIBERIAN COFFEE CULTIVATION IN THE STRAITS.

The English mail of April 14th, brought us a letter from Mr. Thos. H. Hill, formerly well known as a Malacca planter, and a careful experimentalist with new products at a time when coffee *Arabica* was still all the rage in Ceylon. Mr. Hill had long promised to give us the results of his experience as a planter in the Malayan peninsula, and the letter which will be found in our *Tropical Agriculturist* (on page 805) is, he says, the fulfilment of this promise. He sent his manuscript however, first to the *Singapore Free Press*, so being enabled to send us a proof copy. Perhaps the most interesting portion of Mr. Hill's compilation, in the estimation of practical planters, will be the figures showing the actual crops of coffee gathered for a series of years off separate fields at different ages of several Liberian estates. Curiously enough we were able to lay this return before our readers (see page 789) and to comment upon it some days ago, through its publication first in the Madras press. Possibly Mr. Hill had supplied a copy of his statistics to some Anglo-Indian visitor, and indeed the results are so good in average returns of from 7 to 11 cwt. of coffee per acre that Mr. Hill may well be ready to proclaim them from the house tops. With such figures before them intending coffee planters and investors will read with special interest Mr. Hill's remarks under the various headings of nurseries and selection of seed, of soil, climate, &c. There can be no doubt of the encouragement offered, nor of the fact that

the different Straits authorities (central and local) profiting by the past history of Ceylon, are most anxious to encourage and aid as far as possible, *bona fide* planters and capitalists in taking up land for Liberian or Arabian coffee and allied products. Mr. Hill does not say so much in respect of labour supply as we should like; but a curious statement is appended without comment, with the chief heading "Labour," entitled "Return showing the total expenditure on Public Works in the Colony and the Native States" during the ten years 1880 to 1889 inclusive. We do not publish this table, but it shows a very large expenditure indeed, the total (for Singapore, Penang and Malacca, under 'Colonial Government' and 'Municipalities' and for the native States of Perak, Selangor, Sungei Ujong, Negri Sembilan and Pahang,) rising from 659,433 dollars in 1880 to no less than 3,483,743 dollars in 1889. Turning these into rupees, we get an expenditure of about 7½ millions of rupees on Public Works in one year which is very large indeed. We suppose a great part of it must be out of loans, rather than current revenue, and for railway extensions?

But now what object can Mr. T. H. Hill have in appending such a tabular statement to his planting letter and heading it "Labour?" Does he want to show that the States include a very large labour force accustomed to public works and who are likely to help the planters as the Governments slack off in their requirements, or is his object to show how well the country is being opened by roads, bridges, railways, &c. Anyhow, there can be no question that the Malayan peninsula under enlightened administration is being rapidly developed and that there is much encouragement to capitalists interested in coffee and other tropical products, to look to that quarter for investments.

THE POSITION OF TEA.

Discussing the outlook in tea from the wholesale and retail dealers' point of view, the *Grocer* says:—"The general statistical position of this article remains very strong, and the only element of weakness in it is the refusal of the trade to go on buying as freely as they did when prices were 1d to 1½d per lb lower than they are now. Many dealers and others, having well supplied themselves with available stocks, can afford to await the development of events, and while they keep out of the market as leaders of speculative operations the upward movement in quotations is likely to receive some check. The pauses that have occurred at one time and another since the big rise that was established about a month ago, have exercised a wholesome influence on the market, in preventing it from acquiring too confident an attitude, and in restraining both speculators and the more sanguine, not to say reckless, portion of the trade from carrying their ideas of value beyond reasonable limits. Although a material advance in the value of tea has ensued since October last, it must be remembered that it took place on prices which had been at an unprecedentedly low level, at least as far as China descriptions were concerned, and a seasonable rally in prices is not calculated to do much, if any, harm but rather the contrary; as to allow an important article of consumption to become too depreciated for either growers or capitalists to take a lively interest in it is to hinder production and prepare the way for still greater scarcity than may actually exist; whereas to urge in a legitimate manner the trade and consumers to pay a trifle more money as a gentle stimulus to turning out increased supplies is to insure future abundance and guard against the sudden alarms and surprises that grow out of real or imaginary deficiencies long before they are fully realised.

Viewed collectively and in their broadest light, and taking one kind with another, the clearances of tea in

London since January 1st show a decided increase over those in the two previous years, while the stock, owing principally to the serious deficit in China makes, was about 18,000,000 lb. less than in 1889, and nearly 15,000,000 lb. below that in 1888, so that, with much more moderate estimates of the Indian crop for 1890-91 than originally formed, the immediate outlook for those whose purchases are dependent on easier prices being established soon is not of a very promising nature.—*H. & C. Mail.*

CEYLON PRODUCTS: PRICES AND PROSPECTS.

An experienced Ceylon planter who travels a good deal, writes:—

"Certainly *Tea* is coming to the front. Tea planters made a mistake in estimating results from young tea too highly, but I believe they have underestimated the yields of tea after it reaches 6 years.

"*Cocoa* under good shade looks now as if it would have a more extended area of growth than we were inclined to estimate up till now. Since my return I have seen very excellent results on what seemed two years ago barren cocoa by the successful planting of good shade.

"*Prices of coffee* I fear must go down 15s to 21 in value if we are to judge by the clearing-house returns for prospective deliveries. (See Rucker & Benckert's Coffee Circular of the 19th March.)

"The favourable rates of *Exchange* enable us to meet lower prices which must prevail now that Ceylon *Tea* export in 1891 is to be so far ahead of 1890's. India will probably do better than last year, and China tea-men will make an expiring effort this season, the last flicker of the lamp!"

RICHNESS OF LOUISIANA SUGARCANE.

(From the Hills.)

In the *Louisiana Planter and Sugar Manufacturer* of March 7th, published at New Orleans, there is no allusion to the lynching case, but our attention has been arrested by an article on the results obtained by the Caffery Central Sugar Factory in 1890-91. Every possible chemical detail is given, but the general results showing the richness of the canes in saccharine matter must suffice, thus:—

Cane ground, tons, 32,189; pounds, 64,360,000. Sucrose, per cent. of cane, 12.01. Sucrose, per ton of cane, pounds, 240.2. Total sucrose in cane ground, 7,729,636 pounds. Fiber, per cent. of cane, 11.02. Juice per cent. of cane, 88.98. Juice extracted, gallons, 5,433,881; pounds, 48,61,540. Juice extracted, per cent. of cane, 75.14. Per cent. sucrose in raw juice, 13.50. Total sugar extracted, 6,523,808.

Total commercial sugar made and estimated, 6,142,800 pounds; total commercial sugar per ton of cane, 190.88 pounds; sugar made from outside syrups, 650,000 pounds; total sugar made, 6,792,800 pounds.

RESULTS.

	Per cent. of cane.
First sugar of 100 polarization	6.80
Second sugar of 100 polarization	1.74
Sugar in third masse cuite	1.25
Sugar lost in bagasse	1.86
Mechanical loss and by inversion	0.34
Loss not accounted for	0.02

Sugar, per cent. of cane 12.01

It would thus seem that the sugar in the canes was equal to 12 per cent, against 10 to 11 in Queensland and only 8 in Ceylon; but the loss having been 2 per cent, the final result in sugar was 10 per cent of the weight of the canes, about as good a result as can be expected. We suppose. "Except in Peru," we ought to add, if dependence can be placed on the figures given in an article on "The Varying Saccharine Content in Tropical

Cane." From this article I quote as follows:—

Past experience and observation has taught that canes planted in virgin soil after the removal of the forest growth yield an abundant tonnage, with a low saccharine content as compared to those planted in land which has long been under cultivation. Climatic and other conditions cause a variation in saccharine strength in the juice of the cane from about 5 per cent. to as high as 22 per cent., which has been noted in Peru. According to M. Maumené (page 80, vol. 2), the percentage in the beet ranges from 3 to 18, and it is with the beet as with the cane, a heavy tonnage and a high saccharine content are incompatible. The quality of the soil is an important factor in the cultivation of the cane and beet, as it is admitted by high authority (M. Maumené) that "the chemical nature of the soil is entirely secondary; it is above all the physical texture and the corresponding absorptive powers which are of great advantage."

Excessive tonnage is produced by an undue amount of nitrogen or ammonia in the soil, and such must be carefully avoided whatever its source. The amount of ammonia in the annual rainfall varies much according to locality. Sir J. B. Lawes, of Rothamsted, England, found almost exactly one part in a million of rain, M. Boussingault in Alsace found $\frac{2}{3}$ of that amount, and M. Barral nearly $3\frac{1}{2}$ parts in a million of rain water of Paris, France. This source of supply is inadequate for full plant development as proved by analysis, and from whence the balance is derived by the cereals remains for science to divulge, yet the microbes which are supposed to supply the nitrogen in the growth of leguminous plants may in a lesser degree promote that of the grasses. In the production of grain it has been found that it takes over five pounds of ammonia to produce a bushel of wheat, and its equivalent of straw. Such valuable data to the farmer is had by direct field experiments, and it behoves those largely interested in the production of sugar to inform themselves as to what quantity of ammonia is required to produce a ton of cane, and the amount which can be used per acre, and not decrease the subtle element, saccharine, contained therein. The importance of field experiments cannot be too highly esteemed where it becomes almost imperative to produce maximum yields at minimum cost for field manipulations and manufacture.

So high a percentage of sugar as 18 in beets is probably due to free applications of nitrates. But beets seem in danger of destruction by a nematoid worm, as shown in an article from which the following is quoted:—

Mr. George Dureau, editor of the *Journal des Fabricants des Sucres*, has favored THE PLANTER with a copy of his recent pamphlet on the nematode or worm that has been found to be the chief cause of the seeming deterioration of the sugar beet in France and Germany. This worm penetrates into the beet roots, lives on their juice, accomplishes its metamorphoses there and multiplies with such frightful rapidity as to promise to render beet culture ruinous and finally impossible. For a long while the existence of these parasites was unknown, and it now promises to injure beet culture as the phylloxera has the culture of the vine. It was thought in Germany, that the reduced yield of beets was caused by the impoverishment of the soil from the too frequent planting of beets in it, and they designated this phenomenon as *fatigue betteraviere*, or *beet sick*, if we may utilize the analogy of clover sick, a phrase frequently applied in this country to clover lands similarly affected.

A careful study of these phenomena, made by a distinguished German Professor Julius Kuehn, has established the fact that there is no real exhaustion of the soil, and that the beet crops were reduced by the presence of numerous worms in the small, fibrous roots of the beet, and that, their destruction accomplished, the fields resumed their former fertility and gave as abundant yields as ever before.

The presence of the serch in the sugar cane of Java, and of the nematode in the beets of Europe, show how insect or fungoid life is struggling against these two great crops, and here in Louisiana we are

sometimes led to think that we may have exceptional advantages for the production of sugar from tropical cane from the fact that our cold winters destroy so many of those insect enemies that do immense harm in the tropics.

WHAT QUININE REQUIRES

is a Becham or a Squash, who will take it by the hand and lead it forth disguised as the latest elixir of life, who will blare forth its all-curing properties with brazen impudence and trumpets of brass, who will preach it forth as the only perfect panacea on mountain-side, on city-walls, in books, in papers, in all countries, and in all tongues. This has been done to a very large extent in the United States, with the consequence that half the world's supply is consumed there, although fever is not more prevalent than in Europe, nor nearly as much so as in Asia or Africa. Until the drug is well advertised, it will be driven out of the field by patent medicines, not one quarter as beneficial. It must be advertised, but in the meantime we again urge on Government to do all that lies in its power—and it can do great deal with the help of its hospitals, its vaccinators and the headmen of the villagers—to make this drug popular throughout the Peninsula—*Madras Times*.

TEA-MAKING EXTRAORDINARY.

Mariawatte tea fields with their steady average of 1,000 to 1,100 lb. of made tea per annum for several years, have accustomed us to great things in Ceylon and we hear occasionally of fabulous quantities of green leaf being plucked per cooly. We have also the case of the Ruanwella estate that made 300 lb. of tea per acre in one month over a twelve acres field; and we have heard of a well-known Kelani Valley plantation which has given over 7,000 lb. made tea per week for as many as 16 weeks together at a time. But the news we have just heard of Bandarapola, Matale—in rather dry situation—seems to put all these in the shade, for Mr. Fraser has taken in leaf equal to 10,300 lb. of made tea in one week or at the rate of 35 lb. per acre. Well done lower Matale! We are reminded that long ago it was prophesied by a practical, disinterested planter that the long valley (or as Highlanders would call it "Strath") or rather succession of valleys from Matale up to Ukuwella on to Watagama and why not on to Kandy, to Peradeniya, to Gampola and Nawalapitiya, would include about the richest tea growing land in the country.

As for total outturn and crops for the island, the prophecy made by the same planter some years ago of 100 million lb. for Ceylon's exports is not unlikely of realization. He would be a bold man in fact who would say that we cannot beat India in six to seven years' time, provided there is due encouragement to extend, continue and keep up cultivation.

BURMA RUBY MINES.—It has always been a matter for wonderment that the Burma Ruby Mine shares have been freely sold at a discount, when it is considered with what great *eclat* the Company was formed, the unique concession it possesses, and the powerful house under whose auspices it first saw light. The demand for the shares has been rather pronounced lately, on receipt of news from Burma decidedly encouraging to the Company, and we cannot but think that the shareholders who hang on will reap a good reward for their pains and patience.—*Colonies and India*.

THE PACKET TEA TRADE.

As Messrs. Horniman and Co. claim to be the founders of the packet tea trade, their experience as recorded by a representative of *Trade*, will doubtless be of some interest. This firm in the good old days used to make a point of advertising "the leaf uncoloured;" but their more recent transactions in India and Ceylon has altered all that.

"How long is it," asked the representative, "since your firm adopted the system of selling tea in packets?"

"Ever since the year 1826," said Mr. Horniman. "It was the founder of our firm who originated the system. His idea was that if tea were put up into air-tight tin-foil packages its fragrance would be preserved, and it would be possible to place before the consumer a tea which should be of uniform quality. How often does the average purchaser make the complaint that 'this tea is not so good as the last?' By the packet system it was sought to avoid any possibility of such disagreeable comparisons, and to make it easy for the purchaser to obtain an article which would vary neither in fragrance, strength, or price. In short, the aim was to present a tea which should be 'always good alike.'"

"That phrase seems to have passed into something like a proverb?"

"Yes," said Mr. Horniman; "and, what is more, we claim to have acted up to it. If you know anything about the tea trade you will be aware that it was in 1833 that it was thrown open. At that time importers commenced to introduce tea which was artificially coloured, the object, of course, being to pass off inferior leaves. There were two objections to this course, the first being that the colouring matter was more or less injurious to the tea drinker, and the second that a deception made from inferior leaves was sure to be wanting in delicacy and fragrance. We refused to adopt this method, and insisted upon importing a pure uncoloured tea of good quality. Of course, our teas got a name and their reputation, despite the competition of these latter days, is more than maintained."

"Whence do you chiefly procure your supplies?"

"For many years, of course, we had to rely upon China tea alone, for it was not till 1850 that tea was produced in Assam. The very first importation from that province was consigned to us, and since that date we have always been able to secure the best spring growths from the finest of the Indian gardens. Ceylon, as you know, has recently produced some admirable teas, and we now import a considerable quantity of them. You see we devote ourselves exclusively to tea, and as we purchase upon a very large scale direct from Ceylon, India, and China, we are not only able to secure the best tea, but to avoid those extra charges which must be paid if you do your business through middlemen."

"That, no doubt, is the secret of a good many successful firms nowadays?"

"I suppose it is. It is certainly our own. We buy direct and we sell direct. We buy for cash and we sell for cash. The rule of the tea trade is to give three months' credit. We pay cash, and we take five per cent. That, upon a very large turnover, is a profit in itself. You will, perhaps, hardly imagine that we do our own printing. It may seem odd that tea merchants should be printers, but it must be obvious to you that by cutting our expenses down to the lowest point we are in a position to offer to the public tea of a quality which no one else could afford to let them have at the price."

"How did the recent reduction in the tea duty affect you?"

"We were enabled," said Mr. Horniman, "not only to give the public the benefit of the 2d per lb. which was taken off by Mr. Go-chen, but to reduce our prices by still another 2d, without interfering with the quality of the tea article which we offered. This is only in accordance with the principle which the firm has pursued for the last sixty-five years in giving the public the best possible tea at the least possible price."

It is upon that principle that our business has been built, and it would be obviously unwise for us to depart from it."

"Your packet teas have had many imitators?"

