The abandonment of so large a portion of the coffee cultivation of Ceylon, India and Java has left Brazil and other states in South America to stand almost alone in supplying the consuming markets of the world. At the present moment stocks in Europe are unprecedentedly low, and the visible supply for the future is altogether inadequate for ordinary consumption. Under such circumstances it is not to be wondered at that the value of coffee is very much enhanced, and that certain qualities which a few years ago were considered of little value have taken the place of the better kinds, whilst these latter have risen in price above all precedent, Liberian coffee, which used to fetch some R25 per cwt. less than coffee Arabica, has now touched 100s. and attention is naturally drawn to its cultivation. Liberian coffee was first introduced into Ceylon and grown more as a curiosity than anything else; but, as leaf-disease began to affect the estates worse and worse every year, great hopes were entertained that the new and sturdy variety was destined to revive the fortunes of the planters. From one cause or another Liberian coffee did not turn out a success at first—in fact, too much was expected of it. It was planted in unsuitable soils and unpropitious climates; it was slow of growth; the crop would not ripen; when it did ripen it wouldn't pulp; and when it was eventually cleaned and sent to market it fetched a very low price compared with the ordinary produce of the estates. Finally it was found that the Liberian trees were quite as badly affected by leaf-disease and green bug as the other variety—indeed, it has been thought by some that green bug was introduced into Ceylon with the Liberian plants. The great disaster which overwhelmed our planters finally put an end to most of the experiments in planting Liberian coffee; and the cultivation, though a little is still in existence, was practically abandoned. In the meantime, however, Ceylon planters had taken the plant with them to the Straits Settlements, and commencement was made in Johore, the cultivation being afterwards extended to Sungei Ujong, Selangor, and Perak. Just at the time when the demand for coffee has so largely increased, these estates are coming into bearing and showing large profits, and it has been asserted that certain properties belonging to Messrs. Hill and Rathbone are bearing at the rate of 8 cwts. to 11 cwts. per acre. These figures, appearing some six or seven months ago in the Straits papers, were promptly challenged by one or more old resident planters, but the proprietors succeeded in proving that they were correct. It was however explained that these crops were obtained by the help of manure, and though, as regards statistics, there was no necessity to go further into the matter. Messrs. Hill and Rathbone went out of their way to show how fully they were justified in manuring such young coffee in order to take the greatest possible advantage of the high prices at present ruling in the home markets. We quote particulars of crops and acreage of four of the properties. Of the two states in Sungei Ujong we personally know nothing; but we have been told that they are really magnificent little properties, and, as the two total only 110 acres, it can easily be understood they can be kept in first-rate order and made to bear almost anything. Welds Hill estate and Batu Cave estate we have seen for ourselves. Welds Hill is within a couple of miles of the town of Kuala Lumpur, and is a very fine little property. Like the others it has been manured; but, having been planted too close, the trees have hardly got fair play. The outturn of 8 cwt. an acre is certainly very good, but, from the appearance of the estate,

it should be capable of better things unless of course the trees are too crowded. The Batu Cave estate is a mere garden at the foot of immense rugged limestone rocks. The soil is magnificent highly charged with lime, and can be made to bear anything, being only 11 acres in extent. In less favourable localities in Ceylon, and under adverse circumstances of labor and climate, we have seen 24 cwt. an acre taken off a field of 16 acres. There are several planters who have elected to take comparatively inferior land in the neighborhood of Kuala Lumpur, and are planting it up awededly with the intention of manuring and taking advantage, not only of the high prices, but of the facilities afforded them by the railway from Kuala Lumpur to the coast. Had they chosen they could have gone further inland and taken up better soil. These crops then which seem, and in reality are, so large, have been to a great extent produced by the help of manure, whilst the trees are very young, and consequently must not be taken as the standard from which to calculate what Liberian coffee will do in the ordinary soil of the country and with ordinary cultivation. The greater number of estates now in Johore would shew very poor returns; in fact, some of them have been extremely disappointing. The soil undoubtedly is very poor; and, wherever plantations are made on better soil, the result which might confidently be looked forward to would be better than those of the old Johore estates, whilst a similar liberal outlay would no doubt produce similar results to those from the estates in Selangor and Sungei Ujong.—*Local "Times"*

PRUNES IN CALIFORNIA.—There is money in prunes perhaps more than in any other fruit, except oranges. Last season a ten-acre plot in Pomona (Cal.) brought a gross return of £1,583 or nearly £160 per acre. The market for dried prunes is the surest of all. The demand is not likely to be reached for the next 20 years.—*Mildura Cultivator*.

THE CEYLON TEA FUND COMMITTEE is still busy over many things; Agencies and exhibition not being the least of its objects of attention. We cannot see how the business in hand can permit of any reduction of subscription at least this year; but we suppose the Fund is not to be continued for ever or beyond a certain date; for, the day is surely coming when the virtues of Ceylon tea will be fully understood from the Arctic to the Antarctic pole and from China to Peru; and then the Kandy Committee will sing "We have got no work to do."

A RICH DISCOVERY of opals of a finer quality than those of Mexico is just reported from Moscow in the State of Washington, U.S., close to the Idaho Railway. They were found by some labourers while digging a well in a wheat field, the mother rock being a basalt wacke. Opal is an amorphous hydrated silica, and is deposited from water. The finest specimens of the gem or precious opal come from Hungary, but those of Mexico are very fine. The fire opal of Zimapau, in Mexico, is transparent and of a deep red, being coloured by oxide of iron. Small veins of opal have been found in several parts of the United States.—*E. Mail*, March 26.

VINES.—Among the curiosities of the California grape region is a vineyard that may well be called the smallest in the world as regards the number of vines, for it has but one vine. This is a most remarkable one, however, for its branches extend over a space of 12,000 feet, the cane being a foot in diameter. This extraordinary vine is over seventy years old, and was grown from an old Mission cutting by a Mexican woman. It has borne grapes every year since it was two years old, and is good now, they say, for six tons of grapes a year. Clusters weighing seven pounds have been picked from this ancient relic of the Mission days.—*Mildura Cultivator*.

MINES AND MINING IN CEYLON.

We think our exposure the other day of the attempt to depreciate the value of our Gemming Industry was justifiable and satisfactory. We are as anxious to get at the truth as any "roving correspondent" of our Indian contemporaries, and we are equally desirous to avoid exaggeration. But we cannot possibly understand how the total gross returns from an industry, enterprise or speculation which calls forth the energies of 20,000 able-bodied Sinhalese, can be put down at no more than £10,000 per annum. Even if it be said that the 20,000 natives do not work all the year round, but only at certain seasons, and that many of them, failing success in gemming, fall back on their relatives and village resources for means of support, it is absurd to say that so great a number not simply in Sabaragamuwa but in the Southern Province would continue to labour in gem pits—work extremely trying under any circumstances—or even in surface work, for an average return of not more than five rupees per head per annum. On the whole, we consider our estimate of fifty rupees a very moderate one.

But our object today is not to extend discussion which has already so fully occupied our columns in references to Gems and Gemming; but rather to call attention to the other great branch of our local mining enterprise, namely the digging and export of Plumbago. Of the gross returns from this industry there is not room for the slightest doubt or inaccuracy. Every hundred-weight, we may almost say every pound is exported. The rise and progress of this great native industry in our midst has been very remarkable. Going back forty years, we find an export of no more than 23,823 cwt. in 1850, and we give the decennial exports to show the rate of progress:—

Export of Plumbago.

1850	...	cwt.	23,823
1860	...	"	75,660
1870	...	"	85,249
1880	...	"	208,738
1890	...	"	385,754

It was no wonder therefore that "plumbago" mining after the primitive native fashion should attract the attention of Mr. Barrington Brown when in our midst. Whatever difficulty he experienced in collecting correct information for his principals in respect of "gems," he could have no difficulty about plumbago. We have been accustomed to call it our only mineral of "commercial importance." Apart from gems, this will no longer be correct, for the export of "mica" is beginning to make some show. But the great demand for Ceylon plumbago for crucible purposes, has made the industry one of first class importance. Mr. Barrington-Brown did not fail to see this, or to note the practical monopoly which this Colony has of the supply. And yet he found that in connection with the industry, no modern mining appliances, the results of English skill and invention, had been applied. A few natives, it is true, use pumps; but only after a primitive fashion. On this part of his mission, the expert was able to report with confidence. He visited a large number of plumbago mines, and carefully inspected those which had been got on lease, or purchased for his Syndicate, and in nearly every case he was able to show how inadequate was the native mode of working—how when mines got to a certain depth, the aid of capital and skill became indispensable in order to free the pits from water, and how consequently the works are not prosecuted as they might be by European Companies in command of capital.

In one case, Mr. Barrington Brown illustrated the primitive way in which things were being done. There was a boiler fed from a tank supplied with water by two men who hoisted it from a stream, and a Sinhalese watchmaker had arrived to repair the pumps. In this he failed and the water in the pits rose to within 12 feet of the surface. All the time there was a large stream flowing close by which could have driven a waterwheel giving power to the pumps! Scientifically worked, the "expert" felt sure that the plumbago properties secured by his Syndicate would prove very profitable. On this opinion, the London promoters have acted, sending out an English mining engineer and a supply of pumps to erect on some of their properties in the Kalutara district. The result of his operations will, no doubt, be seen ere long; but meantime, we cannot help once more expressing regret that the Syndicate did not see their way to send back Mr. Barrington Brown with power and means to direct operations in respect of both gem and plumbago mines in correspondence with his very practical and valuable Report. Until this is done, we can scarcely feel that justice has been done to local mining industries and a fair test applied to their value and prospects of development.

LETTERS FROM JAMAICA.

JAMAICA EXHIBITION—(OPENING CEREMONY—THE BUILDING AND EXHIBITS—THE RECEPTION OF PRINCE GEORGE OF WALES—THE FESTIVITIES—LEGISLATIVE SESSION—POOR CROPS ON THE BLUE MOUNTAINS.

Per Packet of 10th March.

It is again a long time since I addressed you, and I must apologize for not having ere this sent you an account of the opening of the Jamaica Exhibition; but as you exchange with our local *Gleaner* newspaper, you will no doubt, ere you get this, have received a copy with particulars of the opening ceremony which proved a great success, so that our energetic and hard-working Governor Sir Henry Blake was well rewarded for the trouble he has taken in bringing about this success. Praise must also be awarded to all concerned in the planning and erection of the building which is a very picturesque edifice, and causes regret that being of wood it cannot be permanent; and though it would be a grand thing for the town of Kingston to take it over, and keep it up as a sort of "Crystal Palace," I learn the owner of the land declines to sell, so it is feared that unless matters can be arranged the building must come down and be sold as second-hand lumber, which will be rather a melancholy termination of the affair.

The Exhibition was opened on the 27th January by Prince George of Wales as representative of the Queen, his grandmother, and his father the Prince of Wales, and very well he acquitted himself, won great popularity, and was most warmly greeted and received by the people who turned out in thousands to see him, the occasion having been made a public holiday. On the dais was a large gathering of our Jamaica notables; and also the Earl of Rosse, and other distinguished visitors from King's House, friends of our Governor who had been invited to Jamaica for the Exhibition. The Bishop of Jamaica read a very appropriate dedication prayer, and the choir sang "God save the Queen," "God bless the Prince of Wales" and a hymn suitable to the occasion: after the presentation of the address the Governor asked Prince George to declare the exhibition open, and he moreover made a very nice speech. The aisles of

the building were lined by the police, and Kingston volunteers, and some 7,000 people passed the turnstiles on the opening day, the entrance fee, except for season ticket holders, being 7s 6d up to 4 o'clock.

The building is in Moorish style, the idea, I believe, being taken from the Glasgow exhibition. There is a central dome, and small minarets at the corners: there are aisles and galleries, and the effect within is very pleasing, and the various courts were very fairly complete on the opening day. In the grounds there is an *annexe* chiefly filled with Canadian exhibits. That large country is the principal exhibitor; most of the West India Islands are also represented, but there are not many American exhibits, as "Uncle Sam" took umbrage because he was not officially asked to partake in the Exhibition, not being satisfied with the customary notification sent alike to all countries and nations that an Exhibition was to be held in Jamaica in January. Of course there are several English exhibits, and also many foreign ones, so there can be little doubt that the Jamaica Exhibition will make Jamaica more extensively known than it has hitherto been, and it is hoped it may be the means of extending and reviving our commerce, for Jamaica is neither quite defunct or asleep as is generally supposed to be the case. Neither is it the hotbed of yellow fever so that it need no longer be supposed that a person going out to Jamaica, is sure to find a grave there, any more than a Jamaican visiting England is bound to die of consumption or scarlet fever. It was unhealthy over-crowded Barracks, many close to malarial swamps, the drinking of new Rum, and general fast living that helped to decimate our troops in "old time" days; for now the military mortality in Jamaica can I believe be very favourably compared with other Colonies and stations of that Empire on which the sun never sets.

There is an Art Pavilion in which many very pretty and artistic pictures are exhibited. There is also a Model Dairy for showing people how butter is made, but though Jamaica abounds in horned stock, it has not been possible to get sufficient milk to work the Dairy properly, cows on the many "Pens" being kept not for their milk but for the rearing of stock, so that very few are milked, and they consequently get very wild and have to have their legs tied or to be thrown down before any milk can be got from them. There is a potter from Doulton's; a shed for machinery in motion; there are models of settlers' huts, and some Caribs have been sent over from St. Vincent who work at their basket-making, etc. There is also a theatre in which an English Dramatic and Variety Company performs a panorama showing Canadian views by lime-light, one or two shows, a maze, a shooting gallery, and a large steam "merry go round" which is very largely patronized by the young darbies of both sexes. The band of the 1st West and of the Kingston Volunteers discourses sweet music at intervals, and there is a very good display of fireworks on Wednesdays and Saturdays. Messrs Lascelles, de Mercado & Co. have a pavilion of their own for their special exhibits, and Aston Gardner & Co. have an excellent refreshment room, and besides there is a restaurant within the building "run and bossed" by a Yanke. The building is lighted by electricity, but was at first somewhat a failure. Trams bring the people close up to the building, and the entrance is only 1s. and I should think later on will be reduced to 6d as an inducement to more of the people from the country to come to town and be educated by a sight they are never likely to see again during their lives.

Kingston was in gala dress for the reception of

Prince George; triumphal arches were erected along the route taken to King's House, and an address was presented at the Town Hall; several vessels of war of the West India Squadron were in harbour including the Admiral's ship the "Bellerophon," and the Prince's despatch vessel the "Thrush." There were also one large Russian man-of-war, and two Spanish gunboats, so that the consumption of powder in various salutes was rather extensive. One thing to be missed was that none of the Governors of the other Islands accepted Sir Henry Blake's invitation to be present: it would have added to the importance of the opening ceremony, nevertheless, it was a great success far greater, I fancy, than was generally anticipated.

The Governor gave two balls one in honor of Prince George and the opening of the Exhibition, when the new ball-room was used for the first time; the second the week after was a fancy dress ball which also was a most brilliant success. The Governor was dressed very handsomely and appropriately as Christopher Columbus and Lady Blake as Isabella of Spain: the costumes were copied from old pictures at Madrid. Besides these, there were very many handsome and pretty costumes; and the variety was great and the whole scene very bright and picturesque. Your humble servant appeared as "Santa Claus" alias "old Father Christmas," and was complimented on his appropriate costume, and Dr. Plaxton was simply perfect as an African slave driver and dealer; he was the most observed of all, for it was a real costume purchased on the Coast by an officer of the West Indian Regiment and lent for the occasion. Besides the balls, there were races at Cumberland Pen, cricket and polo, in the latter of which Prince George took part; and it will be many a long day before the Kingstonsians' see the like again.

Our Legislative Council is now in session, and have to pass many important laws. The Governor's opening speech disclose a most satisfactory state of affairs, and there will be money in hand to carry out the building of bridges and improvement of roads.

As regards crop it is very backward this year in the Blue Mountains, and with the exception of one or two properties is not expected to be a large yield. We have had rather a wet February, which is unusual, it being, as in Ceylon, generally the driest month in the year. W. S.

CEYLON'S EXAMPLE TO BE FOLLOWED IN SOUTHERN INDIA.

The following is from the *Indian Agriculturist*:—"There appears to be some prospect of a general increase of tea cultivation in the Wynaad. The fact that this district has been left so far behind in too race with Northern India and Ceylon is attributed by a local apologist to the difficulty of establishing factories for the treatment of the leaf. It is proposed now to start a number of factories as joint stock companies and work them on the Ceylon system, by which a fixed charge of say two annas per pound is allowed for wear and tear of machinery and profit to the manufacturer, while a further charge is made for absolute cost of manufacture, packing, transport, etc., including insurance and all home charges. The average price of tea per pound ruling in the London market is calculated at the current rate of exchange, and the planter obtains this sum, less the fixed charges of the factory. By the adoption of this system it is thought that the cultivation of tea may become profitable on many small estates where the treatment of the leaf by hand is now out of the question as a commercial undertaking."

A COMPLIMENT TO A COLOMBO FIRM.

In an article dealing with this same subject the *Madras Times* says:—"The large fields of tea now planted in the Ouchterlony Valley, with the splendid factory lately erected there by Messrs. Walker & Co. of Ceylon, and the cheap cost of manufacture which this working on a large scale demonstrates, has created a general stir, aided by the very successful planting of Mr. Punnett at Pundalur, whose forty acres of tea by the side of the main road attract the attention of all passers. But the initial difficulty still remains how to dispose of the leaf where no factory has been established to buy at a fair price."

A WELCOME BACK

has to be given to Mr. Thos. Dickson, junior, who left us about a year ago and in the interval has voyaged or travelled (chiefly in America) some 27,000 miles. Mr. Dickson's contributions to our *Literary Register* have been read with much interest and we are glad to say there are more to follow. Mr. Dickson has wandered over the American continent from New York to San Francisco and from New Orleans to Toronto. In the last-mentioned Canadian town, he found large quantities of Ceylon tea in godowns, the brand of "Wangie oya" being prominent. In New Orleans again he found Ceylon tea drunk regularly at the oldest club in the town and he had the felicity of being introduced as the maker of the tea, it being from Lebanon estate. The New Orleansists received the Ceylon planter with princely hospitality. Mr. Dickson was also, as a shareholder, entertained in New York by the Directors of the Ceylon Tea Planters' Company and bestowed the highest opinion of Messrs. Watson & Farr (a firm of such high repute that it is an honour to Ceylon to have their names as promoters of her tea) and also of Mr. Elwood May. The place Mr. Dickson was most tempted to stay in was the vine and fruit growing district of California where with irrigation they seem able to grow anything and have besides a delightful climate. Mr. Dickson returns to the charge of the Lebanon group of tea plantations.

THE AMSTERDAM MARKET.

Amsterdam, March 18.

CINCHONA BARK.—The sales which will take place in Amsterdam on April 2nd, 1891, consists of 6,405 bales, 996 cases (about 599 tons), divided as follows:—Java bark: From Government plantations 429 bales, 29 cases, about 41 tons; from private plantations, 5 976 bales, 965 cases, about 553 tons. Sumatra bark: 2 cases, about 5 cwt. Druggists' Bark: Succirubra quills, 704 cases plus 2 cases Sumatra; broken quills and chips, 614 bales 18 cases; root, 170 bales, 35 cases. Calisaya quills 40 cases; root 8 bales; C. Schulkrafft quills 27 cases. Lancifolia quills 72 cases; broken quills and chips 31 bales, 15 cases; root 21 bales. Manufacturing Bark: Ledgeriana quills 69 cases; broken quills and chips 3,655 bales, 1 case; root 1,161 bales. Hybrids quills 10 cases; broken quills and chips 536 bales, 3 cases; root 136 bales. Officialins broken quills and chips 43 bales. Total, 6,405 bales, 994 cases Java bark; 2 cases Sumatra (druggists' bark.)—*Chemist and Druggist.*

PRECIOUS STONES AND PHOSPHORESCENCE.

Substances which are phosphorescent under ordinary conditions glow with the greatest brilliancy when submitted to the negative discharge in highly attenuated gases. Canton's phosphorus shines with all the splendour induced by strong sunshine. Under the same circumstances the diamond, especially, that from the South African fields, phosphoresces with a brilliant

light blue colour. Diamonds from other localities were found by Mr. Crookes to shine with all varieties of colour, such as bright blue, pale blue, apricot, red, yellowish green, orange and bright green. A green diamond when phosphorescing in a good vacuum gave out almost as much light as a candle, and the different faces of the naturally crystallised gems were found to glow with different shades of colour. The ruby, which is practically almost pure alumina, phosphoresces with a rich full red. A number of rough rubies in a high vacuum glow, when the molecular discharge plays upon them, as if they were red-hot, and with an illuminating effect almost equal to that of the diamond under the same conditions. The colour of the ruby has apparently little or nothing to do with the phenomenon; pure white alumina, rubies of a pale reddish-yellow, and gems of the "pigeon's blood" colour, all emit practically the same deep red glow. The artificial rubies of Messrs. Fremy & Feil, which are of the same chemical nature as the natural stone, behave in precisely the same way when subjected to the discharge in a sufficiently high vacuum, showing that in this as in all other respects the natural and artificial rubies are identical in character. The sapphire, however, which in chemical composition differs but slightly if at all, from the ruby gives out a bluish-grey light, whilst the emerald glow with a fine crimson-red colour.—*Good Words.*

RAINFALL REGISTRATION IN INDIA.—From a Government resolution we quote as follows:—

With regard to the necessity for the definition of a "rainy day," the Meteorological Reporter remarks that from an agricultural point of view, it is not only necessary to know the total amount of rain, but also the character of the rainfall. It is evident that a rainfall of 20 inches during a given period in two or three cyclonic downpours might be destructive to the crops, whilst the same amount occurring as frequent moderate showers in the same period might be beneficial in the highest degree. The only fairly satisfactory way of discriminating the character of the fall is by comparing the actual number of rainy days with the normal number, and the starting point for such a comparison will be a suitable definition of a rainy day. The Meteorological Departments of other countries have generally adopted a rainfall of "01" or upwards in twenty-four hours as defining a rainy day, and this has been followed in the annual reports on the Meteorology of India. A fall of "01" however appears to be too small to be of any value for agricultural purposes in this country. The knowledge of such a fall might be a useful indication of the prevalence of cloudy weather which is some times very desirable for the crops at certain periods. But the comparison usually desired appears to be between the actual number of days on which useful or heavy rain fell and the normal number of such rainy days; and the Government of India concurs with the Meteorological Reporter that a fall of "1" (one-tenth of an inch) in twenty-four hours will be the most convenient and suitable definition.

The proposals for the improvement of rainfall registration which have the approval of the Government of India, may now be summarized. 1st.—That a common hour for registration, viz., 8 a. m., and a common rainfall week ending on Saturday 8 a. m. should be adopted in the whole of India. 2nd.—That all rain gauges should be systematically inspected, the services of the Meteorological Reporter to the Government of India being utilized for supervision of the duty of inspection wherever this is considered desirable. 3rd.—That Symon's rain gauges, tested by the Meteorological Department, should be the only description of gauge used. 4th.—That monthly returns of rainfall be published by each local Government, of which copies would be found together and issued as an annual volume by the Imperial Meteorological Department. 5th.—That the Imperial Meteorological Department should adopt a fixed division of the year into four periods corresponding with the periods of general rainfall for purposes of comparison. 6th.—That for the purpose of calculating the number of rainy days a fall of one-tenth of an inch and upwards be taken to denote a rainy day.

QUININE.

To Dr. King of the Calcutta Botanical Gardens, in his capacity of Chief Superintendent of the Bengal Cinchona Plantations, I am indebted for a specimen of

THE SULPHATE OF QUININE

manufactured at Mungpoo by my good and able friend, Mr. James Gammie. So long ago as March 1876, I saw Mr. Gammie's process of preparing mixed alkaloïds. He has gone on adopting improved methods, until now the Mungpoo Quinine is as valuable in medicine, if not quite so white and flaky as Howard's celebrated preparation. With the present low market prices, the difficulty must be to make the manufacture pay. Prices cannot well go lower, and yet the increase in the consumption of this valuable febrifuge, tonic and remedy against the effects of opium eating and dram drinking, is by no means such as might have been reasonably expected. If only Russia treated her soldiers as human beings, whose lives are sacred, ought to be treated, the consumption of the drug would be doubled at once.

Tea continues to flourish luxuriantly. Exquisitely clear views great rock face of Kirigalpota, varying aspects of Adam's Peak and flanking ranges including Laxapnagala cliffs.

Mr. Hamlin states the great success of 104 acres Coorg coffee on Kondesala under the shade of *Ficus glomerata*, planted 1888-89; crop this year will pay all expenditure. Coffee with cacao amongst it shows no trace of *hemiteia*. Experiments will now be tried on Naranghena 2,000 feet; Delmar over at 4,000.

On other hand old diseased coffee with all attention yields only R25 profit against tea 95 per acre. As Sir Wm. Gregory said 'Can't make an old man young.'

DR. TRIMEN ON JAVA.
(NEW TREES & C., FOR CEYLON.)

From a very interesting letter from Dr. Trimen in answer to questions of ours regarding trees suitable for Ceylon, we venture to quote some passages:—

"All I saw of the hill-country of Java was thus—the sanatorium of Sindanglaia at about 3,500 ft., and the Hill Garden at Tjibodas about a thousand feet higher on the slope of the Gedeh volcano which is always puffing a little. This garden is very poor after Hakgala, but they have a few fine things, notably two magnificent specimens of *Xanthorrhoea hastilis*, and several good conifers of which I bespoke seed. They grow *acacia decurrens* here (the form without suckers) but generally the Australian trees did not look so well as here in Ceylon. I do not fancy there is much in the way of native hill trees in Java worth our attention here, the general character of them as far as I saw being like our own: slow growing, comparatively small and no doubt very difficult to grow. As with us they prefer foreigners. I saw a good deal of *cedrela serrata* ('Red Toon') planted by roadsides and doing well. The Malayan Oaks are very numerous, but by no means particularly hill trees. There are several species at Singapore, prominent trees of the jungles at sea level. I have brought back with me seeds of one called after poor Cantley *Quercus Cantleyana* by King, a very handsome species. There are no less than 104 oaks in the Indo-Malayan region already known: it is curious that we have not one in Ceylon.*

"*Dammara alba* (*Agathis loranthifolia*) is the ordinary species of *Dammara* tree in Malaya, a beautiful

* The reason given by Wallace for the presence of the mountain oaks in Java was its former connection with the Himalayas, but all this abundance of sea level oaks takes us entirely by surprise.—ED. T. A.

pyramidal tree of which I have some fine young plants here received some years back from Sir H. Lowe from Perak, but the Queensland *D. robusta* is a good deal grown in Java as here. I have not seen *D. australis* which needs a cooler climate I think.*

"Cubcbs is a puzzling business. I saw their plantation at Buitenzorg and have specimens from it. Possibly more than one species is grown there. I believe I have already here one of them, but they have not yet fruited and till they do so, it is but guess work. One difficulty is the great difference in the leaves of the young plants and the adult fruit bearing ones. I hope soon to have abundant material for coming to a conclusion; at present not even at head quarters could I get much definite information.

"Buitenzorg is an astonishing place, and Dr. Trenb a man much to be envied. The Dutch Government deserves great credit for maintaining at such a high level and in such a liberal manner an establishment worked on an almost purely scientific basis. There are no less than four fully equipped laboratories in thorough working order, each under a scientific head—Botanical, Bacteriological, Pharmaceutical and Agricultural, all fully equipped with all the latest improvements.

"The Economic or Experimental Gardens (*Cultuur-tuin*) is quite separate from the Botanic Garden (about 2 miles off) and also has a scientific head under Dr. Trenb. It is about 200 acres in extent and laid out in large square plots each devoted to one product, everything well kept and in beautiful order with plenty of labour and appliances. Very large distributions of plants and seeds are made from here to planters and others and *nothing* is ever charged for them; all is given free.

"The Botanic Garden itself is a wonderful and unique place, but without much beauty save in one or two spots. It is very wonderful to see such an enormous number of trees all growing in a classified arrangement. It could of course only be done in a soil and with a climate which will grow anything. But even here many are distorted and stunted and convey very little idea of what the tree is really like. More room is urgently needed, and is to be afforded at once by the annexation of adjacent land.

"I prefer Peradeniya as a garden, combining the *utile* with the *dulce* as it does, but what I envy Dr. Trenb is his large staff of capable trained European assistants, and abundant and liberal funds; also his freedom from nursery-garden work and the absence of any charges for supplying things." All this is very interesting to us as we had Dr. Trenb's guidance over the various gardens in 1881. He also shewed us the fine Museum and Library attached to the gardens. All this liberal support of botanical, horticultural and agricultural science is very creditable to the Dutch Government.

NOTES FROM THE SOUTHERN COLONIES.

(By an ex-Ceylon Colonist.)

My visits to Adelaide, Melbourne and Sydney were very pleasant, but I doubt that I should like to live in any one of them. Unless it be a lucky venture in mining scrip, there is nothing there or here which will give the same return on capital as a good tea estate in Ceylon. The labour question is a big trouble in all the Colonies and has some curious developments which, unless capital is to become the servant of labour, will have to be resisted to the death. The present strike amongst the shearers in Queensland very clearly illustrates one of these

* *Dammara australis* is the New Zealand pine or kauri (not kauri, which is the native name of *Eucalyptus diversicolor*) and it might do well in our higher mountain regions.—ED. T. A.

phases. The men have not struck because their wages are too low or hours of work too long or because of dissatisfaction with their masters' ways or manners, but because their Union has decided that squatters must not engage their shearers direct, but through the Union offices to whom application for hands must be made and who will supply it in quantity and quality at their discretion. Because masters object to place themselves in bondage to such an agreement, the Union shearers have gone out on strike, have assembled in a large armed camp from which detachments go out to drive away, if possible, free labourers, burn down goods sheds, fire ruus, tear up railways which might bring up free labourers, and cut the telegraph lines, and they have been doing this sort of thing for about six weeks in a Colony which has an organisation called a representative Government !! Be thankful that you live in a Crown Colony, the advantages of which form of Government I never realised so clearly as now, and that you have the Tamil cooly for a labourer.

The labour creed has been reduced to rhyme by a labour poet in the following words:—

“Eight hours work,
Eight hours play,
Eight hours sleep,
And eight bob a day,”

This is for our ordinary “pick and shovel man.” Since my arrival in Auckland the shoemakers have gone out on strike for a scale of wages which masters say will make seventeen shillings per day. I am thankful that I brought out a good supply of boots and shoes, for it is likely they will be rather dear in this colony in future. The climate of this place is very nice, something like the shade temperature of Nuwara Eliya and not so hot a sun.

THE KELANI VALLEY TEA ASSOCIATION, LIMITED.

Report of the Board of Directors, which was presented to the Shareholders at the Fifth Ordinary General Meeting on the 16th April:—

The Directors have the pleasure to submit to the Shareholders the Accounts and Balance Sheet for the eighteen months, ending 31st December 1890.

These Accounts, the Directors consider show a very fair result for the first profit-yielding period of the Company's existence. Looking at the final result, it must be borne in mind that the profits for the past season have to liquidate the proportionately heavy balance brought forward from the previous accounts; apart from this balance, the account would show a profit equivalent to nearly 10 per cent per annum.

In the Report issued to the Shareholders on 1st October 1890, it was stated that the Company had acquired the small property “Dover” on favourable terms. The Board have much reason to be satisfied with this purchase which will prove a material factor in the future profits of the Company.

Estimates of Tea for the past eighteen months were:—

	lb.	
From Degalessa	103,020
„ Dover	8,000
		111,020 lb.
Actual production Degalessa	120,727	
„ „ Dover	12,606	
		133,333 lb.

Which shows an excess over estimate of 22,313 lb

Since the date of last Report the Company have purchased a small additional piece of land, in all 7½ acres, at a cost of £27, to admit of a cart road being made at an easy gradient to connect the Factory with the main road across the Ferry.

With a view to the further extension of cultivation of the Company's property, it is proposed by the Board to issue the remaining 397 unallotted shares, and the following Resolution will be submitted to the Meeting, in order to give effect to this:—“That in pursuance of Clause 9 of the Articles of Association of the Com-

pany, the Directors be, and they are hereby, authorized to issue the unallotted Shares of the Capital of the Company, being 397 Shares, at a premium of £1 per Share, and that such Shares be offered at such premium first to the existing Shareholders *pro rata* and in proportion to their present holdings, and that any Shares which shall not be taken by the Shareholders shall be disposed of by the Directors for the best interests of the Company; the premium of £1 to be payable forthwith upon allotment and with the first payment to be made upon the Shares.”

The Net profits shown in the accompanying Accounts is	£546 0 3
Out of which the Directors recommend that a Dividend be paid at the rate of 5 per cent. free from Income Tax, which will absorb	464 0 0

Leaving a sum to be carried forward to New Account of £182 0 3

As a result of the action of the Directors, referred to in their previous Report, the violent fluctuations in Exchange during the past 18 months have not appreciably affected the Company.

BALANCE SHEET, 1ST JULY, 1889, TO 31ST DEC. 1890.

MR. J. L. SHAND AND A NORTH BORNEO
COFFEE COMPANY.

London, April 3rd.

When my last letter was written it was not possible to tell you what Mr. J. L. Shand had determined with respect to sharing in the expedition to the Andes which Sir Alfred Dent has been organizing. But we have learned during the present week that there now exists but little probability that he will take part in it. Mr. Shand would not have been disinclined to go, we think, had it been possible for him to obtain the pecuniary inducement which he considers to be necessary. This, we are told, is not forthcoming, and naturally, therefore, Mr. Shand can scarcely care to expose himself to the risks and hardships which must attend any expedition of the kind.

It is said—indeed it has now been publicly announced—that Mr. Dawkins, first Private Secretary to the Chancellor of the Exchequer, has resigned that appointment to accept charge of this expedition to the Andes. A great deal of surprise has been expressed that that gentleman should care to throw up a position which opens up so many possibilities for the future in order to take part in a venture, successful issue to which must be, to say the least, exceedingly problematical. Even if territory likely to be suitable for coffee growing be found on the slope of the Andes, the question will still remain as to whether it will offer sufficient inducement for the investment of the necessary capital. All the South American Republics have got into exceedingly bad odour lately, and it is very greatly to be doubted if British capitalists would care to risk more money in countries so constantly liable, as they are, to insurrectionary disturbance. We may well feel confident that there would be no difficulty in obtaining the services of any member of young Englishmen and Scotchmen to go out and pioneer the enterprise, however deterrent the conditions may appear to be. It is to the love of travel and adventure which would induce that readiness to go out which has probably actuated Mr. Dawkins to the step he has taken. You, we believe, are already aware that Mr. Clark, of the Peradeniya Botanical Garden, is now on his way home, as we hear to go out with the expedition, and doubtless his services will be of great value. We have not heard the names of any other gentlemen mentioned as intending to take part in it.

The circumstances under which Sir Alfred Dent has arranged for this venture are singular and exceptional. That gentleman is, we believe, the Chairman of the Committee of Foreign Bondholders, and in that capacity, the Peruvian Government being unable to meet its obligations on the bonds issued by it, he received the transfer or allocation by the Peruvian Ministers of certain tracts of land with valuable privileges attached, either as security for the ultimate payment of these bonds or in satisfaction of all the claims which may be made upon them. This must have taken place between 18 months or two years ago, because when Sir Alfred Dent was present at a meeting of the Ceylon Association in London some 15 months or so back, he asked Mr. Leake to recommend to him some gentlemen who might be qualified to go out and report on the suitability of the lands or various forms of cultivation such as are pursued in Ceylon. The contemplated expedition will be the outcome of these arrangements entered into by Sir Alfred Dent in the interests of the holders of Peruvian bonds.

While it seems to be almost certain, as has above been written, that Mr. J. L. Shand will

decline to take any part in the venture described, he has turned his attention seriously to coffee cultivation in Borneo, and since my last letter was written he has registered a Company by the name of the Borneo Coffee Company (Limited), the prospectus of which I have seen. This states the proposed capital of the Company to be £20,000 in £10 shares, the object being to adopt an agreement between Mr. F. Walker and the Company to purchase plantations in British North Borneo and elsewhere, and to cultivate coffee, pepper, cacao, tobacco, &c. The articles of registration provide that the number of the directors is not to be less than three nor more than seven: the first board to be appointed by the subscribers and the qualification to be the holding of 10 shares, the remuneration having to be fixed at a general meeting. Mr. Shand's offices have been registered as the office of the new Company at 24, Rood Lane, E. C. The following list of the first subscribers will show you who the gentlemen are who have interested themselves with Mr. Shand in starting this new scheme:—Mr. H. Walker, 15, Great Russell Street Bedford Square; Mr. W. H. Anderson, Rupert Lodge, Burnham, Bucks; Mr. J. Fleming, 24, Rood Lane, E. C. Mr. A. Walker, 23, Rood Lane, E. C., tea broker; Mr. J. S. B. Ridge, 23, Rood Lane, E. C., tea broker; Mr. J. G. K. Grove, 123, Cannon Street, E. C. accountant; and Mr. J. L. Shand, 24, Rood Lane, E. C. Mr. James Whittall is also one of the first directors, as is Mr. Shand.—London Cor.

THE INDIAN MANUFACTURING IN-
DUSTRIES.

[Iron is so cheaply produced in Britain and the freight to Ceylon is so moderate, that for the small quantity used locally, we do not suppose it would pay to establish the manufacture in Ceylon, even if coal were discovered in our island. All the other essentials,—limestone, clay and manganese we have, with the finest graphite in the world for crucibles. In copying the following article from the *Times of India*, the idea which occurs to us is, that if iron and steel manufactures, on a large scale succeed on India, the day may come when, we shall obtain our supplies, of those metals from the opposite continent in exchange for our pure plumbago.—Ed. T. A.]

Next to iron and coal the minerals of most importance, to any one interested in the development of the Indian manufacturing industries, are those incidentally useful in the working of iron. Foremost among these stands limestone, which is essential if we wish to obtain iron from the ore on a commercial scale. Fortunately this mineral is found in great quantities at or near the probable iron mines of the future. They vary, however, very greatly in quality, many beds containing a heavy proportion of worthless ingredients. Carbonate of lime is the chemical required for foundry work, and that limestone is the best which contains the greatest quantity. The proportions vary immensely, as will be seen from an examination of samples from different beds. Some calcareous tufa in the Darjeeling range showed 98½ per cent of pure carbonate of lime and only 1½ per cent of foreign matters, of which all but an infinitesimal fraction consisted of magnesia. On the other hand, samples taken from the pachete rocks, near the Rancegurge coal fields, showed on analysis only 45 per cent of calcium carbonate, the balance being chiefly made up of 11½ per cent of magnesium carbonate and over 39 per cent of insoluble matter. It is this high percentage of insoluble matter which is the great objection to the use of the

Raneegunge limestone, otherwise the beds of Han-sapather, which show 83½ per cent of calcium chloride, would do well enough if the insoluble matter, amounting to some 16 per cent, could be eliminated. In the Wardha valley, another great iron field, limestone is found containing from 94 to 97 per cent. of carbonate of lime and only 2 per cent. of insoluble matter, an advantage that would tell heavily in favour of any works for reducing iron ore established in that district. The best limestone is found in the Vindhyan range, and could be cheaply transported to any works that would probably be erected. There is no limestone actually available at Salem, though the iron fields there are the richest in India; but it occurs in many places in the Madras presidency some time with only 2 per cent of impurities. So valuable, however, are the Salem iron fields that it would pay to transport whatever limestone might be necessary for works erected there, especially as it can be obtained near the line of rail. Nature has been prolific in her stores of all required to develop the iron ores of India, but we seem unable to realize the wealth lying at our feet.

Next to limestone, fireclay is one of the most necessary products, for imported bricks and clay are very costly. The best fireclays are found in England, as in India, in the beds underlying the coal seam. Excellent bricks have been made from the Raneegunge clays, and have successfully passed very severe tests in the Calcutta Mint. The cost of firebricks made from them is, moreover, only Rs. 21 per hundred—about a quarter of those obtained from England. When the Bengal Iron Works Company was in existence it used bricks made of local clay with good results. Good fireclay is also found in the Madras Presidency and in the Vardha Valley. We have, however, grave doubts as to the value of Indian firebricks, as hitherto made, for the inner layer of iron furnaces. They do extremely well for all parts of the furnace, if fortified with a lining of English bricks. This however, appears to be necessary where great or prolonged heats are obtained. It is quite possible however, that an increased demand might develop some better method of treating the local clays, so that they would make bricks suitable even for furnace linings. That they can be made in all other positions is an enormous saving, and the cost of importing English bricks for lining only would not be excessive, and should not stand in the way of a foundry. Graphite is another substance of great value in a foundry, as the cost of imported crucibles is very great. The drawback of local graphite is the high percentage of impurities. Good specimens have been found in Travancore, which have been worked up into crucibles suitable for all but excessive heats. It is more than probable that if a proper system of manufacturing crucibles under pressure was started in Madras, the results would prove of great value if annealed—a precaution which should be taken in this country even with imported crucibles—and it would perhaps be worth trying. Considering the high position held by Ceylon graphite in the commercial world, it would probably be better to import this material as the cost of transport would not be great, and Ceylon graphite could be made into crucibles as well in India as in England, if proper machinery was set up. It is a valuable industry and well worthy of encouragement, though utterly overlooked up to now. A demand would create a supply, and a steady and scientific attempt to develop local ores would soon create this demand. Everything depends on a start being made in the direction of developing local iron ores; that once done, all the rest will follow. It is useless to try and make graphite crucibles in

India, without hydraulic pressure and the proper machinery, since crucibles thus made crumble too much in the fire, to be able to stand great heats, though useful enough for small brass castings of a few pounds only. It is so important to obtain good local crucibles for economy in working, even if they be made from Ceylon graphite that we wonder the matter has never been taken up before. Possibly the comparatively small demand has prevented any attempt in this direction, but if large local works were established their demand would be considerable, and should be met accordingly.* Manganese is also procurable in India, though no large quantities are known to exist in any one place:—"The commonest ores are manganite or gray oxide; wad or earthy protoxide, pyroluxite or the black peroxide; psilomelane, a combination of the oxide of baryta hausmanite or peroxide occurring with other ores of the metal; and braunite or binoxide in combination with iron peroxide; silica and manganese." The latter is found at Vizagapatam and Bimlipatam, the beds in the former district yielding sufficient for working iron on a considerable scale even as already discovered, while careful search may reveal large beds. Psilomelane and pyroluxite are found in the Central Provinces where it has long been used in glass making, but has not been worked to any great extent. These specimens contain more oxygen than those in the Madras Presidency. Braunite is found in the Nagpore district and was reported by the Executive Engineer of the Kanband district as lying in a bed a quarter of a mile long and ten feet thick. Thus we see that sufficient manganese is already known to exist in India to provide for the necessities of any iron industry likely to be developed in twenty years. Even if no more beds were discovered the cost of importing sufficient spiegeleisen should not be so great as to affect the iron industry materially. Considering the fact that manganese deposits frequently occur in laterite,† it is more than probable that a careful search among the laterite rocks of the Eastern and Western Ghats, in the Rajmahal Hills and in Orissa, would result in the discovery of extensive manganese beds, but no search could well be carried out with the necessary thoroughness until the demand for manganese that must follow the erection of some smelting furnaces in India should make it remunerative, nor could it be reasonably expected. Nickel has not been mined in India hitherto, possibly from the absence of any demand for traces of the metal have been reported from Rajpootana and Khetre, though only as occurring in connection with other metals, such as copper and cobalt. It is, however, unlikely that the Indian iron industries will advance to the point of making nickel steel, at any rate for the present, though the iron ore in Salem and elsewhere is so good that there are no limits to the possible development of the metal. With magnificent ore and fine charcoal, only science and skill are required to produce the very finest results.

Chromium, so useful in the manufacture of chromesteel, is found in the form of chromite in the Salem district. The Porto Novo Company started in 1833 was called the "India Steel Iron and Chrome Company," and opened a chromite mine at Curpur from which ore was exported to England. It is stated in Ball's Economic Geology that "the principal rock in the low hills at the

* In which case there would a fresh market for Ceylon plumbago.—Ed. T. A.

† Has manganese been found in Ceylon laterite? There is no reason why it should not be, if as a recent German visitor to Ceylon states, he found graphite in this rock.—Ed. T. A.

South-west base of the Shevaroy Hills, where the mines are situated, are hornblende, mica and talcose schists, penetrated by dykes of basalt and layers of serpentine, which last is intersected by a perfect network of veins of manganisite. The chromite occurs very irregularly in these veins in lenticular masses of various shapes and sizes; one block was said to weigh a couple of tons. At a depth of from fifty to sixty feet water became troublesome in the mines. It is not surprising, therefore, that mining became too expensive to be continued with profit, there being no certainty as to the proportion which the chromite bore to the mass of rock which had to be removed. At the same time the demand for this ore was by no means unlimited, and the immediate effect of throwing the Indian ore on the London Market is stated to have been to cause a fall in price.* The truth is that all the materials required for a successful iron industry are to be found in India, and only the energy to develop them is wanted. The failure of the feeble attempts that have been from time to time to develop the iron ores seems to have been accepted as proof that they are not worth working. No other reasonable explanation for the supineness of capitalists in this direction seems forthcoming. The power of India will grow with her iron, as without it the resources of the country can never be fully developed.—*Times of India*.

COFFEE SEEDS.

A correspondent of the *Madras Mail* (R. G. H.) questions the soundness of the view of an eminent English authority quoted by Mr. R. H. Elliot, that it is a mistake to make a choice of seed from the best trees on an estate to raise a nursery with, and that the seed should be chosen from trees grown on the poorest and most exposed situations. Mr. Elliott has very little doubt, according to his own statement, that the authorities he mentions are correct, and is also of opinion that the seed procured from poverty-stricken trees should be grown in nurseries composed of poor soil, to ensure, as must inevitably be inferred, a successful estate, and yet he asks for some practical opinion on the subject. This would appear to indicate a misgiving on the part of Mr. Elliot, as to the ultimate success of a venture of the kind. If Mr. Elliot is so thoroughly satisfied about the correctness of the theory that would be presented to him, the best thing to do would be to go manfully to work and experiment upon it. Planters generally are very keen in selection of the richest sites available for making nurseries upon, as also of procuring seed from the healthiest trees, and it is common for nurseries of long standing to be abandoned in favour of new spots owing to the soil being considered too impoverished to grow suitable plants for transplanting into the field. Planters are slow to experiment, and very few, if any, would be induced to make a departure from the method that has been in vogue since coffee-planting was begun, unless unmistakable proof were forthcoming that a greater measure of success had been found at the end of any innovation; and where none will experiment, the information called for by Mr. Elliot is bound for ever to remain a "sealed book." The majority of planters, have, at one time or another, had experience of nurseries composed of poor soil, but in no single instance have I known them to be held in favour. I think it is Hull, in his "Coffee Planting in Southern India and Ceylon," who recommends the growing of plants in poor nurseries if they are intended for planting out in old exhausted fields, or in new clearings not blessed with a rich soil, the idea being that the altered conditions under which plants transplanted from a rich nursery into a poor field would find themselves would prove fatal to them. There is a great show of reason

in this, but it does not affect the question of seed. I was recently told by a gentleman that the trees in the best field on his estate were grown in an extremely poor nursery and were filled with leaf disease when planted out. Here again the question of seed is not affected in any way. The plants may have grown up sickly and weakened owing to the poorness of the nursery in which the seed was sown, although the latter may have been obtained from the best trees imaginable, and when they found themselves in soil and conditions more akin to those in which the parent trees were luxuriating, the latent vitality in them, imbued from the latter, asserted itself and they grew up and proved themselves worthy of the stock they came from. Hull wrote in the palmy days before the advent of leaf disease, that dread scourge which decimated the once fine properties of Ceylon, and which threatens to become so serious a trouble to planters in India that, unless some remedy can be devised to at least minimise its effects, the planters will have to seek "pastures new," as Coorg especially is considered unsuited for the growing of tea. It is believed by planters of large experience that leaf disease does not come from any extraneous source, but is a sap disease,* and that the seed is not free from the taint. Hence the necessity that is felt to obtain seed from the least affected trees to raise nurseries with. The whole question resolves itself into one on the question of leaf disease. Trees grown in poor soil and in exposed situations would of necessity, from being so unfavourably placed, be affected with the scourge pretty nearly the greater part of the year, and especially when there is an additional demand made on their strength to ripen the fruit on them, which can only be removed to be used as seed when thoroughly ripe. It frequently happens that these poor trees, especially if they have lost any considerable portion of their leaves, are incapable of thoroughly maturing the berries on them, they becoming, merely what is called "white ripe." It would, I am afraid, be impossible to grow highly tainted seed of this kind, especially in a poor nursery, free of leaf disease, and they would give but a poor account of themselves in the field, unless kept entirely free of weeds, highly manured, and otherwise carefully tended. High nursery beds thoroughly well drained are conducive to keeping plants as free as possible under existing circumstances, from leaf disease. I don't know how far the analogy sought to be established between wheat and coffee will hold good, but it is sufficient to know that wheat is free from fungi to make it of next to no account in this connection. The proposition propounded by Mr. Elliot might have answered in the good old days, but now I confess that I fear it has become somewhat problematical. I shall have gained my reward if this feeble effort of mine to offer some "practical opinion" on the question will promote a healthy discussion which will lead to the elucidation of a subject of pre-eminent importance to the planting industry.—*Indian Agriculturist*.

[We have no belief in this absurd theory of propagating from inferior seed of inferior trees grown on poor soil. We believe its author has abandoned it.—Ed. T. A.]

ARTIFICIAL RUBIES.—We call attention to an interesting article from the *London Standard* on this subject, given on page 810 as also to the letter in which Mr. E. W. Streeter re-assures buyers of precious stones in regard to the artificial ruby, showing how it can be distinguished from a real gem.

* Which scientists regard as great nonsense. The disease is propagated by spores which of course taint the seed.—Ed. T. A.

"TEA CONSUMPTION."

We have received by this mail a copy of a "diagram-circular" published under the above heading by Messrs. Gow, Wilson & Stanton, and of which they advise the despatch of copies for distribution to our subscribers to be here by next mail. Acting on the hint given some years ago by Mr. Goschen in his budget speech, the well-known Rood Lane Firm show in their first diagram "the estimated number of gallons of Liquid tea yielded by the actual weight of tea used in Great Britain during each of the past 25 years showing the superior strength of British-grown tea." The statistics show that the expansion which has taken place in the consumption of tea as a beverage is really much larger than is represented by the increased use of the dry leaf. In 1890, for instance, the home consumption is represented by 33.40 gallons against 5.07 lb. per head of population. We are told that a point has now been reached in the United Kingdom when a "greater weight of tea will be annually required to supply the expanding gallon consumption of the country owing to the small quantity of China tea now left for displacement; also that any further expansion in the gallon consumption must immediately cause an increase in the weight of dry tea used, a condition which did not exist so long as a weak tea was being displaced by a stronger one." A larger home consumption is therefore anticipated in the future. Messrs. Gow, Wilson & Stanton next summarize the events for which the season just closing has been remarkable, namely:—

- (1) Reduction of duty from 61 to 41, and the sudden increase in Home Consumption.
- (2) The high rate of Exchange ruling and the consequent decrease in supplies of Tea from China.
- (3) The unexpected shortness of the Indian Crop which proves to be about 10,000,000 lb. below the original estimate.
- (4) The quotation of Indian Tea on the London Produce Clearing House.
- (5) The increased use of Indian and Ceylon Teas in Australia.
- (6) The endeavour to increase the sale of Ceylon Tea in North America by the formation of the Ceylon Planters' Tea Company; and efforts to open Russia to Ceylon Tea.
- (7) The growing importance of the tea industry in Travancore.

On the last page we have diagrams showing the "Tea Consumption in Principal Countries." The markets shewn to be most worthy of attention for Ceylon tea planters are those of the United States, Russia, Australia and Canada, and also of the Argentine in South America, if only good government and peace prevailed there.

NOTES ON POPULAR SCIENCE.

BY DR. J. E. TAYLOR, F.L.S., F.G.S., &c., EDITOR OF "SCIENCE GOSSETT."

From time to time a good deal of interest has been taken in the question of the origin of diamonds, especially those of the diamond-fields of South Africa. It is held by many geologists that they are found in a volcanic matrix, more or less decomposed. Dr. Kuop, a German mineralogist, has been carefully studying this matrix or "blue earth," as it is popularly called, of the South African diamond-fields, and finds that it is practically a decomposed serpentine or serpentinitic. The following minerals have been found in it:—Garnet, enstatite, chromite, zircon, apatite, idocrase, rutile, mica and also the diamond. Dr. Kuop regards the diamond deposit at Zagersfontein as having been formed from a serpentised rock, which latter may have been derived from peridotite, and he thinks the relation

of the diamond to the peridotite is analogous to the occurrence of diamonds in meteorites.

Those two indefatigable French chemists, Messieurs Berthelot and Andre, have been working the their favourite subject, viz., the history of the principal nitrogenous compounds contained in vegetable mould. Their observations are quite new and original, and an interesting fact brought out by the experiments is that the nitrogen contained in the volatile organic compounds given off under certain conditions by argillaceous sand is always much greater in amount than the nitrogen given off in the form of ammoniac. The vegetable mould employed was 20 times richer in nitrogen than the argillaceous sand, but gave off the two classes of compounds in equal proportions.

HOW TO MAKE A GOOD CUP OF TEA.

Katharine B. Foot writing in the *American Agriculturist* gives the following practical hints about making a good cup of tea:—

In the first place, the water with which the tea is made should be freshly drawn from the well, pump or faucet and put in a perfectly clean kettle. The water must be brought quickly to a boil, for long simmering takes the life out of it. If the tea is to be made in the dining room or the parlor first heat the silver kettle with hot water, and light the alcohol lamp. Then fill and hang your kettle, and the water will boil up in a moment. While waiting for it to boil heat your teapot and your cups also if the weather is cold, but *always* heat the teapot. A metal teapot of any kind is an abomination; let your teapot be of the most delicate porcelain if you can afford it; or if not that of good china, for poor china or stone ware when heated often gives an unpleasant flavor. Let your tea be of the very best; for cheap tea is always adulterated with injurious substances. Measure the tea with care—a small teaspoonful for each person, and one for the teapot, up to three or four people. Above that number add one teaspoonful for each two. But tea should never be made for more than four people in one pot. If you have more to serve have more teapots. Pour off the water you have put into the pot to heat it, and into the steaming pot put the measured out tea; add from the boiling water in the teakettle sufficient water to a little more than cover it, and shut it up. Let it steep from five to eight minutes, not on the stove but on the table, or, if you make it in a very cold room, on the hearth or on top of the plate-warmer of the stove. Then add boiling water. The quantity can only be determined by careful observation and judgment to be strong or not. Never pour the tea into the cup and add the cream and sugar; always put them into the cups and pour the tea upon them. No real connoisseur in tea would ever touch a cup to which the milk and sugar is afterward added, for it makes all the difference between a good cup of tea and a poor one. If you pour tea for a person who takes more than one cup, pour a large cup full at first; for every one says "the second cup is never so good as the first," but does not know why. The reason is that the tea stands just so much longer, and so gives time for the tannic acid to develop, which makes the decoction bitter.

ECHOES OF SCIENCE.

The effect which living at high altitudes has on the blood of animals has been recently investigated by M. Vialt, who finds that as respects the elevated regions of South America, the proportion of oxygen in the blood of men and animals acclimatised there was the same as that of dwellers at lower levels. This is evidently due to the fact that they have the proportion of hæmoglobin in their blood correspondingly increased so that the absorbent power of their blood for oxygen is enhanced, and thus, although there is less oxygen in a cubic foot of the rarefied air of the mountains, the lack is compensated as far as the creature is concerned. The Sequoia National Park j

the result of Dr. Eisen's appeal on behalf of the big trees which we have formerly mentioned. It secures from settlement as a perpetual preserve the districts of the big trees on King's River and the Big Kern; Mount Whitney (15,000ft.) and its glaciers; the Tehitipee Yosemite on King's River; the Grand Canyon of the South Fork and its cascades; the stupendous cliffs of the Kern; the extinct volcanoes; and the Shagopa Falls. Another tract of big trees in the Fresno district, containing the forest giant known as "General Grant," has also been reserved.

