As regards exports, that of ebony has fallen from 12,352 cwt. in 1888 to 3,880 cwt. in 1889, the reason for which has already been explained in paragraph 87. The exports of satinwood have also been reduced probably also owing to an increase in the market price and partly owing to a better watch being kept on Crown forests. The export of balmilla has increased but the figures evidently do not include the logs exported in the rice dhoneys from the Eastern Province. These latter probably come under the heading "Wood of Sorte," which shows an export of 26,779 logs as against 6,909 in 1888. The exports from the Island deserve every encouragement, as they bring money into the Island, and because we have at present more than sufficient for our local works; while imports require to be diminished as much as possible. We cannot wonder that teak is such a favourite timber. The logs can be obtained of so large a size and free from faults, the timber is so easily worked and from the oil it contains is impermeable to insect attacks and weather influences. But, at the present rate of consumption, the supplies are likely to become scarce. Hence the necessity as well as the propriety of trying experiments with others of the many timbers included in the Ceylon Forest Flora. A portable saw-mill with connected machinery has been applied for, and the formation of an establishment of elephants for dragging timber. The report is altogether so interesting that considerations of space alone prevent our giving it entire. But we must again quote:—

DESTRUCTION OF GAME AND FISH.—There seems to be no doubt that game, once so abundant, is now diminishing greatly, owing to its wholesale destruction by the natives for purposes not of legitimate food, but of trade. The trade is in the hands of Moormen who supply the villagers with gunpowder and shot. The villagers shoot every head of game that comes in their way, usually at night, over waterholes in the dry season. Any one whose duty it is to travel much, especially in remote parts of the Island, will bear me out in saying that seldom a day passes without meeting one or more men with guns in their hands going out shooting, while men carrying pingo loads of hides and horns constitute a regular service. There are also a great many so-called *savants*, usually foreigners, who come here to prosecute their studies and look to pay the expenses of their tours by carrying off quantities of skins of all sorts which they mostly purchase from natives. Last year the village of Mahakekirawa was literally carpeted with drying skins, which one of these persons had by timely notice beforehand induced the natives to shoot and bring in to be purchased by him at market price! When the supply was large, and the buyer a single individual, the market-rate may be easily conjectured—just what he chose to give them.

A great many lives of elephants are recklessly destroyed by elephant catchers, who shoot the mothers in order to get at the calves, or who drive a herd for weeks before they kraal them. The poor beasts are then so exhausted, that in many cases not 10 per cent survive. The killing of elephants in herds should be strictly forbidden and restricted to solitary rogues.

Like the game, fish is disappearing, or has quite disappeared from many rivers owing to the destructive and pernicious habit of driving fish into kraals. As this goes on at all seasons, and as fish of all sizes are taken, the rivers are being drained of their resources.

HERBARIUM OF FOREST TREES.—A herbarium has been started at headquarters. It is hoped that before long it will contain all the commoner kinds of trees of the Island, so as to be of use to forest officers all over the Island wishing to identify trees in their forests.

A small collection of sample Ceylon timber has also been started. This will probably be useful in order to make Heads of Departments and the outside public acquainted with the numerous and excellent Island timbers as yet practically unknown.

GIRDLING OF TREES PREVIOUS TO FELLING.—The great drawback to using palu for sleepers is said to be that

in seasoning it cracks badly. The same timber, or one very closely allied to it that is found in the Andamans, when girdled and allowed to stand for year or so after the tree dies before it is felled, seasons well. Eighty-five palu trees have been girdled in the Central Province, and good results are looked for. White ants will not touch palu.

TENTS.—Two light field tents (double ply, 10 ft. by 8 ft., and weighing only 80 lb.) were ordered from the Cawnpore mills, and handed over to the Assistant Conservators of the Northern and Eastern Provinces for trial. Their cost landed in Ceylon was R212.39. Should they prove suitable others might be ordered from the same source, if they cannot be copied in this country.

Details of revenue and expenditure of the department are then given, and in the following paragraph it is shown that it was high time to intervene so as to prevent the annihilation of the celebrated ebony trees of Ceylon:—

That the benefit to the Department amounts to R80,495, or R63,977 more than the preceding year is matter for congratulation, considering that the expenditure has risen from R247,510 in 1888 to R393,962 in 1889 i.e., by R146,452 of which R38,271 is on establishments alone. It has been said in some quarters that in spite of the appointment of a staff of forest officers the revenue as compared with former years has been small, and has been mostly swallowed up by the expenditure on that establishment. The answer to this is evidently that the forests were recklessly worked, as can be seen from the returns of ebony exported, which alone point to an export of over 1,000 tons annually during the years 1880-87, at which rate of cutting there would scarcely remain a tree left by the end of the century.

Col. Clarke states that

There is a great deal of money annually lost to the Crown by not collecting the drift wood in our more important rivers, the Kalu, Kelani, and Mahawel-gangas, but I hope that this important duty will receive early attention.