"Yes," was the reply, "and some of them have been anything but scrupulous. Our packets, our labels and our titles have been imitated, so much so in fact that it is well for the public to be on their guard. The old advice, that when you ask for an article you should see that you get it, certainly holds good in this case. Perhaps it is not surprising that this imitation has taken place for our labels have become almost universally known. Some twenty years ago and more a considerable enquiry for our teas arose throughout Europe and South America, and to meet the demand our labels were translated into French, German, Italian, Spanish, Dutch, and Russian. Our success in foreign countries led unscrupulous competitors to copy not only our system of packing, but to imitate our trade marks and our titles. There is, however, a very easy method of finding out whether you have the real article or not, and that is by making an examination of the tea itself. Our teas consist exclusively of young and tender leaves, and they are therefore smaller than the large aftergrowth leaf which so largely constitutes inferior qualities."

"Your faith in the packet system, is, I suppose, as firm as ever."

"Yes," was the emphatic reply; "though I cannot shut my eyes to the fact that this system which we introduced has been grossly abused. There are those who find it necessary, in order to effect the sale of their tea, to offer the buyer a teasing-fork or a looking-glass after they have taken so many half-pound or pound packets. We have never found it necessary to resort to any such dodges in order to find a market. I rather think that by this time the public is beginning to open its eyes to the fact that the method I have referred to is a very dear way of purchasing tea. They now recognise that to expect good tea, when the seller has to give them a present of some considerable value in order to induce them to purchase it, is to expect a good deal too much."—*H. and C. Mail.*

COFFEE IN PERU.—The following paragraph among others shows the encouragement to the London Syndicate which is despatching Ceylon planters and other experts to report on land for coffee in Peru in the trans-Andean districts:—

No better coffee is produced in the world than in Peru, more especially that raised at Chanchamayo, in the department of Junin, and in the Province of Carabaya, in the department of Puno. The production amply suffices for the internal consumption, notwithstanding that the latter has much increased during the last few years.

"QUININE AND JAVA CINCHONA."—There is very little of consolation to Ceylon cinchona planters, or to London holders of quinine, in the article under the above heading on page 789. Java's supply of bark is by no means dwindling away—it is rather increasing and although she supplied the equivalent in bark for half the quinine consumption of the world in 1890, she is expected in 1891 to give enough for 4-7ths of the consumption—in other words she is to export about 7½ million lbs. of manufacturers' bark averaging 4-07 per cent sulphate of quinine! There will only be 3-7ths of the total consumption required in bark from Ceylon, India and South America. The only point open to criticism in this article that we can see, is the want of allowance for an increase in consumption. We cannot understand why with quinine at its cheapest—less than 2s per ounce—there should not spring up a demand for so valuable a tonic in new directions; while we feel sure that much larger quantities might be absorbed in Russia, Southern Europe and Africa, if only the cheap quinine were made freely available.

"CEYLON AND ITS GEMS."

(Communicated)

The writer of the article in the *Times of India* (see page 792) is rather out as regards the Gemming Ordinance, which is even worse than he makes it out. Previous to the present ordinance being passed, there were Government regulations for mining for Gold and Gems, and orders to gem on Government land could be obtained on the payment of ten rupees per annum, but no prospecting licenses could be issued. On the other hand Government would grant a prospecting license for gold on Crown lands on the payment of ten rupees, and the area over which the license might extend could not exceed half a square mile while it remained in force for six months.

The grantee had the exclusive right of prospecting within that area for that period and had the option at the expiration thereof of applying for a regular lease of not more than 50 acres within the said area on the terms that the minimum breadth of any lot was to be 70 yards, and the period a term not exceeding 20 years, at the expiration of which the lease was renewable at the lessee's option on such terms as the Governor and Executive Council might fix.

These good regulations have all been repealed, and in their place an ordinance has been passed for gemming on private lands only, and there is nothing said in this ordinance about working for gems or gold in Crown lands; so that if any person wishes to gem or prospect for gold he will have to make a special application to the Government Agent. A more ridiculous and pernicious ordinance has seldom been passed by the Ceylon Legislature. It is a pity that our Government servants should think themselves omniscient, for to this failing may be attributed the many ill-digested ordinances which are constantly being passed and found unworkable in their original form.

As regards your remarks in Tuesday night's issue, I think your estimate of the value of the gems found in Ceylon much nearer the mark than that of the "Roving Correspondent" of the *Times of India*. He also seems to think that the "European speculators" may find gem mining unremunerative; but if this is so, I think it will be due to the "poor native" appropriating the best stones and receiving regular wages besides. Under such favourable circumstances the paucity of "European speculators" is all the native has to complain of; but the "European speculator" may well grumble when he finds his attempts at developing an industry baulked by those who should be the first to help him. Gem digging as practised by the natives encourages them in idleness, gambling and all kinds of vice; but as practised by capitalists it means regular work and wages for the miners without the unnatural excitement which follows such pursuits; that is, of course, provided a plan to prevent staling could be devised.

DISEASES OF PLANTS.*

After a few introductory observations on Phytopathology in its general aspect, the lecturer proceeded to discuss the questions relating to Parasitic Fungi in their connection with Plant diseases:—

The plant diseases caused by the presence of parasitic fungi are almost entirely local diseases; it is quite exceptional to find a plant constitutionally affected. True it is, that in many cases, especially with cultivated plants, the local disease is either so

extensively distributed upon the host, or, more frequently, that the lesions are so numerous, that the host plant is killed by the parasite; but anything analogous to those human diseases, in which an entrance having once been effected by a microbe, the whole organism becomes permeated by disease, as in the case of febrile disorders, is practically almost unknown in plants.

Neither do we find that heredity plays nearly so important a part in the etiology of fungoid plant disease as it does in the animal kingdom. There are instances, and important ones, too, in which something akin to heredity comes into play. Certain varieties of Wheat are more liable to suffer from the attacks of mildew than others; certain varieties of Apple are more liable to canker than others; but these are more instances of the constitutional peculiarity of a variety than true heredity. A better illustration is, perhaps, afforded by the Potato, some sorts of which seem to be hereditarily disposed to take the disease more easily than others; while, on the other hand, certain sorts seem to have the power of resisting it better, inasmuch as their foliage longer withstands the attacks of the *Phytophthora*.

Just as we observe that certain epidemics affecting the human race, when first introduced into a community, assume great virulence, and spread with great rapidity; after a time, the type becomes less severe, and although the cases are not less numerous, yet the disease, we say, wears itself out. The outbreaks of cholera which have occurred during the present century, afford an apt illustration. The introduction of measles into Iceland, and into the Faroe, and the Fiji Archipelagoes took place in recent times. Like smallpox and syphilis, it was much more severe and fatal when thus imported into virgin soil (Fagge).

In like manner, we find that many epidemics of fungoid plant disease, which at their beginning are marked by extreme virulence, after a time change in type, and become less and less severe. The outbreak of the Potato disease in 1845 is an illustration, and although the disease is still present only too severely amongst our Potato crop, yet we have never had so severe a visitation as occurred in the above-mentioned year. More recently, the Hollyhock disease has afforded us a parallel case. The fungus, *Puccinia malvacearum*, which causes this disease, was unknown in Europe prior to 1869, in which year it was observed in Arragon, in Spain. In 1872 it was noticed in the Department of Marne, in France; in the following year (1873), it had extended over France into England, devastating not only the Hollyhocks, but attacking also the indigenous Malvaceae. For several years, so virulent was it, that the Hollyhock practically disappeared from our gardens. The fungus is still present with us, and can be found upon almost any of the common Mallows; but it has lost, to a great extent, the extreme virulence which characterised its first outbreak. Our indigenous Mallows remain with us, and the Hollyhock is beginning to re-appear in our gardens. A very similar case is that of the Celery disease. Some years ago *Puccinia Apii* appeared on cultivated Celery, and threatened to become as serious an affection as the Hollyhock disease subsequently proved. It spread very widely in Great Britain, and greatly alarmed horticulturists; but it soon spent itself, and although the *Puccinia* is common enough on our wild Celery plants now, yet we rarely meet with it in our gardens.—*Gardeners' Chronicle*.

IMPROVED TEA MACHINERY:

JACKSON'S PATENTS:—NEW DRYING AND WITHERING MACHINES.

INFRINGEMENTS OF PATENTS: MORE WORK FOR THE LAWYERS.

Mr. Jackson of Aberdeen, the now famous Tea Machinist and Engineer, was, as we announced, a passenger by the S. S. "Massilia" and the Colombo lawyers will, at least, welcome his advent. For, it would be scarcely necessary for Mr. Jackson to have left the superintendence of his Experimental Workshops at home, save for "legal" business which specially called for his personal presence in Colombo.

* A course of lectures delivered before the Royal College of Surgeons by Professor Plowright, M. D., in February, 1891.

The infringements of his patents which Mr. Jackson considers he can prove before law courts this time—no notice having been taken of business remonstrances—concern two rollers, the one prepared and patented by Mr. John Brown of the Uva Companies, &c., and of which about a hundred are supposed to be at work in Ceylon Tea Districts, and the other, the Tea Roller known as "Law & Davidson's."

But having to come out to consult and direct the lawyers, Mr. Jackson has some interesting new machines which he intends while here to bring before the Ceylon planters. We refer first to his new "Britannia" Tea Dryer which offers great improvements on the "Victoria" dryer, more especially in the tea being fed below and the machine doing all the rest of the work for itself. There is a down-draft connected with it. Three sizes of machines to dry 1, 2 and 3 maunds of tea per day are made, costing about £100, £200 and £300 sterling each. The first of these Dryers—one of the largest size—is about to be erected on Labukella Estate, Ramboda Pass, while others are on the way out. The "Britannia" looks a thoroughly substantial, workmanlike machine strongly made as indeed are all Mr. Jackson's machines, and the patentee is confident of it giving satisfaction.

Perhaps a machine of more general interest is the new patent Witherer which Mr. Jackson is bringing out. This, he is also confident, will prove a practical success. It is not generally known that Mr. Jackson keeps up an Establishment in Aberdeen solely for the purpose of endeavouring to devise and apply improvements to Tea preparing Machinery. Besides Mr. Dalgarno, there is a staff of eight Assistants and Mr. Jackson (like Mr. Edison of inventive fame) has to be the presiding genius. An interesting fact mentioned to us by Mr. Jackson as showing the rapid advance of Ceylon in comparison with India, is that the colony required about as many rollers as India last year, while for 1891, the demand is likely to be a good deal larger for our little island, than for the big continent opposite.

THE JAMAICA EXHIBITION: THE THE POTTER AT WORK.

In obtaining the services of a first-class English Potter the Commissioners of the Exhibition were performing a great service to Jamaica, and contributing to the real objects of the undertaking. The island possesses clay in vast quantities, the capabilities of which have never been thoroughly tested, and it was a happy thought to import a skilled potter, both to test the clay and to show how best it could be practically utilised. The potter is now stationed in the Exhibition, and to witness him at his work alone is worth double the amount of entrance money to the ground.

[The above, from the *Jamaica Gleaner*, shows what might be done if we had a Ceylon Exhibition. We have abundance of fire porcelain and terracotta clays in our island, which could be probably utilized if a skilled English artisan were imported to show the way.—ED. T. A.]

"THE CINCHONA MARKET"—writes an up-country planter—"is deplorable. It is the longest lane without a turning that I have ever had to do with—and I'm beginning to regard bark with well merited contempt. I don't know if that will bring it to any kind of sense of the rightness of things, and what is due to growers?"

CEYLON TEA SELLING AT £10 12s. 6d. PER LB.—Where is this sort of thing to end? If only a certain number of Ceylon estate proprietors instruct their managers to compete with "golden tips" for the sake of the advertisement, Reuter will yet have a good many messages to send us about select parcels of Ceylon tea getting unprecedented prices in Mincing Lane. Meantime all this helps to bring Ceylon tea into everybody's mouth!—and we should be the last to complain. On the contrary we have to congratulate Mr. T. C. Anderson of Garmore estate, Maskeliya, on topping the market and "taking the cake" even from Gallebodde. How long will Mr. Anderson be allowed to remain champion?

SEA-WEED AND COCONUTS.—The seashore between Colombo and Mt. Lavinia—and indeed much farther down the coast—is, at this season, strewn with large quantities of sea-weed washed ashore. This has been the case for many weeks back, and yet only in very few cases so far as we know, has any attempt been made to collect this useful manure and apply it to the neighbouring coconut palms. The apathy of the villagers in this respect is very striking. There can be no doubt that a very little exertion in digging round the roots of their trees, and applying rubbish, sea-weed, &c., (that would be much better in every way if buried), would increase their crops of nuts very materially; yet, with the fewest possible exceptions this is never thought of, and absolutely nothing in the shape of cultivation is attempted.

TEA UPCOUNTRY.—It is quite cheering to note the universal good report of tea from one end of the hill-districts to the other, and of its flourishing so famously even on old coffee estates. For instance, in Hantane, take the upland valley above Kandy, with Oodowelle—opened over 50 years ago,—Oorogalla, Horogalla and Ingrogalla, all giving good tea and promising well. Oorogalla with 280 acres of tea is quite a model of what a well-cultivated old coffee plantation may be expected to do in tea. But the same is true of many of the old Elkaduwa and Matala places, while rivals to Mariawatte are to be seen around Ukuwala; and on the road North of Matala, some of the finest tea in the island is to be seen. Whose is the small field of tea on the roadside near Nalanda, many miles out? It is neglected and all weedy, but the tea is resolved that no other jungle shall have lodgment and is forming a jungle of its own; for as an old Kandyan Arachchi said in the early days of tea "It is a jungle plant and not like coffee at all."

LINNEAN SOCIETY.—At the meeting held on February 5, Prof. Stewart, President, in the Chair. Messrs. Richard Bentley and E. S. Goodrich were admitted; and Messrs. T. F. Bourdillon, C. T. Keane, and A. M. Marshall were elected Fellows of the Society. Mr. Clement Reid exhibited and described some recent additions to the fossil arctic flora of Britain. Mr. Thomas Christy exhibited and made remarks on some specimens of honey: (1), "Arbutus honey" from Turkey, said to produce great drowsiness and sleep; (2), "Eucalyptus honey" from Mount Barker, Adelaide, said to possess valuable therapeutic properties; and (3), so-called "wool honey" from the Euphrates, collected by natives from the leaves of the Oak, and which would be more properly termed "honey-dew," being formed by aphides, and not by bees. On behalf of Mr. Gammie of Sikim, Mr. C. B. Clarke gave an abstract of an interesting paper on "The Tree Ferns of Sikim," in which several moot points were discussed, and difficulties cleared up. At an evening meeting to be held on February 19, 1891, at 8 p.m., the following papers of horticultural interest will be read:—"The Dillenian Herbarium," by G. C. Druce, F.L.S.; and "Some points in the life-history and Rate of Growth in Yew Trees," by Dr. John Lowe, F.L.S.—*Gardeners' Chronicle*.

Correspondence.

To the Editor.

PLANTING IN THE NATIVE ESTATES, OF
THE STRAITS SETTLEMENTS.

To the Editor "Ceylon Observer."

DEAR SIR,—In forwarding you the crop returns of our estates perhaps a few words on the subject may not prove unwelcome.

In 1878, when I was leaving Ceylon, I promised to send to a personal friend a treatise on the rotation of manures, a subject which had occupied much of my attention in connection with the estates of which I was manager in Ceylon.

I finally came to the conclusion in Ceylon that we had started too late, at any rate on most estates, and for estates to become more permanently productive it would be necessary to do more to cultivate the land, and that trees should be younger at the time of commencement to give the cultivator satisfactory returns. The hard life of a pioneer is not calculated to foster writing in any form and therefore my promise was never fulfilled, and as time has gone on and I have gradually been developing what might have been called theories into practice, I have felt less and less inclination to write until I could, as I can now, refer to actual results. I think that the measure of success so far attained will gradually be developed to an even greater extent.

ESTATE NURSERIES.—I will commence with the nurseries of an Estate. These have always been made from seed from carefully selected trees in the youngest planted clearings in some instances, and in others from the older coffee. But recently marking the great improvement in the form of all the last planted clearings in having their primaries quite close to the ground, I have decided only to plant the cherry from the selected trees of the youngest clearings. The seed having been gathered, is pulped by hand, and any small parchment and malformed beans rejected. The seeds are then laid on raised platforms with earth, ashes, etc., to germinate, and as they germinate they are carefully put into the beds in the nurseries, where they are kept constantly top dressed with burnt earth, ashes and lime, if available. In one of the last nurseries out of 16,752 germinated seed 16,750 were put out into the field. I am inclining more to again bring selection into play, by planting my nurseries 8 in. apart and only putting out the selected plants, which it is my intention in future only to put out after they are showing primaries. The clearings, having been planted with selected plants, from selected seed, from selected trees, are only treated in the ordinary way, except that should a plant show signs of weakness in any respects, it is either at once taken out and destroyed or another plant is put alongside it, and when the time comes the selection made as to which is to have its life granted. The youngest clearings are being topped at 5 ft. 6 in. having ample primaries they are planted 9 ft. by 10 ft. but I am inclined to think I shall probably feel my way back to 12 ft. by 12 ft. and putting out much larger plants than I have hitherto done. Stumps come on splendidly, but I have the greatest objection to that little piece of dead wood that you can generally find in a plant, however vigorous, if it is cut across just above the place of junction between the bud and the top of the stump. Even when they are old trees you can find this. From this until the 4th or 5th year the plants receive ordinary care and attention, except that they are pruned every 6 weeks, or at longest two months. From the fifth year at latest commences the cultivation of the land. You will remark I do not say manuring the tree, although at first it really amounts to that.