Visitors to the picture galleries of the Indian and Colonial Exhibitions may remember some river views in British Guiana in which a curious pink flower, not unlike a lily, was seen growing on the rocks in the middle of rivers and rapids. This peculiar plant has not been studied by botanists, and its affinities are obscure. It belongs to the order of Podostemaceæ, and is a kind of water weed. In general it grows under water, where beds of the plant can be seen, but in the dry season, when the river shrinks in its bed the plant is exposed, and takes advantage of the opportunity to flower and fruit. It adheres to the rock by a disc-like root, as sea weeds do, and holds its ground in the midst of the most violent rapids. Happily, Dr. Goebel has gone to Demerara to study the plant from a botanical point of view.
—*Globe*

THE INCREASED CONSUMPTION OF TEA.

Although we must await the publication of the Board of Trade returns before it will be possible to accurately gauge the full effect of the late reduction of the duty on tea consumed within the United Kingdom, a forecast given by the *London Times* renders it possible at least to conclude that that reduction has had the result of largely stimulating the use of tea of all growths. The figures as quoted by our London Correspondent evidence a remarkable and abnormal increase within the limited time during which the reduction has as yet been in operation. It is quite impossible, of course, to assign this increase to any natural growth of population; for were it open to us to do this, a similar increase would have been noticeable in the returns of previous years. As no other cause that is discernible can be assigned, it is a fair and unquestionable inference that it is to the lowered duty that must be traced the very great extension of the quantity of tea removed from the bonding warehouses for home use. We share to a considerable extent in the difficulty felt by our Correspondent of realising that the mere lowering of the price of tea by twopences per pound can have induced the lavish use of the article to the extent indicated by the figures. As we know that the poorer classes in England drink their tea extremely weak, the amount of the leaf which each individual consumes must be relatively exceedingly small. We should say that the outside difference to such consumers can hardly exceed fourpence per month or, one penny per week. Such a trifling amount of saving one, would hardly expect to account for the great change shown by the returns. A working man who drinks beer would hardly permit of so small an item of saving affecting his consumption of that liquid, and yet it must be concluded that on the article of tea, this very limited economy has had the effect which *The Times* has demonstrated to us. The fact augurs strongly for the expectation that a further reduction in the tea duty will even yet more—and possibly in a similar ratio to that further reduction—increase the use of tea among the working population at home.

We must all look forward with interest to those more complete returns which will determine the much-argued question. It will be within

the memory of our readers how very diverse were the opinions expressed when the lowering of the tea duty was at first discussed. Many very competent authorities—among whom we may include Mr. J. E. Sland—were of opinion that the reduction would tell more favourably upon the consumption of the cheaper China teas than upon that of the teas of Ceylon and India. Other authorities no doubt equally competent took a precisely opposite view. It must under any condition, remain an open question as to whether the stimulated consumption has been due to the masses drinking their tea stronger, or whether the number of drinkers has been increased. No return that can be prepared could, we should say, ever clear up this point. The fact of increased consumption, however, remains, and on this point alone we may well congratulate ourselves.

AN AGRICULTURAL SOCIETY FOR CEYLON.

We learn that the Government Agent for the Western Province has made a proposal which may result in the formation of an Agricultural or Agri-Horticultural Society to embrace the whole island. His suggestion is that the Central Committee established in Colombo in connection with the Imperial Institute, together with the several local Provincial and District Committees should be formed into a "Ceylon Agricultural Society," and make their first Show or Exhibition in Colombo, utilizing the specimens now being collected for the Imperial Institute in London. This, we consider, is a happy thought, provided Dr. Trimen agrees that the collection now coming in, will take no harm from the detention and exhibition of the various articles in Colombo, we suppose about the month of August next. We scarcely think there can be any serious objection, and no doubt it would tend to put Agents, Assistant Agents and District Committees generally on the *qui vive* when they learned that their collections were to be brought under the notice of the Governor, Executive Council and general public in a Colombo Show, before being sent on to London. So good an opportunity of comparing the products and industries of the different revenue districts will probably never before have been presented, and the Show ought to be a thoroughly good and representative one, worthy of the "first year" we may say of a new Governor. It is quite time, too, on general grounds that Colombo had another Agri-Horticultural Exhibition.

Then as regards a permanent body to supervise and be responsible for periodical Exhibitions throughout the island, we daresay that no better arrangement could be made than to take advantage of the existing Committees for the Imperial Institute. The Chairmen of the Chamber of Commerce and Planters' Association with leading native gentlemen are already on the Central body, while each local Committee is presided over by Agent or Assistant Agent, assisted by representative planting and native agricultural authorities. Such a Society or Association ought to be able to arrange for a regular series of Shows of Agricultural and Horticultural produce at the capitals of the different provinces. We question if one could be arranged annually in each province—making altogether nine in the year throughout the island? We should say that three a year ought to be sufficient:—say, Colombo, Anuradhapura and Batticaloa one year; Kandy, Jaffna and Ratnapura another; and Galle, Kurunegala and Badulla a third year and so on. Of course if

the Shows were confined strictly to local products and industries, an annual collection and Exhibition might be managed. Such Exhibitions as that recently held at Nuwara Eliya, though no doubt very interesting to a large number of people brought together, have, we fear, not much practical result at any rate as regards the natives. It will be for the several Government Agents and their Assistants to see if District and Village Shows specially for the benefit of native agriculturists, could not be organised, perhaps to follow after the provincial gatherings.

NEW FIELDS FOR THE CULTIVATION OF COFFEE.

It may be presumed that the very limited supply of coffee which Ceylon as well as Southern India and Java are now able to export, affords a very strong stimulus for the search for other lands which may present a prospect of its successful cultivation. Added to this inducement, there is of course the high price which our former staple now commands in the London market, and both of these causes combined may readily account for the desire to find suitable land even in such distant and, in some respects, difficult localities as the slopes of the Andes. Mr. J. L. Shand's name has received frequent mention of late as being among those who have become prominently associated with this endeavour. His venture in Borneo is made in a field which is not entirely new. In this respect it differs materially from that as to which he has at all events been consulted, the endeavour to find an opening in the more inaccessible regions of Peru. It appears that the Government of that South American republic has failed to meet its engagements to its bondholders, as so many other of the South American republics have done. In order to save a national bankruptcy, it has handed over certain lands and privileges as a *quid pro quo* for the indebtedness it is unable otherwise to meet.

Whether the exploration now about to be undertaken and in connexion with which Mr. Clark of our Peradeniya Botanical Gardens is to give his services, will result in all that is hoped for, remains yet to be ascertained. But even if it should be the result of the expedition that land suitable for coffee can be found, a very serious obstacle to its development must be presented by the evil repute into which the events of the last few years have brought the Governments of South America. A very large amount of capital will be required, and several years of patient waiting must pass before returns can be expected by those who may be disposed to invest. No doubt Sir Alfred Dent is a man of exceptional energy and resources; but his highest qualifications in these respects must be demanded to overcome all the obstacles which must present themselves to the success of his new venture. It is probably intended to employ Chinese labour, but then how much farther away is South America than North Borneo from the Chinese Coast. It will be, to say the least, questionable if capital can be raised as readily for cultivation upon the slopes of Andes as for the enterprise in British North Borneo.

But there is a further point to be considered with reference to coffee growing in Peru. Hitherto, South American coffee has failed to achieve any position in our home markets at all approaching that to which the growth of Ceylon and India has attained. Whether this may be due to some defect in the climate of those vast regions, or whether the fact is to be attributed to the less careful preparation given to the berry, it remains that as yet South American coffee has failed to become

a successful competitor with the highly valued product of Ceylon. This disability will have to be taken into serious account by those whom Sir Alfred Dent may delegate to make inquiry on behalf of the bondholders he represents. It will be one thing to find land, it will be another to so cultivate it as to ensure a larger increase of success for its produce than has hitherto been secured for that grown in other countries of South America. With reference to the venture to be made in North Borneo, it is known that that country can and does grow coffee of high quality, and there can be little doubt that, should ever our own remaining fields once again resume their former prolific character, the export from Borneo will be found to be a serious competitor. But under all present conditions, and as far as may be foreseen, there is but little prospect of such a recrudescence of coffee growing in the island, at all events for a good many years yet to come. We can therefore well afford to regard with equanimity these fresh endeavours to enter into competition with Ceylon coffee, and to wish them every possible success, though may much doubt a large measure being attained in Peru.

THE TARING OF TEAS IN LONDON.

We call attention to two further letters on this subject. "Proprietor" resumes his story in order to clear his selling Broker who, it seems, has nothing to do with the "taring" which, being conducted in the docks for or by the Customs authorities, is a matter for which outsiders have no responsibility. But surely it is the duty of the Broker, or, if there be one, of the London agent to see that the rules of the Customs officers are not broken, as seems to be the case in reference to the 28 lb. boxes? The London representative of the Ceylon planter can surely make a big disturbance over an absolute breach of the standing regulations, and if he gets no redress can carry his complaint to some one or other public organ representing the trade. Was anything of this kind done?—But who then benefits by an unusual appropriation for "tars." Did it not come out a short time ago that some of the Dock Companies are in the habit of selling what they called "refuse and sweepings," to which no doubt over-liberal or unjust tares, add considerably. If this be the case, the matter is one which ought to receive the special attention of the Planters' Association or why not rather of its "Tea Fund Committee" who could get the London Association to take the matter up and cause enquiry to be made. One or other of our correspondents who feel aggrieved should address the Tea Committee with a view to action being taken at their next sitting.

NEW PRODUCTS IN THE WATEGAMA DISTRICT.

—It is interesting to learn of the success which has attended the operations, among others, of Messrs. Vollar and Gwatkin in this district. One hundred acres put under tobacco gave so good a crop last year that a visitor from Deli declared he could not wish for finer tobacco from Sumatra and that it ought to be worth some 3s to 4s per lb. This was just before shipment, and when this visitor learned that consignments almost as good had been sold for 4d a lb. in London, he considered the tobacco had been thrown away. It remains to be seen what this last consignment so much praised by the Sumatra visitor, will really fetch. After the tobacco, a crop of cotton taken off the same 100 acres gave R2,000 or R20 per acre profit; and now cacao and coconuts seem flourishing in the same area!

ARTIFICIAL RUBIES.

A paragraph which will be found in another column seems to make it probable that the artificial production of precious stones on a remunerative scale is within measurable distance, for MM. Frey and Verneuil are said to have manufactured rubies which, for all practical purposes, are as good as the natural gems. The two chemists have for many years past been engaged in these experiments. But, hitherto, the rubies and other crystals which they turned out or their retorts, though fine enough to promise better things, could not be pronounced quite equal to the worst that have been discovered in the Burmese mines. In 1878, by heating in a fire-clay crucible a mixture of alumina and red lead, MM. Frey and Verneuil produced a vitreous silicate of lead (the silica being derived from the crucible), and crystallised alumina. When to this was added potassium bichromate, the alumina assumed the desired tint of the ruby. By such a process spirals it is said, have been turned out almost, if not wholly undistinguishable from the natural gems, even after tests of a character never likely to be applied to them, when worn as ornaments, were called into requisition. Still, these gems were on a very small scale, and neither hard enough nor endowed with the tint which satisfied the expert. But since that date MM. Frey and Verneuil have made remarkable progress, and, in a communication to the French Academy of Sciences, intimate that they have at last successfully overcome the difficulties which impeded their earlier efforts, and are obtaining crystals sufficiently large to be of commercial value. Some of those already produced are being used as "jewels," or pivots, in watches, and are affirmed to be in no way inferior to the natural stones. The ingredients differ somewhat from those employed twelve years ago. Alumina and a trace of potassium bichromate are heated with barium fluoride or a mixture of fluorides of the alkaline earths, and a high temperature maintained for several days. Experience has taught that the addition of a small quantity of potassium carbonate to this mixture, so as to render the mass alkaline, facilitates the formation of the crystals. These, it is believed, are produced directly from the interaction of the volatile compounds engendered, and, by employing crucibles of several litres capacity, in gas furnaces, as much as three kilograms, or more than six and a-half pounds, of rubies are produced at a single operation. Such a mass, even admitting that it may not be without flaws and other defects which would render it of little value to the lapidary, is larger than any known natural stone. Tavernier, the old traveller saw one in the Persian Treasury which weighed one hundred and seventy-five carats, and the King of Burmah possessed—and perhaps in his exile still possesses—another as large as a pigeon's egg. The largest in Enropo is that presented by Gustavus III. of Sweden to the Czarina Catherine. But even this gem does not exceed in size a small hen's egg.

If, therefore, the chemist is to turn out of his alembic rubies six or seven pounds in weight, the sooner the holders of the old-sized gems get rid of them the better. For, assuredly, no find in Ceylon or in Pegu has ever attained these dimensions. Even the gem on which Chardin saw the name of Shok Sephi engraved could not have been a twentieth part as large. Among the accumulations of the Duke of Bruswick sold in 1876 was a Chinese idol cut out of a single ruby of immense size, the history of the stone, which was part of the loot of the Summer Palace of Peking, being unknown; but as the Buddha was sold for six hundred pounds, it could not have been of remarkable purity. There are, no doubt, tales, more or less, mythical, of rubies, compared with which even the seven pound confection of the French chemists is not so colossal. Thus, the one which the King of Ceylon had carried before him at his coronation could not have been much less, and Ibn Batuta tells us how he saw, in the Treasury of Arya Chakravarti, a Tamil Chief at ruling Patlam, a ruby bowl as large as the palm of one's hand, while Prior Jordanus speaks of two great rubies belonging to the "King of Sylen," each so big that when grasped it

projected a finger's breadth at either side. Sir John Maudeville goes even further, for he relates how the Emperor of Ohia had in his chamber a pillar of gold in which were a ruby and a carbuncle a foot long. If, however, a six-pound ruby can be produced, there is no scientific reason for believing that the resources of chemistry are exhausted at this stage. A twenty or a hundred pound one—not, perhaps, of very fine colour, but useful for purposes of art and industry—may be the next triumph, and, unquestionably, as the cost is not great, some pieces of these large ruby masses may be put upon the lapidary's wheel. MM. Frey and Verneuil are not the first who have essayed this notable venture in synthetic chemistry. Indeed, not many months ago, it was reported that an analyst had succeeded in manufacturing an emerald out of the refuse of a gas retort. The ingredients entering into this stone are silica, alumina, glucina, magnesia, carbon, and carbonate of lime, while the intensely green colour for which the jewel is valued was said to be due to a slight dash of sesquioxide of chromium, though this tint has by some authorities been attributed to vegetable matter. It may be doubted whether the "gem" so produced was anything more than a good imitation of an emerald, so far as composition is concerned; but it was, in any case, in the line of the research which MM. Frey and Verneuil have pursued so arduously, and, it seems, successfully.

The complexity of the composition of the emerald makes close imitation almost impossible, and as the tint of many precious stones depends entirely upon the presence of a minute quantity of a certain chemical in some peculiar combination, all the ingenuity of the experimenter is thrown away, so far as the production of a gem capable of passing muster is concerned. There is, however, no such difficulty in the case of rubies. For this stone, like the sapphire, the Oriental topaz, and the Oriental amethyst, is crystallised alumina. In the ruby the tint is imparted by peroxide of iron—in other words by rust—and in the sapphire by the protoxide of the same metal, the violet hue being due, perhaps, to an admixture of manganese with the iron. The great difficulty is so to fuse them, and in such proportions, that the results attained during the vast commotion of the earth's crust may be successfully imitated. More than sixty years ago chrysoberyls were produced by subjecting the fluoride of aluminium and glucinum to a very high temperature, and early in the century Berthier fabricated a great many minerals, including chrysolite, augite, and others not of any economic importance. Colourless and blue sapphires are among the triumphs of the laboratory, and, as far back as 1837, Gaudin produced the ruby on a small scale by exposing aluminium to the heat of the oxy-hydrogen blowpipe, and thus obtaining fused alumina, which is readily coloured by the addition of oxide of chromium. The resultant crystals were in the rhombohedrals characteristic of the mineral, and, it is said, had equal hardness and specific gravity. Boehmen arrived at much the same end by dissolving alumina in boric acid, at a high temperature, and on the cooling of the liquid obtained the alumina in a crystallised form, which, with the addition of chromate of ammonia, became, to all intents and purposes, rubies. Again—and this by no means exhausts the roll of experiments—Sainte-Claire, Deville, and Carou, by heating fluoride of aluminium, fluoride of chromium, and boric acid, obtained fluoride of boron, which, escaping in a volatile condition, left a residuum of solid alumina coloured by the chrome. When the mineral is simpler the chances of success are greater. Thus, the diamond being known to be pure carbon, it is a question of time for it to be exactly imitated by the crystallisation of that element. This, it may be remembered, Mr. Hannay actually succeeded in accomplishing ten or eleven years ago, though the cost was so great, and the result so valueless commercially, that the experiments have not been continued. Still, the principle once discovered, the rest will follow. For a long time to come the artificial gems will be inferior to the natural ones. Nature has worked on so large a scale, and with such gigantic appliances, that the puny tools of the chemist can be of no avail.

But there is a possibility, even a probability, that some day the problem may be solved in the simplest fashion, and then the standard of value, which the alchemists in vain tried to alter, must be sought elsewhere than in stones no longer precious. Few people will care to pay high prices for the sentimental pleasure of wearing "real" gems, while the artificial ones cannot be distinguished from them by any tests less exact than those of the chemist.—*London Standard*.

ARTIFICIAL RUBIES.—The experiments of M. Fremy and Verneuil on the artificial production of rubies have been in progress for some years, but it appears, from their recent communication to the *Comptes-Rendus*, that they have now successfully overcome the difficulties which attend their manufacture, and are obtaining much larger crystals. The artificial rubies have already been employed as pivots in watches, and are said not to be inferior to the natural stones in hardness. The process consists in heating alumina and a trace of potassium bichromate with barium fluoride or a mixture of fluorides of the alkaline earths to a high temperature for several days. Recent progress has been due to the discovery that the addition of a small quantity of potassium carbonate to the mixture, so as to render the fused mass alkaline, facilitates the formation of the crystals. It is believed that the crystals are produced directly from the interaction of the volatile compounds produced, and by employing crucibles of several litres capacity in gas furnaces as much as 3 kilos. of rubies are obtained in a single operation.—*Industries*.

ARTIFICIAL RUBIES.

TO THE EDITOR OF THE "STANDARD."

Sir,—I have read with interest your article in *The Standard* of last Saturday on the manufactured rubies produced by M. Fremy and Verneuil. The general buying public may no doubt be somewhat frightened at the thought that instead of the natural gem they may only get at best an imitation. The generality of buyers of precious stones are usually good judges, and not likely to buy anything but the real article. In the imitation, or rather manufactured, ruby, it is noticeable that all the spots and flaws run into one corner, like the tail of a comet, while in the genuine article spots and flaws, &c., are diffused over the stone; and another thing is that in no imitation of diamonds, pearls, rubies, and emeralds can there be found the hardness possessed by nature's own gems.

With regard to the diamond manufactured by Mr. Hannay some years ago, may I add the whilst being exhibited at the Royal Society, I asked Mr. Hannay as to how the stone would act when placed on the diamond wheel to cut it into shape. He informed me that it would, at the first revolving of the wheel, crumble to powder; it is impossible to manufacture the hardness necessary. May I ask you to kindly find space for this, so as to reassure those who own, or contemplate being possessors of, these gems.

I am, Sir your obedient servant.

EDWIN W. STREETER.

Bond-street, London, W., March 16th.

THE SILVER MARKET AND EXCHANGE IN 1890.

Even at this late period it may be worth while to call attention to the facts revealed by a diagram showing the prices obtained for bar silver in London and the rate of exchange in Colombo for demand bank bills on London during 1890. Beginning with bar silver, it was at 44d. when the year opened and the lowest point it touched in its progress through the months was 43½ in February while the highest was 54½ in August. The variations ranged from ½ to 2½, and at the close of the year the price stood at 48—fourpence better than at the start. In January 44½ was what was generally obtained, but in February there was a depression of about a penny. This however was slightly improved

upon in the succeeding month. On 4th April the price was 48¾ and from this it went on advancing a farthing in one week, twopence in the next and other twopence in the third week. From 48 it fell away, however, to 46 in the beginning of May. In the course of that month it made an effort to get up again and was so far successful, 47½ being realized, but it was not able to keep this up and fell to 46½. June coming to its assistance, lifted it till it was within reach of 49, but again there was a fall and it came down to 47¾. From this it made an attempt to rise almost immediately to its former altitude but the effort was too much for it and after just touching 48½ it sank down to 47½. In July there was better fortune and between the second and third weeks 50 was registered. In the fourth week ½ had to come off, but this was merely a temporary reduction, and when August opened the figures—thanks to American legislation—were 51½. At first there seemed to be some uncertainty as to whether the price would go beyond this, but in the second week this was placed beyond doubt. After one or two short leaps it bounded to the height of 54½ from 51½ in one week. In a day or two it fell back ½ but rebounded and when the month closed had attained 54½. It had taken about five months to reach this pinnacle, but it was not allowed to remain more than a few days there. On Sept. 5th it had dropped to 54 and in the following week to 53. In the next week it slightly recovered itself, but from 53½ on 19th Sept. it fell away to 51½ on the 26th. In the course of the succeeding week it touched 50, rose to 51½ and again sank to 50 from which it had not risen more than ½ when it was once more thrown down and continued its descent with occasional interruptions till the middle of November when it was as low as 45. An improvement now set in, and at one bound the price went up 2½, and at another 1½. In the beginning of December there was a sudden drop from 48¾ to 47½. An advance was made upon this in a few days, but another fall occurred which brought down the price to 47½. From this it went up again at one bound to 49½, but came down to its former level in the course of a week. The year closed, however, by showing ½ of an increase.

Turning now to the rate of exchange it started at 1s 5d and the lowest point it touched for demand bills on London, during the year was 1s 4¼d in the middle of Feb. while the highest was 1s 8¾d in the end of Aug. ; At the close of 1890 it had just touched 1s 6¼d. Opening at 1s 5d the rate rose in a couple of weeks to 1s 5¾d, but this level was not long maintained, and in the third week of February it had touched 1s 4¾d. From this point there was a gradual improvement till the beginning of May when the variations became more frequent but generally in an upward direction. From 1s 5¼d in the first week of the month it jumped to 1s 6d between the 16th and 23rd. It was down at 1s 5¼d at the end of May, but in the second week of the next month it had put on a penny. This however, was taken off before the month ended and only partially recovered when July opened. At this time the rate was 1s 6¼d and it rose rapidly to 1s 7¼d, 1s 7½d and so on till the 22nd August when the top point was reached. Between 22nd Aug. and 5th Sept. there were several changes, the variation being from about 1/8½ to 1/8½ and up again. In September the tendency was most decidedly downwards and from 1/8½ on the 5th it came down to 1/6½ on the 26th. In the beginning of October there was a sudden rise

to $1/7\frac{7}{8}$ but this did not last more than a day or two and the rate came down with a run to $1/6\frac{3}{4}$ and down into the third week of November with slight checks now and then to $1/5\frac{3}{4}$. As in the case of bar silver an improvement set in at this point and when November closed the rate had risen to $1/6\frac{3}{4}$. It dropped away again in the first week of December but in the middle of the month jumped up to $1/6\frac{3}{4}$. In the third week it again fell but was rising from $1/6\frac{1}{2}$ when the year closed.

CAKCLING OF HENS.

I have recently published the following letter in the *Field*; but not having so far received any answer to the question which it presents, I should like to republish it in your columns, in order to ascertain whether any ornithologists to whom I have not already applied may have any information to give upon the subject.

GEORGE J. ROMANES.

Christ Church, Oxford, March 28th.

Cackling of the Hens of Jungle Fowl.

"Can any of your readers inform me whether or not the hens of the wild jungle fowl (*Gallus bankiva*) cackle after laying their eggs, in the manner of their domesticated descendants? I cannot find any literature upon the subject; but if wild hens do cackle in the jungle, surely somebody must have heard them. Mr. A. P. Bartlett informs me that, when confined in shrubberies of the Zoological Gardens, they do not cackle; and, therefore, if nobody has ever heard them do so in a state of nature, we may fairly infer that the instinct is a product of domestication. If this should turn out to be the case, it would be a somewhat remarkable fact, and would, moreover, lead to the further question whether there are any parts of the world where domesticated poultry do not cackle."—*Nature*.

NOTES ON PRODUCE AND FINANCE.

(*H. and C. Mail*, April 10th.)

THE PRODUCE MARKETS.—The accumulation of produce during the recess has resulted in extensive public sales, no less than eighty-five being held on the 7th inst. The markets have, on the whole, exhibited a quiet tone, and prices in several important instances show a slight decline.

TANNIN IN TEA.—The best analytical methods of examining the quality of tea have been devised in Russia. A well-known authority upon this subject at St. Petersburg is P. Malscheffsky, who has from time to time contributed many papers dealing with the chemistry of tea to the *Russian Pharmaceutical Journal*. A new method of determining tannin, recently proposed by him, is based upon the action of normal copper acetate. Analyses of about fourteen samples of the teas most commonly met with on the Russian markets were made by Malscheffsky, and gave the following interesting figures:—Tannin varied from 6.10 to 11.03 per cent.; water, 5.59 to 12.48; ash, 3.14 to 9.25; aqueous extract, 17.3 to 39.4; caffeine, 1.09 to 2.88.

EUROPEAN COFFEE.—According to the *Moniteur Industriel*, a species of coffee which flourishes well in sandy soils is now being cultivated in the neighbourhood of the town of Ascholtshansen, in Bavaria, and the cultivation appears to be simple and attended with success. The seeds are sown in the spring; in the month of July the plant commences to bloom, the flowers, being of a sky-blue colour; the fruit ripens a month later, and is pale yellow, greatly resembling in appearance the coffee which comes from Bourbon Island. The aroma is comparable to that of the finest foreign-grown coffee. The taste is very pleasant, but slightly more bitter than coffee usually is. No special care is needed in cultivating this variety of coffee plant, and many families in the district named now grow all their own coffee.

THE GRAMA-RAKSHAKA SAMAGAMA'S AGRI-HORTICULTURAL AND INDUSTRIAL EXHIBITION.

The following are the principal prize-takers at this Village Exhibition:—

Pa'dy, H. F. L. Dharmaratne; Kurakan, S. Perera Weerasinghe; Dhall, L. S. Cabaral; Indian corn, L. S. Cabaral; Cattle, L. F. Caharal; Milch Cow, D. S. Jayatilke; Buffaloes, A. L. Perera; She Buffaloes, P. S. Fernando; Bull, D. W. Appahamy; Milch Cow, Sinnappu; Fruits—Oranges, D. P. C. G. Appahamy; Pineapple, L. Alwis; Lime, H. Martelis Perera; Plantains—Kolikuttu, Sarah Alwis; Sour do, D. E. K. Appahamy; Red do, D. J. Weerakoon; Ash do, M. S. Dias; Vegetables—Green Chilly, R. A. Perera; Brinjals, W. S. Perera; Beans, Don Alpanis; Long Beans, D. L. Fernando; Suake Gourd, W. S. Perera; Kariwila, D. C. Amerasinghe; Water Pumpkins, J. P. Fernando; Bandakka, W. T. Dias; Cucumbers, M. H. Perera; Yams—Dehiala, H. S. Fernando; Kondol, P. S. Fernando; Arrowroot, D. K. Appahamy; Sugar cane Black, R. A. Perera; Pepper, Bastian Fernando; Ginger, G. K. Appahamy; Betel, R. A. Perera; Artwork (Wood), T. J. Fernando; Iron, K. J. Naide; Gold and Silver, K. Marsal; Copper and Brass, B. R. Dias; Brick and Tiles, M. Siano; Pottery, J. J. Fernando; Mats &c., P. Justina Perera; Coir, K. Anjo Hamy; Needle Work, D. S. Amerasinghe; Calligraphy, T. Joseph Fernando; Special Prizes—Motor Steam Engine, D. James Wimalasurendre; Ebony Work, Babun Hamy; Plumbago, D. George Samarantunge; Elk, S. D. S. Gunawardene; Flowers, J. P. Abraham; Paper board writing desk, G. Dias; Fans, Rannage Don Philip; Mangoes, D. Weerakan; M. M. Palle; Pumpkin, J. Simen; Cocoa, D. C. Amerasinghe; Cotton, Bandara; Cinnamon, R. Issac Fernando. Silver medal for special service during 1890, Mr. M. Hendrick Perera.

The prizes were distributed by Mr. George Wall who was presented with an address. The Hon. J. J. Griminton and A. de A. Seneviratne were also present. In acknowledging an address Mr. Wall said he regarded the Society as a most useful and effective agency for advancing the moral and material condition of the people. On behalf of the Society he offered their thanks to the Government for its encouragement by giving pass-books with small deposits in the Savings Bank to exhibitors.

A GREAT WANT OF THE DAY: A BOARD OF AGRICULTURE FOR CEYLON.

The general education now imparted is cried down and technical education is cried up as the means of enabling the people at large to find work and wealth, independent as well as in excess of what the Government provides through its public service. The advocates of technical education are not explicit in their statements as the particular branches of practical knowledge may with advantage be taken up by our youth. It would be idle to expect such arts as painting, sculpture and architecture and such manufactures as the making of matches and paper to pay in Ceylon. Dr. Daly suggests such industries as pottery, sugar cane cultivation, boat-building, bee-farming, improved fishing and fish-curing and poultry-rearing. In the first four of these industries we have no faith; the last three are capable of being greatly improved, and therefore deserve encouragement; but are they likely to meet the requirements and satisfy the aspirations of the thousands whom Dr. Daly describes as being born every year in the country without having before them the simplest aims of their lives?

We think that the prosperity of this island should rest, as its sure and permanent basis, on agriculture, which, under proper direction, yielding adequate results, will attract and occupy all who complain of want of employment. If the sons of the soil could do for its plains and lowlands what European sojourners are doing so successfully for its hills and uplands, Ceylon would, of a

truth, be eminently prosperous and happy. But the natives are wanting in knowledge, energy, and capital and the Government should therefore come to their aid. In a previous article the formation of a Board of Agriculture was suggested. This Board should supersede the Central Irrigation Board, which consists of the Governor and two official and two unofficial members. A Central Board of Agriculture with the Governor as president and a larger number of officials and unofficials intimately acquainted with the country and its wants, will do a great deal more good than the present Irrigation Board. Such a Board will not only direct irrigation much better than has been hitherto done, but give a much needed impetus to agriculture which it is the object of irrigation to benefit. It is a pity that heretofore the Government has simply contented itself with providing the people with water without showing them how it may be applied to the best advantage. Recognizing the defects of the primitive and unscientific system of native agriculture, the Government has established a School of Agriculture in Colombo; but the effect, on the population at large, of the teaching in a solitary school can at best be slow and feeble. The need is therefore felt of personal interest being taken and direct encouragement being given by the Government in the matter of native agriculture which has hitherto received far less attention than other matters of minor importance. The Board suggested, with the Governor at its head and with branch boards in all the provincial capitals, comprising the most prominent and well informed residents and presided over by the Government Agents will do much to rouse the dormant energies of the people, to stimulate agriculture, to introduce new products and bring about a thorough change in the method, and a vast increase in the extent and yield, of cultivation. It is to be hoped that, in the best interests of the people, His Excellency Sir Arthur Havelock will before long establish a strong Board of Agriculture to supersede the present Irrigation Board.—“Jaffna Patriot.”

[It is pleasant to see our persistent advocacy for the past ten years of the need of an Agricultural Board, bearing fruit.—*Ed. T. A.*]

THE TARIFF OF CEYLON TEAS IN LONDON.

We call the particular attention of the trade and those concerned in the metropolis, to the complaints recorded in our present issue, in reference to the Taring of Ceylon teas in the different London Docks. The wide discrepancies (and consequent serious loss) between the weights locally recorded and those reported from home in Account Sales, are attracting special attention, and our correspondents only afford specimens of a number of complaints that are very prevalent in Ceylon just now. It is very likely that the Planters' Association will be moved to take action and endeavour to get a more equitable system established. For, however long-continued and conservative may be a trade practice, if it is found to work unfairly and injuriously to planting interests, it generally disappears or gets modified under the persistent pegging-away of Ceylon planters. Those concerned in “taring” Ceylon teas in the London Docks had better look out, and unless there is more care shown, may begin to set their house in order.

ZOOLOGICAL SOCIETY, March 17th.—Mr. W. F. Kirby gave an account of a small collection of Dragon-flies made by Mr. E. E. Groen in Ceylon. The series contained examples of sixteen species, of which three appeared to be new to science.—*Nature*.

ZOOLOGICAL GARDENS, LONDON.—The addition to the Zoological Society's Gardens during the past week include a Purple-faced Monkey (*Sceloporus leucopygus*) from Ceylon, presented by Mrs. Sutton Sams.—*Nature*, April 4th.

TEA AND COFFEE SUBSTITUTES.

(Continued from page 780)

VERBENACEÆ.

58. *Lippia citriodora*, Kunth.—An undershrub of South America, but cultivated in Europe. The dried leaves have been used as a substitute for tea as well as for flavouring creams and various other confections.

59. *Lippia adoensis*, Hochstetter.—An infusion of the whole plant is used on the Gambia, and it is said to possess febrifugal properties. It is known as Bombor or Gambia tea. A sample obtained from the Colonial and Indian Exhibition is contained in the Kew Museum.

60. *Lippia rubiginosa*, Gil.—Under the name of Tornillo, this plant is common throughout Patagonia, where the Indians use the leaves to make an infusion like tea, which they regard as a stomachic, —they are also used for flavouring soups, stews, &c.

61. *Lantana pseudo-thea*.—This and several other species of Lantana are said to be used in Brazil as tea plants.

62. *Stachytarphota jamaicensis*, Vahl.—A tall growing biennial, native of the West Indies and many parts of Tropical America, where the leaves are said to be largely used, not only for adulterating Chinese tea, but also for preparing a similar beverage. It is further stated that they were at one time imported into Austria under the name of Brazilian tea. They are said to have stimulant and febrifugal properties.

LABIATE.

62A. *Monardadidyma*, L.—A native of the United States, where the dried leaves are known as Oswego tea, and are used in infusion which emits a very grateful and refreshing odour, and is said to have similar properties to Camomile. There is a specimen in the Kew collection.

63. *Sideritis theezans*, Boissier and Heldreich, *S. peloponnesiaca*, Boiss. and Heldr., and *S. Raseri*, Boiss. and Heldr.—Under these names three species of Sideritis have been described as indigenous to Greece, the leaves and flower-stalks of which are gathered and sold by the herbalists as Greek tea. The infusion is said to be agreeably aromatic, with a resemblance to true tea. A specimen of *S. theezans* is contained in the Kew Museum.

64. *Salvia triloba*, L.—Under the name of Athens tea, or Phaskomyia tea, the Greek herbalists gather this plant, dry it, and tie it in bundles, and sell it in the markets. Dr. Landerer says an infusion, or tea, made from it is drunk in all cases of chills, besides which, it is sold in the coffee-houses and confectionery shops. The herb is found in all the poorer people's houses, and on board ships, and Phaskomyia tea is generally drunk on cold days. The plant is also kept on hand in all coffee-houses, even as far as Odessa, and its infusion is a favourite beverage. In Odessa, a kind of punch with rum is made of it. A specimen is in the Kew collection.—J. R. JACKSON.—*Gardeners' Chronicle*.

TEA IN THE WYNAAD.—The *Englishman* writes:—There appears to be some prospects of a general increase of tea cultivation in the Wynaad. The fact that this District has been left so far behind in the race with Northern India and Ceylon is attributed by a local apologist to the difficulty of establishing factories for the treatment of the leaf. It is proposed now to start a number of factories as joint stock companies and work them on the Ceylon system, by which a fixed charge of say two annas per pound is allowed for wear and tear of machinery and profit to the manufacturer, while a further charge is made for absolute cost of manufacture, packing, transport, etc., including insurance and all home charges. The average price of tea per pound ruling in the London market is calculated at the current rate of exchange, and the Planter obtains this sum, less the fixed charges of the factory. By the adoption of this system it is thought that the cultivation of tea may become profitable on many small estates where the treatment of the leaf by hand is now out of the question as a commercial undertaking.—*M. Mail*.

THE RECENT FALL IN EXCHANGE.—Whilst the price of tea has fallen about 1½ per lb since the 6th of February last, exchange has declined at very nearly the same price—from 1/5½ to 1/4 13-16th for demand drafts. With their produce at an average of something over 11d per lb during the last four months, and exchange steadily ruling in their favor, the planters have little to complain of at present; and, when we take into consideration the fact of the stock of all kinds of tea in London being some 16 millions of pounds less than it was at the same date last year, the prospects of the market in the immediate future are by no means gloomy. The following is an interesting list for comparison:—

TEA AVERAGES AND EXCHANGE.

	Tea	Demand		6 months		
		Aver.	Drafts.	Bills.		
	s.	d.	s.	d.	s.	d.
Jan. 4, 1889 ...	0	10½	1	4½	1	4 29-32
Jan. 3, 1890 ...	0	11½	1	4 15-16	1	5 15-32

Feb. 6, 1891 ...	1	0½	1	5½	1	6½
March 6, 1891 ..	0	11	1	5½	1	5 9-16
April 10, 1891 ...	0	10½	1	5 1-16	1	5½
April 24, 1891 ...	0	11	1	4 13-16	1	5½

"KEW BULLETIN."—The February number is devoted to the consideration of the Ipoh or Upas poison, the produce of *Antiaris toxicaria* and concerning which so much has been written. The poisonous effect is stated to be due to the presence of Antiarin, a green resinous substance produced in the tree as growing in Java. Specimens of the so-called poison were sent to Kew from the Malay coast, and were subjected to examination and report by Prof. Sidney Ringer, on two occasions, with entirely negative results. The leaves sent with the poison were clearly those of *Antiaris toxicaria*. It would appear, then, either that the tree is not always, and under all circumstances, dangerous, or that its juice is mixed with some other substance, such as arsenic, to which the fatal effects are in reality due; and there is some evidence that this is the case. It is disconcerting to have one's notions about the Upas tree disturbed! Cutch or Catechu is also the subject of a note in this number of the *Bulletin*. This is the resinous extract of *Acacia Catechu*, much used in medicine as an astringent, and in manufactures as a tanning material. The mode of preparation is detailed as practised in the North-west Provinces of India and in Burma. The article on the production of Cane-sugar is interesting, as showing the importance of studying the physiology, or internal working of the plant, for the purpose of ascertaining under what circumstances the sugar is formed, what conditions are most favourable to its production, and how the amount may be increased under cultivation. To this subject we shall probably recur. The timber of the Yomba country in West Africa is also reported on, and from what is stated it appears that there exist a large number and variety of timber trees easily accessible by the great waterways which extend through the colony of Lagos. The "mahogany" of this region is the produce of *Khaya senegalensis*, the "Rose-wood" is yielded by *Pterocarpus erinaceus* and the *Odum* or *Iroko* of Yomba, in which a trade is springing up, is furnished, as has been ascertained at Kew, by *Chlorophora excelsa*, a tree of the Nettle family, *Urticaceae*. This latter timber, it is stated, can withstand the effects of weather and of white ants, and is, therefore, largely used in house construction. It is also suitable for furniture, as it is very ornamental when polished. Other articles refer to the *Phylloxera*, and to the newly-established botanical station at Lagos, which, through the enlightened policy of Sir Alfred Moloney, is likely to be of great service to the colony. The station is under the direction of Mr. Henry Millen, who was sent from Kew on the resignation of Mr. James McNair. As an appendix is published, a list of seeds collected in the Royal Gardens in 1889 & 1890, and which are available for exchange and otherwise in small quantities, but which are not sold to the general public. — *Gardener's Chronicle*.

PHILANTHROPY AND IRRIGATION.—The *Indian Agriculturist* says:—Steps are being adopted by Government to minimise the prospects of distress in the Kalahasti Zemindary. The Collector of North Arcot has been authorised to place at the disposal of the Dewan of the Zemindari the sum of R10,000 from the loan sanctioned to the estate under the Land Improvement Act to be spent at once on some of the minor irrigation works, the estimates for which are not to exceed R250 each. The amount is made available on the condition that the contract for the works is given to the villagers themselves, and that outsiders are not employed as contractors.

CINCHONA AND QUININE IN SOUTHERN INDIA.—A correspondent recently pointed out in these columns the steady fall that has taken place in the value of the unit of quinine during the past ten years, till it has reached the exceedingly low price of 1½ at the present time, which implies that the bulk of the shipments from Southern India will only realize 3d to 4d per lb., a price which hardly covers cost of shipment. *Succirubra*, or red bark, still forms the largest proportion of the exports, but if the value of the unit falls any lower, we shall find that it will cease to be shipped, the selling price not covering cost of harvesting, baling and shipment. — *Madras Times*.

A GUTTA-PERCHA SUBSTITUTE.—Senhor da Costa, a gentleman well known in Portuguese scientific circles, is reported from Goa to have discovered an excellent and abundant substitute for gutta-percha. It is the solidified fluid which issues from the *Nivol-cantem*, which grows wild in the Concan district of British India, and is generally planted for hedges. Senhor da Costa states that it is insoluble in water, it softens under heat, and hardens in the cold. It receives, moreover, and retains a given moulded shape, can be cast into very thin sheets, and is capable of taking the minutest impressions on its surface. Though white when it flows from the tree, in its dried state it is of a chocolate colour, closely resembling gutta-percha. — *Chemist and Druggist*.

THE WANTS OF CHINA.—A contribution to the *Japan Mail* graphically describes the wants of China:—

The first thing wanted is roads—not even railroads, but good cart roads. The next is judicial reform; and the third is the abolition of universal bribery and consequent corruption. It is urged that as both sides bribe, and that no secrecy is even hinted at, the result in the long run is much the same as if no bribery existed. As a matter of fact, it costs an Englishman about as much to get justice as a Chinaman, only we call it solicitor's and counsel's fees. There are no lawyers or pleaders in China, which in this respect is perhaps to be envied by other less fortunate countries. All the same, the Chinese system works very badly for litigants. Torture plays a conspicuous part in criminal proceedings. A certain specified number of tortures are "legal," but unfortunately, even these are often exceeded, and ghastly horrors are perpetrated in the name of law. As an illustration of a minor and "legal" application of the question, I may mention that while I was in Peking one of the Legation servants was charged with a petty theft and handed over to the native authorities for safe custody. Nothing was heard of him for some days, when the result of inquiries showed that the unfortunate wretch had been kept for several hours each day "kneeling upon chains." As this perhaps does not sound very terrible, let me recommend any sceptical reader to try it for one hour only. Kneeling upon broken glass, which is an unlawful refinement of the chain torture, has been more than once resorted to in the provinces to extort a confession. But most comprehensive works on China give full and hideous details of such matters. One saving consideration, however, must not be overlooked. When did we abolish judicial torture? For a Christian nation I think we kept it up to a tolerably late date.

CEYLON UPCOUNTRY PLANTING REPORT.

SLACKENING FLUSH—WEEDS—AUDITING OF COOLIES' ACCOUNTS—MUHAMMADAN FASTING—CACAO—COFFEE—TREASURE TROVE IN BADULLA—A CONTRIBUTION TO SNAKE LORE.

April 27th.

FLUSH is slackening off somewhat, and some of us are beginning to realize that there are weeds about. We have all been so busy of late securing the harvest of tea leaf, and doing our best to keep up with its rapid growth, that the weeds have had a royal time of it. We always say to ourselves that tea is not like coffee, and that being a little weedy does not matter much; but I suppose it is the effect of early training, that, however much truth there may be in the above theory, we would prefer having it tested by another fellow, he to have the dirty estates and we to have the clean. Under any circumstances April and May are trying on the weeding contractor: there is always such a rush after the first rains that the weeders fall behind and if a loss is made—although I do not believe a weeding contractor ever lost money in Ceylon, though his coolies may—this loss is never forgotten, and you may hear of it at any time. If you express any doubts on the ruinous results of the weeding, you are indignantly invited to examine the accounts for yourself, which accounts happily are never produced. Who could possibly audit coolie accounts? There is no kind of arithmetic in the world that would help an unfortunate auditor, or lead to any thing stable. I had a kangani once who kept a checkroll of his gang on the back of the door of his line. When things were working smoothly the results agreed to a cent with the estate checkroll; but when there was any row on, the discrepancies were appalling. In the latter case I found that even allowing thirty-six working days in the month would hardly bring to us within hailable distance, so we each stuck to our figures and agreed to differ.

The Muhammadans have, I understand, a Fast on at present. I was enquiring of my Malay conductor if he was observing it, as he did not seem to be quite so spry as usual. He replied that he had very hard work and required to be fed, but he was *making his wife keep it*. This sort of thing will not last long, I fear, now that Western ideas of woman's rights are beginning to permeate Ceylon.

The Cacao is looking as if it intended to do well this year again. It is healthy, vigorous, and many trees are just full of blossom. There is always a kind of straggling crop too, which has to be gathered all the year round, but this season it would seem to be more than usual, and bigger than usual. The berer is beginning to come about a little.

COFFEE—what there is herabouts is looking as if it would do some good. What was in good heart has had a tolerable blossom which has set fairly well. But the bug is about, and what that may lead to remains to be seen. The possibilities with bug around are all against the planter.

The showery weather has ruined the chances for any more blossom, and some fine coffee which I saw in Dimbula did not seem as if it would overbear this season. It is to Haputale one has to go to see coffee crops, and there there are certainly some very fine ones. All the same even in that favoured district, the shrinkage of coffee area goes on, and the new favourite,—TEA—is taking its place. Still with the late splendid prices, coffee is receiving renewed attention, and tea is not being planted up quite so freely as it was a little while ago. Few that I know of are planting coffee. I frequently see a little coffee clearing—plants grown from Coorg

seed—which is not without hope. The nursery was badly stricken with leaf-disease, and in the N.-E. of last year the plants were put out with hardly a leaf on them, and very thin otherwise. It was "a sair sight" for some time, but the plants have worked round, and now they have a good deal of vigour in them, and promise well. Of course, between the cup and the lip there may be a good many slips yet.

It is quite remarkable the number of places in Ceylon where TREASURE is said to be buried, and perhaps more remarkable how few attempt to find it. Still now and again a man turns up willing to risk good coin in a hunt after the hidden. At present a search is being made on the hills around Badulla for some treasure said to have been buried by the Sinhalese and the enterprising person who has faith in the tradition was burning a lot of dynamite, and keeping the place lively with the booming of his explosions when I visited the capital of Uva a few days ago. Saturday and Sunday were all alike, and the vigour of the would-be discoverer, was undoubted. A silver lamp was said to have been found in the neighbourhood ever so many years ago, and, as far as I could learn, the interest in the present effort had been increased by the unearthing of some ashes and pieces of broken chatties, which of course was something. When a man goes in for speculation there are always chances against him, but of all lotteries that of treasure-trove seems to have the maximum of blanks.

As contribution to SNAKE LORE I offer the following which my horsekeeper maintains is the only way to cure the bite of the green snake. The green snake, he says, always bites people in the eye, and when it does so the unfortunate falls down as if dead. The snake then escapes up a tree, and it is very essential to notice the particular tree it has ascended. This having been found, a funeral pyre must be built up close to the tree and the snake's victim carried out as if for cremation; then the pyre must be lighted, and when the snake sees this, it will conclude that the unfortunate has been done to death. It will then vomit out its poison, and the person bitten will at once revive. All this is so very simple, and effective that I did not care to keep such valuable information altogether to myself. Perhaps if no treasure is found at Badulla, and time allows, the worth of this veracious statement might be tested.

PEPPERCORN.

Mr. RIDLEY, of the Gardens and Forest Department, has issued today the first number of the "Agricultural Bulletin of the Malay Peninsula" which it is proposed to publish from time to time as occasion may serve. These Bulletins will treat of subjects connected with Agriculture and Horticulture in the Malay Peninsula. Mr. Ridley in his "fore-words" says:—

It is hoped that planters will send to the Director of the Botanic Gardens, Singapore, notes and observations on the cultivations of the various crops under their care. Observations on insect and fungus-pests are especially requested, and these should always be accompanied by specimens of the injurious insect or fungi either alive, or preserved in spirits, except in the case of butterflies and moths which should be sent dry in envelopes.

The first Bulletin contains an abstract of a series of interesting articles written by Dr. Burok, Assistant Director of the Botanic Gardens at Buitenzorg, dealing with his method of treatment of coffee-leaf disease in Java.—S. F. Press.

EXTRACT OF TEA.

In a recent invention the tea to be extracted is placed in a digester of conical form provided with a movable perforated false bottom, and communicating by means of a siphon-tube, with another vessel used as a boiler and placed at a lower level. A supplementary boiler is also added at a higher level from which water is run into the digester. In order to insure the better extraction of the tea leaves, the digester is provided with a rod sliding through a stuffing-box and provided with spokes, and through the lid of the digester a cologating apparatus is passed connected with small chambers charged with wool, which serve to condense the aroma. The tea is introduced into the digester, and hot water is run in from the higher boiler, and a current of steam from the lower boiler. When the extraction is complete, the latter is shut off, and the infusion sucked into the lower boiler, from whence it is run into an evaporator. The liquid is then concentrated until a sample taken out hardens on cooling. During the process it is best to keep the liquid in agitation. Part of the wool on which the aroma is condensed is stored up with lump sugar in a closed vessel, when some of the aroma is abstracted; the rest of the wool is placed in a mixer with sugar, and the whole moistened with water or "aroma-water." The aromatised sugar can be expressed from the wool and stored in suitable receptacles; the wool is washed and used over again. The more or less dried tea infusion is mixed with "aromatised sugar," and the whole heated to 100 degs. in a closed vessel provided with a mechanical agitator, which is worked until it moves smoothly without resistance. After partial cooling the plastic mass is rolled, and out into convenient shapes. The extract may be used for making a "cup of tea" or for the purpose of confectionery; the spent tea-leaves from the digester are compressed and made into blocks to be disposed of as "mauure," or they may be carbonised in a closed retort to obtain tea-charcoal and tea-tar, which contains ammonia, other nitrogen compounds, acetic acid, and similar products.—*Grocer.*

SERIO-HUMOUROUS.

REVIEW OF THE INDIAN TEA TRADE.

The clerk of the Worshipful Company of Tea Tasters presents his compliments to the editor of the *Home and Colonial Mail*, and begs to enclose a copy of the Annual Review:—

REVIEW.

Tea Lane, March, 1891.

The tea season of 1890 being now sufficiently advanced to enable the Company of Tea Tasters to pronounce an accurate opinion on the crop, the master and wardens deem it advisable at once to issue the official review, in order that planters and others interested in tea cultivation may have due time for reflection, and an opportunity to pick out the golden tips before the new season opens. The season just closing has been one of unusual activity. Several estimates of the quantity to be expected had been put before the company during the season; but the Court of Assistants received them with dignified indifference until the month of January, when it became probable that the estimated quantity would not be realised, and a very lively interest was at once displayed.

The imports and deliveries for each month have been duly published by the usual authorities, and the figure heads of the Tea Tasters' Company have regularly discussed them without materially adding to the general stock of information. It is not therefore deemed necessary to make a detailed reference to them at present, as the company does not exist for figurative purposes. It may be mentioned, however, on the authority of a past master, that the crop of 1890 has fallen short of the previous season for the first time in twenty-five years, but seeing that in the last thirty years the production of Indian tea has increased one hundred-fold, this temporary

halt in the onward march is only, as the French say, *reculer pour mieux sauter*. And it may safely be predicted that planters will carefully note the wishes of the consumers in this country, and favour them with an increased quantity next season, particularly in consideration of the more remunerative equivalents now offered them, and because tea planting ought to be a growing industry.

The Tea Tasters' Company view with much satisfaction the gradually increasing size of the breaks of each kind; and it may safely be affirmed that some of the best prices obtained in the Mincing Lane sales during the season have been for some of the very largest breaks offered. It is also satisfactory to notice the gradual appearance from the sale catalogues of non-sampling breaks, which in times of extreme pressure are frequently overlooked. Some members of the Tea Tasters' Company are of opinion that every further increase in the crop of Indian tea should be managed by making larger breaks of each grade rather than by increasing their number. Some, indeed, regard the regulation twelve chests as too small a quantity to draw a sample of, and draw the lid at thirty chests. Others are accustomed to "look at" every sample, small break or large, but only carefully to go into the merits of the desirable ones. Planters will therefore do well to avoid the undue multiplication of breaks, as in the long run the general result is not furthered by such a course. This observation is now much more necessary than it was ten years ago. The values of the different varieties were then 4d to 6d per lb. as under, so that careful sorting had its advantages; but it would now seem to be needless spending labour and pains on making three or more grades when the difference in the market price does not exceed $\frac{1}{2}$ d or 1d per lb. Frequent instances will occur to any careful reader of the weekly record in the HOME AND COLONIAL MAIL in which Pekoe has realised 10d, Pekoe Souchong 9 $\frac{1}{2}$ d and Souchong 9 $\frac{1}{2}$ d per lb, whereas if the three grades had been assimilated in one unsorted conglomeration, it is not at all unlikely that the result might have been 9 $\frac{1}{2}$ d. Certain it is that in the future, unless the assimilation of grades receives more attention in the direction indicated, a deadlock will result in times of pressure which may prove disastrous. It ought to be mentioned, however, that under the auspices of some prominent members of the Court of Assistants an arrangement was come to early in the season amongst the tea importers to regulate the quantity to be offered in public sale each week, so that it should not exceed 35,000 packages. It was hoped that this concerted action would prove a sort of "automatic governor and feed regulator," and it was fairly successful during the autumn. But in January when the machinery was set in motion after the holidays, a quantity of unexpected "fat" was squeezed out, which lubricated every wheel so much that the governors lost control of the machine entirely. The vent pegs got loosened and finally the sluices gave way, and the docks were nearly empty at the end of the month. It was then discovered that 170,000 packages had slipped through during that time. The engineers have since made some show of repairing the machinery, but it is to be feared that it will only work in fair weather, when there is not much need of it, and that directly self-interest prompts anyone to loosen the vent peg, it will speedily be kicked out.

The number of samples reported on by the company during the season has been at times sufficient to tax very seriously the capabilities of the livery. Frequently the obscurity of the atmosphere has been an added difficulty which it was not easy to see the way out of. Grateful acknowledgment is, therefore, due to Professor Hunter, who under these trying circumstances generously afforded the company the benefit of his valuable invention, the Biennial hydrogen pekoscope, a scientific discovery of the utmost brilliancy, by which the fog fiend is effectually defied, in consideration of which it is confidently believed that the proposition to confer on the professor the freedom of the company, enclosed in one of Andrew's patent metal caskets, will meet with general approval.

The quality of the bulk of the crop of 1890 has been tolerably satisfactory and, generally, saleable. There still seems to be a want of endurance about it however, and if by any new method of working the leaf planters could ensure its keeping its flavour until the consumer could get it into the teapot, it would be worth trying for; and if once the produce of certain gardens acquired the reputation of keeping its quality well, it is more than likely that the attention of buyers would fasten on them. It cannot be too frequently reiterated that tea is, in its highest sense, a "beverage" "cheerful, but uninebriating" as Don Franco beautifully puts it. It follows, therefore that in so far as the beverage proves to be refreshing and cheering, just so far does it fulfil its purpose. Golden tips are, no doubt, very beautiful to look upon, and very acceptable to school-boys. Some older boys, too, like Master Watty will even spend their pocket-money very freely in buying them; to look at and talk about, but nobody at the family tea-table cares for appearances so long as he feels refreshed and cheered, and the only ten-guinea leaf for which there is likely to be a permanent demand bears the Bank of England water-mark.

A review of season 1890 would be incomplete if reference were not made to the improvements effected in quickening the delivery of tea after public sale. It has always been a gratifying feature of the business that those engaged in tea importing were thoroughly interested in their work. They were no doubt actuated by a sufficiently high sense of duty to let the public have the offer of their tea in sale. Indeed, the readiness occasionally displayed to show samples almost as soon as the ship was reported in the docks was misunderstood, and made the occasion of grumbling by those who had nothing to lose.