Finally, we quote the conclusion of this very interesting report:—

There is every prospect that at the close of 1890 the Department will show itself self-maintaining, and in 1891 and onward there will be a growing revenue paid into the Treasury. In fairness to Uva, which does not come out well in the table showing benefit or loss to the Department in the respective Provinces, I should mention that it is really entitled to a large share of the outstandings which are put down to the Central Province, these outstandings being mainly due for timber supplied to the Haputale Railway Extension, which runs quite as much through Uva as through the Central Province. Uva has greater difficulties as regards transport than any other Province, and it is rather hard that it should not be able to show one of the few transactions over which it would make a profit at comparatively small outlay.

Ceylon appears to possess many timber trees which have been hitherto considered of secondary value or have been entirely neglected because their qualities had not been properly tested. Col. Clarke seemed determined that this shall no longer be the case; and the zeal with which he has thrown his energies into the task of developing our forest resources is worthy of all praise and justifies the choice of this officer as organizer of a department which promises to be very important and useful.

CHARCOAL OR NO CHARCOAL FOR ORCHIDS.—An interesting discussion is going on in the *Journal des Orolides* as to the value of wood charcoal in potting Orchids. Count de Moran is an advocate for frequent repotting, and does not lay much stress on the employment of charcoal in the compost. He says very truly that the charcoal of itself contributes no food to the plant, but it certainly aerates the soil, and it is of advantage from its property of retaining gaseous ammonia to the profit of the plant.—*Gardeners' Chronicle*

COCONUT CULTIVATION.

CASTOR V. COCONUT CAKE.

A Native gentleman largely interested in coconuts, and who I believe now intends to cultivate his broad acres, recently asked me what I thought was preferable for coconuts—castor or coconut cake. An acknowledged authority on coconut cultivation told him the latter. My opinion, pitted against such an authority, will not go for much: but the analyses of Hughes and other chemists show that the former is far and away the best cake we have for manurial purposes. Hughes' praise of good white castor cake is unstinted. In the analyses of manurial substances he instituted at the instance of the Planters' Association in 1878, castor cake occupies first place among oil cakes. He says, "Taking white castor cake as represented by analysis for our standard of comparison, and taking 100 as the equivalent of such standard, we have the following comparative relation between the cakes." In the table that follows, white castor is represented by 100 and occupies 1st place, and coconut poonac is represented by 53 and occupies a place only above Domba cake, and comes after China bean, rape, gingelly and other cakes. There are more recent analyses by Hughes, and more recent expressions of his opinion of the high value of it as a manurial agent; but I think the opinion I have quoted ought to satisfy anyone that, for matters of comparison manurially, the two cakes cannot be spoken of in the same breath, more especially as at the present moment their price is nearly the same, while a short time back coconut cake was about half the price of castor cake.

On the subject of frequent disturbance of roots I will not now enter, as I have expressed my opinion fully on the subject elsewhere in a controversy with a very old Planter. All I would say is that to me it seems opposed to reason to place food for a tree to feed on, and when it is being consumed and the requirements of the tree are increased, in consequence, to lessen the "mouths" of that tree. I was told recently that my opinion is opposed to experience, because when a tree showed signs of distress by the yellowing of its fronds, the remedy suggested was to cut the roots, and that this treatment invariably proved successful. I pointed out in reply that the yellowing of the fronds may have been due to want of drainage in the soil, and that the improvement in the condition of the tree that followed the turning up of the soil was due to its aeration, and not to the roots of the trees having been cut.

The appearance of sickly trees in a plantation at uncertain intervals and surrounded by healthy trees is an eyesore. The cause for this is so far a conjecture, for no one can say to a certainty what the resulting plants are from the seed he put down. While in European agriculture the selection of seed is considered as of paramount importance, and this mind you in the cultivation of cereals where the results of carelessness need not extend to beyond one crop, here in the cultivation of a perennial like the coconut, where a property is inherited by two or three generations in succession, the selection of seed is not considered to be of primary importance. Those who do not believe that an unhealthy tree is the result of an unhealthy seed, point triumphantly to the laws of heredity being often set aside by a weakly or stupid father having a strong or clever child. They will not allow that these are the exceptions that go to prove the rule. Besides, a child is the offspring of two parents, and very often if it does not inherit the characteristics of either of them, it does those of a member of the family to which they belong even to a few generations back. This is noticeable even in coconuts. All the varieties we have must have resulted from one original stock, as in the case of mankind. In planting coconuts we are not certain that the plants we raise from any particular seed will be true to type. I have on this Estate many trees raised from king coconuts. They bear the red skinned coconut which must have been the immediate progenitor in the first instance of the variety now known as the king coconut. This "harking back" is noticeable likewise amongst lower

animals. We have frequently one of a litter of pups of quite a distinct breed to the parents, and when there is no uncertainty as to the sire. Very often the breed to which this pup belongs is not to be found in the neighbourhood. So in horses. There is one driven by a well-known gentleman in Colombo, known as well by his name as by that of the "Ceylon bell-ringer" in which he glories, that had for its sire a small-sized Tat pony, owned by a road overseer, and for its dam an equally small-sized Acheen. The filly resembles an Australian for all the world, and ought to secure first place for a long while amongst country bred ponies. All this, it may be urged, by no means proves that unhealthy trees result from unhealthy seed. It is not intended to.—Local "Examiner."

COTTON SEED AND HULLS.