For the first year I have used oil cakes of various kinds, ashes and bones mixed with as much earth as possible. In my opinion too quantity of earth with which a fertilizer should be mixed cannot be too great

although it is an advantage to put ashes (the potash being so heavy and sinking so rapidly) on the mixed earth. For the second year I use much the same mixture, with the addition of burnt earth, but differently applied.

For the third year, according to the nature of the soil, I either mulch with balang (*Arundinacea Imperata*) Ellock it is called in Ceylon; or else lime the land with quick-lime, about 40 pikuls to the acre, a pikul being 133 lbs. It would depend upon the nature of the soil, and transport facilities which I should have done first.

This is as far as I have got at present, but the fifth course of the rotation would include digging over the land and turning the weeds in.

I should mention that weeds are allowed to grow sometimes for 3 months on end, after the 4th year, and they have been allowed to grow for as long as 6 months, and then cleaned up and kept clean by weeding, once in 3 weeks, for 6 months on end. I am entirely opposed to an estate being always clean after its fourth year, although I would keep the clearings clean, there being sufficient humus on the soil to absorb the rain and fix the phosphoric acid contained in the rain water.

I will now proceed to give you a few remarks on Climate, which we can only change for the worse willfully; Land, which it is in our hands to improve; and Labour, which with the aid of the Government could be put upon a satisfactory basis.

CLIMATE.—In 1879 I referred to the climate as being near perfect for the growth of Liberian Coffee, and I think that the results may be said to bear out that view, that is to say, the present climate; but if or when the climate is changed by the denudation of forest over large areas we shall probably see that our coffee will fail in the same way that it has in many other places. With this experience to look back on, I submit it would be well worth while the Government considering how this is to be prevented, more especially as they derive an income from export duty and rent on the land. At this stage of the development of the country it would be an easy matter to prevent that loss of moisture in the atmosphere and to prevent any radical changes in the climate. The amount of moisture contained in the atmosphere, the heavy dews and morning mists lying over the trees, often until 8 o'clock in the morning, are some of the most important factors in the successful growing of large crops of coffee per acre. Whilst they exist, with care and cultivation we may look for equally good if not better crops than those the statement I forward you shew. When these mists and dews have disappeared by reason of the forest being extensively felled, we may look for our crops to fall off, as they have elsewhere. This certainly will be remembered by some of the old planters of Ceylon.

How then is it to be prevented? By the Government reserving the right in the public interest to control the felling of the trees. Thus A wishes to plant an Estate of 300 acres, the Government sell him 1,000 or they sell him 300 as he wishes, and retain the 700. When his 300 acres have been planted and perhaps part of it worked out, he applies for part of the 700 acres which should be granted to him acre per acre for his land, that is for the time worked out. That is planted with an agreed number of forest in fruit trees per acre that are visible and subject to verification. But 23 years' observation of tropical cultivation leads me to believe that perennial cultivation, to be successful, is a system of long crops and long fallows, which the system I advocate admits on although I fear the desire of those in charge of new countries to increase the revenue at the cost of the capital of the country, which is as much in its climate, as its soil, and its minerals, may not procure for these views the consideration that the results of cultivation in similar tropical climates would lead one to expect and hope for.

I am well aware that for one or two years the dryer atmosphere will produce even more blossom and sometimes even crop, but the trees will not stand up to it crop or recuperate so quickly.

LABOUR.—This all-important item to the planter might easily and quickly be put upon a satisfactory basis for those who did not object to paying their coolies well. At present labour is not altogether satisfactory but the reason is not far to seek, as you will see from the attached table of amount spent on Public Works and Municipalities during the past 10 years. But when I tell you that neither the Municipalities or the Governments have any fixed staff of labour and that their attempts to import immigrants would not exceed 500 men during those ten years you will see how serious the position is. By the right of the longer purse they can always attract any labour from the estates, so that some planters against their will are compelled to work with indentured immigrants. With two exceptions that I know of, amounting to about 1,800 men, I am under the impression that the labour imported by Government contractors would not exceed 100 men in any one year. I may tell you that very little work is done departmentally, and what is done departmentally the labour is derived from the same sources in the same manner, the so-called open market—that being any coolies that can be obtained locally. Under these circumstances, which I trust the report of the Labour Commission may in some way alleviate, you can recognise that we are driven to employ indentured immigrants against our will, costing on the estate, with which I am connected about \$27 each; of this I may recover possibly \$9, but with runaways, incompetents, sickness and deaths it probably does not exceed an average of \$6. Some of the officials say, "What harm do we do? You get a man on agreement and when it is expired we take him at higher wages," but in my opinion the answer is "As long as you equally supply in proportion to your requirements the local market, we have no cause of complaint, but until you do so, you are strangling planting enterprise in its infancy by competing for the labour they have imported."

There are certainly few if any Ceylon Planters who will not say that a free coolie is cheaper at 25 cents per day than an immigrant at 14.

Paradoxical as it may sound, in my opinion an emigrant is cheaper on a one year's agreement and 20 cents per day, than on a 3 years' agreement and 14 cents, owing to the bulk of the men being of a better class. But the recruiting in India is miserably bad, and owing to the treatment received at the hands of the professional recruiters the men will not go to bring their families and friends as in Ceylon. If you get 35 good and fairly good, 15 of indifferent, bad and absolutely useless in a gang of 50, you may consider are you well off.

It would not matter to us whatever rates the Government paid if they imported a proportion of their own labour, as it would render the countries popular and induce a flow of immigration to them.

So much for the Tamil question, upon which I speak with some feeling, from having been compelled by want of labour to abandon 360 acres of Coffee in Sungai Ujong in 1884 although it had over 5 cwts. an acre on it. Pickers were not to be had and as the crop had all dropped the year before it was useless to spend further money on upkeep.

At the moment I am well supplied on all the estates and I hope to remain so from the growing popularity and a few old connections that have come from India, as free men, but there is the contingency to be faced that the Public Works in connection with the development of the States may at any time be let at such rates that all the labour from the estates may be drawn away.

We have then left Malays, Chinese and Javanese. Malays are excellent labour for many kinds of work, and particularly nice people to work with. If I knew an estate had been planted by Malays I should feel inclined to put a slightly higher value on it. They are such very careful planters and they plant a tree as if they remembered that it was expected to give returns for 30 years or more. For felling, shed-building, timber-cutting, roots and many other works, although their wages are rather high—from 26½ to 35 cents—they are not only very valuable but their work does not become expensive

Chinese as sawyers, carpenters and artisans, when they mostly speak Malay, are largely used and good men at their trades. The coolies are good for heavy work, but the great objection to employing them is all arrangements must be made through the head man who can talk Malay and he almost invariably robs them and tells them it is the employer. They cannot therefore be looked upon as satisfactory to the coffee planter.

Javanese are in much the same category. Few of them speak Malay and they are mostly worked through a mandore. I have had a gang of 50 men working for me for 4 years on end, and on and off for another 3, and never had a dissatisfied word from them, but then the mandore was an excellent fellow, and he still continues to work for me at times although now a man of means.

Watchmen are mostly Sikhs or Bengalis and I have no doubt in time they will bring friends to work on the estates.

SOIL.—Attached will be found the analysis of 4 different parcels of soil. They were all taken from 6 inches below the surface. No. 3 is of course an ideal soil but very wet. No. 1 is the poorest land of the Malay Peninsula, but I have seen fairly good young coffee on it, and it is used by the Chinese or Pepper and Gambier.

No. 2 is the soil taken from Batu estate and from the paper you will see what the crops have been and are, with its surface soil intact. Only over-bearing trees require manure for many years to come.

No. 4 is from Linsam estate and there again you have practical results to judge from. They are noted on the 1-24 by the analyst as being poor in potash and phosphoric acid. The one has been supplied in ashes and burnt earth and the other in the bones.

There are all sorts of soil, and all kinds of land, steep, undulating, flat, rocky and free from stone, stony and extensive alluvial deposits of rich soil.

I cannot conclude this letter without expressing my hearty thanks to all the officials for all the assistance and kindness that they have shown to me both in the Straits Settlements and the Native States and to express the hope that with their continued assistance may become that rare bird, a successful pioneer, owing entirely to the good will and assistance received in difficult times from the many officials who have taken so much interest in developing planting in the Straits

Yours faithfully,
THOS. H. HILL.

CEYLON TEA IN RUSSIA.

St. Petersburg, 4/16th March.

DEAR SIR,—By today's post I have sent you two circulars of the "United Kjachta Tea Co.," which have opened a large business in St. Petersburg. The pictures on the back represent the primitive methods of transporting the tea from China, through Mongolia, Kjachta and Siberia before it reaches Russia. The central picture represents the shop belonging to the Co. on the Nevsky Prospect.* It was my intention, had I remained in the trade, to have started a similar establishment in Petersburg or Moscow and sell Ceylon tea in its pure state or mixed with Chinese in order to suit the taste of the public. This would have been the first step before launching out in a still larger business.

The Director of this tea business informs me that he would like to receive samples of the finest Ceylon teas direct from Ceylon, as he finds the Ceylon tea very suitable for mixing with the Chinese which is wanting in flavour. In case any of your planters wish to start a business in Petersburg he would be quite willing to sell the Ceylon tea in its pure or mixed state. I think this would be a grand chance for the tea planters of Ceylon, and as they are not strong enough in this country to break down the opposition of the wealthy tea merchants, they could not do better than work together with them.—I remain, yours very truly,

WM. BARNES STEVENI.

P. S.—A tea merchant from Irkutsk has also asked for samples of Ceylon tea.

SALT IN AGRICULTURE.

March 28.

DEAR SIR,—I feel very gratified at the support my appeal has received from the Press. I shall in this communication offer a few remarks on the editorial comments on my letters, chiefly to keep the subject before the eyes of the public and the Government, so that the latter might be induced to take action in the matter.

It has been urged that no new arguments in favour of the manurial value of salt, or of the difficulty of rendering it unfit for food are to be found in my letters. I expressly disclaimed any pretensions to originality. What can I, a layman, say that is new of a substance whose manurial value has been acknowledged almost from the beginning of time, and of whose virtues the votaries of Agricultural Science have since sung? What we are immediately concerned about is, nor so much its value as a manure, as its indispensability in coconut cultivation and what is well known is reiterated, that Science has proved the possibility of purifying salt that has been mixed with offensive substances. The practical man is concerned with enquiring whether the average Native, Sinhalese and Tamil, is so conversant with the teachings of Science as to experiment with contaminated salt, and whether there is the slightest probability of his using such salt as food, even were he able to purify it. Those who profess to answer these questions in the affirmative will proclaim their ignorance of the habits and deep-rooted prejudices of

* These circulars can be seen at our office.—Ed. T. A.]

the natives. Mr. John Hughes, the consulting Chemist of the Ceylon Planters' Association, will, I am sure, be acknowledged to be a practical man, both by his training and by his wide experience of human nature. He writes in reference to the refusal of Sir James Longden's Government to issue salt to a planter in the Atras, who had applied for 50 tons at the export rate of R5 a ton, to fight against grub, and who offered to pay the salary of a Government officer to supervise the application: "I wish merely to point out that there are means available for so mixing salt with certain manurial materials, that the subsequent extraction of salt in a condition at all likely to be used for food should be rendered extremely improbable. First of all, I would say why not convert the crude salt into a manure by adding 2 or 3 cwt of finely ground fish manure or dried blood, or even Peruvian Guano to every ton of crude salt? Any one of these materials would so strongly impregnate the mixture, that the natives with their natural caste prejudice against handling any foul matter, much less of having the same brought in contact with their food would certainly refuse to purchase salt possessing any such peculiar odour as the above material would certainly produce. There is no doubt salt is a most useful and cheap source of manure, and it seems a distinct loss that any Government should throw difficulties in the way of its local use as a manure. My own view is that salt applied as an ingredient of a mixed manure is likely to be more effective in an agricultural sense than when applied in large quantity in the hope of destroying grubs." It will be noted that the above remarks apply chiefly to salt as manure for coffee. If I were convinced that the tax on salt were oppressive, and to any appreciable extent restricted its free use for human consumption, I should certainly when advocating its issue at cheap rates, have urged its abolition as an alternative. Though theoretically the tax may be objectionable it is not invidious and oppressive, as the tax on paddy unquestionably is, and I believe nine-tenths of the population do not regard what they get an equivalent for, as they do in the case of salt, as a tax at all, much less as an oppressive tax. Under the circumstances, I think the general denunciation of taxes and the setting up of the masses against the classes, with the issue of Salt for agricultural purposes as a (pre)-text, was both uncalled for and mischievous. A futile attempt was recently made, not by, but on behalf of, the rich "to save themselves and fasten burdens on the poor," when with the aid of specious arguments and sophistry laboured attempts were made to prove that those who issue rice to their labourers at a profit pay the impost on it, while those who deny themselves this profit and give their labourers cash do not pay it. Therefore, the latter ought to pay an export duty on their produce, and not the former.

Though an official was at pains to state that it was not within his knowledge that salt was used in paddy cultivation, yet it is well known to those who take the trouble to observe what they see that those tracts of fields that are periodically submerged with sea water grow as fine paddy as one could well wish for. I have not, as suggested, lost sight of one of the chief attributes of salt, its hygroscopic property. I drew attention to that, and spoke of it as giving salt a value "all its own." I look upon its ability to absorb the moisture of the atmosphere as investing it with a very high value in those inland districts where the tree suffer much from the effects of drought. I applied salt to some coconut plants I put out last season. Dry weather followed almost immediately after. The ever-widening circle of moist earth round the plants of a morning was very noticeable. The information that, though coconuts refuse to grow, or rather do not flourish, near Rangoon, 25 miles distant from the sea, and yet do remarkably well over 700 miles up the river Irrawady, and the reasons for it, are highly interesting, and show how unsafe it is to generalise from insufficient data. The natural conclusion a mind not given to dive deep for the why's and wherefore's of the apparent contradictions it meets with, would arrive at from the above facts would be that salt is not essential for the healthy growth of coconut palms. The true conclusion is the opposite. The

nuts at Bibile, like those at Mandalay, may be extraordinarily large because they belong to the large variety of coconuts. There are said to be eight varieties of coconuts and many sub-varieties. Large sized nuts are known as Siam coconuts. Trees of this variety can be seen at Morris Place, Slave Island. Many people have a fancy for these nuts, and it is possible that a few of these large-sized nuts were taken to Bibile and grown there, and the trees now growing may have been propagated from these. This is a mere surmise based on my observation that soil has no marked influence on the size of nuts, which is almost entirely dependent on variety. Large-sized nuts are no advantage, however, for we get fewer of these than normal sized ones from a tree. I passed through Bibile on my way to Batticaloa about a dozen years ago, and do not remember having noticed any coconut trees there. A very flattering opinion of my attainments suggests my being able to throw light on the reason for the size of the nuts at Bibile. As I said before, I lay no pretensions to being anything but a practical and observant Planter, with a rudimentary knowledge of Agricultural Science. If there be an Agricultural Instructor anywhere in the neighbourhood of Badulla, I would suggest that the Superintendent of the School of Agriculture direct him to make a careful report of the trees in question, with the nature of the soil on which they grow, and send to him a sample of soil within 18 inches of the surface, another from a depth of 2 to 3 ft., and a sample of the water as well. Exceptions go to prove the rule, and as fine trees on hard cabook soil as on sand may be met with on the sea coast, but I think I will hardly instance those at Beruwalla (Magalkanda?) as an exemplification of this, though they certainly are better than trees met with inland on similar soil. The reason for this may be that the salt carried so freely to these soils renders soluble the large percentage of potash they contain as well as phosphoric acid and nitrogen in smaller quantities. Potash forms about 50 per cent of the mineral matter of the coconut tree. It is interesting to know that what observation led me to adopt is practised on the West coast of India. Being impressed with the value of water in coconut cultivation, I sought means to store as much rain water as I could on the estate I supervise. With this end in view I cut trenches as nearly level as possible at right angles to the slope of the land. These not only catch rain water, but improve the texture of the soil. This plan finds no favour with those whose book-learning teaches them that in good husbandry drains must be cut to draw away moisture. This has special reference to the cultivation of roots and cereals with delicate roots and on low-lying land. We should not blindly follow scientific theories, but must adapt scientific teaching to varying circumstances. What is absolutely necessary in water-logged soil and in the cultivation of plants with delicate roots, need not be adopted to the letter in the cultivation of coconuts, and on soils when the lay of the land and its composition favour free natural drainage.—Truly yours, B.