It was after the public sale, however, that natural feeling asserted itself in a disinclination to part with what was loved and lost, until the very last moment allowed by the unfooling clause in the sale conditions. It was felt at last some modification was desirable. Frequent conferences were held, at which free expression of opinion took place between all those whoseemed interested in the subject, and a final agreement was come to by which the importers agreed to surrender their property in three days instead of seven; thereby peacefully and satisfactorily cutting off an almost constant hot water supply.

Reference should also be made to the opening last November of the new Indian tea plunge in connection with the London Prophets Cleaning House. Several members of the Tea Tasters' Company had previously experienced the cleaning out process privately at the Stock Exchange Baths, where the accretions of oil were speedily removed and the boiler lightened of his load. It was a happy thought, therefore, to bring home to Mincing Lane the hygienic benefits of Baden Baden. The operators in China tea were the first to embrace advantages of the new process. And to their honour it must be recorded that so far from desiring to keep all the benefits to themselves, they desired quite sincerely to let in the outsiders. In November it was proposed to open the Indian saloon. A code of rules duly appeared and operations were commenced. The Tea Tasters' Company has taken no official notice of the proceedings so far, but a few of the members have engaged in the game on their own account. A daily contest is held at which some well known and honest person is voted to the Chair. The proceedings commence usually with a certain amount of fencing; indeed on some occasions nothing has been done but the shouting of challenges to one another. It, however, a challenge be given by one party to plunge in for, say four months for a certain sum, and an opponent takes it a desirable contest, the challenge is answered, and the seconds speedily hook the names and take the stakes, and both at once plunge in. Considerable interest is taken in the game, and, as the tide ebbs and flows all through the weary months, both parties watch it with the keenest eyes. Perhaps they indulge their fancy by thinking they are

adding to the lustre of England's commerce. They are doing nothing of the sort. Far otherwise. They are really engaged in a game of chance, in which what one man wins the other loses, and, when at the end of the four months the experts decide that the loser shall hand over so many hundreds of pounds to the winner, both have to accept the decision or forfeit their stakes. It is, perhaps, too soon to pronounce an opinion on the effect produced by these gamblers on the legitimate market. Up to the present there have been some outsiders well cleaned, but the insiders evidently wish to study the development of operations still further. To the ordinary tea dealer the fluctuations in value, caused by so many outsiders plunging in and splashing about, have caused very serious perplexity. But even in this the back will eventually adjust itself to the burden; and there, for the present, it must be left.

As to suggestions to planters for next season, the Company of Tea Tasters' cordially send their greetings to their many friends in India and elsewhere, who have in the past striven with heroic fortitude to do their best. Naturally they are much better judges of how to do their work than even the most eminent broker in the City of London. Let them continue to do their best in every respect, produce a good liquor with a fair leaf, packed in sound chests that will neither taint the tea nor allow it to deteriorate in quality, and their growing industry shall be well supported by the London market, and in due time by all the world. (Signed)

For the Worshipful Company of Tea Tasters,
H. and C. Mail. A. POOREMAN, Clerk.

BAD NEWS OF NEW SEASON'S CHINA TEAS.

The *Foochow Echo* says:—Recent information received about the picking of the new leaf, from the various tea districts, is truly lamentable, in fact it is so bad, that one is almost inclined to believe that no new teas can be expected in the market. We know that natives have the unenviable reputation of being capable of spreading false news. But, after allowing a hundred per cent of what we have been informed to be false there yet remains a very gloomy prospect for the native tea hongs here, and for the growers in the country. Of the former we understand, that only two hongs out of ten have made some very small advances to those tea men of good standing, and these under conditions, that the costs shall not exceed those ruling last season. This no doubt is a wise step, as it will prevent the usual competition in the hills, which may be fairly assumed to have been the chief cause why teas were laid down in this market at such high costs every year. It is also further stated that a well-known and wealthy tea hong has refused *in toto*, to grant any advances; nor does this hong care to have anything to do with tea at all during the approaching season. This action has disappointed many tea men, who are now entirely without hope of obtaining any advances. From the country, we learn that owing to the establishment of a low scale of wages, much difficulty has been created in obtaining labourers, and we understand that many of these have left the tea districts in search of other work. In fact the whole business is in so unsatisfactory a state that the amount of treasure which has been sent up country does not exceed five hundred thousand dollars, (merely a drop in an ocean). That this will cartail to a great extent the gathering of, at least, the first crop leaf, cannot be doubted.—*China Mail*.

PERAK TEA.—A small consignment of Perak tea has been received in London, but has not been placed publicly on the market as yet. Some experts and others have sampled the lot, and pronounce it of good quality. It is of good colour, though slightly strong, and brews out well; it will bear comparison with equal growth of India and Ceylon, —*Straits Independent*, 25th April.

NOTES ON POPULAR SCIENCE.

BY DR. J. E. TAYLOR, F.L.S., F.G.S., &C.
EDITOR OF "SCIENCE GOSSEP."

Mr. E. H. Atton has recently shown that, notwithstanding the prevalent opinion to the contrary, some green plants can assimilate carbon from certain organic compounds in the absence of carbonic acid from the atmosphere. He prepared what he calls a normal "culture solution" for the purpose, and he concludes that green plants cannot normally obtain carbon for assimilation from any substances except carbohydrates, but that a compound may be a source of carbon to the leaves although not to the roots.

A capital and most thoroughly practical scientific use of observation has just been made of the well-known fact that aniline dye kills all sorts of bacteria and bacilli. These dyes, are, medically speaking, quite harmless. So two German physiologists have (after various experiments with guinea pigs, rabbits, &c., all of them successful) begun to treat human subjects affected by bacterial diseases with aniline. Skin ulcers and even eye diseases, wounds and sores suppurating—in short all diseases in which micro-organisms take part—are being successfully treated with this cheap and common dye, given in small diluted doses.

Perhaps the most expensive taste in the world, next to horse-racing, is the cultivation of orchids. How many rich people cultivate these flowers (which represent the tulip mania of two centuries ago) is best shown by the fact that "a new orchid journal" is announced. It is to be edited by a Viscount.

An interesting, if not important paper has just been read before the Geological Society on "The Borrowdale Plumbago, its Mode of Occurrence and Probable Origin," by Mr. J. Poslethwaite, of Keswick. Many of my Australian readers who hail from the old country will remember the famous Cumberland black lead, drawing pencils of their childhood's day. The raw material came from Borrowdale. This was in the days before the graphite now used for "blacklead pencils" had been discovered as a waste product in the manufacture of coal gas. The Borrowdale plumbago or native "blacklead" occurs in veins traversing certain kinds of igneous rocks, which themselves break through volcanic deposits. Mr. Poslethwaite showed that many thousand feet of volcanic rocks must have supervened between the Borrowdale plumbago-bearing beds and the overlying Silurian shales. He thinks he has found strong similarities between the plumbago-bearing rocks in Borrowdale and the diamond bearing rocks of South Africa; and also that the conditions under which the plumbago was originally formed in one lake district approached more closely to those which gave rise to the Kimberley diamonds than to those which originated the plumbago veins in North America. His opinion is that the molten magma, in its upward course, passed through a deeply-seated stratum of carbonaceous material, and tore off numerous fragments. The president of the Geological Society (Dr. Archibald Geikie), in the discussion which ensued, said there were only two possible sources of supply for diamonds and graphite—derivation direct or indirect from organic matter, and (as in the most ancient archæan rocks and meteorites) as an original mineral. Of course there is not! What chemist or geologist could imagine any other derivation for them.—*Australasian*.

HOW TO USE THE TOMATO.

BY MISS MARGARET RYDER.
(From *The Ladies' Treasury*.)

If the housekeeper of half a century ago could step into the modern kitchen and store-room, how extreme would be her surprise to see into what general use as an article of food the "love-apple" of her day has grown! Then it was cultivated only for ornament; now, prepared in a variety of ways, it takes its place on the table for breakfast, luncheon, and dinner.

During the hot days that come in the latter part of the summer, when beefsteak and chops have ceased to tempt the appetite, no more desirable dish

can be sent to the breakfast table than broiled tomatoes. They take the place of meat, and provide a relish.

To prepare this dish, select medium-sized ripe tomatoes; wash, and cut in two. Place the pieces on a perfectly clean wire broiler, the cut side down, over a clear fire. When cooked almost through, turn, and cook until soft. Serve on a hot platter, with cut side up. Sprinkle a little salt and pepper on each piece, after pouring a teaspoonful of melted butter over them.

For lunch, a tempting salad can be made of tomatoes. Select one dozen ripe tomatoes; peel, cut in thin slices and set on the ice. Make a dressing of the yolks of four eggs boiled hard, and rubbed to a paste with a tablespoonful of salad oil; add half a teaspoonful of pepper, one of salt, one of white sugar and two of mustard. Stir in the yolk of a raw egg beaten to a froth, and, last, one teacup of vinegar. Put this on the ice to get cold, and when ready to serve, pour over the tomatoes.

This salad may be made a very ornamental dish by selecting the tomatoes of a uniform size and bright colour, cutting off a round from the stem end, removing the seeds, and filling with the dressing. When prepared in this manner a single tomato should be served to each person, on a small chin plate, resting on a bed of green.

Tomato toast is an excellent dish as well as an economical way of using inferior tomatoes. Pare, slice, and cook half-ripe tomatoes until very tender; add sweet milk sufficient to make plenty of gravy; season with pepper, salt, and plenty of butter. Have the bread nicely toasted and placed in a deep dish, and pour the cooked tomatoes over it.

At dinner the tomato can be offered as soup, as a relish, or a dessert, as the cook may decide to prepare it. Either of these two recipes for soup is recommended:

Tomato Soup, No. 1.—Scald and peel good ripe tomatoes; stew them one hour, and strain through a coarse sieve; stir in a very little wheaten flour to give it body, and brown sugar in the proportion of a teaspoonful to a quart of soup; then boil five minutes.

FAST TRAVELLING.

The following is the record of the fastest mile a single man has thus far travelled by various methods of locomotion.—Swimming, 26.32; walking, 6.23; snow shoes, 5.39½; rowing, 5.01; running, 4.12½; tricycle, 2.49 2-5; bicycle, 2.29 4-5; skating, 2.12 3-5; trotting horse, 2.02½; running horse, 1.39½; railroad train, 40½ seconds.—*S. F. Press*, April 22nd.

HARNES DRESSING.—The following is recommended as the best dressing for harness, a few applications will prevent it becoming dried up in this hot climate:—

Pure rubber	1 ounce
Benzine	18 ounces
Tallow or oil	2 lb.

Dissolve the rubber in the benzine, then add the oil. The benzine carries the rubber into the pores of the leather, preventing it ever becoming hard.—*Mildura Cultivation*.

THAT WONDERFUL CEYLON TEA which is described as having caused such excitement in Mincing Lane could be equalled, says a Darjeeling correspondent, anywhere in the Indian tea districts. Probably about half a maund of it per acre could be turned out for a season before the concern went into liquidation. "I have seen similar samples of tea turned out here, simply and solely for exhibition purposes, and have a small bottle of it by me as I write. The manager in India who tried this sort of thing on an extensive scale would very soon be obliged to join the unemployed list, and to remain on it."—*M. Mail*, April 28th.

BARK AND DRUG REPORT.

(From the *Chemist and Druggist*.)

London, April 9th.

CARDAMOMS.—The following figures refer to the shipments of cardamoms from Ceylon in the period between January 1st and March 16th:—1891, 71,437 lb.; 1890, 96,333 lb.; 1889, 48,572 lb.; 1888, 83,638 lb.

CINCHONA.—Tuesday's bark sales were moderate in extent and consisted almost wholly, so far as saleable barks are concerned, of Indian-grown cinchona. Not only red, but also grey and yellow barks were well represented. The catalogues were composed of the following assortment:—

	Packages	Packages
	208 of which	154 were sold
Ceylon bark ...	208	do
East Indian bark ...	1,605	do 1,521
South American bark	646	do 114

Total ... 2,459 do 1,789 do

No Java barks were offered. A dull tone prevailed throughout the auctions, and prices declined about 10 per cent, as compared with the previous London auctions, thus falling to about par with the last Amsterdam sale. The unit ranged from 3d to 1d per lb., the latter limit being scarcely exceeded even for the best grades of bark.

The following are the approximate quantities purchased by the principal buyers:—

	Lbs.
Agents for the Brunswick factory ...	143,541
" Mannheim and Amsterdam factories	75,799
" American and Italian factories ...	47,610
" French works ...	38,120
" Stuttgart and Frankfurt o/M works	37,936
Messrs. Howard & Sons ...	25,640
Agents for the Auerbach factory ...	23,060
Mr. Thomas Whiffen ...	17,670
Sundry druggists ...	15,430

Total quantity sold ... 424,806

Bought in or withdrawn ... 83,956

Total quantity offered ... 508,762

The following report is given of the result of the last Amsterdam auctions so far as pharmaceutical bark is concerned:—The assortment, which was exceedingly large, was a fairly good one of all grades. There were several parcels from private plantations of exceptionally good appearance and carefully dried; first quality long quill from the Government plantations realised 81 to 120 cents; short quill 60 to 64 cents; second quality was not offered; broken quill and coarse chips, 11 bales of medium quality sold at 11 cents per half kilo. A few parcels of the barks grown on private plantations sold as follows:—Succinbra: Grey without mess, long quill 40 to 52 cents; short ditto 34 to 47 cents; smooth brown long quill 25 to 40 cents; short ditto 20 to 35 cents; broken quill, no dust 25 cents. Lancifolia: Handsome long quill 59 to 61 cents; short ones 46 cents. Calisaya: Schukraft, long thin quill 29 to 30 cents; Calisaya, one parcel of badly-dried thin quill went cheaply at 8 to 10 cents—the supply of this quality much exceeded the demand, and 343 cases were bought in; a few parcels were badly cured, and consequently had a musty smell, and the planters are particularly cautioned against any carelessness in the drying of their bark. The quill of thin bark should not be rolled so as to obtain the appearance of stout quill. If carefully and regularly rolled and of good appearance, thin small quill is always in demand, but the section of it should show an incomplete circle, and not a spiral form, such as is obtained by rolling it round several times.

At the Amsterdam bark auctions on Thursday of last week, out of 7,401 packages offered for sale, 6,200 were sold, at an average price of 5½c per unit (equal to 1d per lb.). The prices paid for manufacturers' bark varied from 3c to 58c; ditto root, from 9c to 49c. Druggists' bark, chips and quills, obtained 7c to 12½c; root 9c to 12c. 3,604 kilos sulphate of quinine contained in the bark were sold at 5c per unit; 5,916 kilos at 5½c per unit; 5,666 kilos at 6c per unit; 2,497 kilos at 6½c per unit; 582 kilos at 7c per unit, according to published analyses. The chief buyers were the Brunswick Works, the Auerbach Works, Messrs. Matthes & Bornemester (Amsterdam), C. L. Schupp & Zouen (Rotterdam), and Gust. Briegleb (Amsterdam). On the day following the sale, most of the bought-in manufacturing barks were sold, but the prices have remained secret.

COCA LEAVES. Thirty-five packages Java leaves sold by auction at Amsterdam on Thursday last at the following prices:—Crushed leaf, 35 to 51 cents (equal to 6½d to 9½d per lb.); rolled leaf, 30 cents (equal to 5½d per lb.).

COCA BUTTER.—The monthly auctions which took place here on Tuesday resulted in a decline. 500 2-cwt. cases of Cadbury's brand selling at 1s to 1s 0½d per lb.

TEA IN GERMANY.

Those of our readers who have noticed the recent articles in this journal on "Tea in France" and "Tea in Paris" (where such vigorous efforts are being made to popularise our vaunted English beverage among the eminently sociable and bibulous French, will perhaps be interested to learn that, in its turn, the big neighbour of France across the Rhine is now to be subjected to a similar peaceful invasion.

The Indian tea planter is on the war-path; Australia, America, Belgium, France—each has been attacked within the last few years; and still, like Lars Porseua,

East and west, and south and north,
He bids his messengers ride forth;
And none shall say him nay.

A movement has lately been set on foot under the auspices of the Indian Tea Association of Calcutta for the introduction into Germany of pure Indian tea, as such, and this by means of an organised packet trade.

The tea, which consists of three specially selected blends, is put up in attractive little packets of ¼ lb., ½ lb., and 1 lb. (German weight), the labels of which set forth in two languages the virtues of the contents, and bear, moreover, clearly printed on each, careful instructions for tea making, together with net weights and retailing prices. The latter, we believe, have been fixed at 4, 5, and 6 marks per ½ kilo, which, in Germany, where 6 marks is quite a common price for quite a common tea, should prove an attraction in itself.

The services of a Hamburg firm have been secured as a sort of general agency or distributing centre for the German Empire, and we understand that a contract has been entered into for a term of years, which includes several valuable provisions. Among these are one by which the agent agrees to purchase a fixed minimum—and yet not a very small—quantity of the tea in each year; and by another, to establish at least one depot for the sale of the new article in every town of over 20,000 inhabitants, and not less than twenty such depots within the first year.

We are only sorry not to observe any arrangement for the opening of tea rooms or other places for the practical conversion of the Teuton from the "bier-seidel" to the tea cup; but doubtless this important point has not been overlooked, and it will be merely a question of time and—time's twin—money.

Possibly their recent experience of the rather costly amusements with "Paris Indiens" and the like in Paris, has a little damped the ardour of the dauntless Indian tea zealots; or haply they are but pausing for a moment to reflect upon the excellent Italian maxim, "Chi va piano, va sano." However this be, we are persuaded that in Germany the enterprising planter has before him one of the most promising fields in Europe, and if he be wise in his generation he will look to it that this new movement in search of tea consumers do not languish for lack of his energetic support.

Already we hear rumours of German Governmental patronage for the enterprise, probably on temperance grounds. Great is the faith of the Teuton in the magic of official favours, and recognition of the undertaking by those having authority should in his country go far towards ensuring success.

Certainly there is much room for the extension of tea consumption in Germany. Let us glance at the figures of the question.

With a population of over 48,000,000 the Fatherland now consumes only some 4,500,000 lb. of tea per annum, or say 0.09 lb. per head, while its prosperous little neighbour, Holland with little over 4,000,000 inhabitants, takes nearly 6,000,000 lb. annually, or say 1.5 lb per head.

It follows that, could we persuade the usually not-thirsty German to absorb even one-half as much of our fragrant beverage as the apparently still more thirsty Dutchman, the tea trade of Germany would at once be increased seven or eightfold—say to 30,000,000 lb. per

annum. Already the consumption in that country has grown to be more than three times greater than that of France, and those best qualified to judge assert that there is no real reason why, with a little pushing, the German tea consumption should not be brought up to at least one pound per head within a moderate period.

In a recent letter on this subject, the secretary of the Indian Tea Districts' Association writes:—

“The annual tea consumption per head of population in Germany is about 41 grammes, against only 14 grammes in France—the population being about 48,000,000 against 36,000,000 so that the quantity of tea consumed is already as four to one. In Holland the consumption is over 600 grammes per head per annum, or fifteen times greater than in Germany. If therefore the German rate of consumption could be raised to that of the Netherlands, the present German consumption of about 4,500,000 lb. would be converted into 65,000,000 lb. to 700,000,000 lb.”

Here, then, is evidently good work to be done for Indian tea. The Germans are eminently a teachable people. They are highly intelligent, and new ideas, if sound, find with them a sure, if not an over-hasty acceptance. They also now travel much; they visit many lands, and sojourn with many peoples. Returning, as thousands of them do, to end their days in the Fatherland, they introduce many fresh views of life and manners, and as it is for the most part with one or other branch of our own race that the traveller in his search of fortune has been in contact, it is not surprising to find that in Germany the word “foreign” is rapidly becoming a mere synonym for the word “English.” Add to this that by far the greater number of visitors to Germany every year are English and Americans, while the influence of things French is dwindling to a minimum, and we see that any changes that may or do come in German national habits must necessarily be in the direction of anglicisation.

Now tea drinking is far too prominent a social custom of all branches of the Anglo-Saxon race to be easily overlooked, and nothing is more noticeable to the English traveller than the improvement of late years in the provision made to meet his requirements in this respect. The request for a dish of tea at an hotel no longer produces, first a blank look then a mild commotion, and finally a lukewarm pot of gingerbeer-coloured liquid, tasting more like the straw in packing-cases than like anything else in heaven or earth. All that is a thing of the past, at least in the better hotels and restaurants—but the quality of the leaf—generally a common China Congou with a peculiar Continental “twang” of its own, still leaves much to be desired. The ordinary price, too, of tea in Germany, when the duty is after all only 6d a lb., makes it still practically the luxury of the well-to-do, who are now compelled to pay from 4 to 9 marks a lb. for a range of teas for the most part much inferior to those sold in England at from 1s 6d to 3s.

It seems clear then, that there is here a most promising opening for his ever-increasing product, which the Indian planter would do well to secure for his own.

Just at present that usually energetic personage is—perhaps naturally—inclined to be somewhat apathetic as he glances contentedly at a comforting fourteen penny average, and indulges doubtless in happy day dreams of an increasingly thirsty forty millions of Britons who will continue *ad infinitum* to absorb greedily all the numberless thousands of tea chests he can empty into the aching void of their tea-pots!

But what if China awakes to the situation? or Ceylon doubles her present out-turn? What is to happen when the whirligig of time brings round another “doppression of trade,” with its instant and inevitable effect upon the consumption of all articles, and especially of things liquid? That all of these cases are possibilities we think none would deny, and therefore those who have the interests of Indian tea really at heart would in our opinion do well to lose no opportunity of creating new outlets in order to provide against a not good, but possibly bad, time coming.—*H. & C Mail.*

A REMEDY FOR POTATO DISEASE.

Since the article on the prevention of potato disease by the use of sulphate of copper appeared in *The Times*, on Monday of last week, a report of similar experiments by M. Petermann, Directeur de la Station Agronomique de l'Etat à Gembloux (Belgium), has come to hand. M. Petermann, like M. Girard in France, made tests with sulphate of copper, but he also tried another remedy—viz., sulphate of iron. His experiments showed that the sulphate of copper dressing was effective, and, whilst it did not injuriously affect the weight of the crop, or the richness of the root in fecula, it most certainly reduced the percentage of unsound or diseased potatoes. M. Petermann used a stronger dressing than M. Girard, his formula being (per hectare), sulphate of copper, 50 kilog.; lime, 25 kilog.; and water, 25 hectolitres. The test showed diseased roots amounting to only 7 per cent. on the total quantity raised, as against 30 per cent. of unsound tubers where the dressing was not used. The treatment with iron is very favourably spoken of, as it resulted in the diseased potatoes being lessened in quantity by 12 per cent. The iron mixture is composed as under:—Sulphate of iron, 50 kilog.; lime, 25 kilog., and water, 25 hectolitres per hectare. It is simply the substitution of iron for the copper, and the cost of treatment, M. Petermann says, is consequently much less. He regards the experiments as of vast importance, and contemplates further inquiry into the subject.

EXPORTS OF TEA.

The large shipments of tea last month from Colombo deserve a special word of comment. It will be observed that the total for April was equal to 7,056,163 lb., and for the four months—January-April—the aggregate of shipments is no less than 21,969,246 lb.! Now if this were an ordinary year, such figures would point to a total export for the year of not less than 66,000,000 lb., for the percentage of our annual shipments sent away in the first quarter or third of the year is by no means so large, usually, as in the other two-thirds. But it is well-known that since December, the season has been an extraordinarily favourable one for flushing. Considering, however, how busy our planters are on all sides, we feel fully certain that for the year, the 60 millions lb. will be exceeded in the total shipments. The estimate of the Indian Tea crop of 1891 given elsewhere is 116,000,000 of which perhaps 109 millions may go to the United Kingdom, against a total for Ceylon of 61 millions of which 57 millions may go to London.

INDIAN IRRIGATION.—The Hon'ble Alfred Deakin, the Victorian ex-Minister, who was the first to carry out practically the suggestion of Bishop Moorhouse to “conserve the waterfall rather than pray for rain” by instituting irrigation works under Messrs. Chaffey Brothers, has returned from his visit to India, whither he proceeded specially to study the system of Indian irrigation. On his return Mr. Deakin observed to a Press interviewer: “Indian irrigation is on by far the largest scale and by far the best of any in the world. As far as engineering work is concerned, it far exceeds anything else I have seen in Egypt, Italy, or America. The white people in the country don't know it. I was the first white man in the country, who was not an official, who went up the Sirhind Canal.”—*Indian Engineer*, April 25th.

PLANTING AND PROGRESS IN JAMAICA.

During the months that have elapsed since our last meeting I have again visited several parishes and everywhere I have found evidences of awakened energy, of hopeful effort in the present, and of confidence in the future. The Island shows signs of a rapid recovery from the depression of the period immediately preceding the year 1889. There is a large increase in the value of real property; the fruit trade is expanding with extraordinary rapidity, and with the daily improving means of communication will still further expand.

The acreage under sugar canes has decreased, but the decrease is more than counterbalanced by the increased acreage devoted to the cultivation of bananas, coffee, cocoa, tobacco and ground provisions.

The improvement in the dwellings of the people is a fair test of their prosperity, and I find that the number of houses paying rates at an assessed value, increased during the year ending 30th September, 1890, by 24 per cent.

The Selection has been made of the Roads to be taken over by the Director of Public Works under the Parochial Roads Law of 1890, and as the selected roads are being transferred to the Public Works Department as quickly as circumstances will permit, I hope that the end of the present year will see over 900 miles added to the 800 miles already included in the Main Road system.

The first section of twelve and a half miles of railway extension has been made and opened for traffic; and telegraph extensions have been carried out from Half-way-Tree to Annotto Bay; from Brown's Town through Barnstable to Ulster Spring; from Shooter's Hill to Balaclava, and from Santa Cruz to Malvero, while to facilitate the timely signalling of vessels telephonic communication has been established between Morant Point Light House and Plantain Garden River Telegraph Stations.

The Exhibition was opened by His Royal Highness Prince George of Wales on the 27th of January, on the day and at the hour decided upon in October 1889.

It would be difficult to over-estimate the importance of the Exhibition to Jamaica. Carried out as this great work has been by the hearty co-operation of every class of the community it has demonstrated how much can be done when all work together for the common good; it has stimulated intellectual activity among the people, and has brought Jamaica with her possibilities and attractions before the world with a prominence unequalled during the present century. The consequence is to be seen in the keen competition for her trade, and there are already indications that the close of the Exhibition will find the Island endowed with more than one valuable industry, hitherto undeveloped, while markets will be found for products till now neglected. Nor will the benefit be confined to Jamaica for the products of the Bahamas, Barbados, Grenada, St. Vincent, and Turks Islands are exhibited in their respective Courts and are being noted by observant eyes. The number registered as having visited the Exhibition up to the present is 78,303, and I have no doubt that before its close a very large proportion of the people of Jamaica will have availed themselves of the opportunity of improvement and advancement afforded by it.

Two subjects have occupied my earnest attention—the introduction of new products, and the adoption of some practical means of industrial training.

The question of Industrial Training for the young people of the Colony is of primary importance; while I yield to no man in my appreciation of the benefits of Education, I am by no means satisfied that a literary education to the exclusion of Industrial Training is an unmixt blessing to the inhabitants of this Island. I have granted a License to the Girls' Industrial School at Alpha Cottage. The Industrial School at Hope has been built, and is now occupied by twenty boys. The work of building the Industrial Girls' School in connection with the Government Training College for Female Teachers at Shortwood will be undertaken without delay, and I hope that

during the present year that School will also be in operation. I am sensible how little can be accomplished by these three Schools to supply the want of technical training, and I am conscious that the Industrial School system, as at present established, will not reach the children of respectable cultivators who form the class to whom technical education is of especial importance, I shall ask you to place at my disposal a sum sufficient to enable me to try the experiment of sending competent instructors to certain districts, whose teaching may so improve the cultivation and preparation of certain of our products as to largely increase the value of our Exports.

A CHEAP SUBSTITUTE FOR TODDY.

The gentle native who, according to Mr. Caine, has been taught by the Englishman to love strong drink, has also apparently taken lessons in the art of dodging the attempts made to check his propensity in this direction. Mr. Subba Row Punt recently brought to the notice of the Abkari Commissioner the manufacture and sale by some people in Tondiarpettah of an intoxicating spirit which was being largely used by the lower classes, especially the boatmen.

The Abkari Sub-Inspector of the locality was asked to obtain samples and all particulars regarding the preparation. From Mr. Lowe's report it appears that the intoxicant is called *sonti soru* and that it is prepared and sold clandestinely in the locality and has greatly displaced toddy, as its intoxicating properties are much greater than those of the former while it is much cheaper, half an anna worth of *sonti soru* being equal to three annas worth of toddy. It is prepared from rice, which is boiled and spread on a mat, and, when cooled, a substance called *shoudu* is powdered and sprinkled on it; both are then gently and well mixed together with the bare hands, over which gingelly oil is well smeared. The mixed mass is then put into pots, the mouths of which are tied over with cloth. The pots are then allowed to stand for three days. On the fourth morning water is boiled and allowed to cool, and a quantity is poured into each pot. The mouths of the pots are again tied up with a cloth and kept till the evening, when the liquor is fit for consumption and sale. *Shoudu* is believed to be a gum which exudes from some plants which grow in Moulmein, from which place it is obtained. The liquor cannot be kept long, as it undergoes very rapid fermentation and decomposition. The Chemical Examiner on analysing the liquor found it to be a fermenting rice liquor containing alcohol, and a mixed sample contained 5.39 per cent. of absolute alcohol by volume. The preparation is, therefore, an intoxicating liquor of nearly the same strength as ordinary beer. Steps are being taken to bring this liquor under the Abkari laws.—*Madras Times*.

JAPANESE ENTERPRISE.—The idea of "going down to the sea in ships" is evidently beginning to exercise upon the minds of the Japanese a charm such as it exercised in the days when their corsairs swept the neighbouring waters, and harried the unhappy shore-dwellers of China. The latest phase of the impulse is closely associated with the names of Viscount Yenomoto and Mr. Arai Ikonosuke. A large association has been formed, having for its object the exploration of the seas south of the Bonin Islands, with the hope of finding some fertile spot inviting colonization, or some new market for Japanese goods. We do not possess sufficiently accurate information about the plans of the company—if, indeed, a company has been formed—to speak in detail of its proceedings, but rumour says that a large number of naval officers on the retired list, or who have resigned their posts, are associated with the scheme, and that a sailing ship will soon be equipped and despatched to the districts southward of Ogasawarajima.—*Japan Weekly Mail*.

THE TALE [TAIL?] OF A FISHING CAT.—The remarks of the Rev. Dr. Stewart, (how "Dr. Macpherson" came to be interpolated is a puzzle,) on Mr. Godfrey J. Macleod's letter on cats, (see *Literary Register*, extract from *Inverness Courier*) are interesting and erudite as the "Nether Lochaber" contributions to the *Courier* as first and so long conducted by Carruthers and now by Barron,* have been for the past forty years or so. As a contribution to the curious points in natural history discussed,—the strong aversion of the cat to water and how the animal's *penchant* for fish sometimes overcomes this aversion, I may recall a case from my reading. It is that of a cat which, in order to secure a dainty dish in the shape of shrimps, regularly fished for them. She placed her tail in the waters of a mill-dam and when it was pretty well covered with crustaceans, bent on devouring it, whisked them out on the grass and ate them at her leisure.

A. M. F.

THE "KITTL" PALM OF CEYLON, so valuable to the natives of the South-Western and Central portions of the island, from the richness of the juice of its flower spathes in sugar, we have always regarded as not only curious but remarkably handsome in its scalloped foliage. The American publication "Garden and Forest," dealing with palms for conservatories, has the following passage:—

Some of the "Fish-tail Palms" or *Caryotas* are very useful and highly ornamental as small and medium-sized plants, though they rapidly attain such proportions, when under suitable treatment, that they are not suited for all collections. Of the *Caryotas* the most common and easiest to procure are *C. urens* and *C. soubolifera*, both of which are good and also easy to manage, as they germinate from seed readily and in a short time and make rapid growth.

Caryota urens throws up its handsome leaves on strong stems, and in a large plant they sometimes reach a length of twelve feet or more. The leaves are bipinnate, which is an unusual characteristic among Palms, and the pinnules are more or less wedge-shaped being from six to eight inches in length and about half that measurement in width. The ends of the pinnules are erose, this giving them an odd appearance and readily suggesting the common appellation of "Fish-tail Palm," while the color of the leaf is dark green. Another peculiarity of *C. urens* is the manner in which it flowers, though this process does not begin until the plant has attained its full size. It begins to flower from the centre of the top of the stem, after which the flower-spikes are produced in succession downward nearly to the base of the trunk until the vitality of the plant is exhausted. The seeds are somewhat larger than a Bush Bean, dark brown in color and quite hard, this description applying to the seed proper after the outer fleshy rind has been removed. *C. soubolifera* is also a fine plant, and is more dwarf in growth than the preceding. It also has bipinnate leaves, which are bright green in color, and as it throws up suckers at the base of the plant it naturally has a more bushy habit than *C. urens*. Other good representatives of this genus are *C. furfuracea* and *C. Rumpliana*, both of which are good decorative Palms. *Acanthorrhiza staracantha*, sometimes known as *Chamerops staracantha*, is another fine Palm which will succeed in a moderate temperature. It has palmate leaves, deeply divided and dark green above while the under side is covered with a silvery tomentum. A distinguishing feature of this plant is the mass of root-like spines which surround its base, and from which its generic name is derived. It is a native of Mexico, and though not yet very common, has been in cultivation for many years.

* I was once in negotiation with this gentleman for employment in connection with the *Ceylon Observer*, which was terminated by my good friend Dr. Carruthers wisely making it better worth Mr. Barron's while to remain in connection with the paper of which he is now editor.

GOLD MINE IN JAPAN.—The *Mimpo* says that gold has been discovered at Naganoyama, of Kotomomura, in Iwate Prefecture. The vein is said to be about four miles in length, and an analysis of the ore gives 0.4 per cent. of pure gold. Permission to work the mine has been applied for. If this story be true, a deposit of very exceptional value has been found. An analysis in the laboratory would, of course, give a greater percentage of gold than the quantity obtainable by ordinary mining machinery. But a yield of a quarter of an ounce per ton—or one part in every one hundred and forty thousand, approximately—is considered sufficient now-a-days to justify the working of a gold mine, and, compared with this, four parts, or even one part, in a thousand is something altogether out of the common. It will be interesting to learn some further particulars about the Iwate vein, if, indeed, it has any existence in fact.—*Japan Weekly Mail*.

HOW THE CURRENT PRICE OF SILVER IS FIXED.—*Bradstreet's* devotes an article in a recent issue to a description of the mechanism by which the trade in silver bullion is conducted, and the price of silver fixed, especially in the United States. The bulk of American silver comes from a number of large smelting works, some of which are associated with the mines. The usual practice, however, is to purchase the ore on an assay value. After smelting, the bullion comes out usually in large oblong slabs, with an average weight of 1,000 oz., which are known as commercial bars. A silver market *per se* does not exist. Over 90 per cent. of the silver produced in the country passes through the hands of a few banks and firms, which make it their special business, in New York and San Francisco. In fact, three or four houses monopolize the greater part of the trade, and to them the silver is consigned for sale by the mining and smelting companies. They dispose of it in the market to the Government (whose purchases under the late silver law are now of great importance), ship it abroad, or buy it themselves. The stock is believed never to be very large, and even during the recent silver agitation was not much more than from 6,000,000 to 7,000,000 oz. Bars weighing 1,000 oz. on the average, are usually .999 fine, and all transactions in them are on this basis, which is the standard of the United States coinage. A number of bars go to the Assay Office to be converted into assay bars, which are thin bricks of silver weighing 200 oz. each, and bearing the official stamp of weight and fineness. These are in demand by silversmiths on account of the guarantee of the stamp. The bullion shipped to Europe is in the form of commercial bars, which are simply carted to the steamer and there placed, unpacked, in the treasure-room. It is quite unusual to pack silver with the care that is bestowed on gold. The bars also form the bulk of the stock held in New York. The price of silver in the market represents the price at which it can actually be sold for export or commercial purposes, and is the selling quotation of the leading bullion dealers. Until recently the New York price was fixed with relation to the price in London, which is fixed by a few houses and banks specially conversant with the business, having regard to rates of Indian exchange and the demand from other countries. But lately speculation in silver bullion certificates in New York has caused silver there to have a special and speculative price which is to some extent independent of the London market. The English standard of fineness is .925, so that American prices represent an allowance for this difference of .075 in fineness, as well as for the rate of exchange, which may vary from day to day.—*O. Mail*, April 3rd.

TEA CONSUMPTION RECKONED BY YIELD OF LIQUOR AS WELL AS QUANTITY OF DRY LEAF CONSUMED.

The coloured diagrams which Messrs. Gow, Wilson & Stanton annually prepare, reveal, in a graphic and striking form, to the eye, the increasing use, so gratifying to lovers of temperance and of humanity, of the "cups which cheer but not inebriate." Progress is chiefly perceptible amongst communities of the Anglo-Saxon race, limited in the United States of America, however, by the truly enormous use in that country of the allied beverage,—coffee, which is so easily and cheaply obtained from the neighbouring republic of Brazil. Next to the Anglo-Saxons,—in "the mother country," in the United States, in the Australian Colonies, Canada and South Africa, come the Slavics of Russia, for the Germans and Hollanders are even greater consumers of coffee than the Americans, although Holland, possessing as she does a tea-growing colony, in Java, is taking to tea after an encouraging fashion. A good deal of cacao or "cocoa" too is consumed in France, Germany, Italy and other continental countries. The effect of the efforts now being made to create a taste in the United States for really good *unburnt* tea, remains to be seen. As matters stand, the United Kingdom, with little more than half the population, consumes nearly 2½ times as much tea as the mixed people (so largely Teutonic), in the United States.

In Britain the increase in the consumption of tea has been marvellous. The figures in pounds for 1890 were 194 millions, so that at the recent rate of increase all the probabilities are that 1891 will show the round 200 millions, if even that enormous quantity is not exceeded. In the quarter of a century between 1866 and 1890, the consumption per head of the population rose from 3.42 lb. to 5.07. But, as in the latter half of the period strong Indian tea, reinforced appreciably by the similar Ceylon product in the closing years of the period, has largely displaced the weaker China leaf, Messrs. Gow, Wilson & Stanton have shewn simultaneously the progress of consumption reckoned by the gallons of liquid yielded. This is calculated on the moderate estimate formed in a report to the Board of Customs to the effect that if 1 lb. of Chinese tea produces 5 gallons of a certain depth of colour and fulness of flavour, 1 lb. of Indian tea will produce 7½ gallons of a similar beverage. Allowing for an apparent arrest of the advancing consumption when the process of displacement was only commencing, the increase in the consumption of tea by the people of the British Isles has been not only steady but rapid, thus:—from 17.98 gallons per caput in 1866, to 24.39 in 1876; 29.28 in 1886, culminating in 33.40 in 1890. The figure for the last year of the series is almost exactly double that of the first, so that, in consequence of the introduction of the stronger product of British growth, the people of Britain have been able to double their consumption of the beverage, although the percentage of increase in the use of the dry leaf has been only from 3.42 lb. to 5.07, an absolute increase of 1.65, while the percentage is not 50 but 48.24. This is a result more gratifying to consumers than producers, and clear it is that we must not rely on the British market alone and must not relax our efforts to open up new markets by creating a taste for our teas, which so largely combine the strength of the Indian product with the delicacy of that from "far Cathay."

Ceylon tea, which a decade ago, was only beginning to intrude itself as a new and suspiciously regarded competitor with products so well-known and established as the teas of China and India, has recently made such rapid progress, that its position in the British Market in 1890, rated by home consumption was such an excellent third as is here shewn:

Indian	52	per cent.
China	30	" "
Ceylon	18	" "

Looking at the process which has recently altered so materially the position of the various products, it requires no prophet to foretell that in a few years hence Ceylon will have distanced China and will be pressing hard on India with its half century of tea cultivation against our really not much more than a decade devoted to the enterprise. In round numbers the consumption of tea in the principal countries importing the leaf has increased from 350 millions of pounds in 1880 to 400 millions in 1890. We may, perhaps, add for the minor consuming countries another 60 millions, in which case we get the figure 460,000 millions. Tea consumption in India and Ceylon is scarcely worth computing, and we believe that the consumption in China has been greatly exaggerated. For, although the Chinese constantly drink tea, much of the liquor is little different from hot water. We cannot help feeling that to credit China and its feudatories with another 500 millions of pounds, is an extravagant estimate. But supposing it near the mark we may take in round numbers 1,000 millions of pounds, or say 6,000 millions of gallons as the world's consumption of tea. If peace can be preserved and wealth and civilization advance, we may confidently anticipate a great increase during the closing years of this century and the whole of the twentieth century,—for large portions of mankind are discovering that alcohol, with its "borrowed fire" is a deceiver and a curse. If the civilization of a community can be tested by the quantity of sulphuric acid it uses, much more certainly can the moral status of a community be judged by a comparison of the quantities of non-alcoholic and alcoholic stimulants it uses. Our Australian cousins are super-eminently a tea-drinking people, and since 1880, when Ceylon equally with Indian tea was furiously denounced as an injurious fraud, the Australians equally with their friends at "home" have learned the superiority of our pure teas to the inferior products obtained from Foochow. So with the Canadians, and there is every hope that ere long the United States of America, the great Russian Empire, and many of the great continental States will be amongst our best customers for teas, which they will discover to be equal in delicacy of flavour, while much stronger than the China leaf, to which many of them still traditionally cling. Of the wretched Latin and mixed races, of the South American republics, with their unpatriotic factiousness and constantly recurring internecine strife, we have about as little hope as of the regeneration of Portugal, once amongst the foremost states of the world.—There is much else in the diagrams and the appended remarks circulated as a Supplement with today's *Observer*. We content ourselves, in closing with a reference to figures which show equally the rapid decadence of China tea in favour of the British producer, with the still more rapid,—indeed phenomenal advance of the Ceylon product. It was really only in 1885 that Ceylon tea was an appreciable factor in the figures for

home consumption, thus:—

(1) China	113,514,000 lb.
(2) India	65,678,000 "
(3) Ceylon	3,217,000 "

The constraint in 1890 was:—

(1) India	101,961,000 lb.
(2) China	57,534,000 "
(3) Ceylon	34,516,000 "

In a very few years Ceylon will be No. 2 of the Tea Countries of the world and her ultimate elevation to first place seems a not over-sanguine expectation.

INDIAN AND CEYLON TEA CROPS.

In our Chamber of Commerce return dating up to 27th April, the total export of tea is given at 20,746,144 lb.; but Messrs. Forbes & Walker in their circular in our commercial column, estimate that this may be increased to 22,500,000 lb. if the shipments up to the end of the month are included. Let us say 22 million lb. for one-third of the year, and it is evident with all we hear of heavy flushes and big gatherings that we are safe for a Ceylon export in 1891 of certainly not less than 60 millions lb.! The only troublesome contingency in the estimation of planters has reference to labour supply—doubt being felt in some quarters as to whether there will be a sufficiency of hands to pluck all the leaf.

This being the outlook for Ceylon, let us see how they stand in India. Through Messrs. W. Moran & Co. of Calcutta we have received the statements prepared by the Committee of the Indian Tea Association of the total "Outturn of Crop for 1890" and "the Estimated Crop for 1891" as follows:—

OUTTURN OF CROP OF 1890.

	lb.
Assam	45,416,721
Cachar and Sylhet	31,474,703
Darjeeling, Terai and Doors	20,022,625
Chittagong and Chota-Nagpore..	1,424,057
Dehra Dun, Kumaon and Kangra	4,000,000
Private and Native Gardens ..	3,500,000
	<hr/>
	105,836,106

The total shipments to all places from the 1st May 1890 to 1st March 1891 having been 104,954,625 lb., the difference represents the local consumption and any small portion of last season's crop still to go forward. It will be seen from the above figures that the actual outturn was less than the original estimate by more than 9 million lb.

ESTIMATE OF CROP OF 1891.

	lb.
Assam	50,650,628
Cachar and Sylhet	35,864,680
Darjeeling, Terai and Doocars ..	23,286,439
Chittagong and Chota-Nagpore	1,488,264
Dehra Dun, Kumaon and Kangra	4,500,000
Private and Native Gardens ..	4,000,000
	<hr/>
	119,790,011

being 4½ million lb. over the original estimate of crop of 1890. Taking the shipments to other places at 10 per cent over those of last year and making allowance for local consumption, there will remain about 112 million lb. for export to Great Britain against 98½ million lb. shipped there during the past season. It is possible, however, that the actual outturn of the crop of 1891 may be considerably less than the estimate as was the case last season.

It will thus be seen that while in 1890 Ceylon gave an export of 46,901,000 lb. or several millions above the average estimate,—in 1891, the export is likely to exceed the most sanguine estimate, if, as we now anticipate, it is above 60 million lb.—India on the other hand was short of estimate last year by 9 millions lb. and the estimate for 1891 is only 5 millions above the original estimate for 1890 while grave doubts are even now being entertained of its realization.

For total export, the return for 1891 is likely to stand somewhat as follows:—

	To U. K.	Elsewhere.	Total.
India	109,000,000	7,000,000	116,000,000
Ceylon	57,000,000	4,000,000	61,000,000

Total lb. .. 166,000,000 11,000,000 177,000,000

If we take the home consumption of the United Kingdom at 200,000,000 lb. for 1891 this would only leave room for 34 millions lb. of China tea.

TEA PLANTING IN CEYLON."

Some time ago we noticed with hearty approval the series of illustrations of Tea planting in Ceylon published by Messrs. H. W. Cave & Co. from the photographs of the late Mr. Clerk. Mr. Cave was anxious to improve his brochure by adding a page of letter-press descriptive of each picture, and we suggested Mr. T. C. Owen as best able to do this if he could spare the time. A copy has now reached us with Mr. Owen's letter-press—admirably adapted and covering 12 pages and the publication with a page of statistics from "Ferguson's Directory" now appended, is one of the most attractive and useful little gifts—costing only a rupee—that can be sent from Ceylon. The Tea Fund Committee should distribute a few thousands of copies.

SALE OF ANOTHER VALUABLE ESTATE IN DIMBULA.

We now learn on the best authority that the purchase of Yoxford estate, Dimbula, the property of Messrs. Baring Bros., has been completed by the Ceylon Tea Plantations Co., Ltd. as from the 1st April. The cultivated acreage is 429 acres and the forest and timber reserve 49 acres, making a total of 478 acres.

The price paid £18,000 is a high one, but as the soil is exceptionally good and the jāt with which the estate is planted is selected Manipuri, the property bids fair to become one of the finest tea estates in Ceylon. The factory is equipped with the latest type of engines and tea machinery. Mr. C. M. Robertson returns to Ceylon next month to take charge of Yoxford. The Ceylon Plantations Co., has now a magnificent expanse of tea on the side of Great Western.

ECHOES OF SCIENCE.

Electricity is a veritable factotum or servant of all work. A Swedish engineer has recently applied it to testing steel and iron for its hardness. It is well known that an electric current of sufficient strength will fuse a thin slip of metal or wire when passed through it. By making a number of experiments the engineer has found the strength of current required to fuse test pieces of iron and steel of different degrees of hardness, and has formed a scale of currents corresponding to a scale of hardness. In order to find the hardness of a particular test piece of the metal it is only necessary to find the current required to fuse it, and this can easily be done by means of an amperemeter. The corresponding figure on the scale gives the hardness of the piece.

Not long ago an ingenious young cadet of one of our scientific corps applied electricity to wake him in the morning, and boil his coffee. The minute hand of his clock was caused to press two spring contacts together, and thus send an electric current, to ring a bell which woke him at the proper time. The current also actuated a small electro magnet,

which allowed some sulphuric acid to run out of a spoon and ignite a match, which in turn lit a spirit lamp placed under the coffee boiler. By the time he was dressed for a parade his coffee was ready.

Rich deposits of phosphate of lime have been discovered by M. Philippe Thomas, south and north of the high plateau of Tunisia, from the Ohotts to Medjerdah. Those of the south-west are the most important, and will be very valuable when a railway has been run to them. It is estimated that in the upland of Gafsa there are at least ten million tons ready to be removed. The beds of the north-east and the north-west also promise to repay their exploitation.

The dental vibrator is an apparatus for rendering the extraction of teeth painless. It is simply an application of the well-known electric shock utilised in medicine and sometimes to be had at country fairs. An induction-coil giving a very rapidly intermitting current is the source of the electricity, and the patient receives the shock by grasping metal handles connected to the poles of the secondary circuit of the coil. The forceps of the operator are also connected in the circuit of the current. The consequence is that the patient feels only the peculiar sensation of "pins and needles," produced by the intermittent current traversing his nerves, and the actual pain of loosening the tooth is said to be masked. The vibrator has been introduced into the Institute of Medical Electricity.—*Globe*.

UVA PLANTING REPORT.

BADULLA, May 1st.—April has been a singularly wet month: very little sun and very heavy plumps in the afternoons. 7.73 in. in 2½ hours on the 8th was the heaviest rain I have ever seen. Slips everywhere. Wash last week a common experience. Tea which did so well in March commenced well in April. Towards the end of the month it fell off owing to insufficiency of sun heat; a little sun would give most of us more than we can manage in the way of flush. May and June generally are our best months. The way tea is growing and better still flushing is most encouraging, and we are all very hopeful and confident of Badulla being second to no upcountry tea district. Clearings in coming season are many, and a large acreage will go into tea next monsoon.

Coffee crop is ripening well, and bug is absent and estimates will be generally exceeded. All lower estates which have coffee in good heart and duly cared for have had good blossoms for autumn, and if the rains had put in an appearance a fortnight later than they did, this would have been the best blossoming season for some years past. Higher coffee is looking well and should do fairly in coming seasons.

Cinchona, at present prices, is naturally looking particularly robust, that very little bark will be harvested this season, for the sufficient reason that it would not pay to do so, except when trees are of especially good character.

LEASE OF VALUABLE PLUMBAGO LAND.

R15,100 PER ANNUM.

The lease of a plot of land situate in Maduragoda Kurunegala district and known as Mopitiyakanda about 11 acres in extent was sold by public auction on Thursday afternoon last at the Kurunegala Kachcheri by Mr. Allanson Bailey, Government Agent. There was a large number of intending purchasers present. Tenders were invited and it was notified that if they did not come up to the amount fixed on by the Government Agent, the lease of the land would be sold by auction. The highest tender it appears was R12,000, and the Government Agent

having intimated that he would not give the lease for anything under R15,000, bidding commenced at that figure. Messrs. Attygalla Mohandriam and Paulis Silva, both large plumbago merchants put in a bid of R100 more and became the purchasers. In the whole land there is only an extent of about 2 acres which it is said to contain plumbago. Considering the amount paid for the lease, what will not the land be worth? It appears that Attygalla Mohandriam who owns a pit near this land, dug the land in question for plumbago and worked for about a year when matters were represented to the Government Agent Mr. Murray, who deputed Mr. H. L. Ward to survey the land. This was done, and it was found that Attygalla Mohandriam was unwilling. After enquiry he was asked to pay up a sum of R1,200, and the land advertised to be sold.

AGRICULTURAL AND INDUSTRIAL ASSOCIATION OF FIJI.

The fourth Annual General Meeting of this Association took place at the Mechanics' Institute, Suva, on the evening of Tuesday last, 27th instant. Punctually at 8 o'clock, his Excellency took his seat, being attended by Mr. Spence, Private Secretary. The Secretary read the fourth Annual Report, as follows:—

COFFEE.—This product has become a thing of the past. Exports for 1890 were nil, against 5 tons in 1887.

TEA.—Notwithstanding the growing demand for this product there does not appear to be any satisfactory progress made in extending the acreage under cultivation. Exports for 1890 were valued at 1s 6d per lb., £140 2s 6d against 9½ tons in 1889.

SUGAR.—This product has asserted for itself no mean position amongst the exports notwithstanding the low prices still ruling. It is impossible however to say how long this export may continue. At present it would appear as not having yet merged from the position of being maintained entirely at the expense of the future. The Colonial Sugar Refining Company have made arrangements for leasing a large area of native land at Labasa on the Macuata coast, Vanualevu, for the purpose of starting a cane plantation. If the soil and climate prove equal to expectations, and there is no reason to doubt otherwise, operations on a large scale will be commenced by the company during the present year in that district which must undoubtedly greatly increase this product. Exports for 1890 were 10,000 tons, value £16 per ton, equal to £260,729, against 13,178 tons in 1889.

COPRA.—There is an improvement in this article of export as against that of last year and there is every prospect of a further improvement both in price and quantity and quality. Exports for the nine months ending 30th September, 3,085 tons value £27,765 as against the year 1889, value £39,138. There is still a very large quantity of copra awaiting shipment at the port of Levuka.

BANANAS.—This product it is satisfactory to note has been steadily assuming proportions which as an industry renders it first in importance to the Colony notwithstanding the persistency with which the shipping companies disregard the interest of the planters.

The export of bananas for 1890 were for 9 months, 509,565 bunches, value, £54,059, against 531,008 bunches for 1889 value, £42,000.

COTTON.—There is every probability of a hopeful resuscitation in the cotton industry of the Colony. The acreage under cultivation, being extended both in suppression of other products and in fresh land. The unaccountable rise in price gave a stimulus to cultivation so that next year's exports may reasonably be expected to largely exceed those of the past year. Exports for 1890 were 50 tons, 16 cwt., 3 qrs., 17 lb. value £2,360 against 17 tons for 1889.

MAIZE.—The cultivation of this product has been entered upon largely by the free Indian population and it is probable it will figure as an export on a larger scale than heretofore during the ensuing year.

The exports for 1890 were for 9 months 2,760 bushels value £720 against 4,704 bushels for 1889.*

MINOR PRODUCTS.—Of these vanilla remains the most important. Judging from the character of the splendid exhibits of this product at the late Exhibition your committee are more than hopeful that the exports of 1891 will number amongst them a superior bean. Arrangements are being made by his Excellency the Governor whereby the beans can be properly prepared in the necessary ovens which will be erected during the year 1891.

TOBACCO.—Hitherto this product has been grown principally for home consumption but there is some prospect of its being cultivated largely for export during 1891. That its successful cultivation will be confined to certain favourable localities is no doubt true, but your committee are sanguine as to its being a future export and believe that with a little patience and perseverance the company now being formed will soon be an accomplished fact.

FIBRE.—Immediately after the first Exhibition of your Association an effort was made by his Excellency to initiate attention to the advantages that would accrue to the colony as well as to those who would undertake the cultivation of some of the many valuable indigenous fibres of the country. Arrangements were made at a meeting held for the purpose whereby certain persons were to cultivate a certified area of any one fibre-producing plant and furnish a statement of cost and yield. The plants were to be supplied by the Government. Your committee are not aware whether this was done, but from the successes obtained in other parts of the world by the production of fibre between the time referred to and the present they feel that a serious and irreparable loss has resulted to this colony by allowing the matter to drop, and while fully alive to the value of some of the indigenous fibre plants, they have, through the Government, sent for the seed of the true Sisal hemp plant and hope shortly to have it here for distribution.

Your committee are satisfied that there is at present in the country sufficient of the true Agave Americana from which the "Pita" fibre is made as will meet the requirements of large areas of cultivation. His Excellency has already been the means of distributing sufficient seed from Tailevu as has planted some forty acres of land, and your committee have been informed that large quantities of seed can be obtained from other parts of the group.

To use an Americanism † your committee are of opinion that there are three products which the climate and soil of Fiji can produce better than any country in the world, viz., Fibre, Vanilla and Tobacco, and that it but wants special attention to be directed to these productions for a short time to thoroughly establish the future prosperity of the country.

It has been reported to your committee that the true Sisal hemp plant has been received by His Excellency from Kew.

LABOUR.—Your committee congratulate you on the satisfactory labour conditions which have existed in the colony during the past year, the grave importance of which can hardly be overrated, and they deem it to be a great satisfaction to know that whilst the import fee for foreign labour is being gradually reduced, that many improvements have recently been made to facilitate the recruiting of native labourers.

[The above is the main portion of a report which the *Fiji Times* denounces as unduly pessimistic. Tea for instance is in such large demand locally that as yet little is exported.—Ed. T. A.]

AVOCADO PEARS IN COLOMBO.—Eight years ago, Mr. Cul. planted two trees in the Royal College ground and yesterday he was able to gather eight of the fruit fairly developed and of good flavour.