Gradually the prejudice against the use of cotton seed and hulls as a food for stock and hogs is being overcome, and their value is being appreciated. During the past winter hundreds of heads of cattle were wintered on the hulls alone, which they eat as readily as hay, and with no evil results. Used with cotton-seed meal, in the proportion of one pound of meal to four pounds of hulls, they have been found at the North Carolina Experiment Station to form a profitable feeding ration for steers. We take the following details from a press bulletin issued by Dr. Battle:

"Four steers fed at the N. C. Experiment Station for 84 days, each ate on an average during this time 1,517 lb. hulls and 383 lb. meal, or an average per day of 18 lb. of hulls and 4½ lb. of meal, which is almost exactly in proportion of 1 lb. meal to 4 of hulls. The average gain for each steer was 148 lb., and the total cost for food was \$6.85 each. The gain in weight and the increased value of the beef over the original cost gave an average profit on the above steers of \$9.38 per head in cash. The value of the manure in addition will doubtless pay for all the trouble."

The roasting of the seed is advised by those who have used them for feeding hogs, and several machines have been introduced for the purpose. The one most commended is like a coffee-roasting mill, but made of fine wire gauze. Into this the seed is placed, and turned slowly over a fire until the lint is destroyed and the seed roasted so that it readily grinds in a mill. Hogs have been fed solely on these roasted seeds, and have made splendid fat animals, with a first-rate quality of meat. With all the facilities afforded by the abundance of cotton seed and hulls, why should the South buy either beef or bacon from the West? It can be produced here cheaper than there, and the freight be entirely saved. It seems almost as though Mr. Atkinson's prediction was yet to come true, that the lint would come to be the least valuable part of the cotton crop.—*Southern Planter.*

"KEW BULLETIN."—The current number contains articles on the cultivation of Anotta in West Africa, and on the preservation of grain from Weevils, for which the employment of bisulphide of carbon, 1½ lb. to the ton, is recommended. A ball of tow is tied on the end of a stick long enough to be plunged to the middle of the vessel holding the grain. The tow is soaked in the liquid bisulphide, and immediately thrust into the vessel. Naphthaline in powder is recommended for the same purpose, applied by means of a tube or funnel. The naphthaline evaporates, kills the insects, and in no wise injures the grain. Colombian India-rubber comes also under notice. This is said to be the produce of one of the many varieties of *Sapium biglandulosum*. The tree grows at higher elevations than most of its race, and is in consequence adapted for a cooler climate. The cultivation of *Agave rigida* in Bahamas is the subject of another note. The fibre is known as Sisal, and the progress of the culture in the Bahamas is described as something marvellous.—*Gardeners' Chronicle.*

CACAO IN TRINIDAD.—Mr. de Lemos has, while away, according to a contemporary, "travelled about a good deal, going, as far west as South America to see a brother who provided him with abundance of sport. He also visited Trinidad and speaks in terms in high praise of the magnificence of the cacao walks there, where cacao trees 100 years old, still bearing heavily and untouched by any disease, are to be seen! Mr. de Lemos also visited the sugar factories in that island and was greatly pleased and interested with all he saw."

MR. HARRINGTON'S INCINERATOR.—Mr. Harrington writes that during the ten days ending 30th June, 19,000 cubic feet (equivalent to 475 tons of refuse was burnt in his incinerator and that the consumption of coal during the ten days was 59 maunds—a trifle over 2 tons. During the three months of July, August and September, the incinerator is to be under official trial; and, to conform to the contract specification, it must burn not less than 2,880 cubic feet (equivalent to 72 tons) of refuse daily. Mr. Harrington writes that he intends to conform to his specification, and that he hopes not to use any coal whatever. The incinerator is now in full operation.—*Indian Engineer*, July, 5th.

TEA AND COFFEE CULTIVATION IN NATIVE STATES.—During the year 1889, there were 27 coffee plantations in the Native State of Travancore and 18 in that of Cochin. The area of the former was 3,917 acres and of the latter 8,452 acres. The approximate yield in Travancore, exclusive of six plantations with an area of 332 acres in Manachel for which particulars have not been furnished, was 376,148 lb. That in Cochin was 533,828 lb. The average yield per acre of mature plants was highest in the Shencotta Taluq (571) of Travancore and the lowest (152) in the Ohengacherry Taluk of the same State. The cost of cultivation per acre ranged between R50 and R100. The coffee cultivated in Shencotta was of the Liberian variety. As regards tea there were 57 plantations in Travancore and two in Cochin, all under black tea, with an average of 16,597 in the former, and 35½ in the latter State. The approximate yield in Travancore, excluding seven plantations measuring 300 acres, was 571,756 lb. and in Cochin 2,048 lb. The highest yield was in Pathanapuram in Travancore, where 788 lb. per acre was obtained, and the lowest 64 lb. per acre in Cochin. The cost of cultivation per acre ranged from R26 to R80, and that of manufacturing tea between 1½ and 6½ annas per lb.—*Madras Times*, July 19th.