MR. HOLLOWAY'S CACAO FIGURES.

DEAR SIR,—It is very far from my object to say anything in the remotest degree detrimental to the cacao enterprise. On the contrary, it is my firm belief that exaggeration and high inflation such as I complain of in the exuberant outpourings from Wategama are themselves the surest source of ultimate harm.

Mr. Holloway's letter of 30th ultimo does not fairly answer my objections. I objected to the suggestion that 6-year old trees would bear 100 cwt. per acre and yield a value of R6,500 value per annum per acre on his figures—of a yield of 300 pods. He now goes further and says "as regards full-grown trees giving from 300 to 400 pods any cacao planter can tell me of many such trees even of Caracas."

Where are we being led to?

One acre of 6-year old cacao is to yield us R6,500

per annum and when full-grown *many* trees will yield 33 per cent more!! He himself has to tax his memory and in support of his assertion recalls his visit to Galagedara in "the seventies." Let him go back to Galagedara in the "nineties" and tell us all about it.

It is not fair to single out rare instances and parade them as an index of ordinary results.

Let us be just sanguine enough to inspire our earnest work but never moved to inflation of our enterprize or ourselves. The production of gigantic pods, or leaves, or gooseberries (may I add, estimates and statements), and calculations based upon them, never had any useful effect in the promotion of agriculture.

The grain of wheat in all that chaff from Wategama is contained in the remark that we have always something to learn.

I learnt long ago to avoid reading paragraphs about enormous gooseberries. I have still to learn.
PLANTER.

CACAO CULTIVATION: MR. HOLLOWAY IN REPLY.

Ukuwala, March 30th.

DEAR SIR,—With reference to the letter signed "Planter" (given above) I can only say that if this planter and the others who consider my figures misleading will visit Franklands estate, almost adjoining Wategama railway station, my son, who is in charge of that estate since October last, will be pleased to show them our Forastero cacao trees, the stems measuring from 20 to 27 inches in circumference, one foot above ground, from 18 to 25 ft. in height with a spread of from 15 to 22 ft. These trees are about six years old. As regards the outturn given in my letter, the pods were selected, weighed, put to ferment and washed under the supervision of my son who had made some arrangement with another planter to cure 100 of Forastero pods while he was to do the same with Caracas from his estate and then compare results. You will remember a pod weighing 2 lb. is not our largest, for the pod sent to you some time since weighed $3\frac{1}{2}$, and Matale 25 Exhibition pods between 2 and 3 lb. each. Anyone can beat the outturn even of one pod and then satisfy himself that I was rather under than over with my outturn of selected pods.

As regards full-grown trees giving from 300 to 400 pods per tree, any cacao planter can tell him that there are many such trees, even of the Caracas. I know on several estates such crop has been obtained on some trees. When I visited Greenwood estate, Galagedara, in the "seventies" I distinctly remember counting on several trees that number of pods; branches were supported by sticks. I then told Mr. van der Poorten if he allowed such crop on his young trees he must give them nourishment at once, else the trees would soon stop giving crop.

I am now planting up about 300 acres on this estate with Forastero cacao for Messrs. Owen, Bayford & Deverell. There is a great difference in quality and depth of soil, lay and aspect of land, in old shade as well as jungle shade. Yet by careful management, though costing a little more than common work, I trust to bring up the plants to be healthy and hardy all throughout and in time to give first-rate crops. An unchecked growth in plants makes the best bearing trees, though at times a stunted tree throws up a good sucker which also bears well.—Yours faithfully,
J. HOLLOWAY.

If those two planters who came the short cut through Goenambil and Franklands on 17th March 1889 and got in the train at Wategama when I was also a passenger (a stranger to them and they to me) will now come down that short cut again they will see that Holloway, though he was successful on Maria and Raxawa, failed at Wategama as they were pleased to say one to the other. They will see "Holloway" let the weeds and turf then grow with an object now obtained, they will find estate clean and trees full of vigour.

Though I am now a planter of 33 years' standing, yet I am not proud to say I am still learning daily. You sometimes hear youngsters who have been out about a year or so one say to another: "Oh, I know all about planting now." We shall never finish learning about the treatment of plants soil and. J.—H.—[Hear, hear.—Ed. T.A.]

MR. HOLLOWAY AND CACAO CULTIVATION

Greenwood, April 13th.

DEAR SIR,—It is only today that Mr. Holloway's letter is brought to my notice, owing to absence from home.

I am at a loss to understand why he mentions my name in it except if he identifies me with his antagonist "Planter" who I am not.

I find that Mr. Holloway honored me with his visit on the 29th September 1882 (not in the seventies). I do not remember that he gave me his valuable advice about giving nourishment to trees which had borne a heavy crop. I may assure him, however, that acting on the secret he thinks he imparted to me or on commonsense, I have tried the process in all its ways, but have found that it would not prevail against the root disease which began here in 1884, and attacks nurseries and young trees before the mature ones. Cinchona, jak trees, coconuts, &c., have also suffered in a great many places since then, but little notice has been taken of this as the change is gradual and I am also inclined to think that it is the cause of the other diseases which affect the coffee. But being no authority on this matter it might be well to put this down to *malnutrition*.

I am quite of the opinion of the "youngsters" that if they have an average intelligence they ought to know all about planting two or three products in the tropics in one year. Those great secrets people fancy having torn from nature are often old and well-known or prove valueless. Nature yet remains inscrutable in the main point which I saw admitted by a scientific authority on Agriculture a few months ago.—I am yours truly,

A. v. D. POORTEN.

A TRIP THROUGH THE KELANI VALLEY.

DEAR SIR,—It is now 12 months since I was up in the Kelani Valley, in my opinion the leading and most flourishing tea district in Ceylon, and it was with pleasure and expectancy that I left Colombo by the 2.30 p.m. coach on Sunday last, the 5th inst., for Awisawella. On starting the coach was only occupied by Europeans and the drive up was a pleasant one, the road being in excellent condition the whole way, and the horses, for a wonder, good. At Hanwella we picked up the popular Police Magistrate of Awisawella, Mr. Philip de Saram, whom I was glad to see looking hale and hearty, and the rest of the journey was passed in reminiscences of home experiences and adventures. I stayed the night at the Awisawella resthouse, and next morning proceeded by hackery to Ruwanwella. The change along this road is vast, as large new clearings are being opened up on the one side, while the other face is one conti-

nous sheet of splendid tea, Dewalakande estate with its fine factory standing prominently to the front. At Ruwanwella's house, where I spent the night, I met Mr. A. E. Scovell of Strathellie, and together we travelled through the Ruwanwella group of estates, which in time should prove the most valuable in the district, as the soil is exceptionally good here, and the clearings are mostly planted up with indigenous and first-class hybrid jats. The new road to Veyangoda, which when finished will be as fine a cart-road as any up-country district can boast of, is making good headway now, passes through most of the best estates at this end, and the fields of tea are a sight worth seeing. Travelling along this road one remembers Mr. Inglis's song of "Tons and Tons, and Tons of Tea," and certainly the words are true. After leaving the Ruwanwella end we drove along to Lavant estate, Yatiyantota, there to be gladly welcomed and hospitably received by its ever popular proprietor Mr. F. J. Wright, whom I was glad to see looking the picture of health and spirits, his appearance speaking volumes for the climate of this end of the Kelani Valley. After spending the evening with him and going round his valuable property the next morning our party broke up, Mr. Scovell proceeding up the Gap to Strathellie, while I retraced my steps to Veyangoda, reaching the station to catch the evening down train to Colombo, which, owing to the Sinhalese holiday, was crowded to overflowing and consequently half an hour late. My trip was a most enjoyable one, meeting old friends and finding everything prosperous and flourishing, and I hope that the Kelani Valley and its "good men and true" will continue to keep to the front, "until the day after tomorrow." M. B.

ADULTERATION OF BONE DUST.

Kandy, April 15th.

SIR,—I beg to enclose copy of a letter from Mr. John Hughes consulting chemist to the Association inviting attention to a new form of adulterating bone dust that has come under his notice, together with the sample referred to.—I am, sir, yours faithfully,
A. PHILIP, Secretary.

NEW ADULTERATION OF BONE DUST.

London, E. C., Feb. 27th.

A. Philip, Esq., Planters' Association, Kandy.
Dear Sir.—As consulting chemist to your Association I should like to direct the attention of your members to a new form of adulterating bone dust which has recently come before my notice. As readers of the *Tropical Agriculturist* are aware Indian bones are now being imported into this country in enormous quantities for the purpose of being used as manure. One firm alone having delivered 40,000 tons during the past year. Samples of these shipments come before me regularly for analysis; and while most of them are of good quality as regards phosphates and nitrogen there are several instances of admixture of sand to the extent of 10 to 15 per cent.

This adulteration however can usually be detected by the dirty appearance of the sample, so that its limits of practice are clearly defined, but the enclosed specimen is of quite a different character, and although having the clean appearance of genuine bone dust it nevertheless contains 10 per cent of adulteration in the form of crystalline carbonate of lime, the presence of which can only be detected by chemical examination, or microscopical inspection. Good bone dust should give no appreciable effervescence with dilute muriatic (hydrochloric) acid, and should present a uniform appearance under the microscope.

On the other hand if you add acid to the enclosed specimen you will notice a marked amount of effervescence as the result of the decomposition of the carbonate of lime; while under the microscope the crystalline appearance of the calcium salt stands out in marked contrast to the organic structure of the particles of bone.

This specimen contained only 47½ per cent of phosphate of lime and 4.06 per cent of ammonia as against 53 per cent phosphates and 4.60 ammonia present in 1st class Indian bone meal.

I trust this information respecting this new form of adulteration as well as the *easy means* of detecting it may be made public for the protection of planters in your island and India against this new fraud of the natives. Shippers of bone dust to this country will do well to take note of it also, and thus spare much disappointment to their representatives on this side who have to make a substantial allowance on all such adulterated deliveries.—Yours faithfully,
JOHN HUGHES.

TEA TRADE WITH FRANCE.

Kandy, April 15th.

SIR,—I beg to enclose copy of a letter from the Secretary to the Ceylon Association in London, transmitting copy of Report, &c., to the Trade and Treaties Committee of the Board of Trade by the Indian Tea Districts Association and the Ceylon Association in London with reference to the Tea Trade with France.—I am, Sir, Yours faithfully,
A. PHILIP, Secretary.

4, Mincing Lane, London, March 13th.

The Secretary, Planters' Association, Kandy.

Dear Sir,—I enclose copy of a report made last December, at the request of the Trade and Treaties Committee of the Board of Trade, jointly by the Indian Tea Districts and our own Association.

On Saturday last at the request of the same Committee a deputation from the two Associations went to the Board of Trade and had half an hour's conversation on the subject of the report.

The Indian Association was represented by their President, General Hopkinson, Mr. Tye (Secretary) and Messrs. Benj. White, Stanton and Seton. On behalf of our Association the members present were Mr. Whittall, Messrs. Dickson, Rutherford, Shand and myself.

The Committee were fully represented and asked many questions as to trade in France both in tea and coffee.

Mr. Mundella, who presided, expressed his admiration of the progress made by India and Ceylon in the production of tea and while pointing out that France was not at present proposing to make any change in the tea duty said that if anything could be done that seemed likely to help on the sale of tea in France it should not be overlooked. He did not, however, see at present how any action could be effectively taken.

I enclose a copy of the first report of the Committee which has lately been issued.—I am, yours faithfully,—WM. MARTIN LEAKE, Secretary.

Joint Report to the Trade and Treaties Committee of the Board of Trade by the Indian Tea District Association and the Ceylon Association in London.

1. The importance of the Tea industry to Great Britain has increased considerably during recent years. Tea culture is now carried on so extensively in India and Ceylon that the welfare of this industry is a matter of national importance. Last season's Tea crop from these two places consisted of over 140,000,000 lb. valued in bond in Mincing Lane at £6,125,000. The present season's crop is expected to exceed this quantity by fully 10,000,000 lb.
2. Owing to the rapidity with which Tea production has been extended in India and Ceylon during recent years, it has become of paramount importance to the welfare of the industry that new outlets should be discovered and existing foreign markets encouraged.
3. The consumption of Tea in France is extremely small and has varied very little during some years past, viz. 1884, kilos: 530,664; 1885, kilos: 479,679; 1886, kilos: 552,676; 1887, kilos: 557,162; 1888, kilos: 516,834; 1889, kilos: 540,610.
4. The present high duty of 208 francs par 100 kilos we believe to be prejudicial to the increase of Tea consumption in France.

MARKET RATES FOR OLD AND NEW PRODUCTS.

(From S. Figgis & Co.'s Fortnightly Price Current, London, April 9th, 1891.)

THE MAGAZINE

OF

THE SCHOOL OF AGRICULTURE,

COLOMBO.

Added as a Supplement monthly to the "TROPICAL AGRICULTURIST."

The following pages include the contents of the *Magazine of the School of Agriculture* for May :—

"OILY AND FATTY MATTERS IN PLANTS."

IN dealing with the oily and fatty matters found in plants, we would best leave out for the present those oils known essential oils, a consideration of

which will be taken up further on: the term oils will therefore for the present indicate true oils, or as they are variously named fatty, greasy, or fixed oils. Fats and oils fall under the large head of organic compounds known as carbo-hydrates, that is compounds consisting of carbon, hydrogen, and oxygen, in which the hydrogen and oxygen exist in the proportion required to form water. They are all glycerides, or normal compound ethers of glycerine, and can be formed by the action of an oily or fatty acid on glycerine. The most important glycerides are stearine, palmitine, oleine and linoleine; the two former are white solids melting at 160° F. 142° F. respectively, the two latter are liquids. The ordinary fats—such as suet, lard, tallow—are mixtures of stearine, palmitine and oleine, in various proportions. The more stearine there is present, the harder and less fusible the fat; the more oleine, the softer and more fusible is it. Olive oil contains palmitine and oleine; almond oil, oleine with a little palmitine; linoleine occurs in linseed oil, hemp seed oil, poppy seed oil and other "drying oils," which when exposed to the atmosphere absorb oxygen, and are converted into a solid varnish. Castor oil consists almost entirely of ricinoleine. One of the main differences between fatty and oily matters is, it will be seen, in their consistency, which is regulated by the proportion of the compounds composing such substances. Oily and fatty matters in plants are numerous and widely distributed; nearly all plants containing one or more. Even cereal grains—as oats and maize—contain oil in appreciable quantities. Some plants contain waxy

substances which give the bloom or shine to different parts of them. Again, some oils contain phosphorus, and are called phosphorised oils; such are the oils got from lupines, peas, and horse-beans. Fatty and oily matters are found in different parts of plants, but principally in the seed—as cotton-seed, linseed, sunflower-seed, &c. They are extracted by pressure, and the quantity obtained varies from ten to seventy per cent of the weight of the seed. Oleine is one of the commonest constituents of vegetable oils. Palmitine is found in palm oil, butter, and bees wax.

The essential oils differ greatly from the true or fixed oils, both in properties and in chemical composition. Unlike the latter they are volatile, non-lubricating, and possess powerful odours. They are obtained from many plants by distillation with water, the oil coming over with the water, and collecting in the receiver, partly dissolved in the water, partly floating on its surface, the watery solution having the odour of the oil. In this way oil (or attar) of roses and rose water, oil of lavender and lavender water, oil of cinnamon and cinnamon water &c. are prepared. Many of these oils, so different in odour, have the same composition as oil of turpentine, *e.g.* oil of lemons. Others contain various volatile substances: such are oil of mustard, and oil of bitter almonds, the latter containing the poisonous principle—hydrocyanic or prussic acid.

Of the true oils produced in Ceylon, the most important is coconut oil which is expressed from the dry kernel (copra) of the coconut by means of the ordinary native mill or checkko, and in a few cases by machinery: the oil specially intended for cooking purposes is however principally got by boiling the scraped kernel, while the clear hair oil made from the king-coconut is generally prepared from the scraped kernel by means of sun heat only. The ordinary oil which is largely exported, is used abroad for the manufacture of candle and soap. Soap is also manufactured to a small extent in the Island, and we were rather surprised by the enquiry for this "Ceylon coconut oil soap," as it was called, by passengers

f a French steamer who claimed for it the property of easy solubility in sea-water. Saponification or the process of soap-making is brought about by treating fatty or oily acids with caustic soda or caustic potash—the result being the production of a potassium or sodium salts of the fatty or oily acids, these consisting soaps. Hard soap has soda, soft soap has potash as a base.