* It is to be feared that the enormous crop reported from the United States will again extinguish this industry in Fiji.—Ed. T. A.

† We do not recognize the Americanism, but we see such English as this:—"sufficient seed ** as has planted"—Ed. T. A.

ARRACK AND COOLIES.

On all sides we gather evidence that the question of labour supply for our tea industry is fast becoming a burning and serious one. Advertisements for coolies are becoming common. Very soon we shall have a repetition of the days of old when notices ran "wanted a manager who can command labour," or "to an estate superintendent who can bring 100 coolies, will give a liberal salary" and so on. From Uva and other remote districts a real cry of distress is likely to go up as successive expanses of tea come into bearing and yield a succession of flushes which it will require many additional hands to overtake. Now it is at such a juncture that all interested in the industry must exert their ingenuity, carefully use their best judgment and urgent endeavour in order to supplement the existing labour supply or to devise means for economising and conserving it. The invention and application of labour-saving machinery and contrivances come under the latter category. There is a fine field here equally for the practical experienced Manager and mechanical Engineer. Improved machinery for the factory can do something, but still more do we want the application of labour-saving machines in the field:—wire tramways (worked from electric motors) to carry leaf to the Factory for instance. It will be more especially for the Committee of the Planters' Association to consider how the labour supply can best be supplemented, whether by special agency on the coast and (or) by endeavouring to move the Government to get its officers to encourage the poorer Sinhalese to take up the very easy and remunerative work of tea plucking in their immediate neighbourhood.

But our object more particularly today, is to call the attention of both the Government and the public to the letter of "H. A. T." from the Kalutara district, showing how the multiplication of arrack taverns is beginning to have a serious effect in diminishing the available strength of cool labour and in demoralizing large numbers of our Indian immigrants. Here is indeed a matter of most serious import and one to which a remedy should at once be applied. The Planters' Association should ask Government for a return of any new arrack taverns opened, say, since 1st January 1890 (all over the island while they are about it) and publish the same. We are beginning to think that the universal increase in the sale of arrack rents this year is likely to prove an unmitigated curse to the community. We think the time has come to insist on repression rather than encouragement—in fact we should be inclined to insist that Government go back to the position occupied in 1874-5 when Sir Wm. Gregory had an Arrack Tavern Map of the Island laid before him to prevent any further extension of places for the sale of intoxicating drink. Then there is another evil which the Planters' Association may well call on Government to deal with in their own interests, as well as in those of the people and especially of the coolies. We refer to the sale of partially fermented toddy in certain districts to an almost unlimited extent, without fee or license, tax or duty to the revenue, but greatly to the detriment of Sinhalese villagers and estate coolies. We refer more especially to the Matale, the Kurunegala, Gampola and some other districts and think a great deal of good might be done by putting a stop to what is in reality an illicit sale of intoxicating drink. Let every District Association consider the subject in the light of local experience, and where there is no district body, a special local Committee might be organised, in

order that reports and full information might be sent in to the parent Association and so the whole subject be dealt with in a practical and complete fashion. In the interests of labour supply as much as of the well-being of the people, the matter is not one to be left alone.

FRUIT FROM TASMANIA AND FISH THEREIN.

At the Melbourne Exhibition of 1880-81, we had the pleasure of making the acquaintance of Mr. Shoobridge, junior, of Bushy Park, Tasmania. To him and the late Mr. Mooly, in truth we were indebted for help in arranging the Ceylon Exhibits, Mr. Shoobridge putting off his coat for the purpose, in true colonial fashion. Mr. Shoobridge himself was an exhibitor of hops which his father and he grow largely on their beautiful and fertile estate beyond New Norfolk, at the confluence of the dark-rolling "Styx" river with the magnificent Derwent, on the estuary of the latter of which the Australian Naples,—Hobart,—is built; rising up the sides of the foot hills of Mount Wellington. This mountain was white with snow and the pools at Bushy Park had ice on them, when we visited Tasmania for the first time in July 1881, and yet the wild rose and the gorse were, at the same time, in beautiful bloom. The dark colour of the Styx, which does not last all the year round, is supposed to be due to peat formations near its source. The noble Derwent originates in Lake St. Clair, which has an area of 10,000 acres. It is one of a series of grand mountain lakes, for which and for a dense forest under-growth, known as "horizontal" (from its habit of spreading) Tasmania is distinguished. Facing the antarctic pole as the island does, the cold of winter, (May, June, July,) is occasionally keen at Hobart and the south side of the island, generally, deep snow lying on the mountains. Launceston, in the north, (on the fine tidal river Tamar, fed by the waters of the romantic south and north Esk) has a much warmer climate and altogether Tasmania ranks next to New Zealand in its resemblance in climate to Britain. Hosts of visitors from Melbourne and other parts of the Australian continent escape to Tasmania from the fierce heats of the summer months, January and February. Better even than Britain, and better certainly than most parts of Australia, are the soil and climate of Tasmania suited for fruit culture. Accordingly, when we visited the Shoobridges in their beautiful and fertile homes on the alluvials of the Derwent, in July 1881, we found that besides hop culture their enterprise included apple and pear orchards which rank amongst the most extensive and the most productive in the world. By one of the great "meseers of the P. & O. and Orient lines which go to Tasmania regularly to load with boxes of fruit, the Shoobridges alone have shipped 2,000 boxes of apples. As each box contains a bushel and each bushel is, on an average, made up of 150 fruits, the aggregate is 300,000 apples. This is only one of a series of consignments to England, and Mr. Shoobridge, as we yesterday indicated, is trying the Ceylon market, where apples ought to be appreciated for tarts as well as for dessert. What a treat it would be to expatriated Britishers in India, Ceylon and the Straits, if rich luscious pears equal in quality to the dozen which Mr. Shoobridge kindly presented us with yesterday, could be regularly supplied, as we hope they may be, although even winter pears do not curry so well as apples. It seems a great point that each particular fruit, free from the slightest bruise, should

be carefully wrapped in tissue paper. In Tasmania, we learn, an apple tree begins to bear in its fifth year, and is in full bearing from the seventh to the twentieth year, the crop being counted by bushels,—we feel afraid to say how many, from each tree. Of course culture and manuring are necessary to enable the trees to produce good fruit in such plenty, although on many farms where labour was scarce, we saw trees laden with fruit amidst grass and weeds a couple of feet in height. It was enough to make a man's mouth water to hear from Mr. Shoo-bridge of the bushels upon bushels of apricots gathered this season from single trees. Apricots can be seen growing splendidly trained on walls at the exquisitely beautiful Botanic Gardens on the banks of the Derwent, near Hobart. Amongst the sights at Bushy Park are a fine oak, an equally splendid cherry tree, and hawthorn growing so strong and tall that poles cut from the hedges are exported to parts of New Zealand where all is grass. When Mr. Shoobridge, senior, originally settled at Bushy Park, he grew strawberries in such abundance that it did not pay to send the fruit to the Hobart market; and so, for many years, it has been an institution at Bushy Park to gather the children from all the Sunday schools within reach for a treat of strawberries and cream. The Shoobridges are members of the Wesleyan Church, and the uncle of our friend who visited us yesterday is a zealous local preacher. Mr. Shoobridge, junior, who came from Tasmania in the "Orotava," (which, by the way, made the voyage from King George's Sound in the unprecedentedly short period of 9½ days,) has gone on to Britain as the chosen representative of the united fruit growers of Tasmania, to watch over and promote their interests and obtain from the shipping companies facilities of stowage and advantages of freight, such as will establish the fruit export enterprise on a steady and profitable basis. The matter could not be in better hands and for the sake of Ceylon as well as the fruit-eaters of England and the fruit-growers of Tasmania, we trust Mr. Shoobridge's efforts may be crowned with abundant success. When, more than a century back now, Britain commenced to send her convicts to Australia and especially to Tasmania, it would have seemed a wild dream to anticipate that from the antipodean colonies, as the products of the enterprise and labour of communities of intelligent freemen, the mother country should now be receiving supplies of gold and silver and copper, of grain and fruit and specially wool, the finest in the world. In the romance of emigration and commerce, there are few chapters so striking as that which records the settlement and advance of Australasia.

En route back to New Norfolk from Bushy Park, we visited, about midway, the ponds and streams devoted to salmon and trout breeding. As far as trout are concerned the experiment has long been a great success, specimens of the enormous size indicated by 26 lb. weight having been captured by anglers in the Derwent. The trout in this river are of the colour and flavour of salmon, but in some streams where, probably, food is neither in quantity nor quality equal to that found in the great river, the trout are white in flesh and deficient in flavour. That there has been success with salmon ova has been hotly debated, but we believe there is now no doubt on the subject. Salmon have been bred, but curiously altered from the normal type by local conditions. One we saw in 1881 was shorter and much broader (probably to the extent of one-third, measured from belly to back,) than those familiar to us in our youth a

caught, in the stages of grilse and full grown salmon, in the waters of a Scottish Highlands river. Lake St. Clair is described as simply swarming with the trout which have made their way down the breeding streams into the Derwent and then up the great river to its mountain source. In the lower portions of the Derwent, especially at Bridgewater, very nice mullet abound which so readily take the bait that considerable bags of the fish can be secured in an hour or two of angling.

CEYLON TEA IN AUSTRALIA.

We call the special attention of the Chairman and Committee of the Tea Fund to the following correspondence. We have never met Mr. Foulkes, so far as we can remember, but all we have ever heard of his career while lessee of Lord Elphinstone's estate, Gikiyanakanda, in the Kalutara district, for many years, has been in his favour. He and his friend and colleague, Mr. C. Knight, did not make their fortune out of Gikiyanakanda—we suppose they rather lost; but the high reputation they both secured from all who knew them, and especially among the Sinhalese of the district, was something worth working for. When the bad times came, Mr. Foulkes went to Australia where the good work he did for Ceylon at the little Tea Exhibition for the Colony will be remembered. He continued in Melbourne and has been for some years now, we believe, working away under much discouragement, trying to create a demand for pure Ceylon tea and to make a living for himself out of the article. Unfortunately his pecuniary returns so far have been very limited and it is under these circumstances he sends us the accompanying letter which we have been advised to publish as the readiest means of attracting the attention of the Tea Fund Committee and the general body of tea planters to the case. But first we thought it well to send the letter on to Mr. Wm. Mackenzie as a gentleman who knows a little of Mr. Foulkes and his work and also of the importance of getting the Australians to drink pure Ceylon teas. We append Mr. Mackenzie's reply and hope his generous offer to sustain one-fourth of the required guarantee, will encourage a few more of the community to come forward to make it up fully. In any case, we agree with Mr. Mackenzie that the case is one well deserving the support of the Tea Fund Committee; for of the genuineness of the man and his work—and he an old Ceylon planter with a special claim on his brethren—there can be no doubt. We quote Mr. Foulkes' letter as follows:—

10, Palmer Street Fitzroy, Melbourne, April 1891.

Dear Sir,—Having taken a great deal of pains for the last 6 years, in pushing Ceylon tea in the Colonies and for want of sufficient means being unable to continue the work, as I should wish to take the liberty of explaining my situation to you in the hope that you may find two or three friends in Ceylon, to put me in a position to carry on the plan I have adopted, which all must agree to be a good one, for advertising the tea in Melbourne and neighbourhood.

First, as to my situation: I have been receiving tea from a gentleman in Colombo and on account of the heavy expenses incurred in pushing a new article amongst strangers, the profits on the teas sent me by that gentleman, have been entirely insufficient, wherewith to make both ends meet, and I have incurred a heavy debt (close on £200) to him and just at the time I was beginning to establish a name, he was unable to continue his support. Had I been able to go on I would have ere this reduced the outstandings by at least 30 to 40 per cent.

My way of distributing is thus:—I have established agencies (having had at one time nearly 200,) at shops in and around, Melbourne, who sell the tea in packets,

on commission (and of these I have still nearly 100) calling on them fortnightly to collect, and on account of my not having a supply of tea in leaden packets, the business is going backward, and I am sure that had I a continuous supply of the same quality, and same wrappers, I should not only soon recover lost ground, but be able to considerably increase the agencies.

The teas in boxes are disposed of to householders, chiefly to those whose acquaintance I made at the Exhibition.

Now as to the terms what would be necessary, namely in that for the first lot of tea sent down, (£100 worth, as on accompanying memo) I be allowed a fairly long credit, and that after that further consignments be sent me in value, according with the amount of remittance sent by me from here, less from 10 to 20 per cent to go off the value of the first invoice.

Everyone must agree that my method of distributing is a good way of advertising, and I thought that there could be no harm in placing my proposal before you, thinking that you might bring it before one or two proprietors, or the Committee of the "Tea Fund."

The objection may at first be raised that there is no certainty as to the date by which the first outlay of £100 would be repaid; this, it would be unwise of me to fix as a certainty, but I believe that in the first 12 months I should be able to dispose of 15,000 lb. weight of tea—to increase yearly—and imagine it 10 per cent only was deducted from the remittances to defray this it would be cleared in 15 or 18 months.

I need not say that this method incurs considerable hard work, but I am thankful to say that I am in sound health, and fit for work, and am very loathe to be compelled to lose the profits that can be reasonably expected, as a result of the hard work I have done already here, and the anxiety I have gone through, to say nothing of a considerable amount of money (£200) received from home I have personally spent as a pioneer.

Surely, £100 invested by proprietors as I propose, would pay them as an advertisement, as it would cost them but the interest on it for a short period, and I know what I have done already has without the slightest doubt considerably helped towards swelling the exports of Ceylon Tea to Australia of late. This I state unhesitatingly without any braggadocio.

Should the guarantee be forthcoming it would be preferable for the Tea Fund Committee or whoever may act to purchase Tea of the "Chief Brand" which is well-known, provided of course there is no reason to the contrary, the matter of chief importance being that thereby a continuation of the same brand, as first sent and as nearly as possible the same quantity of tea. Annexed I send memo. of what the first consignment of £100 worth should be, if you are successful in finding the support I ask for.—Yours very truly,

S. W. FOULKES.

Memo.	£.
Broken Pekoe superfine in boxes 10 lb each	10
Pekoc in 20 lb and 10 lb (mostly 10lb)	20
Do. 1 lb leaden packets	10
Do. ½ lb do. do.	10
Pekoe Souchong ½ lb	45
Do. ¼ lb	5
	£100

Mr. Mackenzie's letter is as follows:—

Thornfield, May 5th.
Dear F.—I have read Foulkes' letter, and can vouch for much of what he says, from my personal knowledge of him when in Melbourne, and from what my brother has frequently written to me lately.

I think this is emphatically a case for the Tea Fund, for which Mr. Foulkes has already worked hard, I mean during the time of the Melbourne Exhibition. Grants on a very liberal scale have already been made to gentlemen pushing our teas in Germany and Russia—and Mr. F. only wants a loan. He has a business—the result of much personal exertion in canvassing—and it would be a pity his hard work should come to nought. Then the teas he sells to small shopkeepers are pure Ceylon teas, which is hardly the case with those sold by any large importer in Australia, blending being universal among such,

I honestly believe *R1,000 lent* in this way, would do more good than *R10,000 wasted* on the *Kiosk*. [Regarding the *Kiosk* I must in fairness say, I have recently met *two* planters of standing who thought it might do good. *Only two* of the many I have questioned]. So convinced am I that Mr. Foulkes' work is doing us good, that I am willing to guarantee *R250* of the *R1,000*, which he wishes the Tea Fund to advance him in Tea.—Yours truly,

WM. MACKENZIE.

We heartily trust that three more proprietary planters or business men may be found to join Mr. Mackenzie in a guarantee of *R250* each, and that the Ceylon Tea Fund Committee may make the needful vote for the tea now required for this honest, hardworking ex-Ceylon planter.

TEA IN INDIA.

The Calcutta brokers' circulars dated the 22nd of April state that weather reports from the districts are generally favourable, although more rain is wanted in Cachar. Samples coming to hand maintain good quality on the whole, although there is a slight falling off in teas from the Darjeeling district. The season will probably be an unusually early one, as some small parcels of tea have already arrived here and been shipped to London.—*Pioneer*, April 28th.

TEA-SEED FOR BRAZIL AND THE FUTURE OF THE TEA-PLANTING INDUSTRY.

(From an Old Planter.)

India and Ceylon should in their own interests, were they wise, refuse to sell tea seed to Brazil.

The man should be boycotted who did. Putting such difficulties in Brazil's way as would retard her progress, even a year or two, means just as long a term of success for us.

The Madras Presidency too, asleep for a century, is gradually awaking to the fact that it can grow tea over an area many times larger than we have here, and that it commands all the labor!

RAMIE.—There appears to be some chance that ramie will yet come into vogue. The *Textile World* has seen samples of fancy worsted silk mix suitings, in which the silk effects were produced by ramie instead of silk threads, and so perfect was the imitation that it would puzzle an expert to detect the difference. Mr. Charles Toppan has now produced suitings entirely of ramie yarn of very perfect worsted appearance, white fine goods very much resembling linen, and now with his silk imitation so perfect, it seems that there ought of be an immense field for ramie in the very near future.—*Planter and Farmer*.

IRRIGATION WORKS IN RAJPUTANA.—The revenue report on irrigation works in Rajputana shows that while the capital expenditure on the three groups of tanks was the same as last year, there was a decrease in actual collections of *R2,466* which is not explained. There was a decrease however, in the working expenses, the cost per acre irrigated being *R1.62* against *R1.83*. Some information as regards the experimental cutting of crops is furnished in the report. The highest produce per acre for wheat crop was 22 maunds of grain and 40½ maunds of straw. The value of these were respectively *R55* and 10, and the expenditure is put down at *R18* per acre, leaving a profit to the cultivator of *R47*. The difference between these figures and last year's is considerable.—*Indian Engineer*.

SCIENTIFIC PEARL FISHING.

So many suggestions have from time to time been made as to improved methods whereby the system of pearl fishing might be more economically pursued, that if there were not some radical objection to be taken to them, it seems to be conclusive that they, or some of them, would ere this have received adoption. When stating this view we would not wish to confine the scope of discussion to our own experience in Ceylon. Pearl fisheries are carried on, on a larger scale elsewhere throughout the world than off our own little island. Those of the Persian Gulf are well known, while around the coasts of Australia, and even in the rivers of Scotland experience has been gained which we think it may be possible would, if patent objection did not exist, have ere this induced those concerned with such fisheries to have employed the mechanical means available which are applied to other forms of fishing.

No doubt the cause for this disinclination to depart from the beaten track, apart from the expense and limited power in sea water of the electric light or other illuminants, is to be found in the special value of the pearl oyster and its susceptibility to rough methods of handling. Currents which bring over the beds which the oyster frequents, the efflux from muddy rivers cause its avoidance of grounds so affected, and very probably the same result would follow were the soil of its breeding banks disturbed by the use of mechanical agencies. There can be no doubt that the grasp of a clamp net would bring up at a single haul perhaps as many oysters as an individual native diver could raise to the surface in a day. But the first operation must entail a scraping of the mud, sand and coral blocks of the bank, which would be strongly resented by the oysters; whereas a diver collecting his prey with his hands and arms would, we should say, produce the minimum of disturbance. Then, again, there is the element of discrimination to be taken into account. Paid as the native diver is by a liberal proportion of the fully developed oysters collected by him, it can be readily imagined that he would reject with some amount of care those among the oysters which might seem to him to be immature, and that he would place in his basket none but those which were likely to make his own share of ultimate profit to him.

This consideration must certainly conduce to the avoidance of "scraping" the banks and causing an entire denudation of them. It would lead to the leaving upon the banks of a certain amount of seed which would in time enable them to re-fruitify. Now the use of the clamp net or dredger could not be possessed of this quality of consideration. All would be fish that came into its net. In other words, its work might prove to be too thorough. The two points mentioned seem to us to be the two chief ones which would disincline the managers of pearl fisheries throughout the world to depart from the existing method pursued and to adopt one which, while certainly likely to be cheaper, would in the long run prove to be the more costly. We must, however, confess to imperfect knowledge of the exact *modus operandi* of the fishers for pearls in our Australian colonies and in the rivers of Scotland. In the latter locality it is not an oyster which supplies the pearls obtained but a mussel, which, however, our own pearl-bearing bivalve is, the difference being between fresh water mussels and the oyster-shaped mussels of the sea. The Scottish shell is found only in fresh water, or at all events in such estuaries as experience a change with the flowing in and out of the tides from salt

to fresh water. Perhaps some of our readers may be able to enlighten us more fully upon any peculiarities which may attend the collection at the pearl fisheries of the Australian continent and of its outlying fishing grounds. There are pearl "oysters" like our own off the coasts of Western Australia, quite distinct from the large mother-of-pearl shells which are the chief objects of search on the Australian coast generally, and regarding the treatment of banks of such "oysters" Sir W. Robinson consulted us and obtained information in 1880. There must be some cogent reasons why no attempt has hitherto been made—so far as we are aware—to reduce the cost of collection by the employment of mechanical means such as are used for the gathering of the edible oyster. It is certain that the plan of assembling native divers is possessed of the elements of uncertainty and trouble which would render the employment of some unobjectionable alternative method very welcome. At the first sight there would seem to be little difficulty in conjecturing what such an alternative might be; but a more careful review of all possible ones inclines us to the belief that none of those which seem to be so simple and ready of adoption are free from possible objections to be taken to them. Wider discussion than has heretofore been given to the subject might help us to a fuller conclusion than has yet been possible.

We cannot help feeling, notwithstanding the failure of all the attempts hitherto made, that success will ultimately crown attempts to breed the pearl "oysters" artificially. Fascines or well anchored and floating lengths of coir rope or matting it water not shallower than five fathoms, might secure the end in view.

JUNGLE-HENS.—Mr. Simpson of the Telegraph Department differs from Mr. Parker, his overseer and Mr. Clark of the Forest Department, in their opinion, or inclination to believe that the jungle, like the domestic, hen cackles after laying its egg. Mr. Simpson holds—and he is supported in his view by Mr. Broun, Acting Conservator of Forests—that the jungle-hen, in view of its many enemies, is most unlikely to make any noise and attract attention at such a time. He also points out that an overseer out watching for pig (at night surely?) could not well be a good authority on the point at issue. Mr. Simpson adds:—"The jungle hen cackles, but only to call its scattered young together to attract the attention of its mate or after being startled or alarmed by an enemy."

THE RECORD BEATEN: CEYLON TEA SELLING UP TO £17A LB WELL DONE HAVILLAND ESTATE, MR. W. A. M. DENISON AND THE O. B. ESTATES COMPANY.—We thought it would come and that Gartmore and its golden tips at £10 12s would be as badly beaten as some of its predecessors in the making and selling of "golden tips." Reuter today reports that a parcel from Havilland estate, Dolosbage,—the property of the O. B. Estates Company and managed by Mr. W. A. Mooyart Denison—has been sold in Mincing Lane for the extraordinary fancy figure of £17 per lb! We shall now have another round of paragraphs, exhibitions, tastings and other forms of advertisement for the benefit of Havilland and of Ceylon tea generally. Well, the more the better. The day is surely fast approaching when even the most benighted will think of drinking nothing else than Ceylon tea—in which case we can defy China, India and even Brazil!

COOLIES FOR NORTH BORNEO.—We hear from the best possible source that the S. S. "Memnon" is about to proceed to bring Hoihow to coolies thence direct to British North Borneo. In this venture we wish the blue funnel line and Messrs. Alfred Holt and Mr. Turner, and all connected with them every success. Planters one and all will hail the new departure we suppose, as it must certainly reduce the cost of labour. The plundering of the coolies in the houses of the Hongkong brokers and on board ship in Hongkong harbour, if it ever was a reality, will cease, and this alone should reduce the first cost of coolie labour. It should also be a ready means in getting a better class, assisting free or unindentured labour, preventing the change alleged to be so frequent of unhealthy for healthy men, and will remove the premium of free passages at present given to Hongkong ex gaol birds.—*B. N. Herald.*

PLANTING NOTES FROM COORG, March 31st.—An inch of rain followed by a fortnight of bright clear weather is all that could be desired to insure a good "set," so that a fortunate few places that got that quantity could not possibly have fared better. The blossom on these places opened on Wednesday last, the 25th inst., and made a magnificent show. Places with an open, friable soil and steep places, which drain readily, have been comparatively free from leaf disease this season; but where the land is comparatively level with a retentive soil, thus rendering it liable to become waterlogged, the trees suffered to some extent. They, however, recovered amazingly after the cessation of the wet weather, and, on the whole, the promise on the North Coorg estates was very good for next season's crop but as pointed out above, some of them have failed to get the rain and others have had too little. In respect of rainfall, the Bamboo, or South Coorg, District, which is the most extensive planting district in Coorg, has fared exactly similar to North Coorg. The ravages of the borer insect are thus early manifesting themselves. One indication of the destructive work of the borer is a grand show of blossom on a tree with poor wood. They invariably bear very heavily; and it is amusing to listen to natives attributing so much discriminating power to borers as to say that they seek out the trees with the best crop on them, as they find them very dainty morsels to feed upon! Thousands of coffee trees are lost year after year through this destructive agency, but this makes small headway in decimating an estate, if kept well under from the beginning, and vacancies supplied as they occur. It is impossible to get rid of the borer entirely. It is only possible to reduce the evil to a minimum. For this purpose continual war is waged against it, all the trees attacked being removed and burnt before the insects have taken to themselves wings and left them—a form of *sati* introduced by Europeans and not interfered with by the law. It will not, it is to be hoped, be out of place in these notes to notice some of the questions raised by Mr. R. H. Elliot in his letter dated 10th March on "The effect of soil on coffee seeds." In a former letter he said that he believed an eminent English authority was correct in recommending him to select seed from trees in the poorest and most exposed situations and to grow them in a nursery of poor soil (the italics are not Mr. Elliot's). He has somewhat modified his views now, as he says the trees need not necessarily be so poor as not to produce healthy plants; but of this no inkling was imparted in what he said before. If by healthy plants, plants entirely free from leaf disease is meant, it will not improbably be found that the nurseries required to grow them will have to be very rich indeed; and even then the chances are, if they are not transplanted early in the season into the field, they take the affection. To strengthen his position Mr. Elliot calls attention to the fact that the English farmer is careful not to remove stock on to poorer pasturage than they have been accustomed to, although he is by no means averse to removing them on to richer. True, but the farmer is likewise most particular to raise his stock from the most exceptional parent animals.—*M. Mail*, April 4th.

Correspondence.

To the Editor.

THE "MOMI" TREE OF JAPAN.

Technological Museum, Sydney, A 10th.

[The Editor, *Tropical Agriculturist*, Colombo.]

DEAR SIR,—Your Nanuoya correspondent, (whose letters I always read with both pleasure and profit,) says, at page 467 (Jan. 1st, 1891) that he cannot find the botanical origin of the Japanese word "Momi."

I have had the enclosed copied from "Rein's Japan" which answers his query and also gives some information in regard to the tree.—Yours truly,
J. H. MAIDEN.

"*Abies firma* S. and Z., Jap. "Momi," is spread over the whole of Japan, more general however in Middle and Northern Hondo, and on the Southern Islands. It is found chiefly, and in the highest development, in mixed forests, among the beautiful deciduous woods, at an elevation of between 1,000 and 1,500 metres seldom isolated.

It develops the most magnificent trunk of all the Japanese firs, and grows in Parks and temple groves to a height of 30 to 40 metres with a circumference of 4 to 5 metres. In its entire bearing as well as in the character of its wood, this tree resembles the European *Abies pectinata*, but has a much slower growth.

Its wood is lighter, rougher, and less tough, than that of the pine, hence cheaper and less valued.

It is seldom used in house building."

[We and our readers are indebted to Mr. Maiden for this information regarding a tree from which so large a proportion of the timber used for tea boxes in Ceylon is obtained, being prepared by American machinery and exported from Japan in shock.—Ed. T. A.]

SALT IN AGRICULTURE.

Veyangoda, April 21st.

DEAR SIR,—I must thank Mr. Hoole of the Happy Valley for his very valuable contribution of Salt and its necessity for cattle, as greatly aiding us in our agitation for its issue at exceptional rates for agricultural purposes. It is a pity that his notes did not receive greater publicity than they did in the columns of only one newspaper. The affection of all animals for salt is notorious, and it is no new thing for a block of rock-salt to be placed in a stable for a horse to lick. For animals upcountry, a free use of salt is more necessary than in the lowcountry, and for reasons that are obvious. The desire for salt in cattle upcountry amounts almost to a mania, and my earliest experience of this was in the way tavalam cattle got at any clothing left in the fences of the gardens surrounding lines. One makes a snatch at it and runs away as if possessed, all the others follow him, and each manages to get a bite of the cloth in spite of the frantic cries of its owner and the endeavours of the tavalam men to save it. All this for the sake of the little salt in it owing to its having come in contact with the human body.

The information contained in Mr. Hoole's letter of the ingenious use made of salt in keeping down the grass on a cricket field, will be of general use to those who find it an expensive job to keep trim a cricket field or lawns and esplanades. In the last *Household Register* I find, on the authority of an English dairyman who experimented with salt, that the quantity of milk in cows from whom salt was withheld for a week shrank from 14½ to 17½ per cent, and that the milk was inferior in quality, and soured sooner than when the same cows received salt with their food. Farmers and dairy-men, it is said, salt their cows once a week, and lest they should forget the day choose Sunday. As has been re-

marked, salt in agriculture is more of a necessity on the hills in the centre of the island, than in districts nearer the sea-borde. As the European planter as a rule knows what he wants and how to get it, it was not necessary for me to dwell on its use and value upcountry.

I by no means advocate the general use of salt in agriculture at its present price. I have heard the opinion expressed that as at present prices the cost of a ton of salt and bone dust is equal, it will be preferable to use the latter. Without pretending to give my opinion on the subject *ex cathedra*, I would say, not invariably. As in the far-famed alluvial flats of the Mahaoya Valley, coconut cultivation is very often conducted in situations abounding in fertility, but with the means restricted for the roots availing themselves of the vast stores of plant food. As is well known, roots are able to absorb only the food contained in the soil. For this, abundance of moisture is necessary, as much to render absorption possible as to dissolve the food. Where a sufficiency of plant food exists it will be a waste of money to add to it, when what trees chiefly require to aid in its absorption is water. To such places I should say, salt is of far greater value than bone dust. For salt, in addition to possessing the property of rendering soluble the chief constituents of all plant food—nitrogen, potash and phosphoric acid—has the additional very valuable property of absorbing the moisture of the atmosphere. The Mahaoya Valley has an exceptionally rich soil and it would be perfect for coconut cultivation, but for the serious drawback of the soil caking as hard as a brick with the cessation of rain. During such periods, growth is suspended and bunches and branches drop owing to the leaves transpiring more moisture than the roots absorb. I am inclined to think that a free application of salt to trees in this district will, be preventing the soil caking and helping it to freely absorb the moisture of the atmosphere, act like a spell.

In this connection it will not be amiss to discuss what will be a fair application per acre. We have nothing positive to guide us. One authority tells us that two tons an acre in the cultivation of roots and cereals is an excessive application, and another recommends five cwt. per acre for wheat. We will have to strike the mean between these two amounts, although it by no means follows that what will be excessive for the delicate, fibrous roots of cereals will be excessive for the tough and salt-loving roots of coconut trees. Yet we do not want to experiment with salt to find out how much we can apply without killing the tree. A correspondent to the *Observer* mentioned during the discussion on this subject a couple years ago, that he applied ¾ bushels per tree to a few trees in the Kurunegala district with wonderful results. This at 70 lb. to the bushel will mean 52 lb. per tree or 1 ton 14 cwt. 92 lb per acre of 75 trees. Well, we can look upon this only in the light of an experiment, and must regard it as an application no one will attempt over a large acreage for monetary reasons. With salt at R5 a ton, many will be inclined I fancy to use that quantity in exceptional situations, while in the generality of instances ¼ a ton per acre will be a very moderate application. This means, at 70 lb. to the bushel, 16 bushels per acre, or about six heaped measures per tree. This I fancy will be a popular dose. Now as to the method of application. Sowing the salt broadcast and working it in will of course be the most desirable method, but its cost and slowness will stand in the way of its universal adoption. Under the circumstances, I think it will be good to scatter it in a circle 10 ft. round the stem and to work it in, not necessarily deep, for the rains will do that, or what will be better, first stir up the soil and then apply the salt.

I appeal first to Mr. Dawson, as the Government Agent of the Province where cheap salt is most wanted in coconut cultivation; 2nd to Mr. Green as the ex-Minister of Agriculture, and who from his present position has greater influence with the Government, 3rd to the Government Agent of the N.-W. Province whose revenues will be appreciably increased by larger sales of salt, 4th to the Hon. Dr. Anthonisz who from

his place in Council has more than once descanted on the value of salt and advocated its issue at cheap rates—to aid us in our present endeavours, by advising the Government, even though unasked, to favourably entertain the agitation for the issue of salt to agriculturists on exceptional terms.

B.
[Has any experiment been tried with Kainit which consists so largely of salt?—Ed. T. A.]

THE "TARING" OF CEYLON TEAS IN LONDON NO. I.

April 20th.

DEAR SIR,—We are constantly being told by our London Brokers "to keep up the quality and not the quantity" of our teas. From the accompanying memos of half-a-dozen of my tea sales, it is clear that *some one* does appreciate quality, to our cost, for it would seem to me the better the tea the more attention it receives, and the higher deductions are made. Take for instance shipment A in which the Pekoe selling at 1s 0 $\frac{3}{4}$ d, 10 lb. out of 2,700 were deducted, whereas the broken pekoe and broken orange pekoe were not so leniently dealt with in this A shipment. I would point out for the benefit of those of my brother planters who seldom if ever see a London account that the 81 boxes of broken orange pekoe contained 17 lb net in each, and each box was under 28 lb gross: what right then had the "some one" to deduct 1 lb from each 17 lb net, when each box weighed under 28 lb. gross? In your *Supplement* of April 11th, you quote from Messrs Geo. White, & Co's. Review for 1890:—"Style of package: Leafy kinds for self drinking often sell well in boxes, but to avoid the 1 lb draft they should be under 28 lb gross." My local agents wrote home to their London representatives, and I wrote direct to the selling broker: all the "satisfaction" we got was to be informed that the Tare must have been wrong (!) and this appears to me to be all the redress one is likely to receive for such a grievance. Is this justice, Mr. Editor, and should not our Planters' Association strive to place our interests on a better footing than they are at present? Who says the Planter is not taxed? Surely a glance at the figures I give will convince anyone that we are taxed and pretty heavily too, and what I have shown only points to the one of many.—Yours faithfully,

PROPRIETOR.

P.S.—Shrinkage of the wood of packages in transit is one of the reasons assigned by the brokers for loss of weight: how about a package leaving the factory under 28 lb gross?

Shipment.	Chests.	Net wegt. in lbs	Price.	Short or deducted.
A	52	Bro Or Pek 1,377	1/11 $\frac{1}{2}$	81
		Bro Pekoe 2,902	1/5 $\frac{1}{2}$	101
	30	Pekoe 2,700	1/0 $\frac{3}{4}$	10
	38	Pek Souchong 3,791	0/10 $\frac{1}{2}$	68
B	95	Bro Or Pek 5,225	1/7 $\frac{3}{4}$	195
	21	Pekoe 2,160	1/0 $\frac{3}{4}$	33
	20	Pek Souchong 2,000	0/10 $\frac{1}{2}$	26
	17	Dust 1,536	0/7 $\frac{3}{4}$	31
	2	Broken Tea 225	0/7 $\frac{3}{4}$	1
O	59	Bro Or Pek 3,287	1/5 $\frac{1}{2}$	104

NO. II.

April 25th.

DEAR SIR,—In your issue of 23rd instant, in which you were good enough to publish my letter under the above heading, in your "Notes and Comments" you refer to the matter as if it was the fault of my selling broker: this gentlemen I beg to completely exonerate, as I believe the brokers have no hing whatever to do with this part of the business, which I am informed is entirely performed by that "monster of a monopoly," the "Dock Company" under the iniquitous system of weighing adopted—and to which we must submit I suppose—by the Customs. If this is not so, I hope some gentlemen more behind the scenes than I am, will be good enough to correct me. "Honor to whom honor is due," and I simply write this in defence of the brokers, who, I understand and believe, have no power or voice in the matter under discussion. The figures I furnished are instructive, and I would call attention again to them. Take for instance shipment B: from the broken orange pekoe, value 1s 5 $\frac{3}{4}$ d, 195 lb. was deducted from a total of 5,225 lb.; from the broken tea value 7 $\frac{1}{2}$ d but 1 lb. was deducted from a total of 225 lb. Once more please refer to the very glaring practice to which shipment A: was treated: from only 1,377 lb. of broken orange pekoe and this too in boxes under the gross weight of 28 lb. in which case I think the general belief is that nothing is deducted; but here we are with 81 lb. taken of tea which sold at 1s 11 $\frac{3}{4}$ d; in the same break pekoe selling at 1s $\frac{1}{2}$ d 10 lb. are taken from 2,700 lb. and from pekoe souchong selling at 10 $\frac{3}{4}$ d 68 lb. from 3,791 lb. Surely some steps should be taken to stop such, what seems to me, abuse.—Yours faithfully,

PROPRIETOR.

NO. III.

Ambagamuwa, April 25th.

DEAR SIR,—You want our experience re taring and bulking of teas in London: to please you, mind me, I will give you the following—only one of several experiences. I had two breaks of tea in London aggregating 6,900 lb. of tea or so of different grades; I had the inestimable (!!) pleasue of receiving my sales with no less than 219 lb tea short weight, only a month ago. There, is Mr Editor! These teas averaged 11d a lb. That is how the money goes, and pop goes the planter.

C. T.

"THEFT OF TEA IN THE LONDON WAREHOUSES."

DEAR SIR,—It is abundantly evident that robbery wholesale and unchecked of our teas is going on in the London Warehouses. I entirely disagree with the theory that the Merchants and Brokers are blameless. That they are indifferent is very evident.

The remedy I would suggest, as a first step, is for the Planters' Association to send a communication to the Home Secretary pointing out the fact that a considerable percentage of tea is being habitually stolen in the London Warehouses and somehow smuggled into consumption without paying duty, thus defrauding the revenue.

Further, every Merchant and Broker in London ought to be called upon to take proper precautions. The London Association ought also to employ detectives.—Yours,

A SUFFERER.

CORAL FORMATIONS INLAND.

SIR,—In the Galle Talpepattuwa, at Miripenna, I have seen people excavating large quantities of coral stones at a distance of about quarter of a mile from the sea in coconut gardens fully fifty years old. Have you any record in Ceylon of how this came about?

TRAVELLER.

[The explanation is that the coral has been formed in the sea and that the land is gradually rising. The Jaffna Peninsula, which rests entirely on a foundation of coral, has, doubtless emerged from the sea, within a period which is geologically recent. So with the southern coasts of the island.—Ed. T. A.]

JUNGLE FOWLS AND THEIR CALLS.

DEAR SIR,—With reference to the extract from *Nature* concerning "Cackling of Hens," the writer wants to know if the wild jungle hen cackles when she lays her eggs. After much observation in jungles for many years, I should say the only noises made by the wild jungle hen are calls to her mate and cries of alarm. A wild bird conceals her nest with the greatest secrecy. The domesticated hen has many habits which are the result of long years of hereditary custom. For instance the wild jungle hen when disturbed with her brood flies off the chickens by instinct, rush and hide in all directions and lie quiet till the alarm is over, whereas the domesticated fowl calls her chickens and shelters them under her wings, which motherly act forms a pathetic theme to poets. I always understood that the domesticated fowl is quite a different bird to the jungle fowl. Even among the jungle fowl there are great differences. The Ceylon jungle cock has quite a different crow from the crow of the Indian jungle cock, and the plumage is different. The writer of the article in question seems to think that domesticated fowls are really domesticated wild ones or their descendants. He might as well reason that domesticated cats which were known in Egypt in the days of Moses are descendants of the fierce untameable fiery wild cat which it so much resembles in shape. One is not the descendant of the other, but both of course came from the same ancestor, and while one has advanced in savageness the other has advanced in domestication.

It would be an interesting thing if it could be ascertained whether the Veddas are the remnants of the enlightened race who built those grand cities (now buried) long before the arrival of the Sinhalese from the banks of the Ganges, or Tamils from the banks of the Cauvery. An originally civilized race run wild is very different from a really wild race; and I question with all humility if there be any really wild human beings in the world. But in the cases of the horse, the cat, the bull, the sheep, and the barn-door cock, and the dog, these animals though they have their duplicates among the wild animals, yet have been domesticated as far back as man has been known in the world. My idea is—

- 1st a common ancestor.
- 2nd a purely wild stock.
- 3rd a purely tame stock

"JUNGLE COCK"

IRRIGATION &c. THE HILLS AND RAIN:
WANTED A METEOROLOGICAL ELECTRICIAN.

DEAR SIR,—I observe that you and your public are interested in irrigation matters: so perhaps some notions that have been simmering in my

noddle for a while may be not amiss in your paper.

Water is wanted to grow paddy, &c., in the regions about Anuradhapura and similar localities. Artesian wells have been advocated. No doubt they are us-ful where found—in France, &c.—but the difficulty is, I apprehend, to find them in the North Central Province, or any other province in Ceylon.

Then the rivers have been suggested for a supply, but somehow they are far away, and to take them where they are wanted means a lot of trouble and expense.

There remains for us the waters of the firmament—the source of all the other supplies, and apparently an inexhaustible source—but the difficulty hitherto has been how to tap it.

It has been suggested that as the firing of cannon in a battle brings down a shower, it might be worth while to send up by balloon a lot of powder into the upper regions and explode it. Let those who are not afraid of wasting powder, make the experiment.*

I had a discussion some time ago on the paddy tax, and afterwards a rainfall of 21 was measured. Anyone desirous of carrying the subject or subjects further are welcome to my experience.

I have an impression, however, that the tapping of the upper strata of the atmosphere is to be found in another direction.

We see they have plenty of water and to spare in the hills. How do they get it? Perhaps some light may be thrown on the matter by understanding the operation of the causes that bring down the rain on the hills; and first as to the fact that the hills do bring down rain. The statistics of rainfall show that not only is the rainfall greater in, and near, the hills, but that those localities of a low elevation that lie in front of the hills in the direction of the coming monsoon have a greater rainfall than places of the same elevation, which have not the hills behind them.

Kalutara, which during the S.-W. monsoon has the high mountain range of Pedro behind it, over 40 miles off, has the greatest rainfall of any place on the west coast during the S.-W. monsoon.

As we take the statistics of rainfall north and south from Kalutara, we find the rainfall decreases towards Colombo and Galle. At Negombo and Matara—both well out of the range of the hill influence—we find a great diminution, and at Manaar and Hambantota, where there is no influence of hills, the rainfall is at the minimum.

Nearer the range of hills their influence on the rainfall seems to increase, as the statistics of Padiapolla and Kotmalie and similarly situated districts testify.

The fact being indisputable the next question is how do the mountains affect the rainfall. One theory is that the hills cool the air and its moisture by the usual process of conduction and radiation, and as the moisture in the air is cooled it becomes cloud and falls in rain.

Now it may be that the hills are cooler than the lowcountry, but has anyone actually tested the matter and proved that the ground on the hills is cooler than on the lowcountry in a dry time.

Be that as it may: however, I think the experience of everyone will bear out this, that the rain when it comes is cooler than the ground and actually cools the ground.

That theory then of the hills cooling the air by conduction or radiation may be set aside as insufficient to account for the rainfall on the hills;

* An experiment in Australia resulted in failure.—Ed. T. A.

and still more as utterly inadequate to account for rainfall on the level ground forty miles in advance of them.

A more scientific theory has been propounded lately to the effect that the hills cool the air by their elevation. As the monsoon breezes with its moisture-laden air advances towards the hills, it has to rise to get over them, and in rising there is less pressure of air above it, and so it expands and the heat in it expands also and becomes less intense, and so the air and its contained moisture gets cooler, and rain is the result.

That this theory is true and the process described goes on, there seems no question. But that does not afford by any means a satisfactory solution of the phenomena of rainfall. If that were the *only* cause or even the *chief* cause in operation, what we would have would be a continuous drizzle on the hills while the monsoon lasted. What we have, however, is showers—heavy showers—lasting generally for half-an-hour to two hours, while the rest of the 24 hours is dry.

Of course there are periods of constant rain on the hills at the burst of the monsoon, but not all through; so that the heavy showers are not accounted for by that theory and the showers on the sea-level are not even considered in it.

To account for the frequent phenomenon of a heavy downpour in the lowcountry after a very hot day, something that is very partial in its action and also very powerful has to be considered. No cooling of air and moisture by the ordinary processes of conduction and radiation is sufficient. The cooling is effected by some agent acting above and not from below as the cold wind that precedes the shower proves.

Every such shower when seen from without shows a radiated texture, dark and light streaks either perpendicular or inclined invariably appearing, giving the impression of the shower phenomenon being akin to the borealis or streamers which are supposed to be of an electric nature.

Should we not find the chief cause of showers in connection with electric action, the thunder storms point to that.

It appears from the books on electricity that under certain conditions heat is transformed into electricity and *vice versa*.

Are we not justified in coming to the conclusion that somehow under the action of the hills, the heat of the atmosphere passes gradually from the state of heat into that of electricity and so is conveyed away rapidly leaving the air and its moisture cooled to come down in the form of shower.

Is it not worth investigating how the hills effect this, and whether any other means could be used for effecting the same end?

Would not the Irrigation Board best serve its purpose by getting out a thorough Meteorological Electrician, or somebody of that sort, and setting him to study the cause of showers and how to produce them.

And then get the necessary apparatus put in order so that a district could be watered, and the tanks filled when required.

If only the way to tap the clouds could be discovered it would be better than Artesian wells or long watercourses.—Yours truly.

EXPERIMENTALIST.

LIBERIAN COFFEE IN THE STRAITS.

Government Plantations, Perak, Straits Settlements, April 30th.

Sir,—Enclosed I beg to hand you a paper show-

ing what is being done in Liberian coffee in the native States.

The figures are Mr. Hill's, an old Ceylon Planter, and speak for themselves, and I should feel obliged if you could publish them as they will interest most of your planting readers.

Mr. Hill has a fine estate in this State (Perak), not yet in bearing, which I have seen. I was greatly pleased with the fine growth and healthy appearance of the trees which give great promise of crops to come.

Coffee Arabica is also being very successfully grown here, and I am trying to obtain statistics of that also.

I shall be glad to give any information in my power as to land, labour, &c., to my old friends in Ceylon.—I have the honor to be, sir, your obedient servant,

OLIVER MARKS.

Supt., Govt. Plantations, Perak,

Kuala Kangsa, April 30th 1891.

[We have already published Mr. Hill's figures and commented on them.—Ed. T. A.]

AGRICULTURAL CHEMISTRY AND A LOCAL NEWSPAPER

SIR,—Not being a subscriber to the local "Times" I had not the pleasure of reading its remarks on "Salt in Coconut Cultivation," till I saw them reproduced in the *Indian Agriculturist*.

It is generally admitted that though common salt supplies no essential ingredients of plant food itself, its action in the soil in many ways makes it a chemical medium that should be easily available to, and readily taken advantage of by, all agriculturists.

Common salt is by far the most abundant of the salts dissolved in seawater in which it exists to the extent of nearly 3 per cent—magnesium calcide, calcium sulphate and carbonate, and a host of other compounds (the difficulty is to find what the sea does not contain, † considering that it is the receptacle of all the soluble and insoluble substances carried away by terrestrial waters) being present in a much smaller extent. But the subject that has been written on till it has become almost a nauseant, is not the effect of seawater but of salt on vegetation, and though salt as produced in our salt districts cannot by any means be said to be pure, still, when the effects of salt on vegetation is discussed, it is the sodium chloride and not the impurity mixed with it that is considered. If, however, there be, as the "Times" suspects, a sufficient amount of impurity of value as plant food (some phosphate or nitrate?) to produce an appreciable effect on the fertility of the land, in spite of the amount being infinitesimal in sea water, rather than sterilize our lands by picking them in salt with the object of getting at its impurity (there is no need to burn down a house to get a roast pig!), the "Times" suggests that we should make an effort to identify our modest benefactor—and with this end in view to begin by analysing, the hot springs of fertile Bibile—and having identified him, proceed to "extract" him from the sea. Such process, in the opinion of the "Times," might introduce to us some substance "not actually sodium" (a metal which, by the way, will be found to be rather a dangerous manorial acquaintance) to be used as a fertilizer.

* As our correspondent is aware, it contains silver in such appreciable quantity, that the extraction of that metal from it by a cheap process, is one of the problems which advancing science is likely to solve.—Ed. T. A.

What potentialities might not the sea be shown to hold out to agriculturists, if that apathetic class of individuals would but adopt such a course as the "Times" suggests! The suggestion, which is put forward "as a matter of scientific interest," is truly worthy of Prince Krapotkin himself!—Yours, &c.,
OLD SALT.

[About a couple of years ago we quoted largely from Madras Government papers, reports of the manufacture of salt and the manurial value of the residuum. The conclusions arrived at were not encouraging, as regards the carriage of the substance to any distance, although it might be useful for coconuts or other culture near at hand.—Ed. T.A.]

THE TEA FUND AND TEA KIOSK AGAIN.—We did Mr. Mackenzie injustice in supposing that he considered enough had been done to make our teas known in America. He would willingly transfer the "Kiosk" vote to the credit of further advertising in the Far West—or to the Ceylon Tea Court in the Chicago Exhibition. But on the other hand, while Mr. Mackenzie declares he is supported by every planter and broker whom he meets in condemning the Kiosk, we have the authority of large Australian tea-dealers for saying that even as regards the Southern Colonies, the Kiosk should be a most important means of increasing the demand for pure Ceylon tea. Nearly all our teas sent to the South at present are *blended*. To give passengers a good cup of tea and then a 2 lb. package or 7 lb. or 20 lb. box of the same, is just the very best means in the world of making our visitors whether from Australia, America or anywhere else, drinkers of pure Ceylon Tea only. But how to secure the good cup of tea? Well with servants doing nothing else and under the check of the utmost publicity—placards on the Kiosk asking passengers to report to the press if the tea is not good—and with a Committee of Vigilance, say of every member of the Tea Fund who visits Colombo, even Sinhalese Appus (having nothing else to do,) might be induced to serve a really good infusion each time. Let us have a trial of the Kiosk and see.

THE "KEW BULLETIN."—The March number contains an article on Dammer gum-resin from New Caledonia, and one on the improvement of the Cotton Cotton Orchid growers will be more interested in crop in West Africa by the introduction of Egyptian the full list of the Orchids which flowered at Kew during the season of 1890. No fewer than 766 species and varieties are enumerated—a number which will create some astonishment. The large number is accounted for by the circumstance, that not only showy Orchids are grown, but also representatives of as many genera and species, showy or not, as can be conveniently got together. In view of the great interest felt in Orchids, it is highly desirable that the family be well represented at Kew, and that full advantage be taken of the present fashion to increase and consolidate our knowledge of the order and to preserve specimens, descriptions, and drawings for future reference.—The largest number of species flowering in any month was 125 in May, the smallest number eighty-five in January, the average for each month being about 100. Among the mere noticeable genera representatives of which flowered last year, there were sixty-nine species of *Dendrobium*, fifty-three of *Masdevallia* thirty-one of *Ceologyne*, forty of *Oncidium*, twenty-eight of *Odontoglossum*, twenty-four of *Cattleya*, and thirty-eight species (excluding hybrids), of *Cypripedium*. *Cypripedium longiflorum*, *Masdevallia pulvinaris*, and *Odontoglossum crispum* might have been seen in flower through the entire year. The total number of species of Orchid now cultivated at Kew is 1342 grouped in 158 genera. We note that in some instances a capital letter is used for personal names, in others not—a variation which is a little puzzling to gardeners.—*Gardeners' Chronicle*.

"COCOA BUTTER"—we see has been selling at auction in London at from 1s to 1s 0½d per lb.; but is this the product of the "Coconut" or of "Cacao"? "Cadbury's brand" of butter must refer to the latter.

THE "TARIFF" OF CEYLON TEAS IN LONDON.—We call attention to the letter of "Proprietor" in our correspondence column, and would like to know if his experience has been a common one upon country among shippers of tea to the home market? As the figures stand the percentage of deductions, in certain instances, seems so outrageous, that we think our correspondent would be justified in changing his broker.

"PHOSPHORESCENCE."—With reference to an article in a home magazine headed "The Cheapest Form of Light," we may mention that a writer in that wonderful repository of knowledge, "the Orient Guide," disputes the correctness of the term "phosphorescence" as applied to the luminosity of the organisms (*medusa*, &c.) which light the ocean so brilliantly. He writes: "The actual nature of the light has hitherto baffled investigation, and whatever it may be, the term 'phosphorescence' is a misnomer. Whether it is the result of an organic nervous force, which in other classes and orders of living beings is exhibited in the form of electricity, cannot be definitely asserted; but we are convinced that it is in this direction that the investigation should be pursued. Singular indeed will it be if the happy inspiration of a poet, clothed in fitting language nearly one hundred years ago, should point to a solution which shall evade the keenest research:—

—the waves

—spangled with phosphoric fire,

As though the lightning there had spent their shafts

And left the fragments glittering in the field."

But, after all, "phosphorescence" and "electricity" are but terms by which we designate phenomena, which even to science are still mysteries in their origin and nature.

MR. D. MORRIS AND THE LEEWARD ISLANDS.—The gentleman who was at one time resident among you to make inquiry into the origin and treatment of coffee leaf-disease, Mr. D. Morris of Kew, has but recently returned from a trip to the West Indies, and he has this week given the Fellows of the Royal Colonial Institute an account of the Leeward Islands. Mr. Morris described at considerable length the geographical position of the islands, which, he said, in point of scenery and in richness of tropical vegetation, forms one of the most beautiful portions of the British Empire. Reviewing generally the old and the new Leeward Islands, he said that the prosperous past of the islands was closely connected with a system of slavery and with the exclusive production of sugar. When slavery was abolished the whole fabric of the prosperity of the island immediately collapsed. It had taken more than half-a-century to attempt to build up another, and we only now began to see some promise of it. If cane sugar was ever supplanted by beet in the markets of Europe it would not be the fault of the West Indies. The lecturer concluded by saying that the islands had suffered from want of capital, from want of good internal communication by roads and railways, and from want of a rapid and suitable steam communication with the markets of the outer world. All these were in course of being supplied, and there was also a likelihood that good hotels would be built and visitors encouraged to make their winter homes in these beautiful islands, where they would become acquainted with the scenery of the tropics and find health and enjoyment in a world as new as it was interesting and instructive. Mr. Morris was cordially thanked for his paper.—*London Cor.*

THE EUCALYPTS.

On many occasions we have been called on to notice the conscientiously elaborated work of Baron Sir Ferdinand von Mueller on the Eucalypts of his adopted country. The "Eucalyptographia" indeed, is, and must long remain, the standard work on the subject. Thanks to a large extent to his zeal and energy, many of the species have been distributed in India, in our colonies, in Algeria, and along the shores of the Mediterranean generally. Some, such as *E. coccifera*, *E. Gunnii*, and *E. cordata*, are hardy in various parts of Britain, whilst in the Isle of Wight and in Arran, other species are found capable of resisting a climate which, in any case, must be less favourable than that in which they grow naturally.