FASTIDIOUS COLONISERS.—Chinamen are, says a contemporary, as tenacious as they seem to be capricious in their preference for certain towns. They are strongly attached to San Francisco, and in a less degree to Rangoon and Calcutta. On the other hand, they avoid Madras and every other point on the east coast of India, and are not to be induced to take up their abode in the Nicobars Islands, a fact which Government discovered as the result of a recent experiment. A scheme was formed three or four years ago for converting these useless islands into a thriving Chinese colony, and fifteen Celestials were bribed to leave Penang for one year and start the new settlement. They went, but refused to work, none of their kith flocked after them; and when the year was up, twelve of the fifteen returned immediately to Penang. The other three made a good sum of money by gardening, but at the end of the second year they too packed up their belongings and departed, for reasons which they kept to themselves. Thus the colonising experiment, which cost R3,000, ended in smoke.—*Pioneer*, July 24th. [The capricious preferences of the Celestials are extraordinary. While Batavia, Singapore and Penang swarm with wearers of the pigtail, the sight of one in Colombo is a rare event.—Ed. T. A.]

SEA-AIR, according to M. Pierre Lesage, has the effect of thickening the leaves of plants and trees. Moreover, plants grown in salted soil produce thicker leaves. There is a notable increase in the number and size of the "palisade cells" in maritime vegetation as compared with that grown inland.—*Globe*.

PLANTING NOTES FROM PEERMAAD.—"Never within the memory of the oldest inhabitant," has there been, at this season of the year, such extraordinarily fine weather as that which we are experiencing; in fact, it is difficult to realize that we are now well into the middle of what we are in the habit of calling the monsoon, but which this year, so far as rain is concerned, bids fair to be conspicuous by its absence. The monsoon, for I suppose we must admit that it has broken, came in so gently last month, that it is almost impossible to fix the exact date of its advent, and after giving us a few fairly wet days, though with constant breaks of unusually fine weather, has apparently left us! For the past 4 or 5 days, not a drop of rain has fallen, and instead of the howling winds, thick mists and heavy downpours which are customary during June, July and August, we are having the most lovely and almost cloudless days, cool and pleasant weeks and the most perfect moonlight nights. Whether this total change in the usual order of meteorological arrangements is to be attributed to the unusually wet weather we experienced during what we call our "hot weather" in March, April or May, or to the eclipse, I am not prepared to say. Coffee prospects are, I regret to say, not particularly cheering. In the early part of February we were favoured with fine blossom showers, and great hopes were entertained of a more than average crop, but the high winds and fearful storms that followed, soon dashed them to the ground, and the coming crop will, I fear, turn out lamentably short. As, however, planters up here have, with a few exceptions, gone in heavily for tea, some of the old coffee estates having been entirely, and most of them partially, transformed into flourishing tea gardens, the effects of a short coffee crop will not be so disastrous as it otherwise would have been. Of the 5,000 acres under cultivation in the district, considerably more than half is under tea and it is satisfactory to note that, with the increasing yield of leaf and improved manufacture, and the introduction on some of the largest properties of the latest steam machinery, good prices are being maintained both in London and New York to which latter port some of the largest shipments are made. In the last "Wynaad Notes," reference is made to the visit of a Government Specialist in connection with the disease that has so seriously affected the cinchona—and Mr. Hooper's* interesting report has lately been published. About 20 years ago a large proportion of the cinchona planted in the Government Gardens up here, suffered in a precisely similar manner to that described by your Wynaad correspondents and at the suggestion of the British Resident, the services of the late Mr. W. G. Melvor were placed at the disposal of the Travancore Government. Mr. Melvor came and saw and reported. He was of opinion that both the climate and soil of Peermaad were unsuitable to the profitable cultivation of cinchona, and, if I remember rightly, advised the Travancore Government to abandon the experiment. In the face of such an unfavorable report, it was only natural that private individuals hesitated to embark capital in the enterprise, and no one thought anything more about cinchona until about 10 years ago when there was a great rush and thousands of plants were put in all over the district and are now doing well enough, no symptoms of canker having appeared amongst any of the trees planted on private properties. Last season's cardamon crop was very short, but the deficit is expected to be more than made up by the coming crop which, I hear, is to be a bumper. This valuable spice is a monopoly in Travancore, the cultivator only receiving 2-5ths of the market value of the crop.—*Madras Times*, July 10th.

* It was Mr. Lawson, the Government Botanist, not the Analyst who reported on the cinchonas.—Ed. T. A.

ENEMIES OF THE COTTON PLANT.—The Hon. W. W. Mitchell writes:—"I enclose papers I have received from the U. S. Consul showing that arsenite of ammonia is a remedy for attacks of enemies to the cotton plant, and if you can publish it for general information, it might be a great boon. We shall give the full details in the *Tropical Agriculturist*. Meantime, can the remedy be bought locally at a cheap rate?"

The plant, known as the "Planters' curse" in Coorg, is spreading fast in Bangalore, and has taken possession of all waste places. The fruits are like currants in appearance and are greedily eaten by birds which convey the seeds all over the place. When well trimmed, the Lantana makes neat hedges, the flowers being of every possible hue and looking quite gay. Just now, the Conservancy Department is engaged in a crusade against this shrub; and it is being cut down and burnt on every side.—*Indian Agriculturist*, Aug. 2nd.