Margosa or Kohomba oil is extracted from the fruit of the Nim or Margosa tree. This oil is largely used in Native medical practice. Gingelly oil is got from the gingelly or sesamum plant. Kekuna oil is expressed from the nuts of the kekuna tree, which contains about 50 per cent of oil. This oil is also exported, and is used in soap manufacture. Caju oil is expressed from the eaju or cashew nut which contains about 4 per cent of oil. Mi oil is got from the fruit of the mi tree, and is used in native medicine. Castor oil from the castor plant is also produced in Ceylon to some extent.

Of essential oils, the principal is—Cinnamon oil distilled from the chips, bark, and in some cases from the leaves of the cinnamon plant. It is exported to a fairly large extent, and is used in medicine and for perfumery.

Citronella oil is distilled from citronella grass, and is exported for use in perfumery and for scenting soaps and pomatums.

Lemon grass oil, distilled from lemon grass, is made use of in the same manner as citronella oil, and to a large extent in the preparation of Eau-de-cologne.

Other less important oil-producing plants found in Ceylon are Mustard, Croton, Domba, Na (iron-wood), Cotton, Pulan (tree cotton), Kon, Groundnut, Sunflower, Malabodda, Duhudu, Weterandua, Dorana, Murunga, and Kina.

OCCASIONAL NOTES.

It is with pleasure we have to record the fact of a new prospect being opened out to the students of the School of Agriculture. A Sinhalese gentleman, who is a large landowner of wealth of standing—but whose name we have no permission to publish—has signified his intention of employing agricultural students who have passed through the School of Agriculture with credit, on his estates, whenever he is in need of Superintendents. He offers liberal terms, and gives his intended employees an opportunity of becoming acquainted with the technicalities of the cultivation of special products before taking up the reins of office into their own hands. This offer opens out a happy prospect to those who are neither fortunate enough to be selected for Government employ as agricultural instructors, nor have facilities for carrying on cultivation on their own account.

Some time ago we referred to the advantages of employing passed students of the School of Agriculture, as pointed out by a private employer of one of our students. It cannot be doubted that the training, theoretical and practical, and the discipline under which the students are brought at this institution will result in making more intelligent and reliable superintendents and conductors of private estates than are found among the ordinary place-seekers of this description. We

have more than once heard of a conductor, who as the result of confusion in his mind with regard to his instructions, has gone ahead working as hard as ever in a wrong direction in blissful ignorance he was doing damage (that was hardly to be remedied except at the cost of much time, expense and labour) to his master's property or crop. Now the average agricultural student can at least be trusted to exercise a good deal of discretion on his own account, and to bring the principles he has been taught in his class-room to guide him in a critical moment.

We will not dilate further on this subject for fear of being credited with a partiality for advertising ourselves. It is, however, a very gratifying matter to find gentlemen, such as the new patron of the School of Agriculture, appreciating the results of the work done here, and encouraging agricultural students by the liberal offers they make.

Why, it has been asked, is not all the teaching at the School of Agriculture carried on in Sinhalese instead of in English? True that by far the greater number of the students are Sinhalese, yet there are generally four or five Tamil students—the Burgher community having been for the past three years represented by one—to whom it would be a manifest disadvantage to be taught in Sinhalese—especially as the men from Jaffna and Batticaloa have so far proved themselves keen students of agriculture, and have always shown a determination to carry on agricultural work after leaving school. There is another objection in the difficulties that would come in the way of a lecturer or teacher doing justice to his subject in the Sinhalese language. If both masters and students were excellent Sinhalese scholars, these difficulties would tend to diminish in a degree; but yet it would be a hard matter to find expressions in the Sinhalese language that would exactly convey the meaning of scientific terms which crop up both in agriculture and the allied sciences taught at the school. It must at the same time be remembered that both the Sinhalese and Tamil languages are freely drawn upon to explain words or expressions whenever such a need arises. On the whole, therefore, it will be admitted that English has advisedly been chosen as the medium through which students should be instructed in agriculture at this school.

In Dr. Kynsey's address before the Ceylon Branch of the British Medical Association, the following appears among the "desiderata for improving the sanitary condition of the country and the well-being of its inhabitants":—"There should be a Veterinary department for the study of the diseases of animals. I believe much loss in the country districts could be saved to farmers by timely treatment of sick cattle, and by early destruction when they are suffering from contagious disease."

In addition to this, one might add another distinct advantage, from a Veterinary Department, and that is that there will be a number of men, qualified to inspect cattle and meat *as they should be inspected*, available for employment as inspectors of slaughter-houses and meat-markets.

The Grama Rakshaka Samagama held what was really their first Agricultural Show on Monday the 27th April at Dalugama; and if the Society does not meet with any serious difficulties—too common, alas, in the case of societies and associations in this country—and grows and extends its influence at a rate at which we can only hope it will, then will this date be a memorable one. The interesting features about the Show at Dalugama was that it was intended solely for the encouragement of native industry and enterprise, and that its object was purely a philanthropic one. For this reason it is unique in our agricultural record, for hitherto, however well the products of the soil have been represented at Agricultural and Horticultural Shows, one cannot help thinking that these Shows were merely nuclei round which to gather a deal of less useful and more frivolous amusement. They always lacked the real business air about them. We heartily congratulate the Samagama (and especially the Secretaries) on the signal success which characterized their first attempt at holding a Show. Agricultural Shows are very important agents in creating a healthy competition, as well as being incentives to industry; but if such Shows are to be held more frequently as has been proposed by the Government Agent of the Western Province with other recommendations worthy of attention—it would be well if, to a great extent, they were "built" on the excellent little model we saw at Dalugama last month.

INDIGENOUS FOOD PRODUCTS: CULTIVATED AND WILD.

BY W. A. DE SILVA.

Rubiaceae.

49. *Hedyotis Auricularia*, L. Sin. Getakola, is a slightly woody spreading herb. This plant is commonly met with growing wild in waste lands and cultivated places. Its slender stem with many branches is swollen at the nodes. The leaves are small, green, and of an ovate shape. The flowers are very small and are borne at the nodes, where the small fruits are also produced.

The leaves of *H. Auricularia* are used in preparing a dry curry, but it is not much used as a food. The plant is believed to possess cooling properties, and is used to some extent by native medical practitioners in treating cutaneous diseases.

50. *Ivora Coccinea*, L.,

is a tree found throughout the Island, growing in both cultivated and uncultivated land. It is abundantly found in the vicinity of streams. The general growth of the plant is a shrub, but it is also found as a tree with well-defined large stems. The stem is much branched and covered with green leaves of an ovate shape, and of a rather leathery texture, the veins being slightly prominent. The flowers which are red with a thin tubular corolla expanded into four petals, are borne in large clusters, which give a characteristic appearance to the trees. A large quantity of nectar is found in the flowers of *Ivora*. The fruits which are borne in clusters are of the shape and size of Ceylon black berries (Dan). They are green and have an astringent character

when immature, but turns soft in texture and black in colour when ripe. The ripe fruits are of a sweetish taste, and are often eaten. The wood of this plant is of a hard texture, but as it does not generally attain to a great height, its timber is not much used except for handles of mamoties and other agricultural implements. The flowers of this plant are reputed to contain properties of purifying the blood.

Compositae.

51. *Emilia Sonchifolia*, D. C. Sin. Kadupara, is a herb found growing in the warmer parts of the Island in cultivated gardens and waste places. It has simple amplexicaul leaves with divided margins. The whole leaf is of a light green colour and is covered with glossy hairs. The leaves are found to vary according to the fertility of the soils where they grow as well as according to the condition of the climate. The flower-heads are small in size and are borne on a slightly long peduncle.

The leaves of this herb are used as a vegetable. They have a slightly acid character, and when made into curries this acidity gives the preparation a pleasant taste. The leaves are said to possess cooling properties, and are used externally in cuts and wounds and also in cases of serpent bites.

Sapotaceae.

52. *Bassia Longifolia*, Sin. Mi.

This is a tree which grows in the warmer parts of the Island up to high elevations. It attains to very large dimensions, and is covered with dense foliage. The leaves are long and narrow; their margins are entire; and the veins are prominent. The leaf is of a tough texture. The flowers are borne in abundance. They have thick fleshy calyces and are of a whitish appearance, with a peculiar smell. The *Bassia* trees flower once a year during the months of May and June, when in many parts of the Island trees are laden with blossoms and the ground strewn with the flowers, while large swarms of bees always resort to the trees at this season. The fruits are formed in July and August, and they much resemble the fruits of the small varieties of mangoes both in their appearance and in their arrangement on the trees. A fruit generally contains two seeds, but it is not uncommon to meet with those containing three to four of them. The fruits when ripe are much liked by birds, especially parrots and flying-foxes. The seeds are about an inch in length tapering both ways and thick in the middle: they are covered with a smooth brittle integument.

The seeds contain a large quantity of oil in them, which is extracted by the villagers.

A sugary syrup is manufactured by boiling the juice of the *bassia* flowers, and is used in the preparation of sweetmeats. This syrup has rather an unpleasant taste and smell, to those who are not accustomed to its use. The dried flowers are pounded and made into flour which is also converted into sweetmeats.

The fleshy portion of the young fruits of the *Bassia* is cut into slices and made into curries. Bees collect large quantities of honey from the flowers for their hives. The timber of this tree is used in house building as well as in the

construction of bridges. The juice of the *Bassia* leaves along with coconut milk is used in cases of burns and for allaying rheumatic pain. The astringent bark is used in fever and also to promote appetite. The oil extracted from the seed is used externally.

AGRICULTURE IN THE NORTH.

SIR,—Since the abolition of the tax on dry grains, many suggestions have been thrown out with a view to encouraging a more extended cultivation of these products; and it is gratifying to read that the Agriculturists of the North are as busy as ever preparing their lands for these crops, and that in all likelihood a good outturn will follow. This is very encouraging news to those who are interested in the affairs of Jaffna, and it is all the more cheering after the late reports of the failure of the paddy crop. When the tax was about to be abolished, it used to be thought that such a relief will bring about a careless and indifferent disposition in the cultivation of dry grains. Happily the reverse has been the case!

The Jaffna cultivator needs no instruction or direction for the raising of dry grains, for the reason that by long experience he has arrived at the most improved methods of cultivating such products; but where he does need help and special guidance is in fruit culture and gardening, for which, though he has a soil of great capabilities, he has little taste and enterprise himself. While thinking over the opportunities for improvement in this direction, by a strange coincidence the *Ceylon Patriot* of the 10th instant, suggested in its columns the idea of establishing Experimental Gardens throughout the Island, and specially recommended the formation of a Board of Agriculture in Jaffna. The *Patriot* goes on to say that "A competent Agriculturist should be in charge of each garden nominally under his local superior, the Government Agent, but responsible to the Director (of the Peradeniya Botanic Gardens); and these professional men attached to these gardens should, in addition to keeping their gardens in the highest state of efficiency, try their utmost to spread a knowledge of the improved method of cultivation, and send annual or quarterly reports to the Director as to the state of their gardens, with remarks and suggestions of their own, as to the economic plants and vegetables suitable to the soil of their gardens, putting in their requisition for such plants as are not obtainable locally and generally; keeping the Director duly informed of every thing which in his opinion will be of benefit to the people. Now that through the laudable exertions of Mr. Green, a batch of graduates are annually turned from the Agricultural School, with a competent knowledge of their subject, their services can be engaged for a trifling sum compared with the enormous expense necessary to get down Agriculturists from England or the Continent."

With regard to the Board of Agriculture, the *Patriot* delivers itself as follows:—

"Devoid, though he (the Government Agent) be of scientific knowledge and training, he will be the means of doing great good if guided by a competent and responsible Agriculturist. The whole force of headmen can be held in leading strings and made *volens volens* to spread a know-

ledge of improved gardening and cultivation of economic plants throughout their respective divisions. To aid the Government Agent and advise him in all important matters, the formation of a Board, consisting of the chief headmen of Jaffna and a few of the leading landed proprietors, independent of Government, will be a very desirable step.

It may thus be inferred from these remarks of the *Ceylon Patriot*, representing as it does the interests of the Tamil community of the North, that the inhabitants of the Jaffna Peninsula are not reluctant to adopt any useful plan that may be suggested and appear practicable.

One good result such a system as the *Patriot* suggests will be the breaking down of a good deal of selfishness and conservatism that clings to the northern cultivator. Take for instance the growing of grapes which is so limited in extent, for the main reason that the secret of their successful cultivation is jealously kept by a few who are loth to proclaim it to their brethren. In this connection I may mention the advantages of such a publication as the Magazine of the School of Agriculture, in which there is at present appearing a useful contribution on the cultivation of the Grape Vine.

Again, in the case of cucumber, cultivation is also confined to a comparatively few. The variety grown here has proved itself a profitable crop, and one for which there is an eager demand in the market, but its more extended cultivation is prevented by unworthy means (such as withholding seed or supplying bad seed) for fear that the result might be a disadvantage to a few favoured but selfish individuals.

It will thus appear that it is very desirable that by some means,—whether through the School of Agriculture in Colombo or the Board of Agriculture at Jaffna,—a more liberal system of cultivation should prevail in the North, that there should be no obstacles in the way of procuring whatever seed is required, and that opportunities should be allowed for the existence of a healthy competition, which is one of the fundamental laws of Agricultural Industry.

I am very anxious that some effort should be made to establish these desirable results, which I doubt not will have the sanction of the Government Agent of the North (himself a successful cultivator of fruits), and it is for that reason that I have touched on the plan put forward in the *Ceylon Patriot*, and endeavoured to supplement and strengthen its remarks in urging the claims of Jaffna for more enlightened direction and supervision of its agricultural affairs.

I am, yours, &c.,
R. C. MUTTIAH.

Colombo, 18th April 1891.

THE CULTIVATION OF MANIOC.

(*Manihot Utilissima*.)

BY W. A. DE SILVA.

The Manioc belongs to the order Euphorbiacea and thrives in warm regions. The original home of the Manioc is considered to be the New World, whence it has been introduced into eastern countries. The plant is in great repute wherever it is cultivated on account of the large quantity of food materials it produces in

a given space of land, when compared with other food products. Its introduction to Ceylon is attributed to the Dutch, who by the way have the credit of having introduced many useful food products which are commonly grown in the villages at the present day. According to Dr. Ainslie, the manioc plant was brought to Ceylon from Mauritius by Governor Van der Graff in the year 1787; and thus it will be seen that the plant has been in cultivation in this Island for over a century. This plant, like the other plants of the same family, possesses acrid properties, in addition to its containing a small percentage of hydrocyanic acid. The characteristic smell of the cyanides being quite perceptible.

It has been found that there are above thirty different varieties of manioc grown all over the world, but these are considered to be only slight variations of two distinct species, *Manihot Utilissima* and the *M. Aipi*, the bitter and the sweet manioc respectively. The former variety has certain poisonous properties in it, in a raw state, while the roots of the latter are quite sweet and harmless. These varieties could be distinguished from their outward appearance by observing the leaves. The leaves of the bitter manioc have seven divisions, and the veins on the under surface are coloured red; whilst the sweet manioc possesses leaves with five divisions of a pale green colour.

So far as I have seen both these varieties are found in Ceylon, but the variety generally cultivated is a slightly modified type of the *Jatropha Utilissima*, the bitter manioc. In all countries this variety is preferred because it yields more abundantly. The bitter principles and poisonous characters of its roots are removed by drying or boiling.

The cultivation of the manioc plant is carried on to a large extent in the Western and North-Western districts of Ceylon. In many other districts it has rather a bad reputation as a food product on account of the poisonous properties which the fresh roots of some of the varieties possess, and on account of frequent deaths which occur by the careless use of the root.

The manioc is grown both in chena lands and in new clearings for coconut. It forms a very paying subsidiary crop along with the latter.

The plant is propagated by cutting the stems which give out buds from almost every node. In cultivating manioc, the land is prepared by hoeing and burning. Shallow holes are made with a manoty four feet apart, or sometimes five, and two pieces of manioc cuttings from nine to ten inches long are placed in the holes and slightly covered with earth. These give out a large number of buds which grow with much rapidity. In planting manioc advantage is taken of a few slight showers, but when growing they are able to stand much adverse weather. The trees generally reach a height of from eight to ten feet, and after ten months they could be rooted out. The yams vary very much in size, and weigh from four to fifty pounds each. In good lands, the quantity of manioc produced is very large, but the average may be calculated at fifteen pounds per tree.

(To be continued.)

REFUSE MATTERS AS MANURES.