In many of our colonies, such as the Cape of Good Hope, and in Southern France and Algeria, many more species may be grown with advantage than is the case here. It becomes, therefore, a matter of great importance to be able to discriminate the species, and apply to them the correct names. Many circumstances render this anything but an easy task, even in Australia. Our highly-valued correspondent, M. Charles Naudin, published, in 1883, a memoir dealing with about thirty species, as then known to him in cultivation. Since that time many new species have been introduced, and much fresh information has been gathered concerning those previously known. M. Naudin, by natural qualifications, long practical experience as a botanist and as a cultivator, and by favourable conditions for study, is specially well fitted to deal with these puzzling plants. He has grown many of them in the rich garden of the Villa Thuret, at Antibes, from the seedling to the fruiting stage; he has had them constantly under observation for many years, and been able to follow their vagaries and unmask the protean disguises assumed by some at least of them in successive stages of their growth.* The great value of the Eucalypts, depends upon their rapid growth. If they are planted for sanitary purposes, this rapid growth is all important, as the trees affect the drainage of the soil by their roots, purify the air by their leaves, and possibly act beneficially by exhaling balsamic vapours, which are prejudicial to microbes, or which render noxious vapours harmless. If they are planted for timber the planter has the satisfaction of knowing that no tree that he can cultivate will "grow into money", in so short a time, and that no tree will furnish a return for the outlay expended upon it in so brief a period as these so-called Gum trees. About a hundred species are known, but of these only a few are suitable for cultivation and in making a plantation of them, the use to which the trees are to be put eventually must be borne in mind. If for timber species remarkable for their rapid growth must be selected, such as *E. globulus*, *E. Muelleris* and *E. gomphocephala*. If timber of great solidity, density, durability be required, preference should, according to M. Naudin, be given to *E. marginata*, *E. rostrata*, and *E. polyanthema*. If planting for ornamental purposes, then such species as *E. robusta*, *cornuta*, *botryoides*, and *leucoxylon* are to be recommended. Outside the region of the Olive, of course, only the hardiest species can be cultivated, such as *E. coccifera*, *E. viminalis*, *E. Gunnii*, *E. urnigera*, and *E. cordata*. *E. globulus* is the best known species in this country, and of that, as we have recorded recently, there are some thriving trees in the Isle of Wight and elsewhere. *E. globulus* is also largely employed in this country in decorative gardening, the silvery foliage being very effective in the flower garden. A fine tree at Hyeres was figured in our volume for May 7, 1881. Of the large tree of *E. coccifera* at Powderham Castle, Devonshire, we give an illustration at p. 169 of our present number. *E. urnigera*, of which there is a fine specimen in Mr. Secretary Balfour's garden at Whittinghame, was figured at p. 461, April 14, 1888; see also p. 628, of the same volume. At

* *Description et Emploi des Eucalyptus introduits en Europe*, second memoir. Par Charles Naudin (de l'Institut) Antibes, J. Marchand, 1891, 8vo, pp. 72.

Menibilly, in Cornwall, is a large tree of *E. Gunnii* with a fine head and well-furnished from ground to top and of which Mr. Rashleigh obligingly sent us fruiting specimens some time since.

There are some who think that the rôle of systematic botany, at least as regards flowering plants, is played out, and that minute anatomy and physiology are the only departments of botanical science worth the attention for serious students—a singular reversal of what was the feeling or the practice at the time when the *Gardeners' Chronicle* was founded, and for a score or more years after. Looking at the matter, however, from a purely practical point of view, without reference to abstract science, we could hardly point to any case in which the necessity for observation and classification are more important than in the case of these Eucalypts. To know which are the right species to plant, we must know what are the qualifications which render them valuable, what are the discriminating marks which will enable us to identify them, and what are the names by which they are called. To effect all this, we need the assistance of the systematic botanist, and M. Naudin tells us in the present pamphlet what are the points to which special attention should be directed. The foliage is very variable at different stages of growth, and an observation of the different modes of attachment, and of the different shapes of the leaves at different ages, is often useful in the task of discriminating one species from another. Thus, M. Naudin makes three groups:—1, those in which the leaves are opposite and all of the same shape; 2, those in which the leaves are alternate and uniform; 3, those in which the leaves present two different shapes. These, however, are to be taken as indications, not as absolute statements, for, as usual, Nature refuses to be tied down by any hard and fast lines and exceptional instances are not infrequent. The configuration and texture of the leaves afford other "characters," as also does the shape of the cotyledons or seed leaves. There are differences also in "habit," in the mode of branching, the nature of the bark, and the way in which it is cast off. The inflorescence or manner in which the flowers are arranged, offers better characters, and the differences in the size, colour, and construction of the flower and fruit, are all valuable aids to the descriptive botanist. Acting on these criteria, M. Naudin furnishes us in the present treatise with a threefold synopsis, one in which the species are grouped according to the disposition and modification of the leaves; another in which they are arranged according to the inflorescence and flower, and a third in which the grouping is made in accordance with the peculiarities observable in the fruit or capsule. These tables are, of course, purely artificial guides to facilitate research. By combining the data thus obtained, a more natural grouping is obtained as follows:—

Section I. Inflorescence in cymes or axillary umbels.

Capsules longer than the calyx-tube.

Capsules shorter than the calyx-tubes.

Cymes three-flowered,

Leaves uniform, opposite,

Leaves uniform alternate,

Leaves of two shapes.

Cymes 3 to 7 or more flowered.

Cymes 7-flowered.

Leaves uniform opposite.

Leaves of two shapes, opposite at first.

Leaves uniform, always alternate.

Cymes or umbels, axillary, more than 7-flowered.

Leaves uniform.

Leaves of two shapes.

Section II. Flowers in terminal panicles or corymbs.

To this tabular statement, which we have abridged for our purpose, is added a detailed description of the fifty-six species known to the author as growing in the gardens of Provence. Other species are alluded to as not sufficiently known to be adequately treated of at present.

It will be seen that M. Naudin has once more enriched botany and horticulture with a treatise which demands and will ensure the gratitude of their followers.

General articles on the subject have been given in our columns on July 31, 1880, and December 24, 1887 and the appended list of species, illustrated in the *Gardeners' Chronicle*, may be of use to those interested in these plants.

BRICK TEA.

In our issue of the 12th September last, and on occasions, we have suggested to our tea planters the advisability of making brick tea, as a means of defeating the fraudulent mixtures which are being sold in packets to the million in Great Britain. This packet system is a serious source of danger to the enterprize, as it introduces spurious mixtures under the name of pure Ceylon tea, or of Ceylon and Indian blends, whereby these fair names are used to obtain currency for inferior stuff. We have frequently warned planters that consumers of these packet teas have no means of knowing that they are not genuine, and they accept them as being what they profess to be. In this way, Ceylon tea may be brought into disrepute, just as Ceylon coffee was, and like that article, may be discarded by the largest class of consumers.

We observe that the London correspondent of the "Ceylon Times" mention, in his last letter, that Messrs. Gow, Wilson and STANTON, the great Tea Brokers, have taken up the idea of making up Ceylon tea in brick form for the African market. Their object in pressing tea into solid cakes, or bricks is to save cost of carriage, facilitate transport, and to preserve the aroma of the tea. By this means the difficulties of transporting a delicate and bulky article, like tea, in the wild country through which our teas would have to pass in order to reach consumers in the interior of Africa, are obviated, or materially reduced. At the same time, the quality is preserved from deterioration, in the rigorous climate of those parts by the compressed form which excludes air, and preserve the aroma. In our original suggestion we claimed this last named advantage, as deserving of consideration collaterally as well as the cardinal one of precluding the possibility of blending or sophisticating the genuine article.

The adoption of the pressed form of cakes or brick by Messrs. Gow, Wilson and Stanton, has for its primary object the saving and facilitation of carriage. The other advantages specified are, for their purpose merely collateral. With us, the primary consideration was to defeat the fraudulent mixtures, which constitute a large proportion of the packet teas that are sent to the manufacturing districts for the use of the million. The saving in cost of carriage, the easier handling of tea in that form, and the preservation of aroma, which necessitates so much care in packing under the present system, are probably the objects originally contemplated by the Chinese in preparing tea in that form for the tremendous land journey between China and Russia. It is quite as easy to compress good teas as it is to make up the inferior stuff that is sent in brick form to Russia. This is proved by the experiments of Messrs. Gow, Wilson and Stanton. There are, therefore, strong inducements for Ceylon planters to try pressed teas for ordinary consumption. By this method their bulk may be enormously reduced the form of package would be simplified, and other economies, besides those above enumerated, in the saving of tea lead, &c., &c., would be effected.

In suggesting the brick form for tea the writer was reminded of a similar form in which gunpowder was submitted to him for trial during his experiments with Ordnance in 1860. The coarsest powder used for large guns was made up

by one of the manufacturers into blocks, exactly fitting the gun, and thus serving the purpose of cartridges. Many experiments were made with charges of powder so made up, and the writer's recollection of them is that there was no appreciable loss of force in the powder so made up. The blocks were subjected to very slight pressure, in order to avoid injuring the granulation of the powder. The Block was held together by an almost insensible firm of mucilage. A plate of glass was slightly smeared with a fine mucilage and the powder was spread on the plate, which was then tilted, when all the loose grains left it, and a thin layer remained adhering to the plate. These were scraped off into a mould and lightly pressed. The block thus formed of the required size and shape, held together firmly, and was much more easily handled than loose powder. Of the ultimate result of the experiment we know nothing more as the writer made the experiments on behalf of the inventor, and had no more to do with the invention afterwards. We now revert to that experiment only to show a method whereby tea might be pressed into any required form of cake or brick. The actual quality of mucilage required, in the powder experiment was surprisingly small, and a still smaller quantity would be required for compacting tea, because a severe pressure would be employed to reduce the tea to the smallest compass practicable, and the adhesion would thus be made more affective.

One further idea suggests itself to us in this connexion. Supposing, for instance, that the mucilage employed were of gelatine, would not its affinity for tannin tend to fix a portion of that somewhat objectionable component part in the process of brewing in the pot? If so, the result of the infinitesimal admixture of the mucilage would be to improve the quality of the brew? Be that as it may, our suggestion of making up tea in brick form has received a great impulse by the experiment of Messrs. Gow, Wilson and Stanton, and we therefore repeat it with our earnest recommendation that some of the more enterprising of our planters should commence a series of experiments on the making up of fine teas into brick shape. We may add, in conclusion, that a cake of tea dust, which was made up some months ago for us by a friend, was tried in the cup last week, after the cake had been exposed during that long interval and we found the flavour still good, and as far as we could judge, unimpaired. This fact, as far as it goes, confirms the opinion expressed by the eminent firm of brokers who have been preparing pressed tea for Central Africa, and adds an encouragement to the further prosecution of what we hope may prove a safeguard as well as an economy in the production of our staple.—Local "Independent."

A BLOCK IN THE GROUND-NUT TRAFFIC AT PONDICHERY.—It is estimated that there are upwards of 600,000 bags of ground-nuts at present stored in Pondicherry waiting shipment. This at 35,000 per load, represents 17 full cargoes. One steamer only is loading and about ten others are being engaged, but in the meanwhile the arrivals continue as heavy as ever averaging about 10,000 bags daily, which alone will require two steamers weekly. The town is filled to overflowing with the kernels and storage accommodation is wellnigh exhausted. The 12 new export sheds and the two large naval coal godowns, which are now being used for the first time, are totally inadequate to meet the increased traffic of the current season including the accommodation of former years. To clear off the accumulated stocks will severely test the shipping facilities of the port. The roads throughout the station are in an execrable state, and with the constant heavy wheel traffic passing over them there is no opportunity afforded for making proper repairs.—*N. Mail*.

SALT FOR THE GARDEN.

Haputale, 21st March.

To the Editor of the Ceylon Examiner.
Dear Sir,—Having read *B's* excellent letter on salt for Agricultural purposes, I would take the liberty to pen a few lines on what has recently fallen within the scope of my experience.

The plants in my garden here were subject to attacks from insects under ground. The worst among them were a kind of red termites or ants. I tried ashes and lime to get rid of them, but with little success. I then used Kerosine Oil mixed with water in the proportion of a wine glassful of the oil to a gallon of water with partial success, but not without injuring the plants more or less. Next I had recourse to salt, which had the desired effect—and more. For by its application I found that not only were the plants free from the pest, but those to which it was applied thrived better than plants of the same kind which were not attacked by the insects, and therefore had no salt applied to them. The salt thus helped to bring on a healthy growth, and the vegetables treated with it were better relished on the table. I believe this is a proof of the disirability of the use of salt in the vegetable garden, especially on these interior hills, where there is little chance of any appreciable quantity of salt being deposited on the land by saline spray carried by winds from the sea.

Besides serving the gardener as an insecticide and manure, salt is useful to him as a hygroscopic; *i. e.*, it helps the soil to take and retain moisture from the atmosphere,—an effect that will not be lightly valued in seasons of drought. I intend continuing my experiments with salt in the garden, and hope to let your readers know the results in course of time. In the meantime, however, I cannot help stating that the use of salt for the above-noticed and other purposes in Agriculture show the desirability of placing it within easier reach of the agriculturist as regards the price.—Yours truly, E. T. H.

THE CEYLON EXPLORERS OF THE UPPER AMAZON.—Our attention has been called to the fact that we were in error in describing both the Land Commissioners selected by Sir Alfred Dent, as "retired" Ceylon planters. Mr. Sinclair is rightly so designated (though he still holds some property in Ceylon); but not Mr. A. Ross who besides holding extensive interests out here, had by no means, given up the idea of returning to work when he went home for health three years ago, and left his affairs in the hands of Mr. Munton of Kandy. Mr. Ross's places in Ceylon we are glad to learn, are all doing well, and doubtless after his trip to Peru, he will return for another spell of work here and he will be heartily welcomed.

THE HIGH-PRICED CEYLON TEA.—"Œdipus" writing to the *Melbourn Leader* says:—

A parcel of Ceylon tea has been sold by auction in London at the outrageous price of 87s per lb., and has been resold for 110s. Not even a sample is now to be had at any price as it has been put into glass cases for exhibition at the retail shops of the purchasing company. Nothing is said about the gross weight of the parcel, nor is there any testimony as to the flavor of the article, so that, after all, it may be that a cup of tea made from the ordinary sort at 2s a lb. may be intrinsically as good as that which would cost 2s a cup. It is a thing to be looked at, perhaps little more. The growers will, however, be stimulated to produce the article in such remarkable quantities as may enable tea drinkers to indulge in its consumption. It is related of Hoboy, the bootmaker, that when in Paris he was fascinated by the appearance of a single boot displayed in a shop window, and he resolved to purchase it. He inquired its price, and received for answer—"Ah no! I cannot sell that boot, because I made it in one moment of enthusiasm." Perhaps the Ceylon tea grower may be in a similar position.

TEN MILLIONS—rather than one million—of acres of land is the limit Sir Alfred Dent's Syndicate are empowered to take up in Eastern Peru!

A NEW METHOD OF BUILDING WELLS.—Mr. Gunga Ram, Executive Engineer, Lahore, has invented a new and cheap method for building wells, for which he has taken out a patent. The secret of the invention lies in the use of specially moulded dovetailed brick, with which no mortar is required, and the bricks can easily be fitted and locked by unskilled labour. The wells would be both cheaper and stronger than those built in the ordinary way.—*Indian Engineer.*

FUEL FOR TEA.—It greatly suggested me to hear the other day from one of the leading men connected with Ceylon planting Companies that for the fuel used upon one of their estates he was paying £4 a ton! This instance is, of course, an isolated one. The estate has no fuel reserve, nor is it situated so as to obtain a supply of timber fuel from neighbouring sources. The consequence is the whole of its curing operation are dependent upon English coal, and the price of this delivered upon the estate is said to be that above given. What are you going to do when such instances become multiplied? It must surely be a crushing thing to have to pay such a price considering how large a consumption of fuel is needed for the preparation of tea. Can any of your readers tell us the proportionate value of wood and coal in such operations? For burning in locomotives the standard of relative values is—if my memory serves me rightly—about 3½ to 1, but this data might not hold in the furnace of a tea-drier. Any way, I realise from the information given to me how serious a question your fuel supply must be to you. You will really have to fall back ere long on some such proposal as you yourselves made some years back, to have wire-rope tramways from the forests of the lowcountry to serve groups of contiguous estates.—*London Cor.*

COLONIAL WINDFALLS.—Great Britain—says the *Spectator*—is not quite so fortunate as the United States, where every year they discover a mountain of cinnabar, or an oil-well yielding half-a-million gallons a day, or a silver-mine which seems inexhaustible,—but still, we have our windfalls too. The new silver-mines in Australia are said to be of unsurpassed richness; Mr. Cecil Rhodes telegraphs about new gold-reef in Mashonaland about once a week; Canada has just discovered a vast deposit of silicious sand, which should enable her to make bottles for the American continent; Ceylon finds that her cocoa fetches double prices;—[strange the editor did not think as well of our tea the finest in the world, our pearl fishery and mines of plumbago and precious stones.—*Ed. T. A.*]—and now it is reported that diamond-mines have been discovered in British Guiana, which, according to the Lieutenant-Governor, will be "a new and unrivalled source of prosperity for the Colony." As no increase of supply appears to glut the desire for the bright little stones, that prophecy may prove correct. We hope it will, for of all the Colonies British Guiana most sadly wanted a fillip, and the presence of capital sufficient to tempt the Colonists into public works. Curious if Raleigh's dream should come true at last, and a city of fabulous wealth arise in British Guiana! We hope the Colonists will have poetry enough in their composition to name the capital of the new diamond-fields Manoa. Mr. Rhodes would, and he will be hardly able to keep his fingers out of that pie.

WHITE WAX IN CHINA.

The native candles of the north are made of sheep's tallow but those of the central provinces are partly manufactured from bean oil which is able to be utilised for this purpose by the addition of white insect wax in the proportion of about one-eighth. Where bean oil cannot easily be procured the seeds of *Stillingia sebifera* are employed. This tree grows most extensively in the south. A picul of its seeds yields twenty or thirty catties of tallow, and when this has been pressed out, subsequent grinding and steaming result in the production of an oil called *ching yu* out of the albumen. Insect-made white wax is added in the proportion of three catties to a hundred catties of the tallow. It is the wax which gives it sufficient consistency to remain thoroughly congealed in ordinary temperatures. From Hankow in 1889 about 120,000 piculs of the tallow of the tallow tree were exported and of this quantity nearly half found its way to Shanghai in the same year. An enormous quantity of candles are made in Shanghai and its vicinity and the pressing out of bean oil for the manufacture employs a large number of water buffaloes. The old industry is that which has for many ages made use of the tallow tree product. The new has grown out of the Newchwang trade which supplies Shanghai with beans. The vast industry which is an essential to the use of the vegetable tallow, began, we are told about six centuries ago. Till recently we knew generally that the wax is made at Luchou Fu, in Anhui, at Kiating in Chékiang, at Hinghua Fu in Fukien, as well as in Hunan, in Kweichow, in Yunnan and Szechuan. But the processes were never fully described and there was a need for fuller information. That want has been recently supplied by the inquiries of Mr. Alexander Hosie of the British Consular service in Szechuan. The tree on which the insects produce the wax is an inhabitant of a different part of the country from that which produces the insects. Chinese ingenuity brings the insects from their birthplace to their new home many miles away and sets them to the work of wax-making. It is this curious history which Mr. Hosie has been the first thoroughly to investigate.

The white wax insect was frequently referred to in old works on China. One object of Mr. Hosie's recent journey to the Chienchang valley near Mount Omi was to procure from the tree on which the insect lives specimens of the foliage and flowers, for Sir Joseph Hooker. These he procured and specimens of the living tree with the incrustated white wax on it as well as samples of the latter as it appears in commerce and of the Chinese candles made from it. The said valley is 5,000 feet above the level of the sea and is the great breeding ground of the insect. The tree is an evergreen with the leaves springing in pairs from the branches, very thick, dark green, glossy, ovate and pointed. In May and June it bears clusters of white flowers; succeeded by fruit of a dark purple colour. The Kew authorities now say it is the *ligustrum lucidum* or large-leaved privet. In March Mr. Hosie saw on the trees certain brown pea-shaped excrescences attached to the bark of the boughs and twigs. Opening some larger ones they presented either a whitey brown pulpy mass, or a crowd of minute insects looking like flour. Their movements were just perceptible to the naked eye. From two to three months later they become brown creatures with six legs and a pair of antennae. These are the white wax insect or *coccus peltæ*. There is a beetle which is a parasite on the *coccus*. It is a species of *bractytarsus*. It is found in many of the excrescences above men-

tioned and burrows in the inner lining of the scale which seems to be its food. When a scale is plucked from the tree *cocci* escape by the hole which is made. It is in the town of Kiating that insect white wax is produced. This city is 200 miles to the north-east of the Chienchang valley. The scales are gathered in the valley and made up into paper packets of about sixteen ounces each. Sixty of such packets make a load and they are conveyed by porters from the valley to Kiating in the night time. If carried by day the insects would develop and escape from the scales. As it is, an ounce is lost in transit. A pound of scales in good years is sold for half a crown. In bad years it is worth twice this amount. In favourable years a pound of scales produces four or five pounds of wax. In the plain round Kiating very many plots of ground are seen edged with stumps from three or four to twelve feet high with numerous sprouts growing from their gnarled heads, as on pollard willows in our own country. The tree is probably *Fraxinus Chinensis*, a kind of ash. The leaves spring in pairs from the branches and are light green, ovate, pointed, serrate and deciduous. On the arrival of the scales in May they are made up in small packets of from twenty to thirty scales which are enclosed in a leaf of the wood oil tree. Rice straw is used to suspend the packet under the branches of the ash or wax tree. Rough holes are drilled in the leaf with a blunt needle so that the insects may find their way to the branches through the openings. The insects creep rapidly up to the leaves where they nestle for thirteen days. They then descend to the branches and twigs and take up a position on them. The females then begin to develop scales on which to deposit their eggs, and the males to excrete the substance known as white wax. It first appears as an undercoating on the side of the boughs and twigs, looking like snow. It spreads gradually till in three months it is a quarter of an inch thick. In a hundred days the deposit is complete and the branches are lopped off. The wax is removed chiefly by hand and is placed in an iron pot of boiling water. The wax on rising to the surface is skimmed off, and deposited in a round mould. This is the white wax of commerce. It is used to coat the exterior of animal and vegetable tallow candles and to give greater consistency to the tallow. It is also used to size paper and cotton goods, to impart a gloss to silk and as a furniture polish. From Hankow each year at present about 15,000 piculs of white insect wax are exported in a year, and the main portion of it finds its way to that port from Szechuan. Chienkiang absorbs 1,000 piculs, and Shanghai 14,000 piculs. At Shanghai one half is for home use and the other half to distribute again to other ports. Tientsin requires 1,000 piculs, and Canton and Swatow a thousand piculs each. Thus it appears that while Szechuan is not the only producing centre of insect white wax it produces enough to furnish the most distant cities with the means to make a sufficient number of candles to maintain the temple worship as well as to enable the people everywhere to equip their lanterns for walking in the evening, and aid in night illumination generally. —N.-C. Herald.

NOTES ON POPULAR SCIENCE.

By Dr. J. E. TAYLOR, F.L.S., F.G.S., &c., EDITOR OF "SCIENCE GOSSIP."

A year or two ago I drew attention in one of my letters to the discovery that the process of tanning could be accelerated by electrical currents. This has now passed into the region of commercial enterprise and is likely to be highly successful. Unfortunately,

for the discoverers, however, the patent was not taken out simultaneously in different countries, and so a lawsuit is the result.

The two hard-working French chemists, Messieurs Berthelot and Andre, have read a paper before the Paris Academy on the presence and influence of sulphur in vegetation. This paper is the result of a series of experiments, all of which indicate, among other things, that the proportion of sulphur increases in plants up to the time of their flowering, after which it decreases.

One of the most remarkable orders of flowering plants in the world is the Podostemaceae, confined to South America, and especially abundant in the rivers of British Guiana. These plants grow on the submerged rocks in the falls and rocky beds of the rivers, where they break out into dense and beautiful sheets of pink blossoms when the waters subside during the dry seasons. The order comprises several genera and many species. The plants adhere to the rocks like sea-weeds by a disc-like base of the stem, which holds them with such tenacity during the stress and strain of the rushing waters that in removing them by main force a portion of the rock is often carried away with the plant. During a greater part of the year the plants are submerged, and they then float like sea-weeds do at the bottom of the sea. They take advantage of the dry seasons to flower and fruit. Dr. Goebel has been specially studying this remarkable group of flowering plants, and will shortly publish his researches.—*Australasian*.

SCIENCE OF THE DAY.

BY A. B. SC.

The amount of agricultural experimenting carried on in the United States is really surprising, and if the American farmers are intelligent enough to take systematic advantage of it great national saving ought to result. As samples of the sort of work being done a couple of recent investigations may be described. The rearing of pigs is more largely undertaken in parts of the United States than in any other county in the world, and the problem with farmers has been how best to fatten pigs at the cheapest rate. Maize-meal has been a favorite feed, but experience has shown that after a certain point pigs cease to gain weight on maize-meal, although they can still put on a good deal more flesh on richer and more expensive diet. It had been noticed that the bones of hogs fed on maize-meal were smaller and weaker than usual, and it was inferred that probably the maize-meal-fed hog put on as much flesh as his bones would carry, and that if only enough bone-making food were supplied the fattening on maize-meal could be carried much farther. Farmers had tried mixing wood ashes in the maize-meal with some success. At this stage the Agricultural Station of the University of Wisconsin took up the enquiry; it was proved first by breaking tests that the bones of maize-fed hogs were much weaker than they ought to be, and meanwhile several lots of hogs were reared on different diets, some on maize, some on maize and wood ashes, and some on maize wood ashes and bone meal or ground bones. The use of bonemeal reduced the cost of putting 100 lb. weight into a hog by 23 per cent. It is evident how important such a result must be to thousands of farmers in the United States, who for years have practically been wasting a quarter of the feed given to pigs.

At another experimental farming station a series of trials were made as to whether it could be made to pay to plant special fields of honey-bearing flowers for bees. The conditions are hard to satisfy, the plants must be such as will grow in waste ground that cannot be put to better uses, the seed must be easy to gather, and easy to sow, and the plants hardy. Three plants of most promise were tried, but the results were pretty clear that so far as these experiments went it could not be made to pay to grow feed for bees. However, the thing is to be still further tried in the interests of the many scientific beekeepers who are

kept anxious by the strange fluctuations in the honey yield of wild flowers.—*Adelaide Observer*.

MANUFACTURE OF SALT IN CHINA.—In China, salt which is a government monopoly, is obtained by the evaporation of the water of the brine wells which abound in certain districts of Sz-chuen. The wells are found about 175 miles from Chung-king, on the bank of an affluent of the Yang-tze River, near the flourishing city of Tzu-lin-tsin. The manufacture of salt, which has been carried on here for sixteen hundred to two thousand years, is conducted somewhat as follows, according to a recent Consular Report: By means of a rude iron drill, holes 6 inches in diameter and varying from a few score of feet to 5,000 or 6,000 feet in depth are bored in the rock. The boring sometimes lasts for forty years before brine is reached, and is carried on from generation to generation. When brine is finally found it is drawn up by bullocks in long bamboo tubes by means of a rope working over a huge drum. In the vicinity of the salt wells natural-gas wells are also found, from which gas is supplied to evaporate the brine in large iron cauldrons leaving the pure salt as a deposit. The product of salt in the district is enormous. There are twenty-four gas wells and about a thousand brine wells now in operation, producing annually 200,000 tons of salt, valued at \$5,000,000.—*Engineering and Mining Journal*.

BAROMETRIC PLANTS.—The *Petit Traite de Meteorologie Agricole*, by Mr. Cana, contains a list of prognostics apropos of the aspect that certain plants present according to the state of the atmosphere. The following are a few examples:—If the head of the gith (*Nigella sativa*) droops, it will be warm; if the head of the same plant stands upright, it will be cool; if the stalks of clover and other leguminous plants stand upright, there will be rain; if the leaf of the wood sorrel turns up, it is a sign of a storm; if the leaf of the whitlow grass slowly bends up, there will be a storm; if the flower of the convolvulus closes, it will rain; if the flower of the pimpernel closes, it will rain; if the flower of the hibiscus closes, it will rain; if the flower of the sorrel opens it will be fine weather; if the flower of the same plant closes, it will rain; if the flowers of carline thistle close, there will be a storm; if the flower of the lettuce expands, it will rain; if the flower of the small bindweed closes, look out for rain; if the flower of the pitcher plant turns upside down, it will rain; but, if it stands erect, it will be fine weather; if the flower of the cinquefoil expands, there will be rain; but, if it closes, the weather will be fair; if the flowers of the African marigold close, it will rain; if the scales of the teasel become close pressed against each other, it will rain.—*Milbourne Leader*.

SWEET-SCENTED FLOWERS.

One of the greatest charms of old-fashioned gardens used to be the number of sweet-scented, flowering and other plants they contained, and the fragrant atmosphere they consequently afforded at almost all seasons of the year. We have few if any roses so sweet as the old cabbage, monthly, and other varieties, and wall-flowers or gilly-flowers, stocks, violets, carnations, lilies, lilacs, and a score of others, as well as sweetbriar, and other, fragrant foliaged plants, were among the chief occupants, and always held an honoured place. We have greatly the extended list of subjects to choose from in these days, but though our gardens may be gaye than of old, they are decidedly not so sweet.

ROSES, are favourites everywhere. For fragrance the old cabbage rose is unequalled; then come the monthly Maldeu's Blush, and many old-fashioned sorts: the more modern tea-scented varieties, and General Jacqueminot, La France, Bessie Johnson, and others among the hybrid-perpetuals; Celine Forestier (Noisette) is also very sweet.

WALLFLOWERS are simply delicious, and a favourite flower on account of their perfume alone. The single dark crimson variety is the most fragrant, though all possess a more or less pronounced scent. Old plants may often be seen in gardens, but the best way to have good wallflowers is to treat them as biennials

and sow seed every year in April or May for the next year's flowering.

VIOLAS, though not so showy, are even more sweetly perfumed, if possible. To keep the plants in good condition the best of the rooted runners should be selected and planted in deep and rich ground annually.

The **LILY OF THE VALLEY** gives very little trouble; if once established in a bed of rich loamy soil, and a rather shady situation, they will remain in condition for several years, and produce an abundance of fragrant blossoms annually. Among the so-called

BEDDING OUT PLANTS there are comparatively few fragrant subjects, though the heliotrope, or cherry pie is unsurpassed for distinct and delightful perfume. Most verbenas are more or less fragrant, also double petunias and some of the single ones, the white-flowered kinds in particular, but these are about all.

ANNUALS are rich in sweetly-scented subjects. Stocks are indispensable where fragrant flowers are valued and mignonette, sweet peas, and the night-scented stock (*Matthiola bicornis*) should be found in every garden.

NICOTIANA AFFINIS.—The sweet white-flowered tobacco plant forms a valuable addition to our list of fragrant plants. It is really a perennial and very early hardy, but is best treated as a half-hardy annual, seed being sown in heat early in the spring, and the plants set out in May or June. Then the charming old white or

MADONNA LILY (*L. Candidum*) and many others are exquisitely perfumed, and candytufts, scabions, and a score of others are all worthy of place.—*S. I. Observer*.
[Meant for Britain, but applicable largely to our Ceylon mountain region.—*Ed T. A.*]

CEYLON TEA IN AUSTRALIA.

We are very pleased to receive a letter from "the gentleman in Colombo" to whom Mr. Foulkes referred (page 858) as so long generously supporting him, in which he informs us that he is prepared to continue to send consignments of tea. This continuance of business will be on certain terms which will no doubt be readily accepted. Under these circumstances, Mr. Foulkes' Colombo supporter does not think it necessary to trouble Mr. Mackenzie and any other planters for a guarantee, nor the Tea Fund for tea. We are very satisfied indeed to have such good news of Mr. Foulkes being able to continue his tea business without intermission. We were just about to look up a letter of a year ago in which the 'senior editor' on his way back from Melbourne gave testimony to the good work done by Mr. Foulkes; but now neither this nor the appeal to the Tea Fund Committee will be necessary. Although not at liberty to publish the name of the writer nor his letter in full, we think we may quote one passage to show how Mr. Foulkes is trusted:—

"With reference to your article in last evening's paper headed "Ceylon Tea in Australia," I can confirm all that Mr. Foulkes says in his letter as I am the gentleman to whom he refers as being indebted to in the sum of £200. For some years past I have been sending Mr. Foulkes consignments of tea, with the result that the good qualities of pure Ceylon tea have been prominently brought to the notice of many, who but for his intervention would probably never have tasted the pure article, but I regret to say the pecuniary returns both to himself and me have been anything but encouraging. I have been most anxious to do all in my power to assist Mr. Foulkes in his arduous campaign, and am still willing to do so; in fact I wrote to Mr. Foulkes a short time ago to the effect that I would continue to send him consignments on certain terms which he himself proposed to me; this being the case, I do not think there is any necessity for the matter being taken up by the Tea Fund Committee, nor is there any necessity for the further advances being made by me, to be guaranteed either by that body or individ-

ual gentleman, as I am quite satisfied that Mr. Foulkes will do his very utmost not only to push the sale of pure Ceylon Tea but to repay me the sums I have already advanced him for this purpose.

AN INSECT COLONY.

Probably Southern California counties contain at present no happier man than A. Scott Chapman—that is, judging happiness from a horticultural standpoint. Mr. Chapman has many friends in this end of the State who will be pleased to know that no longer are his feelings as blue as are the famed skies about his sunny San Gabriel home. A few years ago Mr. Chapman, who is an alumnus of Berkeley and for a time was a member of the State Board of Horticulture, was widely known as a very successful orange-grower. He went into the business energetically and systematically and the San Gabriel Valley contained no prettier groves than he could show on his thirty acres. Then along came the *Icerya Purchasi*, which being interpreted means that the cottony cushion-scale entered the pretty groves and ravaged these thirty acres like the fire eaters the best has always been. Mr. Chapman worked his grove, but the scale worked harder, as it had done in many other of the choice sections of the orange-producing region, and the result was the scale triumphed. No wonder the owner became blue and despondent. Down dropped the product of the grove to 600 boxes, instead of twice 6,000 which it had been producing. But this season, in February and March next, Mr. Chapman figures, in a letter just received by a friend here, these same trees will yield fully 10,000 boxes. That is why he is now feeling bright and happy. The *Vedalia Cardinalis*, the Australian parasite that feeds on the scale, has worked this beneficence. The ravaging scale has practically disappeared from the entire grove. The example is only one of many similar cases among the Southern California groves.—*S. P. Bulletin*.

RICE—RICE MEAL.

RICE.—The British working man fancies that rice is a dear article. He does not reflect that when he buys 4 lb. of potatoes he gets 3 lb. of water and only 1 lb. of food, and that 1 lb. of rice contains 3½ times as much food as 1 lb. of potatoes, as may be seen from their analyses:—

	Water.	Flesh	Fermers.	Starch.	Total Food
Rice	13	..	6.5	..	80.0 .. 86.5
Potatoes	75	..	1.4	..	22.6 .. 24.0

Taking into account the loss in peeling the potatoes, 1 lb. of rice is clearly worth 4½ lb. of the latter article, besides which, rice in boiling absorbs three times its weight of water, hence 1 lb. of rice, costing 1½d, when boiled exceeds in weight, bulk, and food value, 4 lb. of boiled potatoes, costing 3d.

RICE MEAL.—Now we come to rice meal, which is composed of the outer skin of the rice grain, together with the "heavy offal" that is ground fine and mixed into it. The small proportion of husk that the heavy offal contains would not pay to separate; it does not materially lower the quality of the meal, and permits it to be sold somewhat cheaper. "Superfine meal," quite free from husk, can be obtained by those who want it at a higher price, but the bulk of the trade is in the medium quality, which is the best for general use, price and all things considered. In appearance it is exactly like oatmeal, but its somewhat bitter taste soon informs the human palate of its real nature. It is a decided tonic, and like cottonseed cake, it has a slightly binding effect on cattle that makes it the more valuable a food for them when out at grass in a wet season. Although rice meal is so well spoken of by those who use it, the consumption is extremely local, and is confined to but a few of those counties that are in easy communication with London and Liverpool.—*The Miller*.

MORTALITY FROM SNAKE BITES.

Concerning deaths in India from the bites of wild animals and snakes, the statistics recently published are not only enormous, but show an increase over former years in mortality, and Mr. J. Moray Brown, dealing with the subject in *Land and Water*, asks whether the circumstances under which the lives of over 20,000 human beings, and over 50,000 cattle are sacrificed annually, are not worthy of consideration? Not only in India do authorities concur that the evil is great and needs remedy, but in England also the matter is attracting considerable attention, and, though a variety of opinions have been expressed the mischief goes on. It has been urged that as civilisation advances, the *feræ naturæ* retire into the depths of the forest. It is true that, to a certain extent, this is the case, but not entirely, for anyone conversant with the habits of tigers and panthers—in especial—must be aware that there are among them individuals which prey almost exclusively on cattle and human beings, and which lay up for months in the merest pretence of cover, provided it be within reasonable reach of a village. On the other hand, snakes will be found in the most populous parts, and neither the Government House of a Viceroy nor the hut of the humblest peasant, is safe from their intrusion. The lethargy and superstition of natives themselves certainly offer great opposition to any radical cure, but lethargy and superstition can be successfully combated by the energy and determination of Europeans. The poisoning of wild beasts has been tried in certain places, but this is not only revolting to the Englishman in whose breast any of the traditional love of sport of his race is inherent, but is fraught with considerable danger to the individual desired to be benefited. Once poison is laid down, you know not where it may end—very likely in taking the life of some of those you would fain shield, for a certain sect or caste named the Dheres will eat any carrion they may come across. That the mortality from snake-bite is decidedly on the increase seems an acknowledged fact; but this may be due to a better system of reporting and it may also be urged that many deaths are put down to snake-bite which are due to other causes. This latter argument may, however, be met with the retort that many cases of death from snake-bite are never reported at all and so those should counterbalance the deaths wrongly attributed to the attacks of snakes. The matter has, no doubt, attracted the serious consideration of the Government, and Lord Cross has addressed urgent inquiries to the Indian Government, asking if nothing further can be done to check this mortality. The Indian Government, however, seems to be unable to suggest any remedy, and states that the general opinion seems to be that the system of offering rewards for their destruction has stimulated the breeding of snakes by natives, and the only plan that they recommend is that District officers should be instructed to see that all cover in the vicinity of villages is cleared away, while local Governments are left to decide whether they shall, or shall not, continue the system of rewards. Mr. Moray Brown thinks that if the prohibition to enter reserved forests, which has been in force for the last few years, were relaxed, and officers of the army encouraged to spend their leave in the jungles, the carnivora would be greatly diminished, and the forests would be no worse (though Government hope they are better) than they were 20 years ago. Such a course would not unaturally be objected to by many Indian forest officers and official civilians, who would resent their private preserves, kept for their own amusement and the detection of any distinguished globe-trotter, being shot by outsiders. But surely in the vast jungles of India there is room for both, and the measure would be more than compensated for by the knowledge of the country and its inhabitants acquired by military officers, to say nothing of the manner they would thin the ranks of destructive wild animals at no expense to Government! As to the destruction of snakes, though there are numerous varieties of snakes in India which are more or less veno-

mons, the following are the most destructive to life:—The cobra (*Naja tripudians*), the krait (*Bungarus caruleus*), kuppur (*Ecleis, carinata*), the hamadryas (*Ophiophagus elaps*), the rāj-samp (*Bungarus fasciatus*). Sir J. Fyner suggests "that a plain description and a faithful representation in colour of each species would make the people acquainted with the characters which distinguish the venomous from the harmless varieties," and he suggests further that a scale of rewards, varying from eight to two annas should be given for each snake killed, according to its poisonous propensities. Mr. Moray Brown goes further, and proposes that in every village should be displayed in a public place, where every ryot and traveller could see them, life-size painted clay models of the five most venomous snakes. These could be produced at a comparatively trifling cost, and would familiarise the population with the appearance of their great enemies. But he thinks the Government might also appoint men with a knowledge of natural history for a certain period to travel about the country, and after thoroughly investigating the subject, report upon it, and recommend some course of action. Let a certain fixed sum be devoted to this. From R30,000 to R40,000 ought to cover their salary and travelling expenses, and this would not be an out-of-the-way sum to expend on the experiment, and if extended over a period of, say three years, would be hardly felt by the revenue. By adopting such a course the Government would be more likely to obtain a suggestion of some value, and much unnecessary burden would be shifted from the shoulders of a very over-worked class—namely, the Indian civilians who have multifarious other duties to attend to. In conclusion, he says, "we have the men, and have the money to ameliorate, or endeavour to ameliorate the present condition of affairs, then why not make use of both?"—*M. Mail.*

GRAFTING OF COFFEE.

We have received the following letter on the subject of grafting coffee trees from Mr. J. Cameron, of the Lal Bagh Gardens, at Bangalore. It will be of great interest to planters who are thinking of trying the experiment of grafting Arabian coffee on Liberian stocks, for the purpose of rendering it less liable to leaf disease:—

BANGALORE, April 15th.

DEAR MR. FERGUSON,*—I am making a few experiments in coffee-grafting, but they are not far advanced, and I cannot tell you what the ultimate results may be; but for practical purposes in the field, I would strongly advise that experiments of the kind be put in hand to some extent on every estate. The grafted area need not be extensive until the results are proved advantageous. Inarching is the best mode of treatment, and for this purpose two plants of different varieties or of the same variety should be planted near each other in the same pit. When they are big enough they are united. Healthy seedlings of two years' growth would be about the age and size, or perhaps younger. An acre or two planted in this way with a view to inarching would soon discover the merits of the practice. The coffee shrub grafts very readily, and I have united the following successfully:

1. Liberian on Liberian; object, to hasten and improve bearing and to dwarf the tree.
2. Liberian on Arabian; object, the same as No. 1.
3. Arabian on Liberian; object, to strengthen the vegetative growth of the first named, and render it less subject to disease, etc.
4. Maragogipe on Liberian; object experimental.
5. Liberian on Maragogipe, object experimental.

We have grafted at present only a dozen or half a dozen, in each method, but there can be no doubt that coffee, like other fruit bearing plants, can be improved by this treatment.

I have no objection to your publishing my letter on the subject of grafting coffee, but I should first explain that the *modus operandi* recommended for estates, and that

* An Indian planter.—ED. C. O.

which I have practised here, are slightly different. For estate planting I have seconded your suggestion to place two seedlings in a pit, and subsequently inarch them when large enough; but with the object of making the plants portable, the stocks which I have used have been in pots. In fact, I have undertaken to supply a planter in Coorg with a number of grafts, and this was the readiest way of doing it. The pot plant is conveniently placed under the ground shrub, inarched in the usual way and eventually removed to another site. When the monsoon bursts, I intend to plant out the different grafts, a few of each, and cultivate them systematically under irrigation and shade.

Yours very truly,

J. CAMERON.

—Madras Times.

TO THE EDITOR OF THE "MADRAS TIMES."

SIR,—I have been much interested in your article on grafting Arabian coffee on to Liberian coffee, as an antidote for Leaf Disease.

The difficulty of raising strong healthy coffee plants for extension or supplies, has been one of the main difficulties the planter has had to contend with in late years, and really seemed to threaten the existence of the industry. So violent has been the attack of Leaf Disease on even young nurseries, that the idea is current that the disease is now inherent in the coffee seed.

A very interesting experiment is being carried out by Mr. Thomas Murray, of the Glenva Estate, who having read of the successful treatment for smut in wheat, by the parboiling of the seed to be sown, thought that a similar treatment of coffee seed might have the same effect. The object of soaking the seed in hot water, was to destroy the fungus spores that might be deposited in the interstices of the bean, without destroying the vitality of the seed. The results of Mr. Murray's experimental nursery will be of great value to planters. I trust he will eventually make them public. So far the plants are growing well and seem free of disease than plants adjoining, not treated in the same way. If we can get plants that will produce Arabian coffee, I have no doubt that the produce will be more valuable than Liberian coffee. The cultivation of Liberian is now extending rapidly; and the price at the present time is only some 20 per cent. less than Arabian; but this is probably due to the very small supplies of coffee now obtainable, and when stocks again begin to increase buyers will, as of old, make great distinctions in quality; and the comparative value of better and poorer grades of coffee will probably recur. The cost of cleaning and preparing Liberian coffee is also very much greater than Arabian. I think all planters should try this grafting experiment on a fairly practical scale. The result of isolated cases will not be accepted; while, if it is going to succeed, it is well that every one should practice the operation of grafting betimes, so that he may not be behindhand in the supply of plants. The cost of grafted plants may seem very great as compared with ordinary nursery plants. The plants themselves, as two will be required for each pit, will be double old rates: while it will take some time for a good nursery coolly to manage even ten grafts in a day. But, even if the cost of these grafted plants comes to £100 per acre, the extra outlay will be well recouped if healthy plants are secured. I would recommend that the coolies are first taught to cut, notch, and fit together branches of jungle trees of same size until they get proficient; the soft inner bark of many of the *Naur* trees, will form a good bass for binning the grafted trees together. If the air is kept out with good bass. I do not think any claying will be necessary.

J. W. MINCHIN.

—bid.

A UNIVERSAL TEA CO.

By the "Teutonic" just arrived from New York there has come to London Mr. Elwood May, the President of the American Ceylon Planters' Tea Company. Shortly before leaving the States, Mr. May wrote to the Ceylon Association in London

stating his intention of visiting England and placing before the Association his views as to the most profitable course to be pursued with reference to the future disposition of your teas. That letter has been shown to me, and I gather from it that what Mr. May desires to establish is the favourite Yankee method of "cornering." My own judgment upon his proposals to that effect is that they are of a wholly impracticable character. His ideas are quite of the modern American type, but the expression of them would certainly indicate that Mr. May is wholly unacquainted with the past history of the Ceylon tea trade, or of the firm footing obtained by the numerous distributors already working in the United Kingdom and elsewhere.

It is apparent to me that, if that gentleman had been acquainted with the facts as to that history and as to the present position, he would never have ventured upon the propositions set forth in his letter to the Ceylon Association. On receipt of this it was forwarded for the perusal of one of the most prominent gentlemen connected with the Ceylon planting enterprise. He returned it to Mr. Leake with the single word of comment of "moonshine," and that definition appears to me accurately to express what will be the general opinion as to what Mr. May has proposed. His letter opens in a very "high-falutin" style, and enters upon discussion of the large prices which cornering operations have obtained for a variety of products. More especial mention is made of the sugar grown in Cuba. Briefly stated, Mr. May suggests the formation of a Universal Tea Company having its headquarters in Colombo itself; that every Ceylon planter should dispose of his teas to this Company alone and that these should receive distribution throughout the world with the Company guarantee of purity.

Now it was something of this character that was proposed and discussed when first your teas began to make a name. The idea had at that time much to recommend it. It was at all events at such a date feasible. But even then difficulties were apparent which prevented the idea from being acted upon. It argues, we think, a very limited acquaintance on the part of Mr. May with all that has occurred since such an idea was broached that he should, at this comparatively late period in the history of Ceylon tea, deem such a scheme to be possessed of the least practicability. Mr. Mitchell, of Messrs. Darley, Butler & Co., which firm is the London Agents of the American Tea Company, was prepared to receive Mr. May on his arrival in London. We have not heard what opinion that gentleman has expressed upon the letter of the New York president, but we can hardly think he will hold any other but that which is generally entertained and has been above sketched out.

The simple fact that Mr. May deprecates and wants to abolish open competition in Ceylon tea indicates that he is preparing to "tilt at windmills." He will scarcely have been in London a single week before he will be convinced of the hopelessness of "cornering" the trade in Ceylon tea. He will find hundreds of established agencies all working independently of each other, and all on the principle of the widest and freest competition, which it would be hopeless for any Syndicate, however gigantic, to uproot. It is to be feared that Mr. May will suffer severely in his *amour propre* when the fallaciousness of the proposals of his letter is exposed to him; nor can it be anticipated that a gentleman who has shown such a great degree of unacquaintance with the course of the Ceylon tea trade in England can,

by any measure he may propose, beneficially affect the prospects of your planters as regards the trade outside of America.—London Cor.

CEYLON TEA IN EGYPT.

Messrs. Edgar Kirby & Co., of Alexandria have received from the Ceylon Tea Growers' Association a sample of tea very similar in appearance and practically of about the same value as a small quantity of tea from the Gartmore estate in Ceylon which was sold a few weeks ago in London at the fancy price of 10*l.* 12*s.* 6*d.* per lb.

The small sample received by Messrs. Edgar Kirby & Co. is a sample of tea from one of the estates of the Ceylon Tea Growers' association of which a small consignment has been forwarded for sale in London but, of course, it is impossible to foretell wherever buyers will again be found willing to pay price of upwards of 13*s.* per ounce. The tea in question is of marvellous fragrance and Messrs. Edgar Kirby & Co. will be pleased to submit the sample for inspection to any connoisseurs who may favour them with a visit at their offices.

We may also mention that Messrs. Edgar Kirby & Co. are now daily expecting a further consignment of new tea from the last crop grown on the Ceylon Tea Growers' Association's estates.—*Egyptian Gazette.*

VALENTYN'S HISTORY OF COFFEE.

[This might as well appear in the *Literary Register* before it is lost altogether.—Cor.]

"Coffee which makes the politician wise
And see thro' all things with his half-shut eyes."—POPE.

TO THE EDITOR OF THE CEYLON TIMES.

Dear Sir,—I send you for publication, if you think it would be generally interesting, a translation from the Dutch of Valentyn's history of Coffee. It would be perhaps necessary for me to mention, that Valentyn lived in the early part of the 17th Century. As a Dutch Minister of the Gospel he visited a great many parts of the world, and the knowledge and information he thus obtained of those countries, he has given us in five folio volumes, entitled "*Keurlyk Beschryving van Choromandel, Pegu, Aracan, Bengal, Mocha, &c., A. D. 1727.*" There is also a history of Ceylon comprised in the above work which I believe has not yet been translated into English; but it is however when treating of the affairs of Mocha, that he enters into a description of that country and gives a lengthened account of the Coffee tree and its uses. For the sake of convenience, I have divided the entire chapter into several parts, which I will send you from time to time. It will be seen that Valentyn has taken great pains to bring together all the information he could obtain on the subject; and, on the whole, a great many curious facts and circumstances are mentioned by him, in respect of Coffee, and Coffee bibbers, which are deserving of notice, and would no doubt afford some amusement to the public in general, and your up-country Coffee planting friends in particular. With these brief remarks, I subjoin in my first instalment, hoping your readers would excuse any inelegancies and incorrectness of expression I may have fallen into, in endeavouring to preserve the spirit and give the exact meaning of the original.

I am, dear Sir, yours very truly,
P. B.

August 16th, 1856.

THE COFFEE TREE AND ITS USES.

From Valentyn's Description of Mocha.

General description of the Coffee Tree—Its cultivation in Amboina &c.—The Arabian mode of planting—Derivation of the word Coffee—Its preparation for

use—The Author takes tea with an Indian Minister for the first time in his life, and finds it no better than Hooy-water (infusion of Hay) and, three years after, in 1684, takes another sip of the same beverage in Rotterdam.

"Inasmuch as Coffee has now become the principal Article of Commerce, and has drawn so many strangers to Mocha, it would not, I think, be an unprofitable task were I to attempt a description of the Tree, its fruit, and of its use.

There is a striking difference between the tree grown in its native soil in Arabia, and those grown in Batavia, Amboina, and elsewhere from plants obtained from Mocha.

In Arabia the Coffee trees attain a height of from 10 to 12 feet, and is from 4 to 5 inches in diameter; but is tender and weak, though easy of being transplanted.

In 1707 I took six plants with me to Amboina,* of which I retained two, and presented the rest to some of my friends there.

From these plants, and a few others which were brought there a year previously by the Governor of the place Mr. Vanderstel, all the gardens of Amboina were in a very short time well supplied. In the third year after the planting of my trees (which were but a year old when I brought them with me) they yielded more fruit than I and many others had occasion for, whilst the number of trees in my garden did not amount to more than sixty. I found the fruit very tasteful and delicious and not quite so insipid as that of Batavia, and since this period their sprung up a great many more plantations carefully laid out by the Natives in Amboina and beyond it.

With the view of giving the Trees a thick stem, I cut them short, not allowing them to rise higher than a large Albornyn, scarcely 5 or 6 feet high. By this means they became very productive and yielded an abundant crop.

Their stems assumed the thickness of about a man's arm, while the bark partook of a light brown colour and a somewhat rugged and uneven appearance, the leaf resembling that of the Citron tree though not quite so sharp pointed and thick and the colour of a dark green (*donker groen.*)

I made a trial with one of the Trees to ascertain whether it could be made to rise higher in Amboina than on its native soil, or at least, to know to what height it could be made to rise, when I found that it attained a height of about 12 feet, losing in a corresponding degree in girth of stem which was scarcely 5 or 6 inches in thickness, so that it was not equal to sustain the weight of its heavy tuft (*Kruin*) with a goodly load of fruit, in fact the tree seemed bent nearly to breaking, and would, perhaps, have snapped for the slightest breeze, but for the precaution I took to prep it up.

This tree might also be said to resemble a young apple tree of 7 or 8 years. It looks always green, never shedding all its leaves at one and the same time and it blooms, and bears fruit nearly all the year round, ripe and green berries being always found on the trees.

The nethermost branches have a tendency to shoot upwards, presenting sometimes the appearance of a pretty tuft or crown.

To such a branch there are generally from 10 to 12 leaves, two by two (*Twee aan Twee*) at a small distance from each other; the blossoms which are white assimilate with the Jessamine and impart an agreeable odour. The flower consists of five little petals which sprout from between the stem and the roots of the leaves; from this proceed the fruit, which in size can be compared to a *Coernolie* (Cornel-fruit). It is first green, then almost red, and eventually assumes a dark brown colour, when it is in a fit state to be picked and exposed in the sun to dry.

It has an outer black husk, or parchment, which, when shelled, two idle beans are found closely joined to each other and enveloped in a thin pellicle (*zie,*

* One of the Moluccas or Spice Islands.

men de boon twee-ledig tegen een in een vlesje bestoten leggen.) Of the pellicle more anon.

There are some who say that the fruit is edible when ripe, and that the substance which is found adhering to the kernel is very tasteful and palatable, but I have never tried it, the riper the fruit, the tougher and harder the bean, which when properly dried is in a fit state both for exportation and use.

The beans are not however eaten, but are planted and they spring up in 2 or 3 weeks and become fine saplings in a year; and in the course of 3 or 4 years more they get to be trees of about 6 feet high; they are then maintained at this height by constant pinning and by not permitting them to rise higher they bear most luxuriantly.

The Arabians plant them generally at the foot of some mountains and in the vicinity of damp and moist nooks (*hoeken*) for the plants require moisture and the shade of trees, especially when young, and hence, they have watercourses and ditches by which they now and then afford moisture to the trees, and continue to do so, until the fruit is fully matured and about to drop down, when they leave them to dry on the trees.

When the trees are not properly protected against the scorching rays of the sun, the blossoms wither and yield no fruit, and hence it is that the Arabians are wont to plant them under some high and shady trees, in rows.

Had I been so well informed in all matters relating to the culture of these plants whilst I was in Amboina, as I am now, I believe I might then have brought them to greater perfection.

The name of this fruit (or more properly of the beverage we use) is not Coffee with the Arabians, but *Caweh*, and with the Turks—*Caweh*, which some assert is an Arabian, and others a Turkish word, derived from the verb—*Cahcewah* (signifying an aversion to meals) it is likewise a word used by the Arabians to denote wine.

Now to understand how the coffee has so easily acquired that name through a bad pronunciation, it is to be recollected, that a little point or dot when placed over the *w*—*wanco*, changes it to.....cafeh (as the French call it,) and which in process of time the Hollanders designated coffee.

By *caweh*, the Arabians understand in the first instance Wine, and all such liquors as inebriate; secondly a beverage made from the Coffee shells or husk, and thirdly a drink prepared from the beans themselves, which beans they call *Bunn*.

They say, that this fruit grows nowhere else but in their country. Experience has however taught us that it is not so; but what they meant to say is, perhaps, that Coffee grows nowhere better than in their country.

Whether this plant is the natural production of Arabia or introduced there from some other country remains a doubtful point, for there are some who assert, that it was brought there from Ethiopia, and others again that it was carried thence to Ethiopia. The latter supposition appears the most probable, since Mr. Ludolf and many others in their account of Ethiopia say nothing of coffee, for had the plant been indigenous to the country they would no doubt have made mention of it.

Coffee is nowhere procurable in the whole of Arabia except in Yemen, and even there, only in the towns of Betelfagi Sanaa and Salhani. Betelfagi lies 35 miles from Mocha, and yields the best Coffee, and it is from this and the intermediate places between the mountains, that most of the Coffee of Turkey, Egypt, &c. is purchased.

I need not here mention how the common Coffee is prepared, for it is now so well known even to Pedlars (*Kraavers*) who go about from place to place that we need not take any lesson in this particular from Coffee dealers.