ARTIFICIAL COFFEE is now manufactured to an alarming extent, the spurious article consisting of the roasted meal of different cereals, worked up with dextrin. Two factories exist at Cologne which undertake to furnish the requisite machinery and plant, with directions for making the false coffee beans, for £180. The apparatus supplied by these wholesale swindlers is capable of turning out more than half a ton daily, at a cost of about £1 per cwt. good coffee beans being nearly five times this value in the market. The fictitious coffee is difficult of detection by ordinary examination, especially when a proportion of genuine coffee has been mixed with the artificial.—*Madras Mail*, Aug. 15th.

MYSORE COFFEE PLANTER'S GRIEVANCES.—The agitation of the coffee planters in Mysore is at last likely to bear fruit. It will be remembered that the planters complained year after year that the working of the Breach of Contract Act was very defective and involved them in much loss. The Mysore Durbar have now partially redressed this long-standing grievance. It has been laid down that all *maestries* who take advances from the coffee planters and, in consideration of these, undertake to provide them with *coolies*, should register their names in the taluq cutchery and no one will be allowed to pursue the trade of a *maestrie* unless so registered. The effect of this ruling will be that the planters will be saved from the trouble of instituting inquiries in each case as to the antecedents of *maestries* who volunteered to provide coolies, and erring *maestries* can also be easily called to account in case of default.—*Cor.*, *Madras Times*, July 3.

PLANTING IN EASTERN AFRICA.—An upcountry correspondent criticizing the article from the *London Times* in the *Household Register* on "The Geography of the Anglo-German Agreement," says in reference to the country described as fit for rich tea plantations, "How silly not to state what the latitude of Uganda and Unyora is: if you can let your readers have it." The country referred to as 5,000 to 6,000 feet elevation decreasing towards the north is all within 10 degrees north of the Equator. The line of Equator passes through the Victoria Nyanza, a good deal north of the German territory which may be said to run from 1 degree to 11 degrees South Latitude where it borders with the Portuguese territory and on the south-west with the British again. On the coast and up to the Victoria Nyanza, the British Northern territory runs down to 4 degrees south of the Equator, but the fine country spoken of around and north of the lake, begins at the Equator and runs northward for five and ten degrees of latitude. Coffee and tea plantations will no doubt be opened, but slowly, and labour and transport will handicap pioneering work for a good many years to come.

CASSIA LIGNEA IN THE UNITED STATES.—In a review of the spice trade in the *American Drug Reporter* of 17th June we find it stated that Cinnamon compares well with last year, but the current rates remain extremely low, and chips exhibits no changes of importance. Cassia lignea is exceedingly cheap at 2s 6d to 2s per cwt. for good quality, and, notwithstanding a great falling off in the importations, the stock retains a comparative excess of 47,000 pkgs. Cassia lignea at 2½d per lb. must be a formidable competitor with even cinnamon chips.

"TEA" IN FRANCE.—"Claudius Clear" writes to the *British Weekly*:—"Speaking of French conservatism, it is still rash, save in a very few places, to order tea. The traveller should provide himself with the necessary facilities—it is a simple process enough. The French, it seems, use tea as a medicine, and cherish the sound belief that all medicines should be nasty. I am inclined to doubt, however, whether they actually prepare it from the following recipe. Pour two quarts of tepid water on half a handful of chopped hay, add a soupçon of tallow, and one black currant.

THE TEA ENTERPRISE IN MAURITIUS.—The following extract from the proceedings of the "Council of Government" shows that the Mauritians although on tea culture bent, have frugal minds as to expenditure:—

Employment of a Tea Curer for Experimental Farm.—The Committee recommend that, as suggested by the Experimental Plantation Committee, Mr. Corson be employed till the end of the year on a salary of R100 per mensem with a lodging allowance of R25 per mensem, provided that the appliances now in the possession of the Experimental Farm Committee permit of his services being at once utilized, so as to thoroughly carry out the experiment which it is proposed to make. Should, however, it be necessary to obtain machinery and erect buildings for the purpose, the Committee are of opinion that the expenditure above referred to should not be incurred until an estimate of the probable cost of such machinery and buildings has been submitted for the consideration of the Council.—Adopted.—*M. and P. Gazette*.

THE "UNFOUNDED" CHARGE OF CEYLON TEAS NOT KEEPING is thus disposed of in the *London letter of the Indian Planters' Gazette*:—

It is a curious and significant feature of a good market, that when Ceylons are up, one never hears a word as to Ceylon Teas not keeping. On the other hand, directly the market goes down, the old complaint is heard once more. Chaffing a friendly broker about this the other day, he frankly admitted that the complaint is unfounded, and that it was merely an echo of the disappointment felt by holders of fallen Teas. He illustrated this by saying, that, on opening Pekoes bought for 9d last January, now worth 11d, the purchasers can hardly believe their eyes. "Those Teas bought for 9d impossible! What a magnificent show of tip, &c., &c., &c.," and beauties are discovered in those Teas today, now worth 11d, which quite escaped notice when it was a question whether 9d was not rather too dear a price to have paid for them. The January eye was that of the purchaser on a poor market, the July eye is that of the seller on a good market—that makes all the difference; Beauty being in the eye of the beholder. Had the case been reversed, and had those Teas cost 11d and been now worth 9d, the Beauty would have been masked, and the keeping quality of Ceylon Teas would have again been in question. It is only human nature to bestow the blame of one's *faux pas* upon somebody or something else than one's self—if a scapegoat is conveniently handy. So much for the outcry against the tendency to "go off" in Ceylon Teas—we used to hear a good deal to the same effect about Indians once upon a time, when teas were tumbling by 4d and 6d per lb. If the complaint has no more substantial foundation than this, it is safe to suppose that it will be lived down—as Ohinas die out more and more. This confirms the opinion we have always held that "the buyer says it is naught."