Horns, skin, hair, hooves and feathers are all of some value as manure. They are highly nitrogenous substances,—the amount of nitrogen present being the test of their value,—though they are very tardy in their action in the soil. Skin and hooves are not so refractory as the others mentioned; while feathers are particularly slow in decomposing. Skin refuse from tanneries when fresh is very valuable, but it is found often mixed with pieces of tanned leather which decompose very slowly. When made into composts, these substances decompose faster, and become much sooner available as plant food. Sulphuric acid is sometimes used for acting on them, and superheated steam is also employed; the great disadvantage in this latter process being the loss of ammonia which occurs with the escaping steam. For use in slow-growing crops the above are by no means to be despised. Blood as a waste material from slaughter-houses, is a highly nitrogenous manure and decomposes comparatively easily, while it is not easily lost by the soil. It is best applied after being dried and reduced to a powder, mixed with bone or other phosphatic manures.

Ashes from burnt wood, especially young twigs, contain a large amount of potash. Animal charcoal—the refuse from sugar manufactories,—is an excellent source of phosphoric acid, and should be applied ground for the best results. It is sometimes used for making superphosphate by the action of sulphuric acid. Soot which essentially consists of firmly-divided carbon and mineral matter, is valued for the fair proportion of ammonia which it also contains. Soot, besides supplying ammonia, absorbs gases and saline matter, while, by darkening the soil, it raises its temperature.

Gas lime—the refuse from gasworks—should not be used fresh, but must be exposed to the atmosphere for some time before applying.

Gas liquor might with advantage be used for saturating saw dust and coir dust to facilitate distribution.

Many of the refuse substances mentioned above are used by manufacturers for making up artificial manures which are sold in the market under various names. The term guano has been used to designate many of these prepared manures. For instance, European guano, which is a very fair manure, is made up of blood, horn, urine, &c. that have been acted upon chemically, and converted into a powdery fertilizer. Frey Bentos guano owes its origin to Liebig's Extract of Meat Company, and is manufactured from the meat refuse into a good manure.

Fish guano, a nitrogenous manure, much used in Scotland, is made out of the refuse from sardine and other fish-tinning works in Norway. Native guano, which can be traced back to sewage precipitation is, however, not held in much estimation. It will thus be seen that while a great deal of refuse matter is allowed to go to waste with us, it is used to advantage in other countries for making manures of a fairly soluble character, and convenient form for application to the land. The least that might be done by native agriculturists, who think so little of making a return to the soil they cultivate, is to form composts of such refuse matters as are available in towns,

for use on their lands. In this they have an example in the indefatigable Tamil grass-cultivator who will carry away whatever refuse matter he can lay his hand on—often of a useless nature—to place on his land.

AGRICULTURAL LITERATURE AMONG THE ANCIENT INDIANS.

By W. A. DE SILVA.

The diseases which attack vegetation are also dealt with by ancient Hindus, and particularly in the works referred to in my previous contribution. One cause of disease is stated in the following passage:—"Cold winds and scorching sun produce diseases in trees, and the trees turn light in colour and do not put forth new leaves, while the branches become dry and the sap leaves the tree."

The remedies given to meet these results, as well as the recommendations for producing luxuriance in growth, and inducing plants to flower and fruit freely, while they in some cases include measures by no means antagonistic to our modern ideas, generally indicate means, the adoption of which would in these days be considered the height of the ridiculous.

"To cure the plant of these diseases," says this ancient writer on vegetable Pathology, first scrape or otherwise remove with the knife, the parts found dead on the tree; rub over these parts a mixture of *Erycibe Paniculatum* (a plant possessing the properties of a vermifuge), ghee, and mud; and pour at the roots water mixed with milk. If the fruits are inclined to wither, take a mixture of horse-gram, black-beans, sesamum seed and barley, and pour it at the roots:—this will bring about an increase of both flower and fruit. But here are yet more startling recommendations:—"To make trees fruit and flower abundantly, mix two measures of the excrement of the goat and ram with one of sesamum seed, half of rice flour, one measure of water and a hundred tulas or nearly a pound of cow's flesh; keep the mixture for seven days, and then water, creepers, plants, and trees."

A special compost for increasing the size of plantains is the following:—"Use as manure for the roots of the plantain the excrement of the ass and the horse, burning dry twigs over the roots: the plantains will produce fruit as big as the trunk of the elephant.

For increasing the size of yams:—"Dig a pit and burn inside it the dung of the cow and the hog; remove the ashes and fill the pit with earth. The root of the yam will be found to grow to a size sufficient to fill the pit!"

For producing a luxuriant growth:—"Mix with milk the marrow of the fish and the hog, as well as their flesh. Soak the seed of the plant in the mixture, dry it and expose it to the vapour of smoking ghee. The seed when sown will be found to spring up in an unusual and wonderful manner."

These quotations suffice to give one an idea of the nature of plant treatment in ancient works touching on agriculture. Absurd as many suggestions found in them seem to be, it will be noticed that nearly all the prescriptions greatly

favour the use of organic manures for stimulating growth, such as carion, blood and milk. Both the first and second are not to be despised as manurial agents. A carcase is always an acquisition on cultivated land, and what is a loss to the stock-owner is a gain to his soil and the plant; while there are manures in the market which may be called "Meat Manures," for instance that prepared from the refuse matter in Liebig's Extract of Meat Company. In milk we have the most perfect food, as much so for the plant as for the animals, and though it seems ridiculous enough to use meat and milk for manuring plants, yet it must be borne in mind that the population of countries and the occupation of their inhabitants were not the same at that remote period as they are now, and that meat and milk could have well been spared for the purpose for which they have been recommended. It must at the same time be remembered that unacquainted as the ancients would probably have been with the secrets of artificial manures, they did the next best thing, viz., they returned to the soil the product of the soil, whether primarily as sesamum seed, rice flour, barley, &c., or secondarily as the flesh of the goat, cow, pig and fish (the last-mentioned common enough in Ceylon as "fish-manure").

In reading the passages I have quoted, some allowance will of course have to be made for exaggeration,—a common enough failing among ancient writers,—as well as for a dash of superstition (I can call it by no other name) in claiming peculiar virtues for special parts or products of a plant or animal—instances of which are very common among old writers, and are even found associated with old nations yet extant.

There is no doubt that most of the recommendations are based on experience. The composts which are prescribed are evidently meant to supply all the ingredients of plant food, as far as anything was known of this subject. In the mixtures of seed mentioned as composts, care is taken to advise that seed should be first heated or put by for a sufficiently long period to destroy all germinating power; the seed of plants is happily chosen as the storehouse of the most valuable materials in the plant, while the selection of seeds for the mixture is by no means a bad one.

But here I must stop for the present, reserving for another issue of the Magazine a consideration of still more curious recommendations relative to agriculture.

SOILS AND MANURES.

Mr. Robert Tatlock, F. I. C., F. C. S., in a lecture on Soils and Manures, has been condemning in unqualified terms the analysis of soils as it is generally carried out by chemists. The composition of a soil, he says, does not necessarily throw any light on its value from an agricultural point of view, and no information short of a statement of the amount of valuable material yielded by it during the period of, and under the conditions which obtain during growth, can be of service in this respect. Mr. Tatlock suggests a method for the examination

of a soil based upon the fulfilment of the conditions which occur in practice, as nearly as they can be attained. It is as follows:—

"Take a stout tin or zinc box of 2 cubic feet capacity, that is 24 inches deep and 12 inches diameter either way, and exactly half-way between the bottom and the open top insert a division or diaphragm of perforated zinc, which will act as a false bottom. Cut out in one block, neatly, a cubic foot of the soil, and slip it, surface uppermost, into the upper part of the box, its bottom resting on the perforated horizontal bottom of the box. Bury the latter, level with the ground, say, at the beginning of April, and let it remain till the end of September, when it will have received all the climatic influence of the surrounding soil during that period, including rain, which will percolate through it and collect in the bottom part of the box, carrying with it all the ingredients which have been dissolved. This solution is then analysed exhaustively. As 12 inches of rainfall will produce a cubic foot of liquid, there will probably not be sufficient room in the lower part of the box for the full amount, which may be double that or more, so that provision must be made for drawing it off from time to time, say, once a month. This can easily be done by having a piece of ordinary gas-pipe leading from near the extreme bottom of the box up through the diaphragm, and then through one of two perforations in an indiarubber cork, inserted airtight in a common 10-gallon glass carboy, the other perforation being fitted by another piece of piping, which, on being sucked, produces a partial vacuum, and so the fluid passes over from the box to the carboy where it is stored. For convenience, the body of the carboy may be partially buried in the ground. It will give me great pleasure to place such an apparatus for trial on any land, if one of the members will be good enough to give me facilities for so doing, and to analyse the product. The ingredients found should be calculated not only to per cent. of the soil, but to lbs. per acre, and compared with the amount of each of these removed from the same area of soil under favourable circumstances, by such crops as are intended to be grown. Of course, the full amount dissolved out will not be available for plant food, perhaps not one-half of it; but nevertheless, the results are a measure of the amount of the ingredients rendered soluble and assimilable, and consequently of the chemical value of a soil.

"Methods of analysis based upon the solubility of the essential ingredients in acids, more or less dilute, are arbitrary, and not to be trusted, as the conditions are totally different from those under which a soil gives up its useful constituents during plant growth."

And yet Mr. Tatlock considers,—and he thinks that every agriculturist and chemist, who has given his best attention to the subject will agree with him in this,—that no chemical analysis of a soil, however carefully carried out, and however exhaustive it may be, can be of the same value for practical purposes, as field experiments with various manures, systematically carried out by the farmer himself on his own land. This, he says, is simply a method of ascertaining what will suit a portion of actual

soil in a particular locality, and consequently, what will suit the whole of it; and demonstrates what ingredients give the best results, in what proportions they should be employed, how they should be applied; whether together at the same time in a mixed state, or separately, and at different times; and finally, it will show the cost in practice. Another advantage claimed for this simple system is that it requires no knowledge of chemistry. Properly regulated experiments, or "trials" should be part of the work of every farmer, in which a well-arranged series of tests should be well thought out, committed to paper, and carried out, the weighing of the manures, the seeds, and the products or crops being accurately recorded in a book kept for the purpose.

The above remarks on the value of analyses of soils, coming as they do from a professional chemist, cannot be said to be made from any interested motives, and are well worthy of serious consideration, while too much value cannot be placed on the recommendation that each individual cultivator of the soil should carry on his own "trials" and carefully note their results.

GENERAL ITEMS.

Mr. L. P. Jayasuriya, Schoolmaster at Rupaha, in sending a specimen of stone, writes:—This stone found in Rupaha, Walapana, is known as Garundagala, and is of three varieties, viz., Nilgarunda, Kalugarunda, and Kirigarunda. The following is translated by Mr. H. S. Dias, of the School of Agriculture, from a communication to the *Lakrivikirana* newspaper, by Mr. Jayasuriya:—

"There is a stream in the village called Udapalata-Rupaha in Walapana which arises from a lake a little beyond Ragama, and flowing for about three miles eastward, falls into Rupas Oya near the village Rupaha. At a distance about $2\frac{1}{2}$ miles from its source the stream flows by the rock known as Garundagala or Garundapasana. The natives claim healing properties for this stone, and Brahmins come all the way from India in search of it, making pilgrimages such as are made to Adam's Peak. The pilgrims generally stay a few days near the spot, and after having performed certain ceremonies, they carry away specimens of the stone as souvenirs. I have been assured by the natives that they have used the stone as a remedy, and found it efficacious in many diseases, and in part I can corroborate this statement from my own experience. It is said to cure the skin disease known as "itch," and is used as a remedy for snake-bite, and for stomach-ache, and for inducing secretion of milk in females after confinement, the stone being prepared for internal use by grinding some of it into a fine powder and mixing with lime juice. It is averred that those suffering from itch have been cured by bathing in the Nilgarunda Oya, and that abdominal pains have been cured by drinking of ITS WATERS."

Mr. J. T. de Silva, late of the Agricultural School, writes:—Pasdun Korale, in the Western Province, contains a fairly large number of vil-

lages. The land which is generally hilly is of a fertile character, as is evidenced by the general appearance of vegetation. The inhabitants are nearly all engaged in Agricultural pursuits, and the district contains a large extent of paddy land, but the soil yields nothing like what it should under a proper system of cultivation; yet the produce the people get by the unsatisfactory methods which they adopt clearly proves the good quality of the land. The majority of the inhabitants supplement their income by wages received for working in plumbago mines and on tea estates. The plumbago industry is carried on to a large extent in the district, and though the workmen's wages are by no means high, yet, there are men found to undertake the unpleasant and tedious work required in plumbago mining. There are many Tea Estates in the Korale near the Kaluganga, and these supply a good deal of work to the people. But there is yet more land suited to paddy cultivation, waiting to be brought under the plough, and it will undoubtedly be a great boon to the inhabitants if an Agricultural Instructor be appointed to the district, so that they may become acquainted with the advantages to be derived by the use of new implements and the adoption of an improved system of cultivation.

In the last report of the Director of the Royal Botanical Gardens we read:—"The first flowering also of the coco-de-mer (*Lodoicea Sechellarum*) requires special notice. The tree is in its fortieth year, and examination of the immature flowers shows it to be a male. The inflorescence appeared at the end of June (1890), being put forth from the stem between the halves of the split base of one of the leaf-stalks. I regret to say it never got beyond the bud stage, some mischievous person having cut off the whole inflorescence soon after its appearance. We may, however, now expect the production of flowers each year."

Antiaris Toxicaria is the upas tree which yields *Upas antiar* a kind of green resin containing *Antiarin*, a poisonous principle. It is this resin which the Javense use for poisoning their arrows. Curiously the exudation from the same tree grown in the Malay Peninsula is innocuous, as proved by examination of, and experiment with, a sample sent by His Excellency Sir Cecil Smith to Kew.

The earliest forms of Cinnamon occur in the Cretaceous or Tertiary period of geology. In the oligocene deposits found in Europe, the leaves of cinnamon occur in the clays and sandstones, and in some localities fossil specimens of the trees are associated with those of palms, the gum tree, acacias, custard-apple, lotus, camphor tree, and mimosa. Later on, cinnamon is found in the miocene deposits associated with the fig, vine, olive, ebony, and myrtle, thus proving the tropical character of the climate which prevailed over Western countries at that remote period.

The food of ants consists of insects, fruit, honey and honeydew. This last is a sweet

liquid of a viscid description excreted by the aphides or plant-lice from a gland which is situated near the extremity of the abdomen, and communicates with the interior by two tubular filaments. The aphid is a curious little creature which blights our plants and trees, and though it is an enemy of ours it is a great friend of the ants, more especially young ants. It increases in numbers with wonderful rapidity by a process of parthenogenesis, and it will be noticed that wherever plant-lice abound ants are always present. The ant greedily devour the sweet excretion from the aphides, while they can also be observed to stroke and caress these plant-lice till the latter voluntarily exude the coveted liquid. In fact the ant "milks" the aphid, and the latter is therefore with reason called the ant's cow. It is even stated that ants keep aphides in their nests for milking purposes. It a common mistake among some to suppose that ants destroy plant-lice by feeding upon them. The aphides, which live upon the juices of plants, belong to the sub-order Homoptera, to which also belong the *Coccidæ* or scale insects and the *Fulgura* or fireflies.

Mr. Baumgartner, Assistant Government Agent of Matara, has left his station on furlough, much to the regret of the inhabitants of the Matara District. He has made himself conspicuous among Government officials by the interest he took in Agriculture and Horticulture, as well as in the welfare of the people generally. Before leaving, Mr. Baumgartner sent in a complete and excellent collection of specimens of the raw and manufactured products of his district for the Imperial Institute.

The following articles have been received for the School of Agriculture Museum:—Samples of fine grains grown in Kolonne Korale, Rakwana, from Mr. T. W. Goonewardene; an old porcelain plate, and a Kandyan lacquer plate, from Mr. T. B. Pohath Kebelpannala; specimens of Garudugalla from Walapana, from Mr. L. P. Jayasuriya and Mr. H. D. Lewis; a beautiful stalactitic specimen of caju tree gum, four feet four inches long, from Mr. J. P. Ranasinghe.

We have to acknowledge copies of the Jaffna College Miscellany, and the number for March and April of the St. Thomas' College Magazine.

Mr. Manchanayake and Mr. Cooray, late of this School, having both got appointments under the Straits Settlement Government, have left Ceylon for Singapore.

Among the more notable Exhibits at the Grama Rakshaha Samagama Show held at Dalugama on the 27th April, were a young buffalo, 3 years old, covered with fine greyish hair, said to be cross between an Indian and Ceylon buffalo; some splendid coconuts of enormous size sent by Mr. Valerian Perera and Mr. John Ranasinghe; 3 uncommon-looking mangoes, of a reddish hue like those commonly met with in North India, exhibited by Mr. D. M. D. Alvis; and a bunch of gigantic plantains by Mr. Weerakoon.

THE TROPICAL AGRICULTURIST MONTHLY.

Vol. X.

COLOMBO, JUNE 1ST, 1891.

[No. 12.]