The use of this beverage has become now so general in our country that our maids and amstresses could not be without it in the mornings, for they could not manage to tread their heels without

* Arabic.

some stimulus of this sort (of the draad wil door het oog vande naald niet.) I remember very well, that nearly 40 years ago, the use of Coffee as well as Tea was almost unknown in this city; the Messrs. Vander Brouk, and D. D. Leonards (who have been in India) were the only persons who partook of either. But both Tea and Coffee have now become important articles of trade.

I well recollect too, that it was in 1681 that I, for the first time in my life, took Tea with an Indian Minister, and could not then well conceive how it was, that people of judgment and understanding could take delight and indulge in a drink which tasted no better than *Hooj-water*, (an infusion of Hay); nor was I less surprised when, in 1684, I partook of a cup of Green Tea with a gentleman at Rotterdam, which cost him 80 Guilders the Pound; but then I knew nothing of Coffee, nor ever drank it. It has since however been introduced here, and it would appear, that it had for some time before been known to the English also.*

PART II.

How the Turks and Arabians prepared their Coffee—How they made a beverage from it, something like All-opp's Pale Ale and drank it.—How the Hollanders and John Bull attempted Coffee planting and failed, and how the French succeeded beyond their expectations—The Pharmaceutical Garden of Amsterdam and the solitary Coffee plant which grew there which a Right Hon'ble Magistrate of that City laid at the feet of Louis the XIV. of France as a very rare natural curiosity.—What the great Arabian Physician Aboe Ill Sina and Bendjalah an eminent Physician of Bagdad wrote about Coffee, and in what manner it was discovered, that the former knew nothing about it—Petrus Bellonius.—The great Botanist and Arch-Physician of Padua, Prosper Alpinius, and his Latin Treatise on Coffee, mummies, and hieroglyphic—The fanciful Petro Della Valle, who confounded Coffee with the Nopenthe of Homer, and the brave Nairon who bullied him and set him to rights on that point by shewing him that Coffee was Coffee—The Italians import Coffee from the Levant, and the same Faustus Nairon who understood all the known and unknown languages of the East and West writes a big book in Latin about it—A French Treatise on Coffee by Sylvester de Four a Merchant of Lyons—lastly of certain Shepherds who used Coffee as an antidote against sleep, and of certain Monks who kept their eyes open during their nightly vigils, by the use of the same stimulant.

The Turks and Arabians seldom drink their Coffee in the manner we do, unless it were amongst the common people; but persons of respectability and rank generally drink the kingly Coffee, or Coffee-Royal.

They never prepare their Coffee with the beans, but with the bark or parchment only, to which they add a fourth part of the pellicles in which the beans are enveloped, and all those who partook of this liquor (which resembles English Beer) say, that for delicacy and pleasantness of taste, it far surpasses the common Coffee.

Like the Hollanders who attempted Coffee cultivation in Batavia, the English tried the experiment in Madras, but with little, if not less success, which induced them to abandon it. The French had likewise attempted the same thing on the Island of Mascaroigne in 1722, and is said to have been so successful, that 26 pounds of Coffee was put on board of the "Tritou" for the reigning Duke.

An attempt was likewise made to cultivate Coffee in the Pharmaceutical Garden of Amsterdam, where they succeeded in raising one plant which the Right

* It would seem that a Greek servant named Pasqua who was brought into England by Mr. Dan. Edwards, a Turkey Merchant, in 1652, to make his Coffee, first set up the profession of Coffee-man and introduced the drink into this Island.

Vide Ency. Britannica, vol. 5, page 123.

Hon'ble the Magistrate thought fit to offer to Louis XIV King of France, in 1714, as a singular production of that country, since which however many more plants were grown in the same garden.

It is a matter of much surprise indeed that not one, amongst the Arabian or Persian writers in their accounts of the plants and shrubs of Arabia, had ever made the least mention respecting the Coffee tree, its fruit or its use, altho' Turkey, Arabia, Persia, and India were believed from a remote period to be Coffee-producing countries.

There are some, however, who assert, that the great Arabian Physician Aboe Ill Sina, al as Avicenna, and Benjaazlah his contemporary, likewise an eminent Physician of Bagdad, have in their work which treated of the Plants of Arabia, said something of the Coffee tree, and that the former tho' an Arabian has erred with respect to its name and fruit, by describing it as a root available for medicinal purposes, and giving to it the name of Buun, Buu, or Bunk; but it is evident, that he only spoke of the Root Bunk, which is quite another thing and different from the Buun of the Coffee tree.

It is equally surprising that none of those renowned Travellers who visited Ispahan in Persia, Constantinople in Turkey, and Grand Cairo in Egypt, or those who visited Mecca (which lies so close to the Coffee land-) or even those who visited Yemen in Arabia Felix have made any mention of the Coffee tree, or its fruit.

Nor does Peter Bellonius who travelled in the Levant and the East from 1546 to 1549 say anything of the Coffee, altho' he has written with much care and precision an account of the different varieties of plants of Egypt and Arabia.

The first European who made some allusion to Coffee, was that celebrated Professor and Arch Physician of Padua, Prosper Alpinius, one of the greatest Botanists of his time, who accompanied a Venetian Consul to Egypt in 1580 and remained there for 3 or 4 years, and subsequently published a very accurate account descriptive of the Plants and of the Medical treatment in that country, wherein he spoke also in praise of Coffee, and stated, that he first saw the plant in the garden of one Ali Bey, a Turk at Cairo, and that the bean was then called Bun.

This work which was in Latin was printed and published at Venice in 1592, and was subsequently reprinted in 1638 at Padua; and in 1640 another edition of it appeared with some observations of Vellingius an eminent Italian Physician who had been likewise in Egypt, and was thus competent to undertake a revision of the work, but he states that he found no such tree in any one of the gardens there.

Petro Della Vale, the traveller, in 1615, made mention of Coffee too, in the 14th Chapter of his work. He all along supposed, that the nepenthe of Homer (a remedy against sadness which Helen obtained from Egypt) was nothing else than Coffee taken with wine, but this opinion was shewn to be erroneous by Nairon in a neat little work he wrote on Coffee.

In 1626 Chancellor Bacon had likewise made some mention in his works respecting Coffee, though it was then wholly unknown in England.

But subsequently to this period, the Italians imported Coffee from the Levant, and it was then, that Faustus Nairon, a Maronite and Professor of the Oriental or the Chaldean and Syriac languages, at Rome, got a small book printed in Latin, the first of its kind, which treated of the use of Coffee. This book appeared in 1671, but it was evident that the author labored under some misapprehension in regard to the main points. Mention is made of this little work in a Diary of the Italians which speaks of the learned men of their time.

The next account, however, on this subject was written in 1671 by one Philip Sylvester De Four, a Merchant of Lyons, who first of all translated a certain manuscript on the use of Coffee, Tea, and Chocolate into the French language, and published it at Lyons.

We find this circumstance likewise mentioned in an extract from the *Journal des Savans* of 28th January 1675, wherein we find also that Coffee was

known to the English 20 years before the French had any idea of it.

It should be observed, however, that the writer of this manuscript was not fully acquainted with the proper Coffee lands, inasmuch as he had made a great mistake in supposing that it grew about Mecca, for Mecca lies at a distance of 70 miles from the-lands.

Coffee having become somewhat better known at Paris, Lyons, and Marseilles, Du Four wrote a little work on the subject with special reference to what appeared in the *Journal des Savans* of 28th January 1685. This work was printed twice in Lyons in 1684 and 1688, and once at the Hague in 1685.

Mr. Baile, who, in his *Nouvelles de la Republique des Lettres* introduces an extract from this work, as also the Diary of the learned of Leipsic of March 1686, speak with much esteem of the Author.

This work was printed in 1685 in the Latin and German languages also, at Bautzen or Budissen in Saxony; the German being a translation from the Latin by Spon.

This work which consisted of 13 Chapters contained all that was ever known respecting Coffee.

There was afterwards another correct account given by Faustus Nairon to an Abbot of a certain Monastery, from which it appears, that Coffee had been in use with a certain Shepherd as a preventive against drowsiness and sleep whilst he kept watch over his camels and other cattle in the night. This piece of information induced the Abbot to administer the beverage to his Monks as an antidote against somnolency, whilst they were engaged in their nocturnal religious duties, and the thing succeeded to a miracle.

It seems to me as very probable, that Coffee or something like it was not unknown to the Ancients.

(To be continued.)

THE MAGAZINE OF THE SCHOOL OF AGRICULTURE for May is out, and the number provides both varied and useful reading. The contents include articles on the fatty and oily matters found in plants,—especially Ceylon plants,—their character and composition, refuse substances useful as fertilizers of the soil, cultivation of manice, and further instalments of indigenous food products of Ceylon, and agricultural literature among the ancient Indians. Another interesting letter in the condition of agriculture in the north of the island is contributed by Mr. R. Mutiah; and occasional and general notes fill up the rest of the number.

CEYLON AND INDIAN TEA COMPANIES from the subject of some comparative criticism in the *H. and C. Mail* which we reproduce on our last page today. The critic wants fuller information in the Reports and Accounts of Ceylon Companies; but he cannot get over the splendid results in the case of the C. T. Plantations Company. We are glad to see how entirely this Company has adopted the rule, as far as possible, of buying up tea land to work through their existing factories. As a foil to this very prosperous concern, there comes the old Hunasgirya Company under its new tea dress. It is uphill work with such old coffee plantations; but the prospects now are certainly very satisfactory for the Hunasgirya Company.

LINNEAN SOCIETY.—At the meeting of the above society, held on Thursday, March 5, Prof. Stewart President, in the Chair, Captain T. Keene was admitted; and Messrs. T. B. Cato and E. Norman Langham were elected Fellows of the Society. Mr. D. Morris exhibited a dwarf species of *Thrinax*, which he found growing plentifully in the Island of Anguilla, West Indies, and which was apparently undescribed. Mr. T. Christy exhibited the fruit of some undetermined species of tree, which had been introduced into commerce by the name of Monchana, but the origin of which had not been ascertained. On behalf of Miss E. Barton, Dr. D. H. Scott gave the substance of a paper communicated by that lady, and entitled "A Morphological and Systematic Account of the Fucaceous Genus, *Turbinaria*."—*Gardeners Chronicle*.

THE NORTH-EAST MONSOON GOING OUT
LIKE A LION: TORNADO, HAIL
AND RAIN.

The distinctions of cyclonic storm, true cyclone and tornado demand attention in noticing meteorological phenomena. Cyclonic storms are common enough in Ceylon, especially during the South-West monsoon. Cyclones, which are rare, occur generally in the North-East monsoon and are almost confined to the North and East of the island. Tornadoes, which are cyclonic in their character, of extreme violence, but of limited extent and short duration, occur more or less frequently all over the island, but they have so rarely visited the Nanuoya division of Dimbula, that special interest attaches to the short but sharp experience to which the upper division of Abbotsford (elevation of factory 5,700 feet and bungalow 50 feet higher), was subjected on the 7th instant. The accounts which have reached us of this forcible phenomenon are as follows:—

Abbotsford, Nanuoya, May 8th.
Yesterday afternoon at about 2.30 it got very dark, and suddenly there was a bright flash and a crash immediately accompanied by hail and a high wind which blew a big wattle right on to the ladies' bathroom, bending and breaking the pipe, smashing the fence all to pieces, and wrenching 20 sheets of roofing from our factory, and blowing them clean over the whole building into the deep ravine below the cart road: six sheets attached to a reeper all went in one piece. Fortunately no further damage was done and no one was injured: the whole storm only lasted about 40 minutes.

Another account:—

We have had very peculiar weather since you left and have not yet seen the last of the N.-East monsoon. Tuesday was a lovely day with a pleasant N.-E. breeze, but no rain. On Wednesday it poured at the Lower Division where the rainfall measured 1.84, but at the Upper Division where it would be far more welcome there was only a fall of 90 cents

Yesterday (May 7th) there was a terrific squall about 2.30 p.m. which blew down several trees and carried away some 30 sheets of roofing iron from the S.-W. corner of the large withering house. The whole roof would have gone had the wind continued, but fortunately it was all over in a few minutes. The three-inch reeper to which the iron is fixed was smashed to atoms and the iron carried right over the factory and landed on the hillside towards Nanuoya. The reeper had held on some half-dozen sheets which would weigh fully a cwt., and yet they went clean over everything like the single sheets; so you may imagine what force the wind had.

I was of course one of those whirlwinds which we occasionally get towards the latter part of the N. East monsoon.

The rainfall at the Upper Division was only 41 cents but at the Lower, when it was accompanied by some hail, 1.10 fell within 20 minutes; and has no doubt done some damage to roads and drains. I hope this may be the last of the N.-East.

The occurrence of hail, the formation and deposit of which was, no doubt, due to the action of electricity, was a marked feature in this tornado; but it must have been confined to the vortex, as no mention is made of damage to the tea. Another curious circumstance is, that the rainfall should have been so much less at the centre of force than in the river valley 1½ mile distant and 1,000 feet lower in elevation. A memorandum furnished to us is as follows:—

Upper division May 6th '60 in.	Lower division	1.83 in.
" " 7th '42 "	"	1.10 "
		1.02 in.
		2.93 in.

nearly 2 inches difference, in favour of the lower division.

Why all the whirling wind should concentrate at the higher altitude, and the rainfall, due, no doubt to its disturbing effect on the atmosphere, should, in such large proportion, sweep down the distant and much lower river valley, is a curious problem. The significance of the remark that the rain would have been more welcome above is due to the fact that the factory and dam were constructed there, (unfortunately, we now feel), as a time when tea grown on the upper fields, was deemed merely a subsidiary product to coffee of which there were 320 acres. Like so many others, those interested in the estate refused to believe that coffee was fatally stricken until conviction was forced on them by crops and bushes dwindling away. The position of the factory has the advantage of being only two miles from the Nanuoya station, but had it been realized that tea would entirely supersede coffee, a site lower down would have been chosen where copious streams pour down in waterfalls. Statements like this may qualify criticism regarding not only the particular case, but other similar ones. It is hard that the aid of a powerful steam engine should be required on a place where water is so abundant, (at 5,000 feet and under,) that the Tamil name is *Aruvi totam*, "the Waterfall estate." It may be added that this experience of a tornado at the high elevation is unique. By all the laws of meteorology, it ought rather to have rushed through and revolved in the river valley. But who can understand and direct the course of clouds surcharged with electricity or calm the raging wind awakened into abnormal energy by the effects of the subtle and often deadly power or influence which we popularly call lightning? Happily, in this tropic island, though exposed to both monsoons, we know but little of the fiercely cruel and frightfully destructive storms, before which life and property are alike swept off the earth, in the river valleys and on the level prairies of "the Far West."

Since the above was written, the following special telegram from Nanuoya has come to hand:—

THUNDERBOLTS FROM A BLUE SKY.

(Special Telegram)

NANUOYA, May 9, 9 a.m.

Yesterday afternoon at 2.30 p.m., two balls of lightning fell apparently in a garden here, accompanied instantaneously by a fearful crash of thunder out of a perfectly quiet sky. There was a slight flash about 4 p.m., but no rain fell all day.

NOTES ON PRODUCE AND FINANCE.

THE ADULTERATION OF PRODUCE.—At a meeting of Metropolitan grocers held on Monday at the Cannon Street Hotel to discuss the question of trade organisation, Mr. D. R. Harvest, in the course of a speech, proposing a resolution for appointing a committee to carry out the objects of the association, said that an association was sadly wanted to protect the trade as much from the practice of dishonest methods within their own ranks as from outsiders. Prosecutions, he said, were enforced for the adulteration of food stuffs and drugs, and the retail dealers were often entirely without the means or knowledge of ascertaining whether what they bought to sell to the public was pure or otherwise. It was known that an article called pepper had been offered in the market which did not contain one per cent of pepper. On another occasion, a whole cargo of pepper which had lain for some time in a wreck at the bottom of the Thames washed with London sewage, and which stank abominably, and should have been destroyed, was put up and sold to the trade. They knew, too, that the Chinese made little clay balls exactly resembling pepper pods, and these were plentifully intermixed with pepper coming from that sunny land. An association would help them to

guard against these and other rascally practices and enable them to keep dishonest men out of their trade, for retail and wholesale dealers' best interests lay in that direction.

MORE TEA DRINKERS.—The growth of temperance and the increasing consumption of tea are facts which must be taken together. When the labouring classes renounce beer they usually take kindly to tea. The two last reports issued by the Registrar of Friendly Societies show that the Independent Order of Rechabites—the well-known temperance friendly society—is also rapidly increasing. The recent rate of increase is no less than 10,000 adult and 5,000 juvenile members per year, a degree of accession probably unprecedented. The total membership is now over 100,000 adults and 52,000 juvenile members.—*H. and C. Mail*, April 17th.

IMPORTANT APPOINTMENT TO ABERDEEN MEN.

We understand that the Peruvian Corporation (Limited), of which Sir Alfred Dent, K. C. M. G. of Messrs Dent, Brothers, & Co., merchants and commission agents, Old Broad Street, London, is chairman, have just arranged with Mr. Arthur Sinclair, Meadowbank, Cults, with whom is associated Mr. Alexander Ross, to undertake a piece of very important survey work for them in Peru. To the general reader it may be necessary to explain that, in consequence of grave financial difficulties into which it had got, the Government of Peru ceased to pay interest on its public debts (amounting to about £56,000,000) several years ago. And after protracted negotiations, a powerful British-Peruvian Corporation came to the rescue, headed by Sir Alfred Dent, who had done excellent work in connection with the British North Borneo Company of which he is still a director. Amongst the many concessions made to this company by the Peruvian Government, one was the right to select and utilise some 10,000,000 acres of land in the valley of the majestic Amazon river. The commission that has now been entrusted to Messrs Sinclair and Ross, on very handsome terms as to remuneration and otherwise, we understand, is to fix generally the locality for this very large selection, with a view specially to the adaptation of the land to tropical agriculture. For this purpose situation, climate, and the general capabilities of the prevailing soils will all have to be carefully noted and reported upon to the directorate of the Peruvian Corporation; and the work, including the passage to and fro, is expected to occupy not less, we believe, than five months. While it is not a little gratifying to find two local men selected, and appointed practically on their own terms, for such an important mission, no one who knows the career of either will doubt the wisdom of the choice made by Sir Alfred Dent and his co-directors of the Peruvian Corporation. Both have had ample experience of tropical agriculture as planters in Ceylon. In the case of Mr Sinclair, the fact of his having been bred to the occupation of gardener, with a good knowledge of practical botany, enabled him at once to take to the work in which he was engaged for a score of years, or thereby, in the "spicy isle" with the greatest advantage; and for a good many years he acted as general superintendent of a large number of coffee plantations with the highest efficiency, his duties in that way giving him an acquaintance with the conditions of tropical agriculture, generally, as well as with a large part of the area of Ceylon, such as few men have had opportunity of acquiring. And in addition to this Mr Sinclair spent over a couple of years in Australasia, chiefly in Tasmania, where he had further opportunities of observing sub-tropical agriculture. Mr Ross,

whose Ceylon experience as a successful planter also extended over a long series of years, and who goes to Peru on the same terms as Mr Sinclair, is a native of Stonehaven.—*Aberdeen Free Press*.

BARK AND DRUG REPORT.

(From the *Chemist and Druggist*.)

LONDON, April 16th.

ARECA NUT.—For 5 bags good quality the very high price of 30s per cwt. was paid today. This drug is exceedingly scarce.

COCA LEAVES.—Seven packages of Ceylon and Java leaves, both equally badly harvested, dark mould and dull, offered without reserve, no higher bid than ½d per lb. being obtained; this was refused, as it was stated to be insufficient to cover the charges. In New York holders of Huanoco leaves (of which an arrival of 5,000 lb. took place towards the end of March) are very firm, and quote 1s 6½d per lb. c.i.f. for fine dark green. Light green Truxillo (Maranon) leaves may be had at 1½d per lb. c.i.f.

KOLA.—Of about 35 packages, only 2 bags mouldy grey dried West Indian sold at the high price of 6d per lb.

QUININE.—No business is reported on the spot this week, second-hand German bulk being quoted at 10d sellers, and 10½d buyers. At today's auctions, however, 4,000 oz. of Whiffen's brand, warehoused in March 1885, sold ½d 11 to 1 ½d; and 12,000 oz. of Zimmer's quinine, warehoused in 18-8, realised 9½d per oz.; this beating the previous lowest quotation on record. Howard's quinine is quoted by the makers at 1s 2d to 1s 3d in bulk, and 1s 4d to 1s 5d for bottles. The quotation for New York comes at 20 cents per oz. A sale of 10,000 oz. German bulk was reported on Tuesday at 10½d per oz. The arrivals of quinine in New York are falling off somewhat as compared with last year. From January 1st to March 31st they were:—In 1891, 870,520 oz.; 1890, 1,078,400 oz.

MANA GRASS EXPERIMENTS—OPIUM, MALARIA AND QUININE—THEAFOAM—ZAMBESIA COMPANY AND MR. H. S. SAUNDERS—CROCODILE, IGUANA, SNAKE AND BUFFALO SKINS.

London, April 24.

Twenty-two hundredweight of mana grass has just reached the Wrightson-Stanley Syndicate from Ceylon. A letter by Dr. Norman Evans has been shown to me wherein that gentleman strongly recommends that laboratory investigation should first be conducted with samples of this fresh shipment before the expenditure of factory-treatment be incurred; for, Dr. Norman Evans has written "if it is as harsh as the last large delivery, it would be a waste of money to try and boil it with water alone." Some delay may therefore occur before it will be possible for me to write you as to whether our hopes of the ultimate utilization of mana grass for coarse papermaking are to be fulfilled or not. It is unfortunate that in the interval which has passed since I reported the experiments conducted at the Poyle Mills, the proprietor of those mills, has had to wind up its concerns. The experience Mr. Ibotson had gained on that occasion would have otherwise been of great value in the further sets of experiment we hope to be tried; although no doubt other mills exist at which these can be satisfactorily carried out.

The following extract from the *Echo* contains prominent reference to the letter which Mr. John Ferguson addressed to the Anti Opium Society on the question which has lately received such disagreeable prominence in the House of Commons. We are wondering if the initials signed to this communication, W. W. G., can be a misprint for W. H. G., and if it can be due to the pen of Sir William Gregory. You may, however, recognize the individuality of the writer under the initials given.

(13,003) OPIUM.—"Chesham Jacko" will find a genuine blend of quinine taken in place of the opium will remove in a short time the depressed, weak feel-

ings, and ultimately remove entirely the craving for opium. Moreover, the strong tonic principles of quinine will soon rebuild his constitution, and restore life and vitality to his system, which has no doubt been somewhat undermined. There is a splendid blend of quinine known in the trade as "Quinine Pick-up." I cannot give him the name of the makers, but no doubt any respectable firm of medicine agents would direct him. It is reported that 1,500,000 deaths take place annually throughout India from fever alone, causing a heavy demand for some drug to allay the feverish sufferings, and opium is freely resorted to in numberless cases, the use of the article being thus commenced. The fact of so many lives being lost each year by fever is a disgrace to civilisation, when it is well known that quinine is the finest antidote and almost invariable cure for fever and ague. A missionary recently home from India informed me that it is fearful to see the sufferings and fatal results from fever, and that he had found his religious work considerably assisted by alleviating the Indians' sufferings from a supply of quinine forwarded to his mission. Some time since, Mr. Ferguson, in a letter to the Anti-Opium Society, described the prevalence of opium-craving in many parts of the world being due to a low type of fever, especially in China. He considered the main cause of the craving arose from people living in low malarial localities, and suggested that quinine removes the craving and acts as a substitute. Touching the opium question, an authority writing in the year 1880 made the following statement:—"From the vast tracts of country in China where rice is cultivated fever is never absent, opium, being employed as the medicine easiest to be had, and cheapest. He hoped if quinine became cheap enough to compete with opium, that it would produce a revolution in the Chinese consumption of the two drugs. By this process a solution would be found for the dangers, and uncertainties of the large opium revenues of India, and for the perplexing moral questions connected with it." At a time the above was written (in 1880) the price of quinine was practically prohibitive—viz., 11s to 11s 6d per oz., but today it can be freely purchased at 10d or 10½d per oz for foreign brands, and 1s 4d or 1s 5d per oz. for English, being almost the very lowest prices ever known in the history of the article.—*W. W. G.*

My reference to the foregoing matter suggest me to allude here to the course which has followed Sir John Pease's snatched division in the House of Commons on his motion for abolishing the Indian Opium Traffic. Doubtless the complete surrender of that gentleman—which was in accord with my own prediction—will have been wired to you by Reuter, and you will have made your own comments upon it in advance of your receipt of my former remarks on the subject. It will, however, interest you to have some details as to what passed in the House on the occasion of this surrender, to which we here attach much importance on account of the bearing it may possess on the somewhat similar case of the demand for the surrender of your paddy tax.

Some short time back you were told by me of the new drink manufactured from tea and called "Theafoam." A company for the manufacture and sale of this has been just registered with a capital of £10,000 in £1 shares, the declared object of "Theafoam, Limited" being to "manufacture and sell preparations of tea and coffee, aerated tea and coffee, aerated waters, &c." With this letter is sent a copy of the prospectus of the new company, and you will find with it copies of many testimonials received which include one by Cardinal Manning, another by the well-known Dr. Richardson, and by many other persons associated prominently with the Temperance cause. The list also includes an extract from the *Tropical Agriculturist* giving the opinion expressed by myself after testing the new beverage. All tea growers must wish the new company a success.

After receiving the *Observer* containing my letter referring to this processes for preserving crocodile leather and that containing your editorial on the same subject, I paid a second visit to Messrs. Toulmain & Gale. In the course of conversation the question was put by me whether the skin of the cabragoya would make good leather. Mr. Toulmain replied that he very much doubted it, as they had tried iguana and chameleon skins and found them to be worthless. He said that many of these larger lizard skins had really two layers, the upper one of these having quite a steely character, so much so, indeed, that it would spring away from the under layer when touched by the paring knife. He told me also, that, as with the hides of commerce, the quality of crocodile skins varies considerably. Some skins in the same shipment have a very fine quality, while others prove to be so coarse as to be unfit for their—the finest—uses. He further said that all the Russia leather his firm so largely works up is prepared from the hide of the Russian buffalo, and that the skins of that creature are often worth four times as much as those of the buffalo in any other part of the world. I told Mr. Toulmain that I saw the Ceylon buffalo hides scarcely ever fetched the price that Italian and Mexican hides obtained, and he replied that he thought it very possible that the coarseness of the skin might be due to climate or to character of feed; but he could not say what peculiarity caused the hide of the Russian buffalo to have such an exceptional value. He observed, however, that the Russian hides are the finest, softest, and most pliable that reach the London market. On my asking whether snake skins were readily saleable, he remarked that the contrary was the case, that people had a "creepy" feeling about snakes and did not buy ornaments made from their skins freely. "The consequence is," he went on, "we can now buy any quantity of ready tanned snake skins in London at a less price than is demanded for them by shippers abroad. The market is quite glutted with them."

NOTES ON PRODUCE AND FINANCE.

AERATED TEA AND COFFEE.—The prospectus issued of a new company called "Theafoam," Limited. The capital of the company is £10,000 of £1 shares, and the object, according to the prospectus, is to acquire and develop the patent rights for "improvements in the manufacture of concentrated preparations of tea and coffee and of aerated tea and coffee," the provisional specification for which, dated June 6th, 1890, lodged by Messrs. Leonard Butler Wrightson and James Arthur Philips, and numbered 8770, has been accepted; and also to acquire the registered title and trade mark "Theafoam." The prospectus goes on to say;—Messrs. Wrightson and Philips have for some considerable time past given their attention to the production of pure tea and coffee in an aerated form, as being beverages most likely to fulfil these requirements. After repeated trials extending over several years, and involving considerable expense, they have at length succeeded in perfecting a product which they have named "Theafoam," and which they believe amply fulfils the above conditions, and therefore the requirements essential to success. "Theafoam" can be offered at a price within the reach of all. It is a genuine tea preparation (aerated), unmistakably retaining the peculiarly pleasant and well defined flavour of the finest teas. The difficulties of keeping tea in solution with aerating gas, whilst preserving the freshness and fragrance so desirable, have until now been insurmountable. No injurious flavouring or essences are used in the manufacture. "Theafoam" is prepared from the leaf itself by a novel process, the form it

first takes being that of a "Tea Extract" from which the aerated tea is subsequently made. To many persons ordinary cold tea, although its supporting qualities are admittedly great, is considered unpalatable. "Thea-foam" is, on the other hand, a fragrant, palatable, sparkling, refreshing and non-intoxicating drink. The "Tea Extract" is also patented, and will doubtless be recognised in this country and abroad as a ready and valuable time-saving agent for making tea at hotels, railway stations, buffets, &c.

COFFEE CULTIVATION IN THE SOUTH PACIFIC.—The *Fiji Times* is advocating the revival of the coffee enterprise in Fiji. It says coffee was almost abruptly abandoned before it had received a fair trial on anything like a comprehensive scale, and might well come to the fore. Notwithstanding the effects of the disease to which it is subject, there can be no doubt that it can be made a highly profitable production. Fiji need not look far for assurance in this respect. Her near neighbour, New Caledonia, is making a success of it.

TEA COMPANIES REPORTS, 1890.

There is food for what we may perhaps be allowed to call "comparative reflection" in the reports issued by our London tea companies (whether Indian or Ceylon). There are both the question of the result obtained and that of the form and amount of the information furnished to shareholders which deserve attention, and it may perhaps be permitted to us in this place to make a few remarks, which at any rate may be the means of directing notice—more has been done hitherto—to these points. In doing this we shall allude *seriatim* to the companies' reports as they reach us.

The Ceylon Tea Plantations Company issues this year a handy little report, and as results are good, shareholders, will probably take it as read and give a vote of confidence to the directors and managers.

There is, however, a painful absence of the detail to which we are accustomed in most India tea companies reports in a profit and loss account, with a single item at its credit:—Net profit on sale of produce, £30,284 2s. 11d.; and, as pointed out by our market correspondent, we would fain ask for some information as to the gross figures, of which this large sum is the resultant, as well as what actual cost of production per lb. of produce, amounts to. There is also no clue as to what amount of the company's acreage is mature and immature.

From this rather meagre report (good though results are) we turn with some degree of pleasure to the two reports issued respectively by the Lungla and Shumshernugger Companies, both young Sylhet concerns, working on progressive lines. These reports, as pointed out by our Share Market correspondent, leave nothing to be desired in point of clearness and detail. We find clear statements in the report itself:—

Comparative produce out-taru and estimate.

Yield per mature acre of cultivation.

Average price realised.

Particulars of mature and young planted area.

Comparative cost of production (showing also the effect of exchange on the company's cost.)

Statement of labour force.

Detailed estimates for 1891 and estimated cost per lb. of production.

The accounts show firstly on the credit side the gross realisations of the produce, while on the debit all expenditure is given in detail, classified under the three headings of Garden, Calcutta, and London, distinguishing in this last the charges as tea sales from other expenses.

Of office expenses and directorial and other central charges, these companies appear to live in that happy ignorance which is characterised as "bliss!" The profit and loss account is stated in a sensible way, the undivided balance not being carried to any special reserve account, but merely carried on in revenue account, so that it can be availed of in future years for equalisation of dividends, and used meantime for working capital.

An excellent account sale of the produce is appended, while the last page contains a list of the shareholders, which is, though a novel, a very excellent feature, especially as in neither case do they need to be ashamed in any way of their holding.

We must defer till our next issue remarks and reports upon the following, which are also in our hands:—

Chubwa and Nonoi.

Borokai and Indian of Cachar.

—H. and C. Mar.

CEYLON TEA PLANTATIONS COMPANY, LIMITED.

CEYLON.—I.

Offices, 21, Mincing Lane, London, E. C. Directors: David Reid, Esq., Thomaneau, Kincross-shire, chairman; Henry Tod, Esq., 21, Mincing Lane; David Reid Esq., 7, Mincing Lane; H. K. Rutherford, Esq., managing director. Secretary: Sir W. Johnston, Bart. Manager in Ceylon: G. A. Talbot, Esq.

The following is from the report of the directors to be submitted at the fourth annual general meeting of shareholders, to be held at Winchester House, Old Broad Street, E.C., on Wednesday next. The directors have the pleasure to submit the general balance-sheet and profit and loss account for the year ended Dec. 31st 1890, duly audited. The net amount at credit of profit and loss account, including balance brought forward at Dec. 31st 1889, and after providing for general expenses, directors' fees, income tax, &c., is £31,216 0s 1d; which has been apportioned as follows:—An interim dividend of 7 per cent was paid on Oct. 27th 1890, £9,223 18s; it is proposed to pay a final dividend of 8 per cent making 15 per cent in all, (free of income-tax) which will absorb £10,541 12s; it is proposed to pay a dividend of 15 per cent on the new issue of ordinary shares (free of income-tax), which will absorb £984 9s 3d; a dividend on the issue of 7 per cent preference shares was paid on Dec. 31st, 1890, £524 5s 7d; to write off for depreciation on office furniture, £10 15s 9d; to write off for depreciation on buildings and machinery, £4,000; to add to reserve fund, £5,725; and to carry forward to next year a balance of £205 19s 6d; total, £31,216 0s 1d. The directors are pleased to be in a position for the fourth consecutive year to declare a total dividend of 15 per cent on the ordinary shares of the company. After writing off £4,000 for depreciation on buildings and machinery, and providing for a furlough account, to the extent of £1,750, and carrying forward a balance of £205 19s 6d., a sum of £5,725 has been added to the reserve, bringing that fund up to a total of £9,000. The above result may be considered satisfactory, as the rate of exchange was 12 per cent less favourable for the company's business during the year than in 1889. The gross average realised for company's teas sold in London was 11d per lb. being the same as for the previous year, and the yield from mature and immature plants averaged 387 lb. per acre over a plucking area of 3,947 acres. The tea crop compared with that of last year, was as under:—

Year.	Tea made from leaf purchased		Tea manufactured for others.		Total.
	Estate	Teas.	Lb.	Lb.	
1890...	1,528,491	593,427	838,237	2,965,155	
1889...	937,407	799,779	277,149	2,014,335	

The Board has steadily had in view the acquisition of good properties at high elevations, the tea crops of which can be economically manufactured in the company's existing factories, and with this object has since the close of the year, acquired the West Holyrood, Ardallie, and Rathnillockelly Estates, all situated in the Dimbula District. In order to provide for the purchase of the above-named estates, the directors contemplate, with the approval of the shareholders, making a further issue of share capital, at a premium to be afterwards deter-

mined. The company's properties with these recent purchases consist of the following:—Tea planted, 6,307 acres; tea proposed to be planted this year, 688 acres; coffee, 93 acres; jungle and planted timber, 1,693 acres; patana and waste land, 357 acres; total 9,133 acres. It is gratifying to the directors to be able to inform the shareholders that the chairman's visit to Ceylon has given them increased assurance, not only of the value of the company's properties, but also of the thoroughly satisfactory manner in which the estates and business of the company are managed by the Ceylon manager and his staff. Under clause No. 69 of the articles of association, Mr. David Reid, of 7, Mincing Lane, retires on this occasion from the board, but, being eligible, offers himself for re-election. Mr. R. H. Miller, of Messrs. Harper Brothers, auditor, also retires from office, but offers himself for re-election.

HUNASGERIA TEA COMPANY LIMITED.

CEYLON.—II.

Directors: John Brown, Esq., managing director; Edward Conder, Esq.; Henry Hart Potts, Esq.

The following is from the report presented to the meeting of the Company on Wednesday last:—

The following accounts are now presented to shareholders, viz.:—Balance-sheet showing the financial position of the company on Dec 31, 1890; profit and loss account for crop 1889-90. In the circular issued on Oct. 31, 1890, shareholders were informed that the date for closing the crop year had been altered from June 30 to Dec. 31. The present profit and loss account, therefore, comprises the period of eighteen months, from June 30, 1889, to Dec. 31, 1890. It will be seen from this account that the weight of tea sold during the time named amounted to 251,537 lb., the average selling price being 10s. per lb., and the proceeds £10,372 5s. 2d. The crop of Cardamoms amounted to 3,372 lb., and realised £231 4s., or an average of 1s 5d per lb. Cocoa, weighing 37 cwt. 1 qr. 20 lb., was sold for £195 19s 2d, the average price being 10s 6d per cwt. The total receipts from sales of produce thus amounted to £10,799 8s 4d. The total expenditure for the eighteen months in Ceylon and London was £10,014 12s 11d, which, deducted from the value of produce, leaves a profit on crop 1889-90 of £784 15s 5d. A debit balance was brought into profit and loss account, from the previous year, of £774 5s 11d, and after writing off this sum from the above profit there remains a credit balance of £10 9s 6d to be carried forward. Looking at the tea crop figures, the yield is satisfactory. The estimate in the directors' last report for the year ending June 30th, 1890, was 150,000 lb. of tea, and the actual weight secured 150,679 lb. This weight of tea was sold at an average price of 9½d per lb., the result being that the twelve months' working did not do much more than cover expenses. The crop the following six months, however, showed a material increase, the yield for the half year being 100,948 lb., which sold at an average of nearly 10½d. per lb. It was during this half-year that nearly the whole of the above profit was made. A considerably larger profit would have resulted from crop 1889-90 had it not been that during the last half of the past year a sharp rise took place in silver, owing to speculation consequent on American legislation; the rise in exchange, while it lasted, added about 20 per cent. to the cost of working the property. The price of silver has now relapsed to about its former value, and the directors have no anxiety as to exchange with regard to the present crop. Mr. Brown, the managing director, has recently visited the estate, and writes that the tea promises well, and especially so when increased crops allow manuring operations to be more freely undertaken. The estimates for the current year, 1891, are tea 225,000 lb., cocoa 30 cwt., and cardamoms 1,250 lb. The area of tea planted on the company's estate remains as follows:—Over 5 years old, 510 acres; planted July-
Oct., 1886, 86 acres; 1887, 12½ acres; 1888, 40

acres; total under tea, 760 acres. Mr. H. H. Potts, a member of the Board, retires from office on this occasion, and being eligible, offers himself for re-election. The directors have decided to forego their fees for the past 18 months.

At the meeting of the Company on Wednesday Mr. E. Conder presided, and, in moving the adoption of the report, stated that when the prospectus was issued the liquidator of the old company took £18,600 in shares, so that the public had applied for about 4,100 shares, of which number one of the directors took one-third. The total area under cultivation was 730 acres, and by the addition of buildings and appliances they were now able to manufacture a very large quantity of tea. They had thought it wise to buy an engine and a boiler, as they could not always depend on waterpower to drive the machinery. For the first time the balance-sheet showed a profit, which would have been larger had it not been for the sharp rise that took place in silver. For the year 1889-90 their produce had been 150,679 lb. of tea; but in the last half of the last year their improvement was still better, and they went up to 100,948 lb. They were also getting 10½d. a lb., as against 9½d in the former year. Mr. H. H. Potts seconded the motion. In answer to questions, the Chairman said they did not want to issue debentures. The total cost of the engine and boiler would be about £300, which was proposed to be paid out of the revenue for the year. They had thought it better to go in for quantity rather than quality, and were to present making a profit at the rate of about £200 a month.

The motion was carried, and the retiring director and auditor were re-elected.—*H. and C. Mail*, April 24th.

SALE OF ESTATE PROPERTY.

Arslena estate, in Lower Dikoya, or Kelani Valley, has been purchased by Mr. C. J. Backhouse of Dikoya from Mr. T. C. Anderson for £6,500 stg. The estate consists of 220 acres of tea in full bearing, and 30 acres lately planted, with about 80 acres forest. A fully equipped factory is on the property, which yields 100,000 lb. of tea per annum. So the price may be considered a bargain for the purchaser.

A half share of St. Leys estate, in Dikoya, has been purchased by Mr. J. W. Holt, the proprietor of the other half, from Mr. T. C. Anderson for about £3,000 stg. The estate consists of 130 acres tea in full bearing.

TEA PROSPECTS AND "WHAT TO DO WITH OUR BOYS?"

"Paterfamilias" writes:—

"I have no less than five boys at ——— school; now two of whom are just finishing and the question is what should they do? It I could only have bought estates for them even a year ago I think a little would have gone a long way in giving them a good start in life. I fear the time is rapidly passing away when tea land can be had cheap: we are fast getting to the real value of tea property in Dambula. It is only beginning to dawn on people here, how very valuable an acre of tea land is in a district where ten years' purchase cannot be looked upon as too high! It is really hardly ascertained yet by experience what the best land will yield; the best soil held longest and in coffee and has but recently been planted in tea hence it is, at all events not generally known what the yield will be on such places. I say nearer 600 lb. per acre than 0 per acre."

"WALKER, SONS & CO., LIMITED."

It was to many in Ceylon a matter of regret that the old name of "John Walker & Co.," should have disappeared when the business so long associated with the name had to be formed into a

Limited Company. But there was no help for it; because in registering in London, there was no room to register as a Company, a name already on the roll. Various other forms of the name were attempted, but without success; and at last it had to be "the Colombo Ironworks, Limited" in order not to delay business. But no one cared for a name without any personality and few of the old customers ever used it—"John Walker & Co." or "Walker & Co." was the address on nearly every letter, or every reference! Fortunately therefore—as we learn from a circular issued in London by Mr. Frank Walker as Secretary to the Company—another and satisfactory, because expressive, title has been found and registered, namely Messrs. Walker, Sons & Co., Limited, under which title, we wish all success to the old Firm and new Company.

NOTES ON POPULAR SCIENCE.

By DR. J. E. TAYLOR, F.L.S., F.G.S., &c.

EDITOR OF "SCIENCE GOSSIP."

Two French botanists have discovered that the stems of potatoes from various parts of France are attacked by *gangrenes*, and that the latter appear to be caused by the presence of enormous numbers of bacteria in the diseased cells. Similar *gangrene* diseases produced by the same group of micro-organisms have been found in hyacinths, pelargoniums, and other highly educated and abnormally developed horticultural plants. The animal and vegetable kingdoms are growing nearer every day, not farther apart by virtue of their suffering from the epidemical and destructive effects of the same lowly organised and innumerable class of parasitic plants.

All vine-growers are interested in the natural history of the phylloxera, that underground mite which attacks the vine in its most succulent part, the root and rootlets. Its ravages are increasing in the vine-growing regions of the old world, especially in the Italian vineyards. A new fact in its natural history, however, has just come to light. It is stated that the mere perforation of the rootlets by the phylloxera is not the direct cause of the destruction of the vines, but that the latter is due to parasitic fungi which take advantage of the lesions produced by the insects. If this be the case, the top-dressing of vineyard soils with iron sulphate ought to be more resorted to than ever.

The cross-fertilisation of flowers has assumed a new interest since the publication of the two famous books by Darwin and Hermann Muller. Mr. Scott-Elliot has recently shown that in Natal the sun-birds (which in South Africa take the place of the humming-birds* of America) are the usual fertilisers of the banana. These brilliant birds are great flower-frequenter, and they generally visit only one species of flower at a time.

Australia possesses many species of arum. One of them goes by a very opprobrious name, which I may freely translate as "stinkplant." All the arums smell vilely, in whatever part of the world we find them. It has been just discovered here that the fertilisation of arums is mainly effected by carrion-loving coleoptera (or beetles), which are attracted by the nasty odours. In this work, however, they are joined by blue-bottle and other flies.

When in Australia I noticed and wrote about the influence which gall-insects had upon the leaves of the blackwood (*Acacia melanoxylon*), and attributed the change of their shape to their reversion to an ancestral state (atavism). Two distinguished German botanists have just demonstrated that the heteromorphism of the leaves of oak and beech, when injured unduly by cold or insects, assumes ancestral or atavistic forms and shapes.

A German chemist has once more analysed the diamond. The process is a costly one, and therefore must be a careful one. The result confirmed the experi-

ments made before (they are extraordinarily few), that the diamond is chemically identical with carbon, since not only is the atomic weight the same, but on oxidation, both yield exactly the same product.—*Australasian*.

ANALYSIS OF THE ORANGE.

The Boston Journal of Chemistry publishes the following result of the analysis of a medium size orange, purchased in Faneuil Hall Market:

The skin weighed 97.5 grams, which is 23.33 per cent. The seeds weighed 7 grams, which is 2.84 per cent. The pulp weighed 182 grams, which is 83.83 per cent.

The skin contained in 100 parts: Water and volatile oil, 78.00; organic matter, 21.36; ash .64.

The seeds contained in 100 parts: Water, 50.00; organic matter, 48.64; ash, 1.36.

The pulp contained in 100 parts: Water, 90.90; organic matter 8.68; ash, .33.

The pulp contained in 100 parts: Grape sugar, 4.3; cane sugar, 4.2; in free acid, 1.0.

The free acid consisted of about equal parts of malic and citric acid.

The ash constituents of the orange were as follows: Potash, 38.7; soda, 7.6; lime, 23.0; magnesia, 6.5; ferric phosphate, 1.7; sulphur, 2.9; silica, 6.2; phosphoric acid, 14.1.

It will be seen from the analysis that lime and potash are the principal elements of the ash, and hence that any fertilizer to be a complete orange tree food must contain a large percentage of these elements mentioned and also the other chemicals mentioned in the analysis in the relative proportions.—*Florida Agriculturist*.

ECHOES OF SCIENCE.

According to the Russian traveller, M. Grun-Grzimailo, the oasis of Turfan, in Tian-Shan, Central Asia, is a desert, once the bed of a great lake, which has been reclaimed by man with extraordinary labour. It has no water, and the inhabitants have excavated a system of underground canals and wells, some 300ft. deep, to irrigate the soil. These canals collect the underground water and convey it to the surface in the lower lands. The works are so colossal that the members of the exploring party could only compare them with those of ancient Egypt.

At a recent meeting of the Royal Geographical Society, Mr. A. E. Pratt described a journey of his in Ta-sien-lu, South-West China, during which he ascended the sacred mountain of Omei. It is 11,100 feet high, and supports nearly eighty temples. On one side there is an immense precipice, about 11.3 miles in height, from the edge of which Mr. Pratt witnessed the phenomenon called the "Glory of Buddha." Looking down into a sea of mist which filled the valley below, he saw, about 150 feet beneath him, the golden disc of the sun surrounded by rings of rainbow-coloured light. This effect is the great marvel of Mount Omei, and the proof of its peculiar sanctity. Every year many pilgrims commit suicide by throwing themselves over the cliffs.

Lord Howe Island, situated about 300 miles from Port Macquarrie, is marked out as a future sanatorium for the Australian colonies. It is seven miles long, by a mile wide, and contains basaltic mountains 3,000 feet high. The soil is fertile, and covered with vegetation; the scenery is beautiful, and the climate cannot be surpassed. It is likely to become a holiday resort very soon, the sea voyage not being too long, yet long enough to benefit the health. There is a banyan tree on the island covering six or seven acres, and only smaller than the famous one between Poonah and Kolaporo.

The recent bulletin of the American census announces that the ratio of land to water surface in the United States is 98:16 to 1:84. The average number of inhabitants to each square mile of land is 21.03. If, however, the whole territory were as thickly inhabited

* As they do in Ceylon.—ED. T. A.

as Rhode Island is now, the population of the Union, instead of being over 62 millions, would be nearly 946 millions or about two-thirds of the entire population of the world. The United States are capable of supporting 1,000 millions or more.

A company has been formed for the construction of a canal between the Black Sea and the Sea of Azov. It will have a length of 75 miles, and a breadth of 73 feet, with a depth of 13½ feet, increasing to 16 feet at both ends. Six years are allowed for its completion. We may add that the Isthmus of Corinth Canal is expected to be finished in 1883.—*Globe*.

EARLY FLOWERING OF COCONUT TREES.—A few of the coconut palms planted amongst the tea on Eilandhu estate, a few miles south of Henaratgoda, have flowered, although they were only planted out in 1887! But too much must not be made of this fact. The plants were originally of high quality and they were placed in large holes dug in soil which had already undergone considerable tillage and manuring. Then the precocious plants in question are situated near the tea house, and have been forced into premature bearing by liberal applications of ashes from the furnaces of the drier and the steam engine, and other manurial substances. In the case of ordinary plantations, we believe we are safe in saying that although a certain proportion of the trees will bear in the seventh year, and perhaps one half in the fourteenth, the whole plantation will not be in full bearing much under the round score years from date of being put into the field. Then, the popular estimate for bearing is sixty years—sixty years for the existence of the tree is too low,—and one of our shrewdest and most experienced coconut planters is of opinion that, properly tended and liberally manured, it is not possible to place a limit on the bearing life of the palm.

JUNGLE FOWL AND CACKLING.—We draw attention to another letter from *Nature*, in which Mr. V. Ball, the veteran Anglo-Indian Geologist, expresses opinions, the result partly of personal observation which renders the question still more perplexing. For, only the other day we had the express testimony of an old planter, the result of personal observation, to the effect that the domesticated barn-door fowl never cackles when it lays an egg in forest, jungle or away from home. The quiet around affords no encouragement to cackle—for only as it lays at home, does it indulge in cackling! These facts may be of some use to Mr. Romanes; he may be able to experiment with the domestic hen in the woods of the old country. Here is the letter from the latest number of *Nature*:—

CACKLING OF HENS.

It is often difficult to recall an actual instance of what may be a matter of very common occurrence. Such is to a certain extent the case with the subject to which Prof. Romanes's query in *Nature* of April 2 (p. 516) refers.

In a general way it is my impression that the cackling of jungle fowl is not very commonly heard in India, but I feel certain that I have heard it occasionally, and that I once did hear it upon a somewhat considerable scale is impressed very distinctly upon my memory by certain and special circumstances. My tent for a few days in April 1876 was pitched close to a perfectly impenetrable patch of thorny jungle in Orissa. This cover was full of jungle fowl, and I remember hearing the cackling of the hens, which reminded me of the familiar farmyard sounds of home. It is possible that in this case the safety of their retreat may have had something to do with their not fearing to cackle with unusual vigour.

V. BALL.

Science and Art Museum, April 18th.
—*Nature*, April 23rd.

INDIAN PEKOE SOUCHONGS.—"Peripatetic Planter" writes to *Indian Planter's Gazette* from London as follows:—As regards Indian Type (pekoe souchongs) it is openly proclaimed by some, that those will pass the shilling before long! More's the pity, again—a short life and a merry one is not the ideal of those with a permanent stake in the industry. All kinds of sensational rumours are afloat about these pekoe souchongs—ono of the baneful effects of their adoption by the Clearing House, or Commercial Monte Carlo. It is said, that very large transactions in this class have been privately effected, within the past few days, (10,000 chests and 20,000 chests are variously mentioned in the rumours referred to) and *arge* catalogues of the past fortnight's auctions (on Garden or Company Account) are pointed out with scarcely a single line of pekoe souchongs in them by way of partial corroboration of the statements. This looks like the commencement of a corner, but that I know large importers who have not yet been approached with any private offers for this special class of tea; and to establish a corner successfully, would almost demand a *very rapid* grabbing of the greater proportion of the class. Hence, the opinion is reasonable, that the transactions are (1) either mythical, or (2) the sporting act of private speculators, and not of a really heavily capitalised group of speculative financiers. In any case, we are having the first taste of those baneful results which I predicted when the adoption of an Indian Type by the Clearing House was first talked of.

THE MAGAZINE

OF

THE SCHOOL OF AGRICULTURE,

COLOMBO.

Added as a Supplement monthly to the "TROPICAL AGRICULTURIST,"

The following pages include the contents of the *Magazine of the School of Agriculture* for June :—

GUMMY AND RESINOUS MATTERS IN PLANTS.

GUMS may be defined as vegetable products, more or less soluble in cold water, but insoluble in ether, alcohol, and oils. They are generally obtained amorphous and

most of them exude spontaneously, or on puncturing the bark. The most perfect type of this class of substances is gum arabic or acacia, which is compound of a base or bases, generally lime magnesia and potash with arabic acid. Most gums are similarly constituted to gum arabic which is an excretion from various species of acacia, especially *A. arabica* and *A. vera*. The substances known as Barbary or Morocco gum, gum Senegal and East India gum are inferior commercial varieties of the same substance from other species of acacia.

Resins may be described as vegetable substances which are solid at the ordinary temperature, more or less transparent, inflammable, readily fusible, which do not volatilize without decomposing, are insoluble in water, but soluble in alcohol, and easily mixed with fatty substances by fusion. Liebeg described them as "oxidised essential oils."

As a common example of a resin may be mentioned rosin, the residuo left on distilling turpentine for the oil. Gum-resins combine the properties of both gums and resins—they are partly soluble in water, and partly in alcohol. A com-

mon gum resin is assafoetida got from the root of certain Umbelliferae. Balsams, about which there has been much difference of opinion, may be simply described as solutions of resins in an essential oil.

Turpentine may be defined as an oleo-resin, generally got from pines.

Lac is a resinous substance combined with much colouring matter, produced by the puncture of the female of a small insect called the *coccus lacca* or *ficus*, upon the young branches of several tropical trees, especially the *Ficus Indica*, *F. Religiosa*, and *Croton lacciferum*.

Now most plants contain what are known as intercellular spaces, that is small spaces approximately triangular in shape between the cells of tissue, occurring where the walls of cells meet. These spaces are formed by the unequal development of the common cell wall in endeavouring to become round, the shape which the ordinary cell wall inclines to in thickening. As a result of this a splitting occurs along the middle of the common wall, and thus the intercellular space is formed. These spaces generally contain air, but in some cases they are filled with an excretion, it may be mucilage as in cactus, oil as in orange and citron, or gum, resin, gum-resin and turpentine.

Among the gum producing plants of Ceylon may be mentioned Kaju (Cashew nut), Divul (Wood-apple), Hik, Imbul (Tree cotton), Kihiniriya, Welan, and Na (Ironwood); gum-resins are produced by Kekuna, Del (Breadfruit), Kos (Jak), Amba (Mango), Domba, Pol (Coconut) and Goraka; resin by Hal; lac on Keppitiya.

OCCASIONAL NOTES.

We omitted to make mention in our notice of the Grama Rakshaka Samagama's Show at Dalugama, of a locally made plough exhibited by Mr. Lobus Dharmaratne, Notary. It attracted much attention from the fact that it was of an improved type, was made in the district, and had been long used without showing signs of deterioration. On enquiry we found that the gentleman above-mentioned had some years ago seen one of the improved ploughs introduced by Mr. Green at work and being struck with the efficient manner in which it turned over the soil, was led to believe that it would be an advantage to have an implement of that kind to work up his paddy-land. In fact there is little difference between the Dalugama plough and Howard's "Cingalee," except that the share in the latter is about two inches broader than that in the former. The arrangement for the regulation of the depth of furrow is simple and convenient. There was some mistake about the cost of the plough as stated at the show, the price named there being that which was paid to the workman who was supplied with the materials. The true cost is twelve rupees, and it is marvellously cheap at the price. One of these implements has just been sent to the school of agriculture at our request for trial, and we hope to fully test its work shortly. Considering that the implement is the work of a village-smith it is a most creditable piece of workmanship.

The latest volume of "Proceedings of the Royal Physical Society" includes a paper on the classification and distribution of earthworms by Frank E. Beddard, M.A. F.R.S.E. F.L.S. Of the species allotted to the Oriental region, the following are given as occurring in Ceylon, and as having been identified in a trustworthy manner:—*Perichaeta cærulea*, *P. affinis*, *P. Houletti*, *P. Ceylonica*, and *Deodrilus Jacksoni*. The insufficiently-known species found in Ceylon are given as *Perichaeta leucocycla*, *P. Viridis*, *P. Brachycycla*, and *P. Cingulata*.

The *Saturday Review* is convinced that the three best oriental fruits are the Mango, the coconut, and the Durian. The Mango is lauded as a "divine" fruit—the "real ambrosia." Few in Ceylon will be inclined to agree with the *Saturday Review* in its opinion as to the three best fruits of the east.