TEA-DRINKING sometimes causes indigestion, which, it is said, may be obviated by tying the tea in a cambric handkerchief, before placing it in the pot. The handkerchief absorbs the steam.—*Madras Times*.

The Belgian Legation at Mexico has reported to the Belgian Government on the guimbobo or angu, a textile plant found in the State of Vera Cruz. The fibre is of a very superior quality, while the plant is easily cultivated, and yields a nutritious fruit. Unlike ramie, cotton, or hemp, the fibre is within the bark, which can be removed by a simple machine. Its lustre is like that of silk, it is strong and fine, and of a creamy white colour.—*Globe*.

A magnificent sum of from three to five million dollars has been left by Mr. H. Shaw to endow the Botanic Garden and School of Botany in St. Louis, Missouri, U. S. The trustees propose to improve the gardens, house and the herbarium of Dr. Engelmann in a fire-proof building, establish a botanical museum, and further botanical research. To aid in the latter purpose, travelling scholarships have been established.—*Globe*.

A wonderful revolution in flour-barrel-making is promised by a patent which has been granted for the making of barrels out of cotton-duck instead of wood. The new material is impervious to water and resists fire for a long time. It weighs to the barrel about fifteen pounds less than the wood and can be manufactured 10 per cent. cheaper. The cotton-duck barrel can be rolled up into small space and returned to the mills for frequent use. The flour merchants of Atlanta, Ga. pronounce it a success.—*American Grocer*.

A German engineer, Buss, of Linden, Hanover, was granted a patent some time ago for what he terms caoutchouc pavement. Within the past year it has been used for a bridge roadway at Hanover, with good results, and is now being laid down in one of the streets for a length of nearly a mile. Experiments are being made with it also in several streets of Berlin and Hamburg. According to the *Wochenschrift des österr. Ingenieur und Architekten-Vereines*, the new pavement gives rise to no noise from passing vehicles, and at the same time appears to be as hard as stone and is not affected by either heat or cold.—*Engineering Record*.

"TIMBERS, AND HOW TO KNOW THEM."—Dr. Wilham Somerville, the newly-appointed lecturer on Forestry in the University of Edinburgh, has translated from the German the third edition of Dr. Hartig's work under the above title. It forms a small treatise of some eighty pages, with numerous illustrations. It is needless to say the book is good of its kind, and likely to be useful to beginners, especially if used as a guide-book and aid to the study of the woods themselves; but it is to be hoped that Dr. Somerville may be induced to extend it in a future edition by an introductory chapter relating to the formation and growth of wood in general, and the circumstances which favour or hinder those processes. Much might advantageously be added to the details relating to particular kinds of timber, such as the rate of growth under different conditions, the capacity for resistance, the specific gravity, &c. Dr. Hartig has a well-earned reputation as a botanist, but he hardly acted up to it when he suffered such a statement as this to pass:—"The 'Rose-wood' of commerce is got from various, especially Asiatic, species of trees!" Fig. 16, on p. 52, is said to refer to *Platanus occidentalis*, and it may be rightly, but we should have liked some assurance that the tree intended is not *P. orientalis*, which seems, on the whole more probable. The statement that the wood of the Austrian Pine (*P. Laricio var. austriaca*) cannot be distinguished from resinous wood of the Scots Pine is one that, had it been made by anyone else but Professor Hartig, we should have ventured to question. At any rate, the timber of the true Corsican *P. Laricio* seems different from that of the Scots Pine. Dr. Hartig's is a good book for beginners, but we have more than one English botanist who could have produced a more satisfactory one.—*Gardener's Chronicle*.

MR. OSWALD has a paper in the *National Review* on Anti-Poverty Receipts, in which he argues in favour of substituting nuts for wheat as the diet of mankind. The Corsican chestnut will provide more food on waste land than anything else that can be grown by man.

TROPICAL PRODUCTS IN QUEENSLAND, NATAL, &c.—With reference to the inquiries of your correspondent "N. Z.," I know of several planters who, nearly ruined through the coffee-leaf disease, emigrated from Ceylon to Queensland in the hope of retrieving their fortunes, but they found the labour supply too deficient and expensive for practical purpose, although coffee appeared to thrive fairly well. I also know a gentleman, an experienced tea planter from Assam, and son of a well-known clergyman in Aberdeen, who started tea culture in Natal, but gave it up as he found it did not pay; he told me the rainfall seldom exceeded 40 inches per annum. In the best Indian tea districts the rainfall varies from 120 to over 300 inches per annum. Apart from the labour question, your correspondents would find New Zealand too cool for the profitable culture of the products he mentions. The labour question is a very serious one, as he would have to compete with the Ceylon and Indian coolies, who barely earn sixpence per day. Cinchona has had its day for the present, and there are thousands of acres of mature trees in South India waiting to be cut whenever the market shows a favourable opportunity, which is not likely at present with sulphate of quinine at 1s 6d and 2s per ounce. The *Tropical Agriculturist*, published in Ceylon, is by far the most reliable work on all matters connected with tropical planting. I have seen it advertised in your columns occasionally, notably on the back of the current year's Almanac. If "N. Z." is a novice in tropical planting, as he appears to be, I shall be happy to forward him full details on tea, coffee, and cinchona planting. *S. S. Gardener's Chronicle*, Aug. 9th.