THE CEYLON TEA FUND AND THE KIOSK.

We call attention to the following forcible letter from Mr. Wm. Mackenzie condemning the proposed Colombo Tea Kiosk *in toto* and calling for a reduction in the subscription to the Tea Fund. Mr. Mackenzie

thinks the Kiosk will be worse than useless if the object be to ensure better tea to visitors than, on the average, is got by them at present in the hotels, and knowing the difficulty in our own experience of getting native servants to serve two successive pots of tea of equal infusion, we are inclined so far, to agree with him. But surely tea-drinking was not the sole purpose of the Kiosk? Is it not to be as well for the sale of packets of pure Ceylon tea, to the numberless visitors—Cook's tourists included—who pass through Colombo from all parts of the world. Mr. Mackenzie is wrong even in thinking that all the Australians or Americans have been reached. There are many still to whom pure Ceylon Tea in an unknown beverage. There is something enterprising and attractive too in putting an ornamental Kiosk to advertise Ceylon Tea in the very forefront before all passengers as they emerge from the Colombo jetty. We want them to carry away as their first and last impression that tea is the most important of Ceylon products and the pure article the only tea worth drinking. A year or two of the Kiosk can, at least, do no harm! and after that if the Ceylon Tea Fund Committee have no more worlds to conquer, they must gracefully disappear from view, selling the Kiosk and its good-will and placing their funds for the endowment, say, of a Convalescent Home for Planters. One word as to the leading "official" Planters who now condemn the Kiosk—why did they not speak out before? The general public like ourselves look to all "official" planters as the responsible leaders in such a movement, and if they do not dissent at once when a proposal of the kind is made, we refuse to give them credit afterwards for wisdom or prudence. They rather merit condemnation.

THE CEYLON TEA FUND AND THE KIOSK.

To the Editor,

Colombo, April 15th.

Sir,—In a para touching on the Ceylon Tea Fund Committee (see page 828) you write:

"We cannot see how the business in hand can permit of any reduction of subscription at least this year; but we suppose the Fund is not to be continued for ever, or beyond a certain date," &c.

My principal reason for proposing a reduction is that the Fund is now so large that in order to get rid of some of the money, the long proposed Kiosk is to be erected. For what purpose? We are sending large shipments of tea to Australia now, and if we could afford to take prices similar to those paid in Australia for Indian teas lately, we might easily double our shipments.

Of Indian and Ceylon teas, about 9,000,000 to 10,000,000 lb will go to Australia this year, showing that no Kiosk is required to introduce our teas to that market.

Is the Kiosk likely to aid in getting China or Calcutta residents (almost our only passenger visitors, besides Australians) to drink our teas? If not, for whose benefit is it intended? It will hardly help us with Russians, French or Americans.

Then are teas at the Kiosk to be so much better than the much-run-down decoctions we get at the various hotels? I give the managers of these establishments credit for doing their best to serve good teas, and unless there be a European manager to see to the making of each separate pot of tea, I feel certain complaints will be as frequent as at the hotels.

But European management means a large expense, and, under its weight, there would be a yearly loss.

Then on the demise of the Tea Fund which you foresee, what is to become of the Kiosk? Even now, the Tea Fund Committee is not a trading body, and how is it to own and conduct the Kiosk?

If I could believe there was any chance of the Kiosk being a success, or of doing our trade any good even if conducted at a loss, I would be very sorry to do anything to cripple the energies of the Committee.

Or if the Committee had any large scheme on hand to which the money proposed to be spent on this Kiosk could be directed, I would not propose any reduction in the subscriptions.

But I have taken the opinion of many representative planters and have found no one who had a word to say in favor of the Kiosk, except that the money had been voted and therefore must be spent. I do not think because a folly has been proposed, it need be perpetrated.

Of the two leading members of the Planting community at present—*leading* because unanimously approved of for their present offices—one told me a few days ago he agreed with me, but as to the folly of building the Kiosk he feared it was too late to stop it. The other said the same, and added he believed its erection would prove a *disaster*! Will someone give us the arguments on the other side?—
Yours truly,
WILLIAM MACKENZIE,

EXPERIMENTAL GARDENS IN THE NORTH.

A JAFFNA BOARD OF AGRICULTURE SUGGESTED.

The very interesting and instructive annual reports which Dr. Trimen, Director of the Botanical Gardens, is so punctual in issuing through the Government press for the information of the Public, have suggested to our mind a doubt as to the general utility of these gardens. A considerable sum is every year spent from the Public Treasury on what some consider a luxury, others an attraction and a sight to travellers, and all an ornament to Ceylon. Admitting the gardens to be a luxury and one of the attractive sights of "the utmost Indian Isle, Taprobaue" where every prospect pleases, we are not disposed to indulge in a wholesale condemnation of the Gardens of which we are truly proud. In all magnificence of Oriental display, watered as the garden is on three sides by the largest river in Ceylon, the beholder in it for the first time is lost in wonder, when gazing on the sublime tropical vegetation in all its rank luxuriance, the plants and vegetables laid out in systematic beds, creepers with a wealth of buds and flowers entwining the lordly stems of more robust trees, the innumerable clusters of fruits varying in size and colour, the richest crimson blending with the ripest yellow, all inviting the passer-by, the melodious singing and twitter of birds which find a welcome abode among the innumerable branches—truly all these conspire to make the visitor believe that he treads on the sacred soil of the veritable Paradise of his forefathers. But a massive bungalow built in the Gothic style soon undeceives our visitor that the grand panorama before him is but the result of scientific cultivation. What an agreeable surprise! Fact is indeed stranger than fiction. Such is the effect produced on a globe trotter who rushes through the world at Railway speed. But let us see, if apart from affording this transitory pleasure, the gardens cannot be turned to some profitable account. That the gardens have contributed in some degree to the benefit of the people there is no doubt, but is the little good they have been the means of doing in any way commensurate with the large outlay necessary for its upkeep? Have the gardens justified this expenditure? Cannot they be made to yield greater profit without unnecessarily increasing the expenditure? These are some of the questions which naturally suggest themselves to a thoughtful mind. Whatever doubt we may entertain on the first two questions, there can be none on the last.

We cannot at present lay our hands on facts and figures in connection with the gardens, but a few suggestions as to how they could be turned to advantage would not, we apprehend, be out of place.

To the three Botanical gardens, Peradenia, Hakgala, and Heneratgoda—the two latter branches of the first—we believe, with a trifling outlay, each Province contributing its quota, other experimental gardens on the same lines as those of the existing ones, can be added in the provincial capitals, each to be nominally under the respective Government Agents, but all controlled by the Director, for the time being, of the Peradeniya Botanical Gardens. A competent Agriculturist should be in charge of each garden nominally under his local superior, the Government Agent, but responsible to the Directors; and these professional men attached to these gardens should, in addition to keeping their gardens in the highest state of efficiency, try their utmost to spread a knowledge of the improved method of cultivation, and send annual or quarterly reports to the Director as to the state of their gardens with remarks and suggestions of his own, as to the economic plants and vegetables suitable to the soil of their gardens, putting in their requisition for such plants as are not obtainable locally and generally keeping the Director duly informed of every thing which in his opinion will be of benefit to the people. Now that through the laudable exertions of Mr. Green a batch of graduates are annually turned from the Agricultural School with a competent knowledge of their subject, their services can be engaged for a trifling sum, compared with the enormous expense necessary to get down

Agriculturists from England or the continent. If the Government is so minded, we think a "Department of Public Gardening" may be organised on the same lines as those of the "Department of Public Instruction" and the greatest good can be done with the least possible expenditure. Apart from the Government gardens in each important town, there may be private Grant-in-aid-gardens receiving a small annual amount from Government, if they show good and satisfactory results.

We say advisedly that the Government Agent of the Province should be the nominal supervisor of the Government Experimental gardens; for without his taking a lively interest in these projects, the experiment is doomed to failure. The Government Agent being the all-in-all in the Province the success or failure of a scheme depends entirely on his hearty cooperation or indifference. Devoid though he be of scientific knowledge and training he will be the means of doing great good, if guided by a competent and responsible agriculturist. The whole force of headmen can be held in leading strings and made *volens volens* to spread a knowledge of improved gardening and cultivation of economic plants, throughout their respective divisions. To aid the Government Agent and advise him on all important matters, the formation of a Board consisting of the chief Headmen of Jaffna and a few of the leading landed proprietors independent of Government, will be a very desirable step. Such a Board in addition to giving the agent the best local opinion will also considerably add to the moral force of his actions. The Board may well claim to be a consultative assembly, but we do not see why the administrative and executive functions should not be vested in it. Whatever powers the G. A. and the Board may possess, in all matters of a purely scientific nature the Director should be the supreme authority.

One of the first steps the G. A. and the Board, are to take should be the starting of an experimental garden in a central spot where an inexhaustible supply of water could be secured. If the Putoor tidal well can be fitted with a large pump, we think there can be no other better ground for first operations than the plots about it. The water in the well is demonstrated to be practically inexhaustible and the analysis of the water has revealed many valuable constituents necessary for plant life. The soil is also good and suited for the ordinary plants and for the first start different varieties of cotton and tobacco may well be tried and seeds of the best variety in each distributed largely throughout the villages. As time goes on more valuable plants and fruit-trees may be cultivated and seeds and cuttings of these distributed to the people on their application with a small remittance which may from time to time be fixed upon by the Agent, and his Board. For the first one or two years the project may involve the Government in some expenditure but after that we are sure the garden will pay its own working expenses, if it will not leave a margin of profit for the Government. Breeding of different varieties of cattle imported from India, Aden, etc. may well form another industry connected with the Gardens and now that our breed of cattle is becoming degenerated owing to several causes, this suggestion should commend itself to our Rulers. We have put forward these suggestions for the consideration of those who have the interest of the people at heart and we have reason to believe that if things are only properly represented to our Government Agent he will give his best attention:—Jaffna "Patriot."

AMERICAN QUININE—Messrs. Powers & Weightman of Philadelphia, have issued a circular in response to the widespread reports that they had ceased manufacturing quinine themselves, and simply bottled and labelled foreign quinine as their own brand. They aver that they have never relinquished the manufacture of quinine since they first began it, shortly after its discovery some sixty or seventy years ago, and say that the work of making and packing it is all done by them in Philadelphia.—*Chemist and Druggist.*

BARK AND DRUG REPORT.

(From the *Chemist and Druggist*.)

LONDON, March 25th.

CINCHONA.—The fortnightly auctions which took place here on Tuesday were rather heavier than their recent predecessors. They consisted of:—

	Packages	Packages		
Ceylon cinchona	780	of which 633	were sold	
East Indian cinchona	2,086	do	1,814	do
South American cinchona	475	do	177	do
Java	284	do	256	do
African West Coast	23	do	28	do

Total 3,653 do 2,908 do

The assortment was distinguished by the unusual predominance of East Indian bark, mostly from Beporo and Calicut, and nearly all of recent import. The bulk of this consisted of *Succirubra*, including several parcels of very good chips and shavings, and there was also a fair quantity of Ledger bark, but the *Officialis* barks were badly represented. The sales generally passed off flat and lower, especially towards the end, holders selling freely. Some of the brokers at the close of the sales declared that the prices obtained were absolutely the lowest ever accepted in public sale in London.

QUININE.—The market is dull, and no business reported. The nominal quotations are: Sellers 10½d, buyers 10d per oz., for second-hand German quinine in bulk.

PLANTING NOTES IN SOUTHERN INDIA.

Mr. Philip Home has a second excellent letter of advice to his nephew in the *Indian Planter's Gazette*, dealing with Calcutta Agents. He commences his letter by remarking that there exists between planters and their Agents a little—perhaps sometimes more than a little of what he calls race or class antipathy. "The causes of friction," he proceeds to say, "arise in a want of community of view."

This phrase hits the nail square on the head. The planter is not a business man. A letter couched in the usual cautious business phraseology reaches him at the end of a long anxious and harassing day. He is tired and irritable. There is some sentence which reads to him as implying distrust or reflecting on his work. He takes up paper and pen. He does not 'beg to own receipt of the favour' nor 'has he the pleasure to bring to the notice,' nor 'the regret to observe.' He writes briefly and makes his sentences crack and sting. The firm is to him an impersonality. By the time the 'stinker' is complete, his ill-temper and irritability, caused not by the Agents, but by the worries of the day have been worked off. Agents are human. They read in all probability merely what is written, not what is between the lines. They retort, making some allusion to money matters. And the ruction grows.

That the planter as a rule is not a business man is generally admitted. He argues thus, to quote Mr. Home again, "what is the use in spending much of my time over vexatious accounting and correspondence with all the planting to look after and coolies coming in." There is some truth in this, but on the other hand, time should be found for accounts and correspondence, and failure and heavy loss has more frequently than not been due to the neglect of these. The Agents, sitting at their office tables, with their clerks and their peons, forget that letters and accounts are a very different matter when all the coolie work has to be done by yourself. They blame the planters often unreasonably for their delay in forwarding returns, and in replying to their letters. So here again is want of community of view.

"There is another cause," continues Mr. Home, which has set up antipathy between improvident planters as a class and Agents. A Manager works for some years, saves a little money and comes in, we will say, for a small legacy. He, with a couple of other men in the same position, takes up a piece of land and sets to work to make a tea garden. They open out beyond their means and borrow money from the Agents on the security of their property. They have

a bad season, and misfortune comes in other shapes and forms. They get more and more heavily in on the wrong side of the Agents' books. They are foreclosed on, and the firm takes over the property, which backed by ample capital turns out a very good thing. The firm has done nothing but what is perfectly justifiable, but the man who opens the garden doesn't look at it in that light. It is gall and wormwood to him to see the familiar bushes, which he worked so hard over planting when seedlings, grown from seed brought out of his savings,—yielding profit to others. He stigmatises the entire agency fraternity as vultures and cormorants capable of every rapacity and meanness."

Just so. No matter whether the case is exactly similar to the above or whether it arises from reckless opening by an inexperienced youngster, or from unsuitable soil or a succession of seasons going from bad to worse.

Planters are apt to confuse the capitalist with the merchant. Taking it as a general rule, the former is prepared to let his money lie idle for a length of time, provided there is a reasonable chance of it bringing in a good return eventually. The merchant requires a good return on his money almost immediately either directly or indirectly. It is contrary to the first principles of mercantile rule to lock up capital for an indefinite period. An application is made for a loan. A merchant has a balance lying idle. By utilising it he sees it will bring in business. The estate, as time goes on, cannot pay its way, and he is not prepared to invest further money without the direct management of it. So, as in an example used by Mr. Home the estate is taken over; more capital is sunk, with the result that a handsome profit accrues. But of more frequent occurrence are the cases when money has been lent, but hardly any return, except on paper, received. The merchant realises that he has made a bad investment; he is naturally anxious to get back as much of his money as soon as possible, he declines, as it seems to him, to throw good money after bad. He shows forbearance so long as he can afford to, and then forecloses. Can anyone fairly blame him?

More friction is caused in all these transactions. The planter, who has probably never borrowed before, does not realize how quickly interest mounts up. Items appear in his monthly account which he does not understand. All that is intelligible to him, is that they help to augment his debt. He knows his ignorance and believe that it is being made use of to swindle him, and freely expresses these views. The Agents are frequently not even in their treatment of a borrower. At first they are too eager to see the property improved and high cultivation undertaken. Latterly they grow nervous and are in too great a hurry to keep expenses down to the lowest pitch.

Then too there are instances of planters taking advantage of the willingness of Agents to help them, to incur a debt which they cannot expect to pay; instances of agents placing cheque-books in the hands of a young planter with *carte blanche* to draw on them to any extent.

So the antipathy is fostered. More's the pity. If only both sides would realise and keep continually before them the difficulties, the embarrassments and the worries that surround the other; if only both would display a somewhat greater desire to forget the cases where the actions have not been quite according to Cocker, and to remember the much more numerous ones where consideration and kindness have been shown, how much better for all. The Agents are as necessary to the success of the planting industry as the planters, and the less the friction and the antipathy between them, the greater is the success likely to be.—*St. Louis in the Madras Times*.

PLANTING NOTES FROM PEERMAAD.

After an unusually boisterous land wind season followed by very hot and dry weather, splendid rain has fallen all over the district, and has brought out very fine blossoms, so that all those who are still the fortunate possessors of coffee—alas! that their number has so terribly diminished—are particularly cheery, and

year was R20,758.48, of which R4,842.78 were on account of the permanent product, and at Matale the total expenditure was R26,640.00 of that R14,490.43 were on account of the permanent product.