Dr. Bonavia, in his work on the oranges and lemons of India and Ceylon, recognises two distinct types of "Sweet-oranges":—The Malta or Portugal orange which is close-skinned, and the Suntara orange of India, a loose-skinned fruit. Both these he thinks came into India originally from China or Cochin China. The Seville orange which was the first to reach Europe is found wild in Cochin China, and, in only one place, in India; but Dr. Bonavia does not believe it could have been the progenitor of the other two. The pummelo, which De Candolle ranked as a distinct species, is considered by the author to be a giant variety, developed under tropical and sub-tropical conditions of luxuriance from the Portugal orange, and to have acquired its modern charac-

ters in the Malayan Archipelago. The original wild pummelo has never been discovered. The Keoula orange is placed in a distinct group, in which Dr. Bonavia includes the mandarin. This latter says the *Indian Agriculturist* is grown with some difficulty in India. It is mentioned as growing well in the Peradeniya Gardens in Ceylon. Besides the above varieties there is the "Khatta" or "Karva" orange, the pulp of which is very sour though free from bitterness. Of this it is said that it is very distinct from the others, and that it is not certain whether it should be classed as an orange or a lemon. "I am informed," says Dr. Bonavia, "that this Khatta orange makes a good sweet jelly, and also a good marmalade. I know the decoction of its fruit is a good febrifuge, and also a good splenifuge."

Dr. Wagner is reported to have said in a lecture recently delivered at Darmstadt, that "our experiments show clearly that green manure enables us to make cheap atmosphere nitrogen accessible even to those plants which are not capable of taking it up directly. The only condition is that we employ as green manure plants which are really "nitrogen increasers," viz. lupins, peas, clovers, horsebeans, serradella, vetches &c. Dr. Wagner is evidently an upholder of Hellriegel's theory, regarding the source of nitrogen in leguminous plants, which, however, English experiments have negatived. That the leguminose have peculiar facilities for collecting nitrogen is admitted on all hands, but that they do so from a source other than the soil still remains to be proved. The results of foreign and British experiments have differed before now. In the early days of agricultural chemistry. French experiments tended to prove that plants absorbed free nitrogen from the air through their leaves, but this idea is now quite exploded.

THE CULTIVATION OF MANIOC.

(Concluded.)

II. (*Jatropha Utilissima*)

BY W. A. DE SILVA.

The use of the Manioc yam as food is restricted to certain districts of the Island especially the Western and the North-Western. In other provinces the cultivation is only sparsely carried on, probably as the demand is so small, as well as because people are naturally afraid of being poisoned by eating the yam. Cases of poisoning by manioc are very rare and they very seldom occur in the districts where it is largely consumed. One possible reason of this is, that by repeated cultivation the manioc in these districts may have lost to some degree its poisonous properties, for by cultivation plants are improved to a great extent. Even in places where the yam is largely grown it sometimes proves to be poisonous and occasionally causes death. The disastrous results often occur by using the yam without proper preparation, either by means of drying or boiling.

The poisonous principle in the manioc is believed to be hydrocyanic acid, a nitro-carbon compound, and in proof of the presence of this acid it may be mentioned that the leaves and yams

give out the characteristic smell of cyanogen and the cyanides. The process of drying or boiling always removes the traces of this acid and with it the poisonous properties. There is a popular belief among the villagers that this poisonous property is contained in the rind and core of the yams. With this idea many take the precaution of remove the core before preparing the yam for food. There is, however, no reason to believe that the poisonous property is contained in this particular portion of the yam only. There is another popular idea, that the cases which prove fatal by the use of this root are due to eating such yams as have been bitten by poisonous serpents. Any danger from manioc-poison is easily averted by taking some simple remedy, such as salt and water.

The bitterest and the most poisonous varieties of manioc, the like of which we do not find in this Island, are largely consumed by the West Indians without the least danger. Waterton in his "Wanderings in South America" says. This most useful plant is to the Guiana natives what corn is to us. It is a tall unbranched plant growing irregularly and knotted at intervals, and having leaves with a purple gloss. The root is the portion that is eaten and it is scraped down on a board stuck full of sharp flint or other stones and called by the name of *Tumarrie*. In order to extract the poisonous juice, the scraped cassava is forced into a long narrow basket called a *Matappi*, made exactly on the principle of the "Siamese links." When the *matappi* is full it is scarcely half its length when empty, but is more than double its thickness; it is then tied to a branch of a tree or to a beam of a house, and another pot is placed under it and a heavy weight is tied to the lower end. The weight of the stone causes the *matappi* to increase in length but to diminish in thickness, thus exerting a powerful pressure on the cassava, and squeezing out the juice, which runs through the interstices and so down the *matappi* into the pot. The dry cassava is then removed, rubbed through a basket work sieve, formed into flat circular cakes about two feet in diameter and a quarter of an inch in thickness, and baked upon a flat heated stone or plate of iron. Meanwhile the poisonous juice has been kept out of reach of children, poultry &c., and on being boiled and flavoured with red-pepper or *Cassiana*, becomes the well known *cassareep* or pepper pot of the West Indies. When the cassava bread is eaten it is generally dipped in the *cassareep*."

The prepared manioc is known in commerce as manioc arrowroot or cassava flour and in another form as tapioca. The manioc arrowroot is prepared much in the same way as the real arrowroot. The root is well rinsed in water, and the outer bark having been first removed, the inner white mass is scraped into water, well squeezed, washed several times and the particles taken out and carefully dried. The other form of cassava is largely consumed and is prepared as follows. After the cleaned roots have been well smashed the starch which is obtained is placed on heated iron plates when it forms into granular masses. Thus prepared and packed the substance keeps well for a long time and forms a desirable article of food. Both these prepared varieties of manioc when manufactured on a large scale are made in factories where the different processes are carried on with the aid of various appliances.

The extension of the cultivation of this product in Ceylon is very desirable as it is found to grow well in most parts of the Island. It yields a large quantity of food materials which could be advantageously used locally for both man and beast, and a large and profitable trade could be opened with great advantage, if the product is cultivated to any extent. Sir Samuel Baker in his work on Ceylon mentions, that this plant was at one time grown in Colombo at Mr. Thurstan's Industrial School and that the flour was prepared and sold largely.

A REPORT ON COTTON.

The Agricultural Department of Madras has issued a bulletin, consisting of a report on the results of an inquiry as to the growth of cotton in Tinnevely by Mr. S. T. Iyer one of its Agricultural Inspectors. The enquiry was mainly directed to the method of cultivating, and the yield of, Tinnevely cotton, with the object of enabling the Department to devise such experiments as might best improve the staple and increase the out-turn. In the inquiries into the subject of weather and seasons, it was found that dews and sea-breeze were beneficial to cotton, but fogs, especially after rainfall, proved highly injurious by withering up the fine bolls and flowers, while the strong N. E. wind dissipated moisture from the soil and plants, causing the leaves of the latter to wither and droop. Observations tended to prove that cotton requires somewhat dry weather for its growth, and that heavy rainfall is disadvantageous.

As a rule cotton is cultivated on various sorts of black soil in Tinnevely, and rarely on red soils. The various kinds of black soils are distinguished by particular native names, and they are generally divided into (1) superior friable black soil, (2) inferior ditto, (3) stiff black soil, and (4) saltish black soil. The first, which is considered to be by far the best, has a substratum of limestone, and the second a substratum of gneiss: both soils being mixed with particles of the underlying rocks. The red soils are divided into red loam and red sand; the grey sandy loams and gravelly soils are very rarely used for cotton cultivation.

The different kinds of manures applied to cotton soils are (1) cattle manure by itself or mixed with earthy matter, (2) some form of earthy matter, (3) sheep manure, and (4) green leaves and twigs. The earthy matter referred to is generally silt taken from the beds of tanks, pools, and from the sides and beds of streams. It appears to be the practice to fold together all the flocks of sheep of one or more villages in each man's field successively, though each man tends his own flock. The manure is not generally applied to the cotton crop itself, (1) because it is found that in the year of application the crop has unequal growth, while in the second year the crop is more uniform, and (2) because the ryots find by experience that crops to which manure is applied suffer more than unmanured crops from protracted drought.

On the different kinds of black soil cotton is raised generally once in two years, and ryots generally arrange to cultivate some one particular crop, cotton or another, extensively in the village

Though co-operation is seen among the Goiyas of Ceylon in paddy cultivation—so far as labour of men and animals is considered—still it is a system which might be more extensively adopted. The plan of manuring the land by folding all the animals of a village for a time on each man's land is well worthy of imitation, but the Ceylon Goiya has first to learn the value of cattle manure as well as the advisability of keeping his cattle together instead of allowing them to stray about. Again the system of a number of village cultivators who individually own but a few acres combining for the cultivation of a particular crop—and especially cotton—is greatly to be commended.

For thoroughly clean land, three ploughings are ordinarily sufficient for cotton; but if it is very foul it is ploughed as many times as possible. The soil is ploughed in a dry condition, and to more than the ordinary depth, so that it may be thoroughly cleaned, as cotton particularly needs a clean soil. Under ordinary circumstances the cotton plants are cleared in August-September, about 10 months after sowing. If rainy weather prevails, picking is carried over a longer period. In 1888-9 cotton picking was continued in some cases on to the middle of November. In fact cotton is picked till the yield becomes too poor to necessitate further delay in cleaning the land. The plants are generally fed off by sheep before they are cleared. They are pulled up after rain, tied into bundles and stacked, to be carted off later. The stalks are generally used for fuel, and when thin, are also used for thatching; but when the stalks are long and branchless they are used for weaving into mats or manure baskets or large baskets for preserving grain. In Ceylon there would be further use for cotton stalks in the manufacture of tea baskets. It is recommended that cotton should be sown in lines (as is done in some parts of India), so that the land would admit of being ploughed while still under crop, when the first rains in May occur. Cotton is sometimes sown in lines with Horse gram or other kinds of gram, or sown mixed with coriander, Hibiscus Cannabinus &c. Two varieties of cotton (*G. Herbaceum*) are grown: the one variety has white coloured and round seeds, easily removable white lint, a woody stem spherical bolls and white stamens; the other has dark coloured elongated seeds, less white lint removable with difficulty, a fibrous stem, conical bolls, and red stamens. The former is generally preferred for the better classes of lands. Cotton is said to grow better when a rotation (ordinarily two-course) is adopted—the other crop of the rotation being generally Varagu (Sin: Amu) and Cumbu; both of which are cultivated in Ceylon to some extent. Good cotton seed for sowing, which the ryot generally purchases from dealers who clean cotton, sells at R5 to 5½ per 240lb. It is stated that the second picking appears to furnish seed of the best quality. The quality of cotton-seed is roughly tested by a small quantity being chewed. If the mass of chewed seed is yellowish, the seed is considered good; otherwise it is rejected. The seed is ginned a very short time before it is required for sowing, lest the seed should damp and spoil. Before sowing, the seed is freed of all adhering lint, formed into a heap over which a thick solution of buffalo dung in water is poured, and rubbed on the ground to fully

coat the seed with dung; then it is spread to dry. Six standard measures of seed, weighing about 10lb. 5 oz., are sown per acre. The usual time of sowing is October but sometimes it is delayed, owing to want of rain, till the middle of November.

Cotton is scarcely ever irrigated in Tinnevely, though it is stated that irrigation stimulates it to better growth and production. The Hon. Mr. Mitchell was very sanguine of cotton being cultivated with success under irrigation in Ceylon, and was exceedingly anxious that the experiment should be tried. A passed student of the School of Agriculture might be told off to lay a few acres under cotton and cultivate the crop with the aid of irrigation. Further particulars are given with regard to the cotton plant as grown in Tinnevely as follows:—

The first bloom appears about the 8 or 9 weeks after sowing; the first bolls begin to open about 90 days after sowing; the first picking commences about 105 days after sowing.

The cost of raising cotton is given R9¼ per acre: the value of outturn at R34½; the profits at R25¼ per acre. It is admitted however, that the price of cotton at the time this estimate was made, was rather higher than usual. In fertile soils and under good treatment, 1,000lb. of seed-cotton per acre is no unusual out-turn; an ordinary good yield may be taken to vary from 750 to 900 lb. of seed-cotton; while 500lb. may be taken as a fair average. It is assumed by dealers that 6 pods (of about 328lb. each) of seed-cotton are required to produce 500lb. of lint, and therefore the average out-turn of an acre is 125lb. lint. Not only has the area under cotton in Tinnevely extended of late, but the out-turn has also been increased, owing to the stimulus given by the rise in price, which, at one time as low as R7 a podi, has risen to 3 and 4 times that value. The following pests, to which cotton plants are subject are mentioned:—beetle, grasshopper, borers, bollworms, cotton worms, plantlice, rot of boll, mildew, and rust; but no remedies are suggested.

An appended statement shows that ⅔ of a ryot's holding is on the average allotted to cotton. About ⅓ of the cultivated area of dry land in the district is ordinarily bought under cotton, and the author of the report gives it as his opinion that there is hardly any scope for extension of cultivation though there is some prospect of increasing the production by better cultivation, for which suggestion are thrown out, such as more careful selection of seed, improvement of mechanical and chemical condition of soil, sowing in lines, alteration of time of sowing &c. It would appear that no fair trial has been given to foreign varieties of seed, and but for a few stray Bourbon bushes, there is no evidence of new varieties of seed being used or tried by the ryots.

Altogether the report under review (forming Bulletin No. 19 of the Agricultural Department of Madras) is a most exhaustive one, and reflects the greatest credit on its author. It is in reports such as this that one sees the good results to be expected from the establishment of Agricultural Departments, and how very necessary it is that Agricultural Inspectors or Itinerary agricultural officers should be appointed in connection with any body that is concerned with the improvement of agriculture, so that useful and valuable reports on

matters into which enquiry is called for, may be drawn up. But it is still more necessary that these reports should be entrusted to competent hands. It is an anomaly to depend for agricultural reports on those who have little knowledge of the subject and less judgement to exercise in agricultural affairs; and that these reports should be submitted to men who have made no study of the science and practice of agriculture, who have no sympathy with any movement for the improvement of agriculture, and whose opinions and recommendation are therefore of no value. So far as Ceylon is concerned the sooner a competent board of agriculture is appointed, the better for all concerned in the improvement of native agriculture. It has already been stated through the press that the establishment of a veterinary department is in prospect, surely on agricultural department should have precedence. In fact, veterinary work might with advantage be made a branch of the agricultural department, and double duty be done by the officers of the department, who will be both agricultural and veterinary inspectors in the rural districts. There is of course no radical reform to be brought about in native agriculture, but yet there are scores of ways in which an organized body of qualified and experienced men can encourage and help native agriculturists, and further their interests. The material is available, but it is for the Government to bring about the organization and to stamp it with its imprimatur.

SILICIOUS SOILS.

The reply which the enquiry of a correspondent to the *Ceylon Observer* on the silica question has elicited from Professor Geikie—we suppose Professor James Geikie—has naturally caused a good deal of consternation to some of our tropical agriculturists. It is to be noted however that Professor Geikie who has no pretension to be an agriculturist, does not give his own opinion as to the value of silica in plant economy, but that of Professor Johnstone. Now as there is more than one professor of this latter name, we are naturally anxious to know who and what Professor Johnstone is; while we do not hesitate to say that the statement attributed to him is a very misleading one. The import of Professor Johnstone's opinion is evidently intended to be that silica is "injurious" to the generality of plants inasmuch as the fertility of land (as generally reckoned) is in the inverse ratio to the amount of silica in the soil; but as it is expressed, the statement would naturally convey a wider and less correct meaning to the ordinary reader. There is no doubt, as Professor Wallace remarks in his work on India, that plants draw a much larger supply of their nitrogenous food from the atmosphere, in the tropics, than they do in temperate regions, owing to the fact that there is so much electricity in the atmosphere of the tropics. Electricity is admitted to be the only original source of combined nitrogen, producing by its action nitrous acid which is oxidized into nitric acid by ozone or peroxide of hydrogen. Thus it is that the almost pure siliceous soils of the tropics are not barren wastes, and are enabled to support their own peculiar natural

growth of vegetation, which cultivation has in particular cases raised to economic importance. Nitrogen is the only incumbustible (or organic, as it is sometimes less satisfactorily named) element of plant food which there is difficulty to account for a sufficient supply of. Silicious soils generally contain fragments of more complex minerals than quartz which slowly increase the ash or mineral constituents available for the plant. It is also very probable that from the more general, more complete, and more rapid rate of decomposition in tropical climes, the proportion of ammonia (very variable in quantity) in the atmosphere is much higher than that in temperate regions. If however a sandy soil is composed of pure silica it cannot supply any plant food: and though the difficulty as to the supply of the chief incumbustible elements of plant food may be got over, the lack of the essential mineral ingredients will render such soils sterile whether in temperate or tropical regions.

THE GRAPE VINE.

(*Vitis Vinifera*.)

6. *Preparation of the land.*—The land selected for a vineyard should be dry and sufficiently elevated to prevent any water stagnating on it during heavy rains. If it slightly slopes so much the better. Open drains should be cut in order to prevent 'wash'; and under drains must be constructed if the subsoil is not sufficiently porous to drain away all superfluous water. Stones broken to the size of the "metal" generally used for roads, or a little bigger, may be used for the subsoil drains.

It is very important that the tillage of the land should be thorough and efficient. In Jaffna Batticaloa and other parts of Ceylon where grapes are grown, we seldom find more than a couple of vines growing in a garden. No proper system of tillage has therefore been practised as yet in viticulture here. It is customary to dig a hole, say, about 4 feet square and 3 feet deep and to fill it up with half-rotten cowdung and soil, and then to plant the vine in the centre of the hole. So long as it is young the plant thus treated seems to thrive as well as can be expected, but as it grows older it will be seen that there is a two-fold disadvantage by this pit-method of planting: viz,—(1) The roots of the vine instead of freely spreading out laterally will be confined to the pit, crowding and coiling up in the loose rich soil in it as they would do in a flower pot.

(2) The lower roots are encouraged to go too deep regardless of the nature of the soil below,—whether it be sweet or sour, cold or warm &c.

To give some idea of the tillage adopted on the famous and extensive vineyards of Australia, I shall quote a few lines from the annual report for 1889 of the Agricultural Department of Queensland, as reprinted in the *Tropical Agriculturist* of February 1890. In the course of some remarks about Mr. Searle's vineyard, the report says:—"Although as Mr. Searle admits, he is but an amateur viticulturist, he appears to be possessed of a good deal of common-sense, and is quite aware that it is not sufficient for the growth of vines to dig a hole and stick a vine into it, or to

plough the land shallow and then lay out the vineyard and plant the cuttings. All the ground in this vineyard is trenched to a full depth of two feet, the soil well turned up to the weather, and by these means a good crop of fruit has been secured even in dry weather." It is such thorough tillage that we ought to adopt here in Ceylon in the culture of grapes as well as that of many other crops.

Haputale,

E. T. HOOLE.

22nd May 1891.

(To be continued.)

GENERAL ITEMS.

Mr. J. P. Manchanayake writes from Kuala Lumpur, Strait Settlement:—The climate here is rather warmer than that of Ceylon, and the rainfall excessive—June and July being the wettest months. The frequent showers mitigate the heat to a great extent, and the place is rendered of a fairly healthy nature. Kuala Lumpur which is the seat of Government of Selangor, is situated in a valley about 22 miles away from Klang where the steamers touch at, and which is connected by a railway with the Capital. Wild animals are numerous in these parts, and are a cause of much danger in clearing forest lands. Tin is mined to a considerable extent, and gold is also found in some parts. There are splendid timber-trees to be found here, and most of them straight-grown and rising to a great height. The Chinese section of the inhabitants go in for cultivation on a large scale, and work with great skill. I have seen no plough used here, work being done by the mamoty which is handed more dexterously than I have seen it done in Ceylon. The cultivators besides using cattle and pig manure, also use human excreta very largely, especially for vegetable cultivation. Paddy is not grown to any great extent, and rice is imported from Siam and other parts. Coconuts grow well, but are not cultivated on a very large scale—such plantations as I have seen being small in extent, though the trees in them are fine specimens. Coffee and tea are also cultivated, and the former is doing well.

The *North British Agriculturist* has a long and interesting article on agricultural education, the great importance of it, and the best means of imparting it. Among other considerations it notices the importance of specimens and drawings as a means of instruction. It is with this idea that the school of agriculture museum was stated, which, while it is illustrative of agriculture in so far as it contains a fair number of specimens of agricultural products or models of them, also represents the allied sciences of Botany, Geology and Chemistry and Zoology to some degree. The museum is yet in its infancy and is growing very slowly, inasmuch as it depends almost altogether for supplies on what the students of the school could find in their foraging expedition during the holidays.

The oldest cotton mill in India, says the *Indian Textile Journal*, is the Savana Spinning and Weav-

ing Mills in Pondicherry; this concern was established in the year 1830. In Bombay the first cotton mill was established in 1851. In Calcutta the oldest mill dates from 1864. At Madras the first mill dates from 1874.

To this we may modestly add that the first (and only) mill in Colombo (and in Ceylon) was established in 1889.

The Half-yearly examinations at the School of Agriculture commenced on the Monday, the 25th of May, and continued throughout the week. The School will remain closed during the whole of June for the Summer vacation.

Received for the School Museum, some samples of paddy and two coconuts of abnormal size from the Secretary Grama Rakshaka Samagama, and a mass of fossil resin, dug out of a marsh in the Narampitiya fields, from Dr. Driberg.

The Australian Irrigation Colonies, which were commenced three years ago on the river Murray, in Victoria and South Australia, by the wellknown firm of Chaffey Bros, Limited, continue to make remarkably rapid progress, the number of settlers from Great Britain already amounting to several thousands, a large proportion of whom belong to the wealthier classes. From the last report of the Directors of the Company engaged in the construction of the gigantic irrigation works, it appears that the steady influx of population previously reported has been fully maintained. The sale of land for the past six months has been substantially in advance of any previous like period. The area disposed of now exceeds 11,000 acres, and is for the most part being rapidly brought into a state of productiveness. Heavy crops of grapes have been gathered from vines planted but two seasons. The currants and raisins have been declared superior to those imported, and the apricots have been pronounced equal to the finest French. As anticipated a great advance in the value of land has followed these demonstrations of the productiveness of the soil, offers of £75 and £100 per acre having been refused for lots planted but twelve months ago.

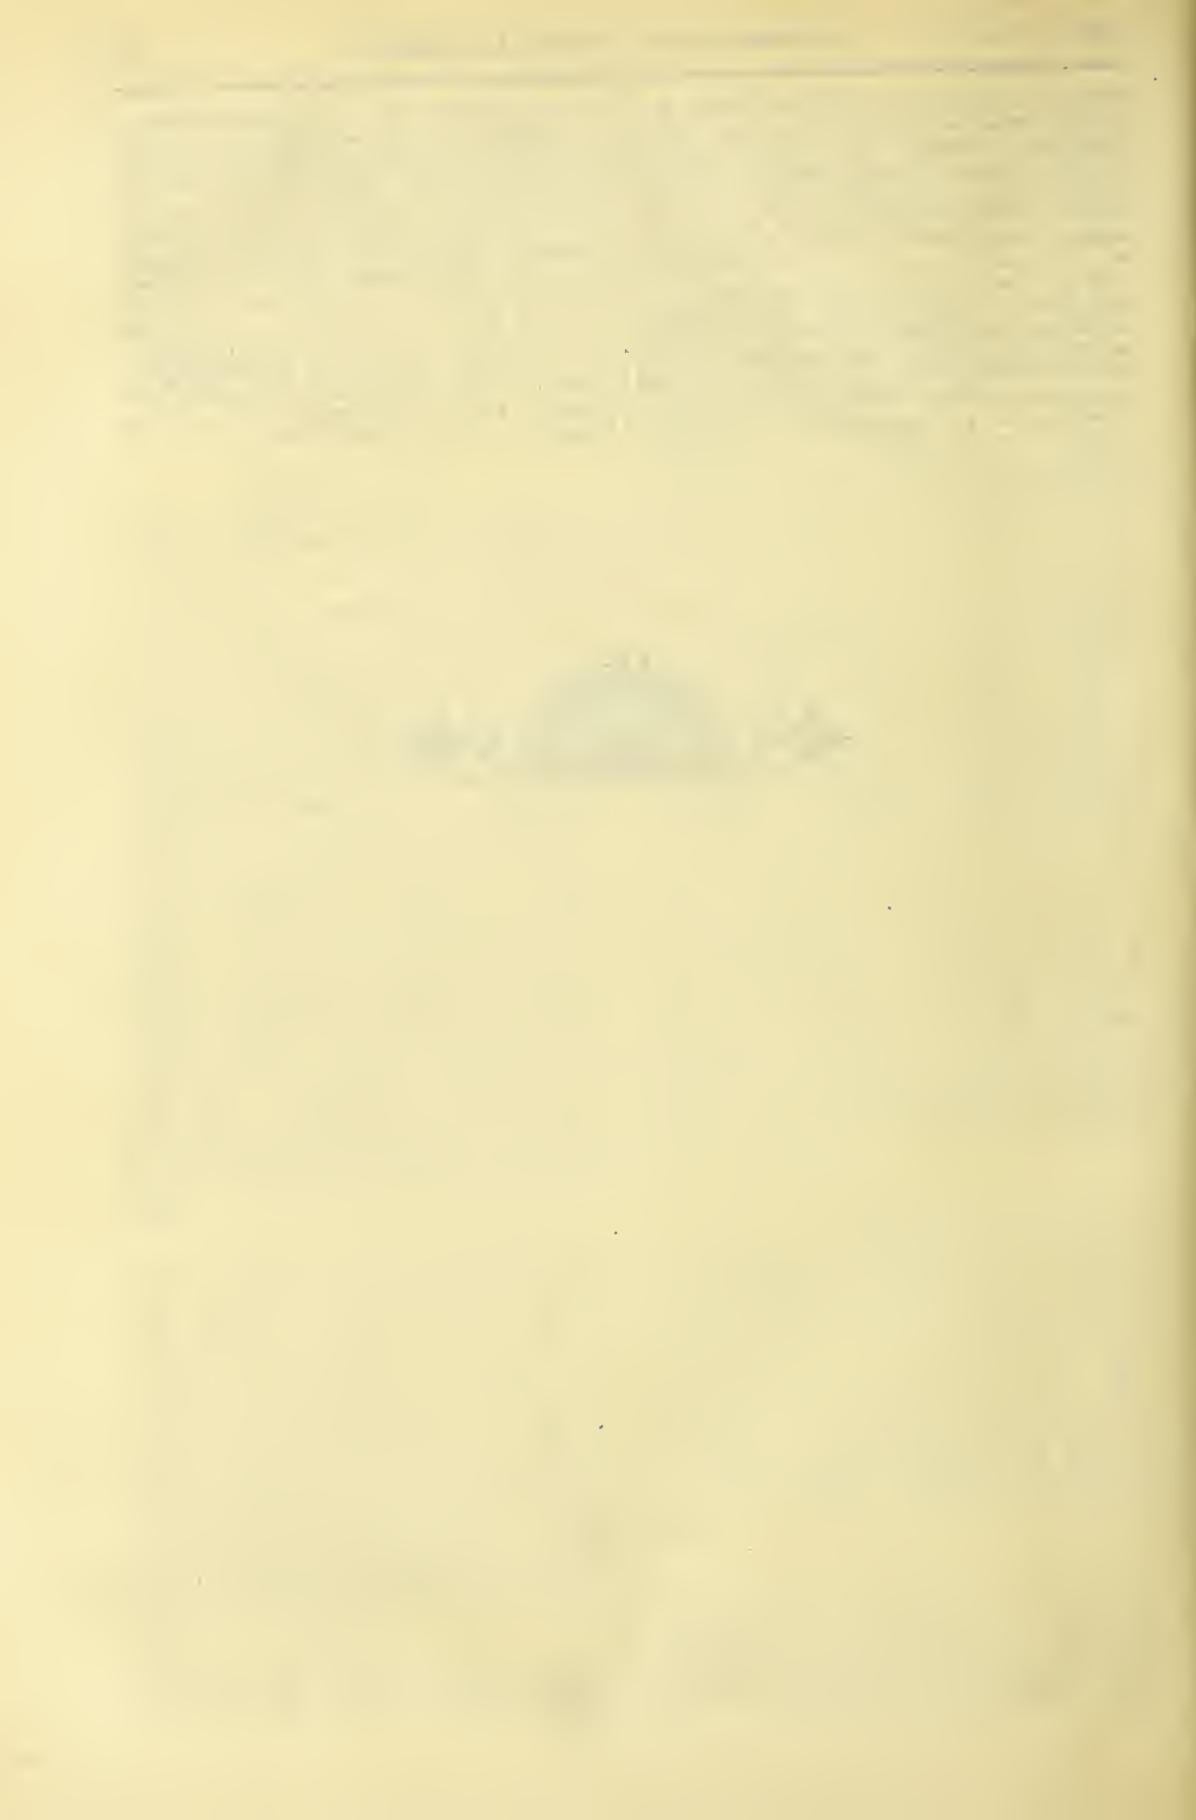

The life of the agricultural labourer in Italy does not appear to be a happy one. He can rarely earn more than 6 to 7 pence a day, which often has to support also a wife and family. The consequence is that many labourers can only afford to have one meal of polenta (Indian corn) a day, and this has to be eaten without a sufficient allowance of salt owing to the costliness of that commodity which is a government monopoly. As a result thousands are suffering from a disease known as pellagra, produced by bad food and want of salt. The poor Goiyas of Kolonne Korle, Walpane and other unfortunate districts in Ceylon have thus their co-sufferers in the more enlightened West.

John Bechmann in his "History of Inventions, Discoveries and Origins," says that the real Tourmaline was first brought from Ceylon, and made known by the Dutch, about the end of the 17th or beginning of the 18th century. Dr.

Dunmuis averred that in 1703 the Dutch first brought from Ceylon "a precious stone named Tourmaline, Turmale or Trip." "In the catalogue of the collection of Natural Curiosities belonging to Paul Hermann who was in Ceylon from 1670 to 1677, sold at Leyden in 1711 was a stone named *Chrysolethus Turmale, Zeylon*. This was evidently meant to be Tourmaline, and the circumstance is considered to prove that both the stone and name had their origin in Ceylon. In 1719 the Academy of Sciences at Paris announced in their Memoirs for 1717, that in the latter year Mr. Lemery had laid before them a stone found in a river in Ceylon, answering to the description of Tourmaline.

In the Dictionary of Natural History, which is often printed with Hübner's preface, under the article *Trip* the following passage occurs:—"This stone was brought to Holland by some persons who had travelled in India, from the Island of Ceylon, where it is found pretty frequently among the fine sand near Colombo, and sold to the German Jews. These caused it to be cut thinner, and the price of it soon rose to 8 and 10 Dutch florins. It has been since much dearer; but at present it is cheaper." The first person who thought of explaining the property of the Tourmaline by electricity was Linneus, who in his preface to his *Flora Zeylanica*, calls it the electric stone.

ROYAL BOTANIC GARDENS.

EXTRACTS FROM THE REPORT OF THE DIRECTOR FOR 1889.

1.—*Pérádeniya Gardens.*

THE cumulative work of the past ten years has at length resulted in the whole extent of these grounds being in fairly satisfactory order and well in hand, all that is now necessary being to keep them up at the improved standard they have reached. For this purpose our labour force is sufficient, and the increase made during the past year to the vote for Garden requisites has raised that also to an amount more adequate to meet the various demands of a large botanical establishment.

Lawns.—The fine stretches of turf have had much attention devoted to them during the year, and are very greatly improved. A large staff of boys has been constantly at work digging out the *Elephantopus* and other disfiguring weeds, levelling, removing anthills, stones, &c., working the meadow-mower and smaller machine, and sweeping up leaves. The large meadow-mower was thoroughly repaired in the early part of the year. The extraordinary rains of April brought on the annual attack of beetle-grubs earlier than usual, and by June the lawns were almost bare, but as usual they quickly recovered themselves.

Though not connected with the Botanic Gardens, this seems also the right place to put on record the successful establishment at Colombo of the great Brazilian water-lily, *Victoria regia*. Two plants of this, from the Agri-Horticultural Society's Garden at Madras, were brought by the Honorary Secretary, Mr. Thurston, to Colombo in October, and having been planted in a new tank in the Fort Public Gardens produced flowers in January, 1890.

Labelling.—The majority of the trees and shrubs of interest are now provided with clear and conspicuous labels, this work having been vigorously carried on during the year, two or three men being kept constantly employed. The interest and usefulness of the Garden to visitors have been very greatly increased by the information thus given. The labels now used are made of brick, and are beyond the attacks of white ants, and very permanent. This is the cheapest material that can be obtained, and the only defect is a liability to break across near the ground, owing to imperfect baking. The lettering is in white paint on a black ground, and this is the principal cost. I am also experimenting with another label, in which printed tickets can be employed (thus much reducing cost); these are made of cement, in which a piece of glass is inserted over the name, and if these are found to be watertight they will probably be the best and cheapest form.

Large labels bearing the names of the Natural Families have been set up in their respective places in the Herbaceous Ground.

Visitors.—No less than 1,534 persons (not resident in Ceylon) signed their names in the visitors' book, a considerable increase over last year. The opening of the new station at Pérádeniya, which took place on December 1, has rendered it easy to visit the Gardens by train, the station being no more than about a quarter of a mile away.

Weather.—Though the rainfall for 1889 was about the average in quantity, its distribution was very unusual. As a rule, our two wettest months are October and June, but their places were

occupied in the past year by April and July, months with usually but a moderate fall. The rains of the north-east monsoon, in the three last months of the year, were also remarkably slight in amount, only 18.42 in., against an average of 31.10 in. for the previous six years, and the deficiency here was made up (so far as the whole yearly amount is concerned) by the extraordinary fall in April—nearly double its average for the previous five years—and in July. The unusual distribution has considerably affected the averages of past years.

This comparative failure of the north-east monsoon has not injuriously affected the vegetation of the Gardens in any way, but the premature and excessive fall in April stimulated the giant bamboos to send up their culms a month or more before the usual time; they grew, too, with great rapidity—one which Mr. Clark measured lengthening at the rate of $13\frac{1}{2}$ in. in twenty-four hours. The fine mass of this species, which I mentioned in my last report as having suffered from the flood of 1888, appears to be still further weakened by this excessive growth, and one side of it has died. The whole clump will have to be removed.

2.—*Hakgala Garden.*

Many improvements have been carried out here during the year, details of which are given in the Superintendent's report printed below. The most important are the continuation of the retaining wall along the high road, the remaking and metalling of the old carriage drive, the repairs to the Conservatory, and the clearing and transformation of an abandoned tea and coffee plot below the nurseries. So many new roads and paths and other alterations have been made in the Gardens during the last eight years, that it is now very desirable that they should be re-surveyed, and an accurate plan made.

I again wish to urge the necessity of an examination and report by an expert on the best mode and probable cost of a constant supply of water to the Garden. Its want was not experienced to any serious extent during the past year owing to the even distribution of the rainfall, but severe droughts may at any time occur again.

The number of species in cultivation in this Garden is now over 2,500, and is constantly increasing; it is in contemplation shortly to affix labels to the more interesting and attractive plants.

During my absence in Europe on leave Mr. Nock acted as Director of my Department, and carried out his duties in a very satisfactory manner.

Hares and Porcupines.—These animals have been very troublesome during the year. The former do great damage to the Herbaceous Garden and Nursery, as well as in the little experimental plots of grass. The porcupines destroy such plants as iris, lilies, cannas, dahlias, and others with roots of a bulbous or succulent nature. We have tried to catch them with snares and traps, but have, as yet, failed.

Visitors.—The number of visitors during the year was 1,185, being an increase of 69 over that of last year. The largest number in any month was 194, in January, and the smallest 31, in June.

Weather.—The weather was remarkable for an excessive rainfall during the first nine months of the year, for the late and very light north-east monsoon, and for the strength and continuance of the wind of the south-west monsoon till quite late in the year. It did not really settle down and come steady from the north-east quarter till the end of November. During the south-west monsoon the wind continued at a higher rate of speed for a much longer period than has yet been recorded from this station, and in consequence much more damage was done to the trees and plants than usual. I may state that the anemometer shows the true direction of the wind that passes over this Garden during the south-west monsoon to be N.N.W., and that during the north-east monsoon is E.S.E.

The total rainfall for the year was 88.34 inches, which fell on one hundred and eighty days. This is a little less than last year, but still about 1 inch higher than the average for the previous five years, which was 87.36 inches.

The average mean temperature of the air for the last six years is 63.1.

The highest temperature in the sun's rays during the year was 154 on March 10, and the lowest on grass was 37 on December 31.

The mean amount of cloud for the year was 6.8, the cloudiest month being November, with a mean of 8.2, and the brightest month was, again, February, with a mean of 3.9.

3.—*Henaratgoda Garden.*

The Muhandiram in charge reports that the very wet season from April to September caused much wash and necessitated a good deal of work in renewing the paths. No record of rainfall is kept here except of the days on which it falls, which were 163 in the past year.

The Garden is in excellent order, and its contents generally in a flourishing state. A few improvements have been made during the year. New gates have been put up at the entrance, the plant house has been improved by the erection of brick stages and a roof of coir matting, and the Conductor's house painted and his office enlarged; this building requires tiling. About half an acre of the remaining jungle has been cleared and a plantation of black pepper, grown on *Erythrina* sticks, formed. Two hundred brick labels from Peradeniya have been painted with the names of some of the most interesting trees and set up in their places.

Very few persons now visit this charming little tropical Garden; there were but twenty-nine in the course of the year. As I have remarked before, this is due to the fact that the quick trains

no longer stop at Henaratgoda station, and that the nearest resthouse is at Mirisweti, three miles from the Garden. By leaving Colombo, however, by the slow train at 6 A.M., it is possible to spend some three hours at the Garden and get back to Colombo before midday.

4.—*Anurádhapura Garden.*

We have had much difficulty this year in obtaining water for the Garden, the supply from Tissa tank being only occasionally available for us. Moreover, the small pond in the Garden is so nearly on a level with the point in the *ēla* from which our open channel is supplied, that, even when allowed to enter, water will scarcely flow. After consultation with the Public Works Officer, it has now been decided to deepen the pond, and to supply it from a point in the *ēla* much closer to it, by a short sluice through the bank. It is hoped that this alteration—the cost of which can be met from the small Provincial vote annually placed at my disposal—will be effected early in the year, and that thus, being able to fill the pond periodically, we shall be able to tide over times of scarcity. The rainfall for 1889, however, 49·76 in., though rather below the average, was fairly well distributed, falling on no less than eighty-eight days. As elsewhere in the Island, April was an extraordinarily wet month, 10·73 in., falling on fifteen days, being registered.

A portion of the Garden which was very rough has been levelled, the Arachchi's bungalow thatched and repaired, and cooly lines partly built. No prison labour has been available for work in the Garden during the year, owing to all being engaged on the clearing and excavation of the ruins. I was able to purchase 200 loads of manure for the Garden this year, which was much needed.

5.—*Badulla Garden.*

Progress here is but slow; want of labour, a very irregular supply of water, and the trespass of cattle are some of our principal hindrances. With regard to the first, it has been a subject of some surprise and disappointment to me that my frequent requests for the use of some of the large number of prisoners employed on public works in Badulla have been met to the extent of only ten men for five days during the whole of the past year. I hope, however, that now certain large improvements in the town have been completed, more assistance in this way will be provided for the Garden. The conductor would be enabled to make considerably more progress if a small number of prisoners were regularly told off for work here, and the practice steadily continued for some time.

As regards the water supply, it is expected that this will be provided for by means of a channel which is to be carried across the Garden for the supply of an artificial lake in the centre of the adjoining racecourse. In connection with this channel, it is intended to make a tank in the Garden, and I have the assurance that for this work prisoners will be allowed.

A fairly good supply of manure is regularly received from the town. By its use many of the trees and shrubs are making good growth and beginning to give some shade to this very exposed piece of land.

8.—*Notes on Economic Plants and Products.*

Tea.—It has been my custom in these annual reports to place on record the exports of the leading plantation products of the Colony, and make some comment upon them. The story, however, from year to year is now of much the same character, the tea enterprise having so greatly overshadowed all others and engrossed so much attention, that there is less and less to report on other products.

The export for the commercial year ending September, 1889, reached over 32½ million pounds (32,516,682 lb.), nearly 12 million lb. more than in the previous twelve months. For the calendar year 1889 it amounted to 33,383,035 lb. The Australian Colonies took of this somewhat over 1¼ million pound (1,134,156 lb.), a considerable increase over the year before, but still a very small proportion of the 24 million pounds annually consumed in those Colonies.

The price of our tea in the London market has been subject to remarkable fluctuations during the year, being very low in the middle, but more than recovering towards the end; and the average for the whole year may be put at somewhat over 11*d.* per lb., which is very little less than that of the year before. Bearing in mind the greatly increased quantity, this must be considered a decidedly satisfactory position.

Encouraging, too, is the general absence at present of any serious drawbacks to cultivation in the way of insect or fungus enemies. Green bug is troublesome in a few places, and at least one attack of *Helopeltis* ("Mosquito Blight") has been recorded, but these are of little account. It is, however, most earnestly to be hoped that this present general immunity from any serious pests will not blind planters to the necessity of providing against future possibilities by paying attention to other cultivations.

Cinchona.—The export for Ceylon for the commercial year has been 10,498,487 lb., a further fall of over a million pounds in the gradual lessening which has been going on since 1886. The

diminution is further exhibited if we take the figures for the calendar year 1889, which are only 9,179,280 lb., and the process must now continue at a rapidly increasing progression. As a consequence, the price of bark may be confidently expected to rise, though it must be remembered that our place as dominating the market is being taken by Java. The question, however, arises whether a revival of cultivation here should be recommended, and it is well worthy of consideration. Speaking generally, I consider it has been sufficiently proved by experience that neither the soil nor the climate of Ceylon are well suited for cinchona trees, which have shown themselves here to be, as a rule, short-lived and unhealthy. I refer especially to the wet and windy localities so frequent in the planting districts; the mortality here is indeed so great among young trees as to render it almost impossible to cultivate cinchona with success. But in the drier districts the case is different, and in places where *C. officinalis* and *C. robusta* hybrid do well the cultivation is likely to again prove very profitable. But with the large consignments of bark of high quality from Java to compete with, it will be more than ever useless to grow inferior varieties.

Coffee.—An export of 86,440 cwt. for the commercial year—84,749 for the year 1889, a decrease of over 50,000 cwt.—shows coffee to have at length come down to the position of a quite secondary product. Nor—in spite of the encouragement of high prices—are there any signs of a general attempt at a revival of this cultivation. Reports, however, of the great improvement of coffee under shade in Coorg and Mysore have led to the planting up of some estates with trees, especially with the native *Ficus glomerata*, which is considered in India to be peculiarly suitable. The effects of shade on the appearance of coffee are undoubtedly striking, and in very dry climates (as the districts of India mentioned) particularly so; diseased and exhausted bushes are doubtless kept living and retain their leaves longer when shaded, but the quantity of blossom and crop is, I should suppose, not likely to be increased. Moreover, it should be remembered that the shade-trees themselves are an additional burden on the land (an important matter on a poor soil). On the other hand, they undoubtedly afford some protection against continual and excessive infections by the spores of *Hemileia*; and their general absence in Ceylon in the past doubtless helped on the very rapid spread of leaf-disease through the Island.

Cacao.—There has been a considerable increase in the export of this for the commercial year 1888–89, 14,461 cwt.; and that for the year 1889, 17,164 cwt., is the largest yet recorded. It is much to be regretted that so small an area of the country appears suited to this cultivation. Even in suitable localities cacao still suffers somewhat from the attacks of *Helopeltis*; and larger enemies that have to be kept down are squirrels and wild cats.

Caoutchouc Trees.—With reference to the remarks I offered in my last report as to the great desirability of Government taking up the cultivation of *Hevea* (Para rubber) on a large scale, I have now the satisfaction of being able to record that the Forest Department has made a commencement by the selection of land near Nambápana, in Sabaragamuwa, a portion of which is to be cleared and planted during the ensuing season. This decision was not come to till too late in the year to enable the seed of 1889 to be used for the purpose. We had a large crop at Henaratgoda, and a smaller one at Pérádeniya. As I have often had occasion to point out, these seeds quickly lose their vitality and have to be sown immediately. About 8,000 were sold, a considerable number sent properly packed to Queensland, and the remainder sown at Henaratgoda, where there are now several thousand seedlings, which, when “stumped,” can be rendered available for planting out.

I have supplied the Forest Department with such information as our experience of this tree at Henaratgoda has afforded us. It may be useful, as showing the rate of growth, to bring together the records taken at the end of each year of one tree at Henaratgoda for the past ten years. The tree was four years old in 1880; the circumference is taken at 3 ft. from the ground.

		ft.	in.			ft.	in.
1880	1 4	1885	3 7
1881	1 9	1886	4 1
1882	2 1½	1887	4 5½
1883	2 6	1888	5 0
1884	3 0	1889	5 5

The Panama rubber trees (*Castilloa*) do not now grow rapidly; the best tree at Henaratgoda has increased during the year half an inch only, being now 3 ft. 5 in. in circumference. At Pérádeniya the trees of this species are not looking healthy or thriving well.

In March last the conductor at Henaratgoda experimented on the rapidity of the flow of rubber from a Para, a *Castilloa*, and a Ceara tree respectively, and reports that to obtain 4 oz. rubber it took, from a Para tree 3½ hours, from a *Castilloa* 2 hours, and from a Ceara 5 hours.

To illustrate the importance of the caoutchouc trade, I may quote some figures of the imports from Brazil into the United Kingdom. In 1887 no less than 113,955 cwt. were imported, valued at £1,655,115, or about £14 per cwt.; the greater part of this was Para rubber, the price of which during the past three years has varied between 2s. and 3s. 6d. per lb. This enormous quantity is wholly

obtained from wild trees, and additions to the sources of supply are urgently needed ; indeed, there is every probability that in the long run, as with cinchona so with caoutchouc, it is upon systematic plantations in the Old World that we shall have to depend for our supply.*

Guttapercha.—The increase in these slow-growing trees is but slight. *Payena Leerii* is 23 ft. high and 10 in. in circumference, and *Dichopsis pustulata* 14 ft. 9 in. high, with a circumference of stem of 9 in.

Cotton.—The mills of the Ceylon Spinning and Weaving Company at Colombo being now in working order, the company is prepared to purchase at certain rates any quantity of Ceylon-grown cotton : and a considerable quantity of the Tinnevely sort and smaller quantities of Egyptian and New Orleans has come in from the Jaffna, Batticaloa, and Anurádhapura districts.

In continuation of previous consignments (see my last report), Mr. Mitchell sent, in January, seed of the Bourbon variety. This was tried at Henaratgoda, Badulla, and Anurádhapura, and in the latter Garden afforded a small but fairly good crop of pods. At Badulla it suffered much from red bugs, and at Henaratgoda it failed completely.

A very successful experiment with Sea Island cotton on an estate in the Dumbara district requires some notice, as showing what may be done by careful cultivation in a favourable season. A very fine crop is now (February, 1890) being harvested off 90 acres sown at the end of August in good soil, after experiencing an eminently favourable north-east monsoon.

By the kindness of the proprietors I have been provided with the record of rainfall for the last three months of the past year, the critical time when the pods were ripening, and of the two previous years ; and as the result so strongly confirms the remarks made in my last report as to influence of dry weather on this cultivation, the record is here given :—

			1887.		1888.		1889.
			Inches.		Inches.		Inches.
October	8·82	...	10·55	...	7·47
November	11·51	...	6·31	...	4·68
December	*...	...	17·21	...	9·64	...	3·03
		Total ...	37·54		26·50		15·18

The contrast of the past season, as compared with 1887 and 1888, is very marked, especially in December, and the failure of the rains of the north-east monsoon, however injurious to some cultivation, proved most beneficial to the cotton crop. The only insect enemy which proved serious in this locality was *Helopeltis*, which almost destroyed a patch of a few acres ; but its ravages were stopped completely by a systematic catching by hand.

Tobacco.—A large quantity of tobacco, chiefly of the Sumatra sort, has been grown and cured in the Mátalé and Dumbara districts, and at the present time (February, 1890) as much as 62 tons of cured leaf is being sorted and stacked on one estate in the latter district, where most of the curing is carried on. It remains to be seen how Ceylon high-class tobacco will fare in the home market.

Cubeba.—My efforts to obtain this plant for the Gardens have been continued. On June 5, we received from our correspondent at Soerabaya, Java, a Wardian case containing twelve plants and six cuttings, with the assurance that the greatest care had been taken to insure the acquisition of the right plant. The cuttings were dead, but nine of the plants were in good order, and these were at once planted out, and are doing well both at Pérádeniya and Henaratgoda. None have yet flowered, but from the foliage alone I fear that again we have failed to obtain the true *P. Cubeba*. I still, however, hope to get from Java ripe seed (as to which there could scarcely be any doubt) sown in a Wardian case and allowed to germinate before leaving.

Gambier.—This product has been suggested as a desirable cultivation for the natives in the wet districts of the south of Ceylon, and an application from the Government Agent of Ratnapura for a large supply of seed has been forwarded to the Singapore Government. I made a few remarks on the plant affording this substance in my Report for 1887 (p. 14), and on the difficulty I had found in getting either plants or seeds here alive. In August last we again received a small supply of

* The only plantation of *Hevea* in the East at present is that under the Indian Forest Department at Mergui, Lower Burma. According to the last Report (1888-89) there are here 49 large trees—probably the survivors of the 500 sent from Ceylon in 1878—6,358 put out in 1887 and 1888, and 15,607 in nurseries.

seed, but none germinated, and in November two plants arrived in a Wardian case, but soon died. I am now informed by Mr. Ridley, Superintendent of the Singapore Botanic Gardens, that these seeds do not retain their vitality after gathering for more than twenty-four hours. But the plant grows like a weed at Singapore, and if once successfully introduced here would probably flourish equally well.

Sarsaparilla.—The “Jamaica Sarsaparilla” of commerce is the produce of *Smilax officinalis*, and comes chiefly from the Cordillera of Chiriqui in the Isthmus of Panama. It derived its name “Jamaica” from being formerly brought from Central America to that island, whence it was exported to Europe. Of this plant next to nothing is known, but a *Smilax* has been cultivated in Jamaica itself for many years, and affords a sarsaparilla which is exported to a small extent. A local nurseryman having recently forwarded a sample grown in Ceylon from plants of this kind imported from Jamaica, attention has been again called to the plant, of which several specimens from Kew are in cultivation at Pérádeniya. I gave a woodcut illustration of the base of the stem and roots of this *Smilax* in “Medicinal Plants” (sub t. 289), in an account of *S. officinalis*, to which species the late D. Hanbury considered it to belong: but as I there pointed out, the specimens do not well agree with DeCandolle’s description of the type-specimens of that species. Quite recently also Sir J. Hooker has expressed his opinion (Bot. Mag., sub t. 7054) that the cultivated Jamaica sarsaparilla and *S. officinalis* will prove, when their flowers are known, to be different species.

Disease in Coconut Leaves.—Some alarm was caused in the early part of the year on a coconut estate at Véyangoda by an affection of the leaves of this palm. The disease was seen to commence as small yellow roundish spots, which gradually die in the centre, and by spreading and coalescing finally result in the death of considerable portions of the leaf. A parasitic fungus at once suggested itself as the cause, but a careful microscopical examination has not revealed to me the presence of any species likely to cause the damage. Mr. M. C. Potter, of Cambridge, however, who investigated some material which he took home with him from Ceylon, informs me that he finds a fungus in the patches allied to *Helminthosporium*, which he thinks may do some damage. This I did not detect in the specimens examined by me, and I have arrived at the conclusion, from an inspection of the trees and from the history and local character of the affection, that the malady is due to some cause affecting the general nutrition of the trees attacked. The disease does not show any decided tendency to spread even in the neighbourhood of the worst cases.

Oranges from Queensland.—The loss of a consignment of grafted oranges from the Queensland Acclimatization Society in 1886 was recorded in my report for that year (p. 10); and I am now glad to report the arrival of a second assortment in September in excellent order, from the same source. There are twenty-four selected named varieties, and a plantation has been formed at Pérádeniya, where they are doing well.

Kei Apple (Aberia caffra).—Bushes of this at Hakgala of some age, but of the origin of which we have no record, fruited during the year. This large spiny shrub is a native of Natal and Kaffraria, and grows well in South Europe and other warm temperate regions; in Natal it is much used for fences. The fruit has a very agreeable acid flavour, and is well adapted for preserves. The plant is a near ally of our native “Kétembilla” (*Aberia Gardneri*), the smaller fruit of which is also edible.

Fruit Garden at Hakgala.—Mr. Nock reports:—

The beds for the fruit trees were completed in January, and the plants set out 6 ft. apart. They commenced to grow at once, and the cherries and raspberries bore a good many fruit. The apples, pears, plums, cherries, and peaches made very fair growth, and the wood ripened well. They began to rest in June. The strong winds at this time blew off nearly all the leaves, and they had a very rough time of it. Early in November all were pruned that required it, and it was hoped that they would then start into active growth, and to induce them to do so they were lightly syringed night and morning. Nearly all the apples and a few of the pears and plums started into growth in December, but I regret to have to report that none of them look really healthy, and I am afraid that very few are likely to do much good.

Trial of Potatoes at Hakgala.—Mr. Nock, having received from England tubers of twenty varieties of potatoes, has been able to make a trial of them, and gives the results as follows:—

They were planted, in good soil, on February 6 in a plot of ground facing the east. They began to show on the 15th; by the 20th were all above ground, and by the end of the month most of them were earthed up.

During the first three or four weeks they suffered a good bit from grub, especially Nos. 2, 8, 10, 15, 18, and 19. They grew very fast, and looked remarkably well till the heavy rains at the end of March, and immediately after the rains some of them began to show signs of disease in the tops, the worst being the Kidney varieties, Nos. 5, 9, 13, 15, and 19.

The weather continuing wet they were all lifted on April 22, having been in the ground only seventy-five days. If the weather had been fine they would have been allowed to stay in the ground a fortnight or three weeks

longer. The sets were all carefully counted and weighed before they were planted, and the tubers produced were counted and weighed as they were lifted. The following table will show the result:—

No.	Names.	Number of Sets.	Weight in Ounces.	Number bitten off by Grubs.	Number of Tubers produced.	Weight in Ounces.	Remarks.
1	Magnum Bonum ...	15	28	1	250	336	Stood the rains well
2	Vicar of Laleham ...	16	28	6	36	146	Do. and tubers all large
3	White Roses ...	15	22	1	170	336	Do. and tops not much diseased
4	White Elephant ...	15	28	1	86	216	Do. do.
5	Ashleaf ...	8	7	2	30	11	Very badly diseased, and very small
6	Adirondack ...	13	29	—	140	336	In every way satisfactory
7	Weber's Early White Beauty	17	21	1	130	352	Do.
8	Mona's Pride ...	8	8	6	36	32	Suffered from grub, otherwise good
9	Racehorse ...	4	3	—	22	15	Badly diseased
10	Tom Price's Black Prince	9	9	6	24	16	A capital potato, no disease, but badly cut off by grub
11	Reece's Kidney ...	4	4	3	4	1	Suffered from grub
12	Chiswick Favourite.	4	7	—	32	64	Stood the rain the best, and in every way satisfactory
13	Bowyer's Kidney ...	5	6	3	16	16	Badly diseased
14	Imperator ...	10	18	3	80	208	Stood the rains well, a capital potato
15	Premier ...	6	7	6	—	—	Came up weakly, and all were taken by grub
16	Beauty of Hebron...	4	5	—	21	64	Suffered badly in the tops, but a fine potato and of large size
17	Cosmopolitan ...	6	9	2	26	48	Suffered badly in the tops, but fairly good crop
18	Yorkshire Hero ...	5	6	5	6	3	Did no good
19	Myatt's Prolific Ashleaf	14	21	10	36	24	Suffered most from grub, and produce very small
20	Sutton's Seedling ...	19	25	3	145	240	Suffered badly in the tops, but gave a good round crop

It will be seen from the above that ten or twelve sorts gave capital returns, Weber's Early White Beauty being the best,—producing 22 lb. from 22 oz. There is no doubt that potatoes can be grown very profitably at elevations from 4,000 to 5,500 ft. if they are planted in the dry months, but a week's heavy rain, or even a soaking of 2 or 3 in. of rain, generally brings on disease and puts an end to their growth, and when this occurs the sooner they are lifted the better.