PLANTS FOR OVERCOMING DRIFTING SAND.—A correspondent, whose letter we inserted yesterday, writing on "Tree planting in Ganjam" stated that an excellent work in the matter of planting was being carried out by the Local Fund Board of Ganjam under the supervision of the Overseer of Chicacole. "Upwards of fifty acres of casuarina have been planted on the drifting sands of the Vamsadhara near Maripam. The wind has forced the sand into dunes, and it is constantly invading the high road, in fact near the river the road is completely obliterated. The planting has been carefully done; each individual plant is manured and those on the steep sides of the dunes are tured round. . . . If the plantation succeed they will amply serve their purpose and not only protect the road but the fields behind them and the canal distributories." Another way of overcoming the effects of drifting sand would be by planting lupins, which have been proved most effective for the purpose. In Australia drift-sand is often very destructive to farms and pastures near the borders of rivers, and many thousands of acres have been rendered useless by the driving showers of grit which assail and cut all kinds of vegetation. Mr. Bunday, of East Wellington, writing to the Commissioner of Crown Lands last October, said that he had sown lupins with this view for fourteen years, and in no case had he to sow the land a second time. He had reclaimed 100 acres of the worst sand drive on the river by sowing lupins—the only plant that will stand the fearful cutting of the drift-sand. When grass begins to grow between the plants he lets the seeds fall naturally upon the land, and the result is that after the second year sheep can be put upon the pastures.—*Madras Mail*, Aug. 15th.

SUGGESTIONS AFFECTING THE PRESERVATION OF TIMBER POSTS FOR TELEGRAPH WIRES AND OTHER PURPOSES.

A correspondent writes us that it has only been within the last few years that he has observed means to be taken for roofing in, so to speak, the tops of telegraph posts; but that he noticed recently that it is now the practice at home always in some way or other to neutralize the effect of sun and rain upon such exposed transverse surfaces. According to our own recollection of the telegraph posts which carry the wires of electric communication along the less-frequented routes in this island, protection having such an object has always been ignored. The presumption possibly may be that, having regard to the relative rapidity with which the portions of such posts inserted in the ground decay, this matter of sheltering their tops is of comparatively little consequence. As to the justness of such a presumption, we cannot pretend to decide; but as we know that efforts have been made—and with a great degree of success—to lengthen the duration of life of our telegraph posts in-so-far as that is dependent upon the preservation of the part below ground, it might not be unworth the while of the officers of our Telegraph Department to consider some method of protection to their tops.

Whether, however, that department may be content to ignore this suggestion or not, it is certainly the fact that the question of timber protection may be usefully considered by our planters and all other users of timber. For, given a soil which in a greater or lesser degree preserves timber placed in it—and many such soils there are known to be—the life of timber posts exposed to weather might be greatly prolonged beyond what is now normal to them. We can recall very many instances of employment in which our suggestions might prove to be of exceeding use. The top of a post of course lays bare both to moisture and excessive sun heat (both conditions tending largely to hasten decay) the constricted vessels formerly containing sap which have been exposed by the transverse cut. It is well known to engineers and architects that the more the natural taper that is preserved to a pole, the longer will it remain sound. We have seen endeavours made to imitate this natural taper by cutting an artificial point. This is of course an absurd method; for it necessarily lays bare a larger area of cross cut vessels than would a merely flat top, and such cuttings expose further a large conical section of the vessels to which we have referred as being formerly sap-holders, while the area offered to perpendicular rainfall is precisely the same as if a flat top surface had been left.

There have been various methods adopted at home for protecting from the effects of weather the tops of posts. In the instance of square posts, two small boards mired and nailed together will afford a sufficient roofing, and these are to be observed constantly fitted in the case of dressed signal posts. But for round posts, such as are the majority of those used for the support of telegraph wires, these miniature roofs will not do, and on most cross country lines in England a metal cap with a finial is fitted. We shall, however, have fulfilled our present object if we direct the attention of those who may use timber posts for fences or other purposes to the importance of giving protection to the tops of such timbers. Thought for the portion below ground only is not economical.

In very many cases posts are found to be decaying downwards, while below ground they are as sound as when first put in. Indeed, as we have said, many soils are known—and clay among these very prominently—to have a directly preservative effect upon timber, and in such cases it may be regarded as almost certain that a post will become useless from downward decay long before it has to be drawn owing to that due to the soil it has been placed in. It certainly is not a common thing to see any precaution of the nature we would recommend adopted here, and we believe many among our readers might profitably give heed to our suggestion.

THE ANTISEPTIC QUALITIES OF COFFEE.