Audited and found correct, JOHN GUTHRIE, E. & O. E., Kandy, 25th March 1891. A. PHILIP, Secretary,

In moving the adoption of the Report the CHAIRMAN remarked that in consequence of the want of rain the tobacco crop harvested was not as large as was anticipated and the quality was disappointing but the present prospects of the company since its formation were satisfactory and experts consulted had with some qualification reported favorably on the samples of tobacco leaf submitted, as would be observed. Ceylon tobacco had failed to realize the price of Sumatra tobacco. The

Directors are unable to fathom the reason of this but it should be remembered that Ceylon tobacco is a young product. It was possible that the system of manufacture in Ceylon might require some modification. The Company however, being in possession of some very fine lands have therefore decided to devote attention to forming valuable coconut and cacao and tea estates. The Company's interest in tea would be comparatively little in this respect differing from many of the other agricultural Companies. The Company would not be entirely dependent on tea, its interest in that product being no more than $\frac{1}{4}$ or 1-5 in his opinion the Company will in course of a few years prove to be one of the best and soundest in the colony. The Company owns some of the fine lots of land between Katugastota and Matale, land which is beginning to be more appreciated daily, and the soil of which is of very valuable quality. The Company has a lot of cacao on Matale Estate 50 acres already planted. The land certainly was of very fine quality and should make a very valuable cate. The Directors felt some disappointment at the tobacco but he had great hopes for the Company and did not think that he was unduly sanguine in anticipating that the shareholders would ultimately receive good dividends; even if not successful in tobacco the Directors believed that they would make it successful in other products. Mr. Christie, Mr. Hill and Mr. Owen were leaving the Island Mr. T. C. Owen retires by rotation but is eligible for reelection, but they would wish rather to remain as Directors as otherwise Mr. Armstrong would be left to act alone on the Board of Directors. The shareholders were not to suppose for a moment that the Directors were leaving a sinking ship owing to the coincidence of a temporary absence.

Mr. ALEXANDER and Mr. BORRON suggested that it might be convenient to put any questions before the adoption of the Report.

The CHAIRMAN having replied to Mr. Borron's questions, Mr. Hugh Fraser desired to explain his position and made some observations on sales of Ceylon Tobacco in the London market and on the prospect of tobacco growing in Ceylon.

The CHAIRMAN replied at some length to Mr. Fraser's remarks and those of other shareholders and having taken the sense of the shareholders on the matters submitted for consideration he put the Report to the meeting when it was unanimously adopted.

A resolution proposed by Mr. ALEXANDER TAIT and seconded by Mr. D. Fairweather :—“ That the remuneration for 1891 of R1,000 per annum be paid to the Directors,” was unanimously carried.

It was proposed by Mr. A. G. SETON and seconded by Mr. J. ALEXANDER :—“ That the retiring Director Mr. T. C. Owen be re-elected and that in view of the absence at home for sometime of some of the existing Board, Mr. Orawley-Boevey's name be added ” and this was also carried unanimously.

Mr. J. ALEXANDER proposed and Mr. A. G. SETON seconded :—“ That Mr. H. Drummond Deane's name be added as a Director.”

Mr. SETON rose to express the satisfaction he felt after having visited this morning the Estates of the Company at Matale and at Ukkuwella, he felt sure that ere long the shareholders should do uncommonly well in possession of such properties.

Mr. ALEXANDER moved a voto of thanks to the Chairman of the Board and to the other Directors, this was seconded by Mr. A. Tait, and was unanimously carried.

This concluded the business of the Meeting.

CINCHONA IN BRAZIL.—There is a cinchona plantation, it appears, at Theresopolis, in Brazil, which contains already over 20,000 trees. Analyses of the bark produced there are said to have shown an average equivalent of 1.92 per cent of quinine sulphate. The Brazilian Government have instructed Professor W. Michler of the Rio Polytechnic School, to make a series of fresh analyses of the Brazilian bark and report upon the prospects of the culture.—*Chemist and Druggist*, March 28.

COCONUT SUGAR.

Hyderabad Estate, Batticaloa,
November 27th, 1849.

Messrs. Lemarchand & Co., Jaffna.

Gentlemen,—I am in safe receipt of your favor written in reply to the questions addressed to you, and I beg to offer my very best thanks for the same, conveying as it does, much new and valuable information about the subject which is now occupying a great deal of my attention. I neglected writing till I could more satisfactorily give you a kind of result of our trials, and from which I hope you may draw the same conclusions that I have. As for the palmyra toddy, I consider that at present the most important affair in Jaffna, and only wish I could have a chance to try what could be done, I myself think that the fact of the season beginning and ending in 3 or 4 months a great advantage indeed. I make no doubt that the paane could be purchased from the natives at a remunerating price, and that they would get to prefer so selling it, to making that abominable compound, which they do now. I have proved that paane can be brought always in all seasons, in the hot sun or rainy weather, in the land wind or monsoon, $5\frac{1}{2}$ miles in chatties on coolies' heads, not reaching me till 4 p.m., and yet not suffer any deterioration whatever, and that from it, however highly limed it may be, a most superior quality of muscovado sugar can be made. The weather is now so very rainy that I can do nothing, but when it clears a little, I will try and get some more and make you a sample. Even that excellent sugar you sent me deliquesced considerably on the way, and I am afraid that mine, being still only muscovado, would do so entirely, still I chance a few grains in this letter. Our experiments are not yet sufficient to determine precisely whether bark or lime would be used; but in consequence of a recent discovery I am inclined rather to the latter, as there is then no risk of fermentation taking place. This day a paper on the subject, with samples, goes to the Asiatic Society, whom I have requested to have a full report thereon made and sent to the papers. I have little doubt they will do so, and then you will see the whole detailed, as far as we have yet gone.

I am curious to hear what the Jaffna planters say, and if they have tried it as yet on any of their bearing trees; also, if they anticipate that we shall have any difficulty in obtaining toddy-drawers. A friend writing from India affirms that we shall not, but that any number can be procured from Mysore, Tanjore, &c.

My brother has made a very fair trial on two small trees having tried them 2 months, (7 paales were cut altogether on the two trees; 8 might have been cut, but one was left in the middle of the experiment, and now he is letting the trees run to nuts, as a further proof, each proceeding paale was uniformly larger than the one before, and yielded more toddy.

The last cut trees yielded the most. A paale will run 40 days' cutting twice a day. With lime, the toddy may be taken down once in 24 hours, and in the evening the paale only stirred. The first 30 days the two trees yielded on an average $3\frac{1}{8}$ pints each per day. The second 31 days they gave $4\frac{1}{8}$

—
2)7 $\frac{1}{2}$

—
3 $\frac{3}{4}$ average.

But it is a question whether the first month should be counted. Thus a tree seems to be able to acquire as it was a habit of giving toddy; and probably the more it is cut the better. The paales which have come out since have abundance of nuts now on the flower stems, adding the $\frac{1}{4}$ th for the paale nuts cut we have, on the average of the two months about 180 gallons per annum from a tree, and taking the second month, over 200 or rather exactly 200. I am sure this is much more than any one expected. In all the processes I see no difficulty which may not be overcome, or rather which has not been overcome, and on the first December we hope to start,

with 50 trees, but that depends on whether we can get a certain pail made.)

I have only further to say that if any planter in Jaffna wishes for information or any particular point which I can afford, I will do my best to afford it him. I dare say they already number among them some sugar planters. I have a book by a Mr. Whitehouse of Jamaica. Is he any relation to your son-in-law?

But it is possible, as I am acquainted with most of the late discoveries, &c., or rather improvements in the art, that something may occur, if they really wish to try and if in time for next palmyra season; if anyone thought seriously of it, I would be willing to come to Jaffna (if could get leave) and assist them to erect any works necessary or forward any plans or sketches of the same on remunerating me a trifle for the loss of time. There are some things particularly needed by this paane (as it seems now) rather different from what is necessary in the case of cane juice; but, if any one procure and boil some paane, they will soon see it. As our paane averages 9:5 Beume, there is no fear but every gallon will yield a pound of muscovado sugar, and my trial leads me to think that $1\frac{1}{2}$ lb. may be looked for. None of my experiments have been quantitative ones; it cannot be done in open earthen chatties.

As to the refining of the Jaggery, it can be done; and I have done it, but how much better to act on the raw material! Notwithstanding, when the season opens, I will ask you to buy and send me some for a trial on a large scale, say, perhaps, a ton. I will advise you of this.

Meanwhile, please make this quite public. I shall have no secrets, though of course the practical part of the business can never be explained, it must be seen and experienced. The cost of apparatus, however, will not be very great. If any one is going to set about it as I said in time for the palmyras, they should lose no time.

A few lines in acknowledgment will be esteemed a favor. Please tell me if the sample arrived at all presentable, and, if so what the sequel is priced at? If it is really in good condition when you get it, Perhaps you would let Mr. Dyke see it? Perhaps you have heard also something or other new on the subject since. By-the-by, you omit to say which sized baskets are sold 300 for a shilling. I should like to know the nett weight (minus baskets) of a given number of baskets, their size, and price. You do say 8 to 10 baskets one pound weight, but not which kind size is here specified. We have not got to make such good sugar, I think when Capt. Reddie was here; this is made by a new process discovered lately.

With many thanks, I remain, Gentlemen,
Yours faithfully,
(Signed) J. GLANVILLE TAYLOR.

FIXATION OF FREE NITROGEN.

The subject of nitrogen in its relation to vegetation has occupied the attention of agricultural chemists, more or less, for nearly a century, and it is just about half-a-century since a Boussingault commenced experiments to determine whether plants did assimilate the free nitrogen of the air—his conclusions being that they did not.

Thirty years ago a series of experiments on the same subject was commenced by Lawes and Gilbert at Rothamsted, the results of which confirmed those of Boussingault. The authors then stating that in view of the evidence afforded of the non-assimilation of free nitrogen by plants, when grown under conditions of sterilisation and of enclosure, it is very desirable that the several actual or possible sources whence they may derive combined nitrogen should be more fully investigated.

Since that time the question of the sources of the nitrogen of vegetation has continued to be the subject of much discussion and experimental enquiry, both at Rothamsted and elsewhere. But during the last few years, however, the discussion has assumed a somewhat different aspect. The question still is, whether the free nitrogen of the air is an important source of the nitrogen of vegetation; but whilst few now assume that green-leaved or chlorophyllous plants directly assimilate free nitrogen, it is never-

theless supposed to be brought under contribution in various ways. Coming into combination—by the agency of electricity, within the soil, or within the plant; or under the influence of microorganisms, or of other low forms, either within the soil itself, or in symbiotic growth with a higher plant.

In July last, Professor J. H. Gilbert delivered a lecture at the Royal Agricultural College, Cirencester, in continuation of a series on the results of experiments at Rothamsted with different crops, taking, as his subject, the "Fixation of Free Nitrogen," and giving a description and some of the numerical results of experiments made at Rothamsted in 1888, a description, and some illustrations of the growth in 1890, and also a brief account of the experiments still in progress. This lecture, with additions, has now been published, and the following abstract may be taken as giving the main conclusions:—

HOW IS THE FIXATION OF NITROGEN TO BE EXPLAINED?

Revising the whole of the Rothamsted results there can be no doubt they are abundantly confirmatory of those obtained by Hellriegel and Wilgarth, which are, that plants of the gramineous, the chenopodiaceous, the polygonous, and the cruciferous families, depend on combined nitrogen supplied within the soil; while leguminous plants do not depend entirely on such supplies. Also, that the fact of the fixation of free nitrogen in the growth of Leguminosæ, under the influence of suitable microbe infection of the soil, and of the resulting nodule formation on the roots, may be considered as fully established. Although, as Sir J. B. Lawes and Dr. Gilbert admit, we must obviously know more of the nature and mode of life of the organisms which in symbiosis with the leguminous plant bring about the fixation of free nitrogen, before the nature of the action can be understood.

It is a point of importance that it should be established, as it appears to be, that in the development of the parasite, the cortex of the root of the host is penetrated, and so an intimate connection between the two—indeed, a symbiosis—is set up. Then there is abundant evidence that the nodules are very rich in nitrogen. So far as the facts at command go, it would seem that, in certain stages of their development, their dry substance may contain a much higher percentage of nitrogen than that of any part of the growing plant itself; and in some cases, even higher than in that of the highly nitrogenous leguminous seed.

But whether or not it may eventually be established that nitrogen is fixed by microbes within the soil independently of leguminous growth, there is evidence that in soils and subsoils containing organic nitrogen, lower organisms may serve the higher plants, by taking up, or attacking and bringing into a more readily available condition, combined nitrogen not otherwise, or only very slowly, available for the higher plants. For example, it is probable that fungi generally derive nitrogen from organic nitrogen; and in the case of those of fairy rings, there can be little doubt that they take up from the soil organic nitrogen, which is not available to the meadow plants, and that, on their decay, their nitrogen becomes available to the associated herbage. Then in the case of the fungus-mantle observed by Frank on the roots of certain trees, it may be supposed that the fungus takes up organic nitrogen, and so becomes the medium of the supply of the soil nitrogen to the plant.

More pertinent still, is the action of the nitrifying organisms in rendering the organic nitrogen of the soil and subsoil available to the higher plants. It may well be supposed, therefore, that there may be other cases, in which lower organisms may serve the higher, by bringing into a more available condition the combined nitrogen already existing, but in a comparatively inert state, in soils and subsoils.

As to the undoubted fixation of free nitrogen in the growth of leguminous crops under the influence of suitable microbe infection, and of the development of nodules on the roots of the plants, the alternate

explanations seem to be:—

1. That the plant is enabled, under the conditions of the symbiosis, to fix the free nitrogen of the atmosphere by its leaves.

2. That the organisms become distributed within the soil, and there fix free nitrogen, the resulting nitrogenous compounds becoming available as a source of nitrogen to the roots of the higher plants.

3. That free nitrogen is fixed in the course of the development of the organisms within the nodules, and that the resulting nitrogenous compounds are absorbed and utilised by the host-plant.

Dr. Gilbert seems to think that the balance of the evidence at present at command is much in favour of the third mode of explanation.

PRACTICAL IMPORTANCE OF THE QUESTION.

In regard to the practical importance of the newly-established source of nitrogen to the Leguminosæ, considered in its bearing on the known facts of agricultural production, and especially on the question of the sources of the nitrogen, not only of Leguminous crops themselves, but of crops generally, it may be stated that both agricultural investigation, and direct vegetation experiment, have clearly shown that Leguminosæ do take up much soil-nitrogen, and, at any rate, in great part, as nitrate. But the evidence does not justify the conclusion that the whole of the nitrogen has been so derived; and while the balance of experimental evidence is against the supposition that the higher plants growing under sterilised conditions can assimilate free nitrogen; it is established that, at any rate, in the case of some leguminous plants, they may acquire nitrogen coincidentally with the development on their roots of tubercular bodies with bacteroid contents; and the evidence points to the conclusion that it is the lower organisms, and not the higher plants, that fix free nitrogen. And further, that when such plants are growing in soil and subsoil containing an abundance of combined nitrogen, lower organisms may serve the higher, at any rate, in part, by bringing the already combined nitrogen of the soil and subsoil into a more readily available condition.

SUMMARY AND CONCLUSION.

There is no evidence that the leguminous plant itself assimilates free nitrogen. The evidence at present at command is in favour of the supposition that the observed gain is due to the fixation of nitrogen in the development of the lower organisms in the root nodules, and that the nitrogenous compounds produced are taken up and utilised by the leguminous plant. Further, the development of the supposed nitrogen-fixing bodies is obviously dependent on due infection with organisms essential to the setting up of the symbiotic life in the particular leguminous plant to be grown.

It seems probable that, in the growth in practical agriculture of leguminous crops, such as Clover, Vetches, Peas, Beans, Lucerne, &c., at any rate some, and in certain cases a considerable proportion of the large amount of nitrogen which they contain, and of the large amount which they frequently leave as nitrogenous residue in the soil for future crops, may be due to free nitrogen so brought into combination by the agency of lower organisms.

It has yet to be determined under what conditions a greater or less proportion of the total nitrogen of the crop will be derived—on the one hand from nitrogen compounds within the soil, and on the other from such fixation.

Incidentally the question suggests itself—how far the failure of red Clover, or of other leguminous crops, may be due to the exhaustion of the organisms necessary for nodule development, and for the consequent fixation of free nitrogen, and how far to the exhaustion of combined nitrogen in an available condition, or of the necessary mineral constituents, within the range of the plant-roots.

Assuming it to be established that a considerable proportion of the nitrogen of our leguminous crops is due to fixation under the conditions supposed, it is obvious that such a fact will not only serve to explain the source of the hitherto unaccounted-for amount the nitrogen of those crops themselves, but it will

also aid the explanation of the course of the increased amount of nitrogen which other crops acquire, when they are grown in association, or in alternation, with Leguminosæ. Lastly, it will help to explain the source of part of the accumulated combined nitrogen within our soils, and the comparative slow exhaustion of their stores of it, by cropping, drainage, and in other ways.—*Gardeners' Chronicle*.