Shantung Cabbage.—Seeds of this Chinese vegetable, the “Pé-tsai,” were received from Kew early in the year. A good account of this cabbage will be found in the Kew Bulletin for May, 1888 (p. 137). It is the *Brassica chinensis*, L., and is considerably different in appearance from the ordinary varieties of cabbage. The seeds were sent to Hakgala, and the following report is now forwarded by Mr. Nock:—

It grows, I find, remarkably well here. In appearance and habit of growth it is like a gigantic Cos lettuce, bright pea green in colour, and when cooked possesses a very agreeable and delicate cabbage flavour. It also has the great advantage of standing the rains well, and growing quickly to a size ready for use. The stalks of the leaves being thick and succulent, can be dressed and eaten like seakale, and taken altogether it may be considered a valuable addition to the kitchen garden.

In China it is also eaten uncooked as a salad, and said to have a very delicate flavour.

Stachys tuberifera, Naud. (*Stachys affinis*, Bunge).—In continuation of last year's report Mr. Nock writes:—

The crop of this vegetable was taken up in September, and weighed 20 lb. This was the produce of a small patch of land 9 ft. long by 4 ft. broad. The soil was literally full of the small edible roots. They are, however, I fear, too small and insipid to meet with much favour among Europeans. The roots were stored in dry sand, but they did not keep well, and a good many very soon decayed. All the sound roots were again planted in December, and commenced to grow at once. We have now a good stock of plants, and can supply any one who wishes to try them.

This vegetable seems to be very popular in France, and at Amiens a preserve is made from it. The English name for it in some catalogues is “Vegetable Whitebait.”

Ullucus tuberosus.—The following further information on this vegetable is sent by Mr. Nock :—

The crop of these tubers was lifted early in the year, and the produce from 30 square feet was 15 pounds, and from another little patch was gathered 9 lb. Reckoning 15 lb. from 30 square feet, they cropped at the rate of 9 tons to the acre. But the whole crop of 24 lb. was taken from a space of 100 square feet, which gave a yield of, say, 5 tons to the acre. This shows a variation, of, say, $4\frac{1}{2}$ tons an acre for a bad crop up to 9 tons for a good crop. Fifty of the largest tubers weighed exactly 20 oz. The 12 largest weighed 6 oz., and the largest single tuber exactly $\frac{2}{3}$ of an oz.

They have very much improved in strength of growth and size of tuber since last year, and I think by selection and careful cultivation there is no reason why they should be produced in a few years as large as ordinary potatoes. And if the flavour can only be improved in a corresponding degree, it would become a valuable vegetable, as it grows well, and so far has not been subject to any disease.

The above anticipations of Mr. Nock have been since confirmed by the results of lifting, on February 26, the crop yielded by 50 selected tubers planted on June 10, and weighing only 17 oz. He writes :—

I found the yield to be 52 lb., and the largest tuber was a little over 2 oz. One root gave 636 tubers, weighing 6 lb.. These were grown in a bed only 32 ft. long by 3 ft. wide ; the yield per acre would be enormous.

Mr. Nock sent me twelve of the best tubers for trial as a vegetable, and boiled in well salted water until quite tender, and served with white sauce, they are excellent. They are a little "waxy," but I think that in this tuber, if we have not exactly a substitute for the potato, we have a very good addition to our vegetables.

Conifers at Hakgala.—The yield of timber of two trees at Hakgala cut down this year is worth nothing—one, *Cryptomeria japonica*, about sixteen years old, produced 90 ft. of 1-in. boards, measuring in width 16 in. at bottom to 6 in. at top. The other, *Cupressus torulosa*, about twenty years old, gave 176 ft. of 1-in. boards, much like white pine in appearance, and easy to work.

Library.—The MS. catalogue of the contents of the Library, which I prepared several years ago, and have since kept up, has now been printed, forming a little pamphlet of 28 pages, which was issued in February. The titles are systematically arranged under thirteen classes of subjects.

The Library contains a good working collection of Botanical books, but their careful collation showed that a good many were imperfect. The most serious gaps were in that most necessary constituent of a Botanic Garden library, the "Botanical Magazine," and these, I am glad to say, we have been able almost to fill up by means of a special vote. This was sufficient to purchase the whole of the first series (53 volumes), and seven volumes of the third series, leaving only eight volumes needed to complete this valuable work, which has now reached its 116th annual volume.

Museum.—During the coming year I hope to make a good commencement with a Museum of Economic Botany at Pérádeniya, a small vote for the purpose, long promised, having at length been granted. This will all be expended on glass-fronted cases and glass-stoppered jars, experience having shown that all dried vegetable specimens must be protected from the air. Four rooms of the house formerly occupied by the Director are available for the Museum, of which two are now occupied by timbers, and I purpose, at all events for the present, to restrict the collection to the wild and cultivated productions of Ceylon only. And I may take this opportunity of appealing to all who have the means of obtaining specimens and samples suitable for exhibition to assist me in making an adequate display of raw and manufactured vegetable products of all kinds, and from all parts of the Island, by forwarding such to Pérádeniya.

TEA, COFFEE, CINCHONA, COCOA, AND CARDAMOM SALES.

No. 12.]

COLOMBO, JUNE 19, 1890.

{ PRICE:—12½ cents each; 3 copies
30 cents; 6 copies ¼ rupee.

COLOMBO SALES OF TEA.

Messrs. A. H. THOMPSON & Co. put up for sale at the Chamber of Commerce Sale-room today, 28th May, the undermentioned lots of Tea (8,891 lb.), which sold as under:—

Lot No.	Mark	Box No.	Pkgs.	Description.	Weight lb.	c.
1	N G	1	4	hf-ch bro peo	200	37
2	O K O	2	2	do dust	170	24
3	Esperanza	3	5	do bro or pek	280	58 bid
4	Do	4	15	do or pek	690	72
5	Do	6	54	do pekoe	2268	46

Supplement to This Day's Issue.

EXTRACTS FROM THE REPORT

OF THE

DIRECTOR OF THE CEYLON BOTANIC GARDENS, 1890.

Cultivation.—For some time past I have been desirous to show to greater advantage various attractive climbing or twining plants of moderate size, which are soon lost to sight if planted out amid the general mass of vegetation ; and in the early part of the year I erected near the conservatory five domed trellis-work frames for their support. These are 8 ft. in height by 6 ft. wide, composed wholly of iron rods and wire net, and each accommodates six creepers. For the most part these plants have done well, and a good display of flowers kept up.

Among the plants which have flowered in Pérádeniya for the first time during 1890, the following may be noted :—*Impatiens Hawkeri*, *Lysidice rhodostegia*, *Eucalyptus alba*, *Kalanchoe carnea*, *Grias cauliflora*, *Mouriria guianensis*, *Oxyanthus natalensis*, *Gardenia Thunbergia*, *Ardisia Oliveri*, *Paysonia Leerii*, *Araucaria grandiflora*, *Solanum pensile*, *Odontadenia Harrisii* (= *Bignonia regalis*, Bull), *Jacaranda mimosæfolia*, *Thunbergia affinis*, *Æchmea Weilbachii*, *Costus mosaicus*, *Zingiber corallinum*, *Eucharis Sanderi*, *Griffinia hyacinthina*, *Erythrotis Beddomii*, *Anthurium Rothschildianum* ; and of orchids :—*Burlingtonia candida*, *Saccolabium giganteum*, *Epidendrum vitellinum*, *Pleione humilis*, *Cattleya Lawrenceana*, *C. velutina*, *C. Percivaliana*, *Vanda gigantea*, *Chysis bractescens*, *Cypripedium Argus*, *C. Lawrenceanum*, *C. Roezlii*, *C. Spicerianum*, *C. Sedeni* var. *candidulum*, *Dendrobium crassinode*, *D. undulatum*, *Oncidium flexuosum*, *O. reflexum*, *Phalænopsis rosea*, *Bifrenaria Hamiltoniæ*, *Brassia maculata*, *Stanhopea graveolens*, *Miltonia Clowesii*, *Gongora (Acropera) sp.*, *Acineta Humboldtii*, *Cælogyne speciosa*.

The first flowering also of the coco-de-mer palm (*Lodoicea sechellarum*) requires special notice here. The tree is in its fortieth year, and examination of the immature flowers shows it to be a male. The inflorescence appeared at the end of June, being put forth from the stem between the halves of the split base of one of the leaf-stalks. I regret to say that it never got beyond the bud stage, some mischievous person having cut off the whole inflorescence soon after its appearance. We may however now expect the production of flowers each year.

A fine talipot palm came into flower in the middle of November, and is in full blossom at the end of the year. I believe this tree to be in its fiftieth year.

Race-course Ground.—This piece of Crown land is immediately opposite the Garden frontage, and has lain waste for many years. Since the foundation of the Gardens it has always been more or less under our control, and since 1886 it has been placed under my general care in the interest of the Kandy Race Committee. But I have never possessed any funds for its improvement.

At the end of 1888 the proprietors of the adjoining tea estate applied for a lease of the land for extending their plantation, and the matter was referred to me. I recommended that the portion out of sight of the road should be so leased, but that the remainder forming the frontage to the high road should remain under my charge. This was done, and about eighteen acres remain so reserved. The small sum received as rent is also handed over to me towards the upkeep, and with this I have cleared the land and levelled it. A hedge of dwarf bamboo has been planted along the whole front, and for the present I contemplate keeping the whole under turf. The abolition of this wilderness of weeds close to our bounds has much improved the appearance of the entrance to the Gardens.

Visitors.—The book kept at the Lodge shows that 1,454 persons signed their names during the year. These are almost wholly visitors from home or from foreign countries, residents in the Colony not being asked to sign.

New Edition of Hand-Guide.—The second edition of this little book having run out, I prepared a third, considerably enlarged and brought up to date. Though printed in January this was not actually published till June, the delay having been caused by the time required for the production of an excellent new plan of the Garden printed in colours at the Surveyor-General's Office.

Weather.—The rainfall for the year was only slightly under average, yet the usual monsoons were not well-marked, and there was remarkable deficiency in the usually very wet months of May and October. On the other hand, January and February were much more rainy than usual, and April and September slightly so, whilst the fall in November greatly exceeded the average. Though we experienced a sharp thunderstorm with rain from the south-west on April 4, the regular south-west rains did not set in till June 11; and the north-east monsoon was not evident till the heavy rains of the middle of November.

The following is the record for the year 1890, with averages for the past seven to eight years :—

		1890.		Average.			
		Rainfall.	Rainy Days.	Rainfall.	Rainy Days.		
January	3.61	... 7	1.86	... 4	} for 7 years 1884-90	
February	4.85	... 8	1.43	... 4		
March	1.95	... 7	3.59	... 8		
April	10.94	... 18	9.48	... 13		
May	4.17	... 7	7.67	... 12		
June	8.79	... 17	9.94	... 20		
July	8.24	... 18	7.66	... 16		
August	3.36	... 13	6.62	... 15	} for 8 years 1883-90	
September	8.47	... 16	7.83	... 14		
October	6.30	... 19	11.21	... 18		
November	12.75	... 19	9.96	... 17		
December	8.75	... 9	7.92	... 11		
Year	82.18	158	84.99	149	for 7 years 1884-90	

The heaviest fall in any twenty-four hours recorded was 3.34 in., which fell on December 4.

2.—*Hakgala Garden.*

I give below, as usual, copious extracts from Mr. Nock's report of the work carried on during the year. Every attempt is made to keep the Garden up to a good level, but to do this thoroughly and pay full justice to the numerous and varied kinds of plants now grown require a larger expenditure than our limited means allow. The character of the Garden, its situation, and climate, render its upkeep an expensive matter, and I hope that it may soon be found possible to grant a somewhat more liberal vote for its maintenance, and so enable us to carry out more perfectly the objects of this useful and attractive institution.

A few improvements require special remark. The design of relieving the conservatory from having to do duty also as a propagating house has been partially met by the erection of a building for the purpose, as described below; and a larger house with a similar object will be put up during the coming year.

I am glad to report that the Officer of the Public Works Department has submitted a plan and estimate for the restoration and improvement of the storage reservoir for the supply of water to the Garden, and that these being approved, work is to be commenced immediately.

The picturesque appearance of the lower pond having become impaired by serious leakage through the bund and retaining wall, which caused the level of the water to be often much below the spill, repairs have been effected and the level restored.

A further portion of the old carriage drive has been remade, and another piece will be taken in hand shortly. Nothing is more required at Hakgala than the improvement of this badly-traced, irregular, and uneven road.

The only very unsightly building now remaining on the grounds is the thatched shed for visitors' carriages. This is in a dilapidated state and not worth further repair, and ought to be superseded by a more permanent and ornamental structure.

The following extracts are from the Superintendent's report for the year :—

Fernery.—A great deal of work has been done in the fernery, and this took up the greater part of the labour for two months. It was found that the jungle shade trees had thoroughly exhausted the soil. Some of the beds were literally one mass of entangled roots, and the ferns and begonias could not hold their own among them. The beds and borders were taken one by one, and nearly all the plants were lifted. The ground was deeply dug over and the roots removed, and a large addition of fresh soil made, composed of leaf mould, old silt from the lower pond, a little manure, and the decomposed portions of the rubbish holes. To show the heavy nature of this work I may mention that no less than 20 cartloads of roots were removed, and 60 cartloads of leafmould, silt, &c., were used in remaking the beds, 8,500 ferns were replanted in them, and the duplicates were planted under the trees near by.

After this was done a liberal dressing of lime was sprinkled all over the surface of the soil and pointed in. The little paths here are in bad repair, but it is intended to put them in order soon.

It would greatly add to the beauty of the fernery if the undergrowth of the surrounding jungle was cut away, but with our present supply of labour we are unable to find time for this.

In August a bed was made at the top of the fernery for the comparatively rare and striking red balsam, *Impatiens Walkeri*. Plants of this curious species were brought from the Ramboda district, and 76 set out in the bed, where they are now doing well.

Plant Sheds and Nurseries.—A large stock of useful and ornamental plants has been kept up, both for distribution and for the use of the Garden, but a good deal of this work is disappointing. There is but little demand for plants, yet a certain amount of stock must be kept up in case it is asked for; thus a great number of plants soon grow out of hand and have to be thrown away, as the vote allowed for the Garden is not sufficient to enable us to prepare land and plant out any large quantity of duplicate plants. For instance, we have now between 2,000 and 3,000 young oaks growing well in nursery beds, and the number is quite enough to form a respectable plantation as a trial. It was hoped to plant them out on the patana land above the Garden, but it has been found impossible to spare the labour necessary to prepare the land for them, which, if done at all, ought to be done well. This is only one instance of many, and it seems a pity that the trouble and labour, as in this case, of several years' attention should have to be wasted.

There were 487 pans of seeds sown, 49,400 seedling plants were pricked out or transplanted, 89,950 cuttings were put in in nursery and propagating house, and 6,372 plants were potted. Several beds of seeds were sown in the nursery, and some annuals in the open borders.

Borders, Shrubberies, &c.—54,500 plants of ornamental trees and shrubs and garden plants and annuals were set out during the year in beds, borders, and shrubberies, the majority of course being herbaceous plants and annuals; and several new borders have been made.

The rough and unsightly plot of ground immediately above the plant sheds was taken in hand in the early months of the year. The lower part was levelled to give room for the new propagating pit, and the low rough bank above was made even and turfed.

All the undergrowth weeds and rubbish were cleared away from the plot of land below the herbaceous garden, and during the rains in August 17,300 roots of *Paspalum conjugatum* were planted out in it. These are now growing well and will, it is hoped, soon form a nice green carpet.

To the north of this a piece of land has been set off to form a rubbish and soil yard. The site is conveniently suited for this purpose, but it will be necessary to hide it from view by a high hedge. This piece of land has five sides, and in order to give a trial to several plants a different kind has been planted on each side. The following plants and cuttings were put in:—*Frenela rhomboidea*, English oak, *Cryptomeria japonica*, *Duranta Plumieri*, and *Pittosporum undulatum*. All have made a good start, and appear likely to answer the purpose well.

Between the entrance to the fernery and the steps leading up to the office, a retaining wall, 71 ft. long and 3 ft. high, was built, to do away with the uneven crumbling bank that existed there. Sedums, Echeverias, Begonias, and other plants have been planted in the joints between the stones. This now forms a pretty bank. The border made at the top of this bank is planted with a line of *Cineraria maritima*, in a serpentine fashion, to form twenty-four spaces. The spaces in front are planted with different sorts of verbenas, and those at the back with varieties of geraniums. A row of golden feather is planted in front, and between this and at the top of the wall five kinds of ivy-leaf geranium.

A row of box, 65 ft. long, has been planted on the west side of the carriage turn at the end of the flower garden. The plants are growing well and bid fair to make a good hedge.

Along the lower side of the carriage drive from the corner of the new pond to the entrance gate plants of *Cupressus macrocarpa* have been planted out 12 ft. apart. These are intended to form an avenue to replace the scrubby-looking casuarinas now growing there.

During the dry months, when the water in the lower pond was very low, the opportunity was taken of cleaning out a quantity of silt and to make another attempt to stop the leaks. A large trench was cut across the main road to allow the leaking water to escape, and another trench was opened at the back of the retaining wall to the depth of the leaks. This was then filled in with tempered clay, well rammed. The cracked joints in the face of the wall were cleaned out and filled in with cement concrete. This so far has answered well, and I trust will be a permanent success.

When heavy falls of rain come the rush of water flushes over the edging and has several times caused great damage to the drive. To prevent this another course of bricks is required, which would turn the water to the mouth of the outlet.

Turf verges, measuring 430 running yards, twelve inches wide, have been laid down along the sides of the new paths and the part of drive which was reinstated. 1,020 square yards of turf were laid down on banks and in flower garden.

Flower Garden.—As the turf in the flower garden had become uneven and the beds more or less out of shape, it was found necessary to rearrange the whole. All the turf was taken off and the ground levelled and returfed. It was then carefully rolled once a day (a handy iron roller being kindly lent by Mrs. Baker of Nuwara Eliya for this purpose) until it had begun to grow freely, when a new design of twenty-nine beds was cut out in it. These beds were thoroughly prepared and raised to the proper level, and in December were all planted with various showy plants.

Rose Garden.—The rose plants have done very much better this year. Towards the middle of August all the plants were pruned down close. The soil was removed down to the roots, and those that were too low were lifted up and fresh soil placed among and over the roots. A good dressing of leafmould and ashes, with six cart-loads of well-decomposed manure, was then laid on the surface and pointed in. After this treatment they began to grow freely and towards the end of September they were in good bloom. No less a quantity than 4,320 buds and expanded blooms, in 87 varieties, were counted on the 171 plants on September 30, one plant of Lamarque having 675 on it. There was also a good show of roses in the early part of June, 76 varieties being out at the same time, and the blooms were of good colour and substance.

Herbaceous Garden.—This garden has received a good deal of attention in the way of supplies and additions, manuring, and general cleaning up. A good many interesting plants have flowered during the year. I may mention especially a plant of *Eucomis undulata*, about five years old, which threw up a remarkably healthy flower spike bearing a head of forty-eight flowers, all being expanded at the same time. The umbel of flowers measured 2 ft. 6 in. across, the flowers, which are well spread out, bright pink in colour, being borne on stiff peduncles 1 ft. long.

The wedding flower, *Moraea Robinsoniana*, was in flower for several months. This handsome plant was also in bloom at the Horton Plains resthouse garden during the months of November and December.

Cyphomandra fragrans has proved a very handsome flowering plant, and continues in flower a long time through May, June, July, and August. The bunches of flowers, 6 to 8 in. long, hang down from almost every joint, and give a very pretty effect. The Flame tree, *Sterculia acerifolia*, flowered well here this year for the first time. During the end of April and all through May it was quite covered with its brilliant red flowers. A good many pods of seed have set, and they are now ripening up.

May this year was remarkable for the great number of flowers produced. On one day, the 16th, we counted no less than 610 distinct species and varieties in flower—50 distinct varieties of roses were in bloom together, and the bloom on some of the kinds might have been counted by hundreds.

Elk, Hares, and Porcupines.—These animals have done considerable damage during the year, especially the porcupines. These have pretty well cleared out all the *Lilium* tubers from the body of the garden. The hares have been most destructive to African marigolds, carnations, verbenas, and Phlox Drummond; while the elk have turned their attention to the succulent leaves of Arthropodium and other liliaceous plants, and the tops of the tree Fuchsia, Habrothamnus, and Stillingia. They have also barked many plants of Pinus and other trees, which have died from the effects.

Influenza Epidemic.—Nearly every person belonging to the Gardens suffered from this in April. This caused the labour supply to be very irregular during that month, and much time was lost. The time the sickness lasted in different individuals varied from three days to three weeks.

Cattle Disease.—This was very bad in this locality in April and May. Seven of the cattle here were very seriously affected and four died.

Visitors.—The number of visitors during the year was 1,319, being an increase of 134 over that of last year. The greatest number in any month was 154 in December (against 194 in January of last year). The lowest was 46 in June against 31 in June the year before.

The number of tourists has greatly increased, and the Garden is now visited by persons from all parts of the world.

Weather.—The weather during the year was remarkable for its short rainfall and for very light monsoons, both as regards wind and rain.

Permission was granted by the Hon. the Surveyor-General to remove the anemometer and wind vane to a more convenient site, which has presented itself since the Gardens have been opened out, at a distance of not more than one hundred yards from the office. This was done on the last day of June after seven years' observations, which give a good average, of the direction and force of the wind which passes over the Garden. The new site, though not so exposed as the old one on the patana, is one of the windiest places in the Garden, and will be a very fair test of the force of the wind which passes through.

The total rainfall for the year was 70·97 in., which fell on 172 days, being 16·55 in. short of the average of six years, and of rainy days less by 10.

Below I give the usual table showing the monthly rainfall and averages from July, 1883, to the end of 1890, and the number of days on which rain fell during the nine years, 1882-90 :—

	Jan.	Feb.	Mar.	April.	May.	June.	July.	Aug.	Sept.	Oct.	Nov.	Dec.	Total.

* Average of nine years.

† Average of seven years.

The greatest pressure of the wind occurred on June 19, when 3,808 lb. per square foot was registered, being equal to 27.60 miles an hour. This was very low compared with the highest pressure last year, which was 7.372 lb., equal to 38.40 miles an hour, on June 1.

The mean daily horizontal movement of the air for the year was 145.41 miles, against 205.26 miles last year.

The windiest month was June, with a mean daily horizontal movement of 384.37 miles, against 467.24 miles of June last year.

The calmest month was December, with a mean of only 33.51 miles, against 92.1 miles in February the year before. This may be due to the change of the site of the anemometer, and February may really be the calmest month.

The barometric pressure and temperature of the air for the year are given in the following table :—

<i>Barometric Pressure (5,581 ft. elevation).</i>				<i>Temperature of the Air.</i>			
1890.	Mean.	Range.		1890.	Mean.	Range.	
January	24.536	... 192	January	...	60.1	... 27.6	
February	24.573	... 273	February	...	61.0	... 29.8	
March	24.553	... 199	March	...	64.5	... 30.2	
April	24.537	... 203	April	...	64.9	... 27.1	
May	24.507	... 192	May	...	66.2	... 26.0	
June	24.469	... 222	June	...	63.3	... 23.0	
July	24.501	... 158	July	...	62.0	... 21.0	
August	24.507	... 148	August	...	62.3	... 25.4

October	24.516	... 232	October	...	61.2	... 22.0	
November	24.581	... 199	November	...	61.1	... 18.2	
December	24.583	... 217	December	...	58.6	... 24.0	
The 12 months ...	24.530	... 367	The 12 months	62.3	... 38.2	
Highest reading	24.716, on February 3.			Maximum temperature of air, 73.2, on May 12.			
Lowest reading	24.349, on June 10.			Minimum temperature of air, 40.0, on Dec. 23.			

The highest temperature in the sun's rays during the year was 149.0 on May 10, against 154.0 on March 10 last year.

The lowest on grass was 36.5 on February 18, against 37.0 on December 31 of the year before.

The mean amount of cloud was 6.6, against 6.3 last year. The cloudiest month this year was April, with a mean of 7.5, January and November coming next with 7.2. The brightest month was, as usual, February, with a mean of 6.0. This is nearly double what it was last year, viz., 3.9.

3.—*Henaratgoda Garden.*

The rainfall, though moderate, falling on only 96 days, was well distributed over the year. From the commencement of 1891 rainfall records will be kept at the Garden, a gauge having been provided by the Public Works Department.

The condition of this little Garden continues to be very satisfactory, and the various plants are for the most part in good health. A considerable improvement has been effected at the entrance, by clearing the land on the left so as to form a lawn, which has been planted up with palms and ornamental trees.

The plant conservatory has been much improved by the substitution of coir netting for the tiles which formerly covered the roof.

The Garden well has been replanked, and a pump fixed to take the place of the buckets hitherto in use.

I am glad to observe that this interesting Garden has been somewhat more frequented this year. As many as 90 visitors have entered their names in the book kept there, and not a few have added remarks showing their appreciation of the place and of the intelligence of the Mubandiram in charge. The little shelter put up for the convenience of visitors has been re-thatched and whitewashed.

Among the Economic Notes below will be found information as to experiments carried on here with Para Rubber, Gambier, &c.

4.—*Anurádhapura Garden.*

The difficulty of obtaining sufficient water continues, but in this we suffer along with the whole community of cultivators in the place. The scanty rainfall in the catchment area of Kalawęwa has kept Tissa tank very low (there were about 5 ft. of water at the end of the year), and we get water only on one day in every two or three weeks. The alteration in our means of supply referred to in my last report has indeed been carried out by the Public Works Officer, and the improvement is considerable, but the ela we take from is too low, and we need a supply from some higher point. Tissa tank itself would be the best, but whilst it continues to be so empty this would be impossible.

A terribly dry year has been again experienced, only 40·77 in. in all, and of this 18·02 in. fell in one month. As in last year, this wet month was again April. During the next five months only 2·69 in. fell, and by the end of September the condition of the Garden was pitiable: not a blade of grass to be seen, and the larger plants dead and dying. A good fall of 6·27 in. occurred, however, in November, and though the usually heavy rain of December was represented by only 4·36 in., yet by the end of the year things had much improved.

It is indeed remarkable how comparatively well some trees stand the drought which would have been expected to fail to do so. Thus the breadfruit ripened last year, and good plantains of the *kólikuttu* variety were abundant. The only bamboo of those tried that seems likely to succeed is the male bamboo (*Dendrocalamus strictus*).

This Garden rarely has a visitor, but it is becoming a very pretty spot, and the show of flowering shrubs and trees a fairly good one.

5.—Badulla Garden.

Much has been effected here during the year, and at length this Garden is beginning to be an attractive place. Considering that it was planted only so recently as 1886, I am very well satisfied with the progress made.

The season of 1890 has been favourable: a good rainfall—the exact amount of which cannot be given owing to want of records for April—well distributed through the year, has kept up a steady growth, only checked by the dry weather in July to September, and even this was less marked than usual. Heavy rains occurred in January and April and in October and November.

The great improvement of the year, however, has been the provision of a constant water supply instead of the uncertain and intermittent one upon which we had formerly to rely. As was arranged (see my last report), the ornamental lake in the centre of the race-course is fed by a channel which is carried through the Garden, and in its course there fills a small reservoir. This was constructed in April, and is 20 ft. by 9 ft. and 4 ft. deep; it keeps constantly full. The channel cuts the main drive and three smaller paths, and under these culverts have been built. All this work has been done, without cost to my Department, by the Public Works Department and under the eye of the Government Agent, Mr. Fisher, to whom my thanks are due for the active interest he has constantly shown in the progress of the Garden.

Some alterations have been made at the western side of the Garden, where a narrow strip of land adjoining the Mohammedan burial ground, on the north side of the road of approach to the Garden entrance, has been taken in and fenced off with a good hedge of Madras thorn. This faces a similar narrow strip on the opposite side of the road, and an avenue of trees (*Castanospermum australe*) has been planted on either side. It will be necessary to remove the gates from their present position so as to include this avenue within the Garden bounds.

The supply of manure from the town, thirty cartloads a month, was intermittent during the early part of the year owing to the cattle murrain, but has since been steadily kept up. This is a great advantage to the Garden, and its use has had a very marked effect on this old paddy land. I think, too, that the larger trees and shrubs have now got through the exhausted upper layer of soil, and are beginning to get the benefit of the untouched lower strata. Certainly their growth is now stronger and healthier than at any previous time. Some of the young trees of *Cedrela odorata* are already 2 ft. in girth at the base and 16½ in. at a yard from the ground. Our chief trouble now is the vast abundance of white ants, and these are specially destructive in the nurseries.

The unsightly little dwelling of the Conductor was hurriedly put up at the commencement of the Garden, and is badly placed and unhealthy. As two of his children have suffered here from typhoid, I have recommended that a new and better house in a different position may be built for the Conductor, and I trust this may be done during the coming year. The other wants of the Garden are a permanent conservatory for pot plants, better coolie lines, and the proper metalling and drainage of the main drive. Some or all of these I hope soon to supply.

6.—Interchange of Plants and Seeds.

Our exchanges with other Botanical establishments have been less active during the past year than in any previous one of my occupancy; and it is obvious that such a time must at length arrive. Not only do we, as gradually year by year our desiderata are supplied, find that there is less and less to be got, but, at the same time, as we supply other Gardens with their wants we find our resources becoming exhausted, since we have less and less to offer that they require. Indeed, I now find that the receipts from other Botanic Gardens consist principally of things which we have already here.

During 1890 we received in exchange only six Wardian cases and five boxes of plants. They were from the following:—The Royal Gardens, Kew (two cases, two boxes); the Botanic Gardens

of Singapore (one case, two boxes), Calcutta (one case), and Mauritius (one box); and Messrs. F. Sander & Co., St. Alban's (two cases).

Packets of seeds have been received from the Botanic Gardens at Kew, Calcutta, Darjiling Madras, Penang, Buitenzorg, Melbourne, Port Darwin (N. Australia), Hongkong, Jamaica, and Trinidad; from the Acclimatization Society of Queensland; and from Mr. J. Gammie, Bengal; Baron von Mueller, Melbourne; and Messrs. Reasoner, Florida.

The following residents in Ceylon are also to be thanked for exchanges or donations of plants and seeds:—Lady Havelock, Mrs. Baker, Miss Booth, Mrs. N. G. Campbell, Mrs. Wickwar; and Messrs. T. Farr, J. Ferguson, J. Fraser, T. C. Huxley, A. J. Kellow, A. C. Lawrie, F. Mackwood, J. Morris, C. Palliser, E. J. Thwaites, G. Wall, W. R. Waller, A. Whyte, and W. G. Wood.

The Gardens in exchange have sent out during the year eight Wardian cases and ten boxes of living plants to the following:—To the Royal Gardens, Kew (three cases, two boxes); to the Botanic Gardens, Calcutta (two cases), Singapore (two cases, one box), Glasgow (one box), and Cambridge (one box); to Messrs. Bull, Chelsea (one case and several packages); Messrs. Veitch, Chelsea (two boxes); Messrs. Sander, St. Alban's (two boxes); and Mr. Griffith, Nilgiris (one box).

Packets of seeds have been despatched to the Botanic Gardens at Kew, Paris, Cambridge, Calcutta, Singapore, Hongkong, Mauritius, Trinidad, and British Guiana; also to Messrs. Bull, Chelsea, and Mr. Wilson, Soerabaya, Java.

The usual gratis distribution of plants and seeds of useful or ornamental character has been made on application to the following public places and persons in the Colony:—Queen's House, Colombo; Pavilion, Kandy; Queen's Cottage, Nuwara Eliya; the Government Agents of Kandy and Badulla; the Assistant Agents of Mátalé, Nuwara Eliya and Kégalla; the Mayor of Colombo; the District Engineers at Katugastota, Mihintalé, and Maradankadawala; the Forest Officers at Ratnapura and Nuwara Eliya; the Police Stations at Haldummulla and Rágalla; the Hospital grounds at Kandy, Matalé, Lindula, Kelebokka and Nuwara Eliya; the Station gardens at Gampola, Watawala, Watagoda, and Katukurunda; the Post Office compounds at Nuwara Eliya and Uḷa Pusséllawa, and the Resthouse, Horton Plains.

7.—Additions to the Collections.

For the reason given in the last section, our list this year is not a large one. There are however a few valuable additions; and there has been a considerable increase in our collection of orchids, which is wholly due to the liberality of Messrs. Sander, of St. Alban's, who have sent two valuable consignments of fine plants.

The vote for purchases of plants has been expended on a collection of roses from Messrs. Cannell, a selection of seeds of ornamental garden plants from Messrs. Carter, a collection of hardy ferns for Hakgala from Messrs. Veitch, and a variety of seeds and bulbs (also for Hakgala) from Messrs. Boehmer, of Yokohama, Japan.

8.—Notes on Economic Plants.

Tea.—It is not necessary for me to make any observations on this great and increasing cultivation, the excellent condition of which remains in all respects unchanged. The exports for the commercial year ending with September reached over 43 $\frac{3}{4}$ million (43,864,233) pounds, an increase of more than 11 million over the previous twelve months, whilst for the calendar year 1890 it was nearly 47 million (46,901,554) pounds, or nearly 13 million more than in 1889. The average price per pound for the year 1890 in the London market was 11*d.* It is encouraging to observe that the export to Australia (over 2 $\frac{1}{2}$ million pounds) has nearly doubled; and that a direct export to America (over 204,000 pounds) has commenced. Over 75,000 lb. have also been shipped direct to the European continental ports of Hamburg and Bremen, and this it is hoped is but the beginning of far larger exports to these markets in the future.

Coffee.—Nor is there any occasion for me to do more than note, for comparison with previous years, the diminished export of this once leading product—90,104 cwt. for the commercial year, or 86,009 cwt. for 1890.

Cinchona Bark was exported to the amount of 8,686,243 lb. during the commercial year (8,728,836 for 1890). This is still a very large quantity, though the smallest since 1883. No revival of this cultivation in Ceylon has taken place, or seems likely to do so.

Cacao.—The Customs returns give the export for the commercial year as 18,268 cwt., a considerable increase over the previous year, and, it may be suspected, somewhat too high.* The

* In the Report for the year 1890 of the Planters' Association Committee the exports of cacao are given as 15,942 cwt. only.

prices obtained in the home market have been excellent, comparing very favourably with those of Trinidad and West Indian sorts, and the industry here may be considered to be in a satisfactory, and improving condition.

I am sorry to observe, that in spite of the encouragement given by Government, but slight progress has been made by the villagers in cultivating this valuable product. For many years past I have made a large gratis distribution of seed through the kachcheries of the Central and Sabaragamuwa Provinces; but the visible results seem so lamentably small, that I think it desirable to call attention to the matter. During the past eight years, 1883-90, I have distributed in this manner all the pods remaining after supplying purchasers. From Pérádeniya have been supplied 14,823 pods, and from Henaratgoda 11,900; in all 26,723 pods, equivalent to fully 700,000 seeds, besides small quantities of plants. These have been sent to the kachcheries of Kandy, Ratnapura, Mátalé, and Kégalla for distribution, and the question cannot but suggest itself as to what has become of them all. I fear that there is good reason to believe that a considerable proportion has never really reached the poor villagers whom it is intended to benefit, and in this belief I have, during the past year, made a small gratis distribution directly to suitable applicants at the Gardens. I would suggest that this personal distribution, without the intervention of clerks or headmen, be carried out for the future on a larger scale, either at the kachcheries or the Gardens, as the only way of reaching the villagers.

A good deal of interest attaches to the question as to the *kinds* of cacao in cultivation here, and I may supplement the remarks I have made on this subject in previous reports by a few further observations. There is no reason to suppose that we have under cultivation more than one species of *Theobroma*, but every probability that all the varieties trace their origin to a common wild parent. It would be interesting to know which of the two fairly well-marked races recognised in Ceylon is the nearer to this original type, and the facts could probably be ascertained in Central America. The names "Criollo" and "Forastero" applied to them simply mean "wild and foreign," and seem to have had their origin in Trinidad, but it is doubtful if the former was ever really a native plant there. It was, however, the sort at one time exclusively grown in that island, where having died out its place was supplied by the "foreign" sort, no doubt obtained from the mainland.

As seen in Ceylon, the "Criollo" (called also here "Caracas" and "Old Ceylon Red Cacao") presents very little variety, but the "Forastero" shows a remarkable range in form, size, and colour of pod and seed. It was of this sort that the whole of the plants we received from Trinidad in 1880-81 consisted, though some were labelled "Criollo," and for a time led to some confusion. The small plantation formed of these at Pérádeniya now consists of 33 trees, the remainder of the original 42 having been cut out, being inferior varieties, to avoid danger of crossing by them. Of these some are much better than others both in yield and quality, and about six or seven are obviously very superior. Three trees which have the fruit yellow when ripe, are especially good: these came labelled "Cayenne." Another, with a very dark metallic-looking fruit, bore the name "Cundeamar." But, as before remarked, I attach but little importance to these names, which are evidently applied in Trinidad very loosely.

No doubt crossing goes on freely in plantations even between the two main races, and it is well known here that seed from a single tree gives a very varied progeny; but a very curious remark has been recently made to me by a large grower, who has great opportunities for observation, that the "Forastero" varieties, which he chiefly cultivates, appear to be gradually changing their characters and becoming more like the "Old Ceylon Red," the seeds losing their dark colour on section and becoming pale or nearly white. It will be very interesting to observe whether these observations are confirmed by longer experience.

The excellent prices brought by our product in the home market has attracted serious attention in Trinidad, and at the request of His Excellency Sir W. Robinson, Governor of that Colony, I have recently afforded him some information as to the process of curing followed here, a portion of which, referring to the artificial drying of the beans, he has embodied in a useful paper he has communicated to the Trinidad "Agricultural Record."^{*}

As regards the relative values of the two classes of cacao, I may refer to the remarks in my report for 1883. Further experience has however somewhat modified that estimate. The opinion of planters now is by no means unanimously in favour of the "Old Red Ceylon" sort, and in the market the two sorts are often very evenly priced. As an example, lots of both grown on the same estate and kept carefully separate were sold in London on the same day in March last: they fetched respectively, "Caracas," average 106s. 7½d. and "Forastero," average 107s. per cwt.

^{*} I may here usefully refer to an excellent account of the preparation of cacao in Ceylon printed in the "Tropical Agriculturist" for December, 1890, p. 401.

Caoutchouc Trees.—Para Rubber (*Hevea brasiliensis*). The Forest Department has planted at Edangoda, in Sabaragamuwa, with 9,000 seeds supplied from Henaratgoda at the end of August. They germinated freely, but I understand that some of the land being subsequently flooded, many of the young seedlings were drowned. To supply these vacancies I prepared in October several thousand "stumps" (the seeding time being past), but these, though applied, were never fetched away. A very small commencement has thus at length been effected in the cultivation by Government of this valuable tree, but it is to be hoped that it will be more vigorously carried onward, and that a very much larger area will be devoted to it, as on a large scale it must prove highly remunerative.

That the yield of rubber is improving as our trees get older, is evidenced by a further experiment made at Henaratgoda during the past year by the conductor. The tree selected was the same one as was tapped in 1888, the results of which were recorded in my report for that year. The tree is now 13 years old, and its stem girths 4 ft. 11 in. at a yard above ground. It was tapped on the following days: on 7 in January and February, on 6 in July and August, and on 4 in November and December. The method followed was to smooth the surface by scraping off a little of the outer bark to a height easily reached, and then to make, with a $\frac{3}{4}$ in. chisel, numerous V-shaped incisions. At the foot of the trunk coconut cups were fastened with clay, and the milk conducted into them by little ridges of clay. Most of the milk, however, dried on the tree in tears. The tapping was done in the afternoon and the rubber collected in the morning.

From this tree (which yielded nearly 2 lb. in 1888) we obtained this year 2 lb. 10 oz. of good dry rubber, partly in sheet but mostly in tears. The tree appears none the worse for the operation, and I consider the result very encouraging. The whole cost of collection was under a rupee, and in course in operating on a large number of trees in a plantation this would be very greatly reduced.

Our largest tree of *Hevea* is now 5 ft. $9\frac{3}{4}$ in. in circumference at a yard from the ground.

Ceara Rubber (Manihot Glaziovii).—Interest in this plant has of late years very much died away, the yield of rubber having been found too small to satisfy the planter's expectations. Thus we have made no report on it since 1884. There are, however, considerable plantations on some estate and now that the trees are older it is found to be profitable to harvest the product. Several shipments have been made to London during the past year, and have realised very good prices. Of course the quantities have not been large: one shipment of 4 cwt. fetched 1s. $8\frac{1}{2}d.$ to 1s. $9\frac{1}{2}d.$ per lb. net, showing a profit here of about 37 cents (of a rupee) per lb. A planter estimates the cost of collection at about 36 cents per lb., and reckons that trees of eight years old afford at least 30 cents, whilst some ten years old gave half a pound. The collection is done in a somewhat primitive way during the dry season, January to March. After the outer flaky layers of bark have been peeled off, the inner bark is pricked copiously; the tears of rubber which exude are allowed to dry on the tree and are picked off, the resulting product being quite like the "Ceara Scrap" of commerce but in smaller tears.

The present opinion of planters seems to be that this kind of rubber "pays to harvest, but not to cultivate," and they are prepared to destroy their trees to get the crop. But even on such a system (which has been also largely followed here with cinchona) extensive areas of bad soil could surely be profitably occupied with this tree, so grown as to provide a crop annually ready for tapping.

Of other caoutchouc trees I have nothing particular to report. *Castilloa* does not answer my expectations as to growth; our largest tree now girths only 3 ft. $6\frac{1}{2}$ in.

Gutta Percha Trees.—One of our trees of *Payena Leerii* flowered for the first time in December at Pérádeniya, and finally settled any doubt still felt as to the correct determination of the "Gutta Sundek" of Perak. There is a good figure of this species in Dr. Burck's paper on Gutta Percha in the "Annales" of the Buitenzorg Garden, vol. V. The trees of this at Henaratgoda are now 25 ft. high, and nearly a foot in circumference.

Gambier (Uncaria Gambier).—A Wardian case containing nineteen plants of this was received from Singapore at the end of May; five were dead on arrival. Of the rest, three were planted out at Pérádeniya, where they have all gradually died, and eleven sent to Henaratgoda, where they seemed a better chance of their surviving. At the end of the year there remained six plants living of which five are healthy, and likely to do well. The acquisition of this interesting plant is thus at last accomplished. It is however clearly very fastidious and difficult to propagate, but it ought to succeed in our hottest and wettest districts. Naturally an extensive climber, it is in cultivation kept down by cutting so as to form a low bush of 5 or 6 ft. A good account of this production will be found in the Kew "Bulletin" for October, 1889.

Cubebis (Piper Cubeba).—I am unable to report any further progress in my endeavours to obtain this plant, which still remains a desideratum. Recently a Java planter has been advertising plants for sale, but I am not aware whether any have been received in Ceylon from him.

Kola Nut (Sterculia (Cola) acuminata).—This tree is commonly cultivated in Jamaica, here it ripens its seeds in September, growing well in places with a moderate rainfall up to at least 1,600 ft. of altitude. In answer to my request I received from the Botanic Garden there a box containing 190 seeds, which have germinated well, and will, I hope, succeed. I shall be glad to have a stock of young plants, as the only two trees we possess (at Henaratgoda), though now seven years old, have not as yet flowered. The Kew "Bulletin" for November, 1890, contains a full account of this product.

Sisal Hemp (Agave rigida, var. sisalana).—Much interest has been recently taken in this tree plant in consequence of the very large and important industry developed in it at the Bahamas. Several applications about it have been made to me, I applied to the Director of Kew Gardens for specimens, and in May received a box of plants from that establishment. These were planted out at Pérádeniya in September, and are growing luxuriantly.

New Zealand Flax (Phormium tenax).—Mr. Nock sends the following note :—

Several inquiries were made about this fibre plant at the beginning of the year ; and in order to ascertain what weight of leaves a single plant would give, one about eight years old was selected, which was growing in good soil on the margin of a pond in the Garden. It produced 225 leaves, and these varied in length from three to eight feet, and weighed 107 pounds. An acre, at this rate, reckoning the plants at 6 ft. apart, would produce the enormous yield of about 54 tons.

Nutmegs.—A rather large sale of seed has been made during the year at Pérádeniya, where an grove of old trees continues to yield large crops throughout the year. Several planters in the low-country are now taking up this cultivation seriously. Judging from our experience here, it can scarcely fail to be a very-profitable one when the trees once reach full bearing.

Chinese Ginger.—In my report for 1885 I recorded the receipt from Kew of the roots of the plant said to afford the familiar "preserved ginger" of commerce so largely exported from China, and remarked that it was clearly quite distinct from the ordinary ginger plant. As it has never made any attempt to flower with us, it has been impossible to determine its name with any kind of certainty, though it appeared to be a species of *Alpinia*. A few years ago, at the request of Mr. Ford of the Hongkong Botanic Garden, I sent a specimen to that Garden, and Mr. Ford now informs me that it has flowered with him, and proves to be nothing but the common and well known *Alpinia galanga*. This, the "kaluwala" of the Siñhalese, is commonly grown in all native gardens, and grows here freely. On a comparison of the foliage of the two plants I can certainly see but very slight differences, the leaves of the Chinese ginger being merely somewhat shorter and broader, of a ricker texture, and darker in colour especially beneath. The rhizomes are identical, and both have the taste well described by Roxburgh as a "mixture of pepper and ginger accompanied by some degree of bitterness." The Siñhalese use the rhizomes in native medicine, but never as a condiment. According to Harbury and other writers this is also the "Java Galangal," or "Greater Galangal," of the London drug market, and the "Galanga major" of the old pharmacists. It is a little difficult to believe that the "preserved ginger" of commerce is the produce of the same plant, especially as the rhizome has not the appearance of the commercial article ; and I cannot help suspecting the possibility of a mistake having been made when originally sending the plant to Kew.*

Tuberous-rooted Vine (Vitis Martinellii).—This species of vine, native to Cochin-China, has been written of as affording a grape of good flavour. We obtained the plant in 1883 from Hongkong, and during the past year it for the first time produced fruit at Henaratgoda in September. It in no way answers to its reputation, being small, very slightly juicy, and, like most of our wild species, with a harsh and bitter taste. In its present state it is quite useless as an edible fruit.

Fruit Garden at Hakgala.—Mr. Nock reports :—

During the early part of May a good many of the imported fruit trees started into active life after their long rest, but, as was to be expected, the high winds which occurred soon after checked them, and the growth they made was not at all satisfactory. However, one plant of "Kentish Fillbasket" apple set twelve healthy fruit ; these, on account of the small size of the plant, were thinned out to five, all of which came to perfection. The largest measured nine inches in circumference, and was well-flavoured. "King of the Pippins" apple bore six ; four of them ripened up and were excellent in flavour and colour. Two Morella cherry plants made very fair growth, and each plant ripened a few fruit, as also did the raspberries. The figs, too, have grown well, and one kind, "White schia," has borne a quantity of very good flavoured fruit. None of the other imported plants look at all well, and have remained dormant for many months.

The blackberry plants raised from English seeds have done very well. Several kinds have flowered, and one sort, *Rubus mucronatus*, has borne a quantity of good-sized well-flavoured fruit. One spike had on it 32 berries, and

* In an article on the plant in the Kew "Bulletin" for January, 1891, however, I see that the determination is accepted as correct.

most of them ripened. The largest berry measured two inches and three-eighths in circumference. This compares very favourably with the size of those usually grown in England, and being so productive there is no doubt that with good cultivation this sort at least will thrive well in the hills.

Two hundred and ninety-two scions of the large plum were grafted on to stocks of the small inferior kind and the greater part have taken well and will be soon ready for distribution.

Potato Cultivation at Hakgala.—Mr. Nock has forwarded the following valuable practical information :—

There is no doubt that potatoes can be grown very profitably in this locality, provided they are planted at such a time as will enable them to make their growth during the dry weather. The main thing to be borne in mind is to plant them in rich, well-drained and well-prepared land, and to use good varieties and good sets. It is best to use whole tubers of an average weight of from one and a half to two ounces, and not to cut them until the are being planted, at which time a little piece is sliced off. This is merely to assist them to decay as soon as possible after the sprouts have taken good hold of the soil. It is time well spent to prepare the sets for planting by laying them out in a room exposed to the light, occasionally giving them a turn round. This causes the eyes to send out strong sturdy sprouts, and when these are from one-half to one inch long they are in the best condition for planting. For all ordinary sorts the rows may be two feet apart and the sets one foot apart in the row. The very strong growing sorts may be allowed a little more room between the rows. When the sets are prepared as above described they start into growth as soon as planted and show above the surface in about seven days. In a week or ten days more they will be fit for moulding up. From the time they begin to show above ground a sharp lookout must be kept after the black grub, which is very destructive, and has a special liking for young potato shoots. These must be carefully sought for and killed by hand. I know of nothing else that is practicable, but the following mixture is of some use :—Equal parts of soot, fresh lime, and sulphur lightly dusted about the shoots makes them distasteful as also does a mixture of one tablespoonful of soluble phenyle to two gallons of water. The mixture must be kept well agitated, and applied to the roots with a syringe or fine-rosed water-can.

The stems of the potatoes should not be earthed up more than six inches, as more would place the tubers too far out of the influence of the sun and air.

It may be interesting to give the results of a crop of three varieties which were planted here on August 22 and lifted on November 14—thus they were only in the ground 84 days. During that time 12·70 in. of rain was registered. This fell on 47 days. On only 10 of these days did 50 or more fall. On 27 days the amount registered was 15 or less, so that this was just the sort of weather that suited them.

The tubers used were saved from the third crop grown in Ceylon, and were prepared and planted in the way above described. The result was a beautiful even crop, both as regards shape and size, as follows :—

Chiswick Favourite.—From 48 sets the produce was 482 tubers, weighing 85 pounds. The twelve largest weighed 7 pounds and the largest single tuber, 11½ ounces.

Imperator.—From 48 sets of this sort 375 tubers were produced, weighing 75 pounds. The twelve largest weighed 8 pounds and the largest single tuber 12 ounces.

Adirondack.—From 48 sets the produce was 457 tubers, which weighed 65 pounds, the twelve largest 6 pounds, and the largest tuber 11 ounces.

Every tuber of the two first-named was perfectly sound, but 15 of “Adirondack” were diseased; all these were taken from the bottom of the row, where the soil was a little damper. As this was the fourth crop grown here from the produce of imported sets, a little over two years ago, I think it proves that with careful selection and preparation of seed tubers the potato improves in this locality instead of deteriorating, as, I believe, is generally supposed.

Shantung Cabbage.—Mr. Nock reports from Hakgala :—

The seeds of the two varieties—white and green—of this vegetable, received from Kew this year, came up well and were carefully planted out, but nearly every one ran prematurely to seed—a circumstance which usually occurs when plants are kept too dry or too crowded. As far as I am aware, the plants in question, however, were subject to neither. The cold windy weather which prevailed during the early part of their growth is the only cause I can suggest for this result.

9.—*Herbarium and Library.*

Ceylon Herbarium.—Considerable additions have been made during the year, and very numerous specimens laid into their places. I made two collecting tours, one to the Jaffna and Mannár Districts in February and another to Haputalé and Horton Plains in September. The former of these was very productive of interesting species, and afforded several additions to our flora. The coast-country between Punakari and Mannár has not been botanized effectively since 1781, when the Danish Missionary Koenig, from Tranquebar, who was a first-rate botanist, travelled along it collecting: I was so fortunate as to rediscover some of his finds, which had not since been collected in Ceylon.

From Mannár itself I have since also had the pleasure of receiving from Mr. M. S. Crawford, Assistant Government Agent, about 200 species carefully ticketed by him with the Tamil local names.

General Herbarium.—The only addition during the past year has been a valuable donation from Dr. King of the Royal Botanic Gardens, Calcutta, consisting of 405 sheets of mounted and named duplicates from the herbarium there.

It is much to be wished that the specimens in the General Herbarium should be mounted on paper like those of the Ceylon collection, but this would be a very long and laborious piece of work, and I see no chance of my finding time to undertake it.

The Draughtsman has added to the fine series of drawings forty-six finished botanical figures of Ceylon plants and twenty-six of cultivated orchids during the year.

Handbook to the Ceylon Flora.—Ever since the commencement of my residence in Ceylon have kept before me the production of a book which shall not only give a systematic and complete account of all the plants of the Island, but also enable residents and others who possess the necessary knowledge of the structure of flowers and of botanical terminology to ascertain the name of any plant met with, and so be in a position to learn all that is known about it.

Every day's experience shows me that such a book is much needed here, and as time and opportunity have served I have brought together much of the material necessary for its production. During the past year I have made some solid progress, but it will be readily understood that to work out and describe accurately the members of a flora of the size of that of Ceylon, comprising at the least 3,000 species, requires a very great deal of time, and more freedom from interruption than I can command. It also needs, to secure accuracy in references and nomenclature, access to many books and authentic specimens which I cannot consult here. It is therefore not possible for me to promise any very speedy completion of the work, but it is steadily progressing.

It is right for me to acknowledge here that much of the work has been done for me in the past by my predecessors Gardner and Thwaites. The "Enumeratio" of the latter is a first-rate book, but it is now twenty-seven years since it was completed, and it is out of print. It is moreover a purely scientific work, and contains no descriptions beyond brief ones in Latin of the species then new to science, and is thus of little use to any one but a professed botanist. My task is also rendered much more easy by the existence of the "Flora of British India," a book of immense value and vast scope, commenced in 1872 and now rapidly approaching completion. Its extensive range includes Ceylon; and all our species find their place in it, but of course intercalated amongst their allies from the Indian and Malayan Peninsulas, Afghanistan, the Himalayas, and Burma. Upon this great work my smaller effort must necessarily be largely based, but I purpose to give a much fuller treatment of, at all events, the more important plants than has been possible in a treatise which had perforce to be restricted to the briefest description.

In connection with this contemplated handbook it is my hope that means may be found of publishing a selection of the fine series of coloured drawings made by the native Draughtsmen here, in a manner which shall do them justice and be creditable to this Department. This will of course be very expensive, and it is at present premature to discuss how it might be carried out, but such illustrations of the most remarkable members of our flora would add greatly to the value in every respect of such a book as I contemplate.

Library.—Two additional book-cases have been put up during the year, making now ten in all. A number of valuable books have been added in 1890, and several of our imperfect works have been completed.

10.—*Museum and Laboratory.*

Museum.—The small vote granted for the purpose of fitting up a Museum of Economic Botany at Pérádeniya has been spent to good purpose. Six glass-fronted wall cases have been set up in one of the rooms, to contain such specimens of the food-stuffs, raw products, drugs, &c., of the country as had been accumulated. All these have been put into glass-stoppered bottles, of which twenty-six dozen of various sizes were purchased in Germany at a very moderate cost, and all are properly labelled. The remainder of the vote was expended on preparing, labelling, and mounting timber specimens, especially the best portion of a series from the Pasdun Kóralé presented in 1884 by the late J. Pieris, Mudaliyár.

The timbers occupy two rooms of the Museum building, the other Ceylon products one room; and I hope next year to fit up a fourth room for products from India and other foreign countries for reference and comparison. The other two rooms of the building are in use as the Laboratory and the Office of the Director.

Laboratory.—No student has come out to occupy the Laboratory during 1890, but I am expecting shortly the arrival of Mr. J. Bretland Farmer, Fellow of Magdalen College, Oxford,* who will use the resources of the Laboratory in his researches on the Hepaticæ.

The British Association has added to the debt of gratitude we owe to it already by a further vote of money, and I have devoted £25 of this towards supplying the Laboratory with water, Government having liberally provided the balance necessary to carry out the work properly. This was successfully completed in October, and adds greatly to the convenience of students working here.

* Mr. Farmer arrived on January 27, 1891.

National Bank of India, Limited.

SUBSCRIBED CAPITAL £988,000
PAID-UP CAPITAL £466,500
RESERVE FUND £140,000

ANALYTICAL LABORATORY,

79, Mark Lane, London, E.C.

Westland's Ceylon Tea Agency.

THE first established and oldest Ceylon Tea Agency in Britain. In 1873 W. WESTLAND (brother of two Ceylon Planters) received a present of the new Ceylon Tea, and recognising its extraordinary strength and fine quality, resolved to open an Agency for it alone. Since then the popularity of Ceylon Tea has increased immensely, till it is now recognised as the Leading Tea of the Day. All should use it. Prices—2s, 2s 4d, 2s 6d, 2s 8d, 3s, and 3s 4d per lb. $\frac{1}{2}$ lb. Sample by Post 2d extra. 4 lb. Carriage Paid.