It has for a long time been thought that ground coffee possessed antiseptic or disinfectant properties. During some experiments upon the food value of coffee recently undertaken by Liadevitz, which were reported in *Pharmaceutische Centralblatt*, the chemist found that bacteria were retarded in their development in nutritive gelatine by relatively small quantities of an aqueous infusion of coffee. Bacteria, as doubtless everyone knows, play an important part in the phenomena of putrefaction. The caffeine contained in the coffee appeared to be the ingredient which is thus specially active in retarding bacterial growth; but on making experiments with pure caffeine upon infusions containing various species of bacterium, it was observed that its action was quite inconsiderable. It is rather to the empyreumatic substances formed during the roasting of the coffee-berries that the anti-bacterial action of ground coffee must be attributed. In connection with these results we may recall a fact which has long been known, namely, that when fresh raw meat is dusted over with ground coffee it can be dried without the least sign of becoming putrid.—*Grocer*.

THE COCKCHAFFER.

Great injury is done to the roots of plants of all kinds by the grub or larva of the cockchafer, one of the largest of beetles, the noisy flight of which may now be heard in the twilight. The grub, says a contemporary, spends several years in the soil, and, as it is a voracious feeder, it is frequently the unseen cause of much damage to crops, its ravages being nowhere more apparent than in young plantations of forest tree. In the extensive forest areas near Cracow in Poland, the mischief had progressed to such an extent that the maintenance of nurseries was found to be impossible, the grubs invariably destroying the seedlings. Dr. Laszezynski now reports, however, that the lupin has proved itself of great value as an insectifuge plant. Last year, after the usual planting of seeds of forest trees, one part of the area was sown with seeds of the yellow lupin and the young forest trees upon this portion were untouched by the grubs of the cockchafer, whilst on the rest of the area the seedlings were, as usual, destroyed. It would be desirable to test amongst field crops the value of a remedy which has proved so efficacious in the case of forest seedlings, and it is suggested that beetroot and other field crops which suffer from this pest might be protected by the sowing of yellow lupin seed.—*South of India Observer*.

[Many long years ago Liebig advised the coffee planters of Ceylon to grow lupin as a green crop amidst their coffee trees, to be turned into the soil as manure. Had the planters heeded the advice it seems probable they would not have suffered as they did from grubs. Lupins as insecticides could well be grown on our upland patanas.—*Ed. T. A.*]

PROGRESS OF TEA CONSUMPTION IN BRITAIN:

RISE AND PROGRESS OF BRITISH-GROWN TEA AND DECADENCE OF THE CHINA TRADE.

Messrs. Gow, Wilson & Stanton have prepared one of those periodical reviews of the tea trade illustrated by coloured and graduated diagrams which convey distinct and vivid impressions regarding the progress of tea consumption and the progress or decadence of the supplies received from different sources. This document will be circulated to our subscribers with an early issue, and meantime we proceed to notice some of the more salient facts in the advance copy with which we have been favoured. On the first page there are nine circular diagrams showing the advance in the home consumption of tea during nine quinquennial periods between 1849 and 1889. The size of the last circle of the series is considerably more than three times the size of the first, the increase having been from 50 millions of lb., all China, in 1849, to 185½ millions, mainly British-grown, in 1889. For the first three quinquenniums only China was consumed, the figures rising in the period ended 1859 to 76½ millions. In the 1864 period commenced the competition of Indian tea, but China continued to advance until it attained its maximum in the 1879 period with 126½ millions of lb. Then commenced the "down grade" process, to 110½ millions in 1879 and only 61 millions (the figure previously attained in 1854) in 1879. The red colour inside the circle indicating Indian tea continued to enlarge until from 2,800,000 lb. in 1864 the figures rose to 96 millions in 1889. Ceylon was late in the field; but its progress from a small yellow spot, indicating 1½ million of pounds in the 1884 period, was phenomenal: the yellow having enlarged to a proportion of 28½ millions in 1889. Up to the end of 1859 only China tea was consumed in Britain, and of that only 76½ millions. In 1864 the consumption rose to 88½ millions, of which 2,800,000 was Indian. In 1889 the figures for home consumption in Britain were:—

China	61,100,000 lb.
Indian	96,028,491 "
Ceylon	28,500,000 "
Total	185,628,491 lb.

Together it will be seen that Indian and Ceylon tea made up 124,528,491 lb. British-grown against 61,100,000 China,—or more than twice the quantity of the famous product of Cathay which once monopolized the market. So compete a revolution and in so short a period has seldom occurred in the trade in any great article of consumption and the progress of supersession has by no means reached its final limits.

The compiler of the paper remarks:—

In 1889 the quantity of China Tea used in Great Britain was less than the Home Consumption in 1854—35 years previously.

In 1889 the quantity of British Grown Tea used was more than double the entire Home Consumption in the same year, 1854.

In 1889 the quantity of British Grown Tea used was in excess of the entire Home Consumption in 1871—18 years previously.

In the first six months of 1890, the consumption of China tea was only 28,686,000 lb. against 31,418,000 in the corresponding period of 1889 or 30 lb. percentage per head of the population instead of 35, or from above one-third of the whole to considerably below that proportion. In the case of Indian the rise was from 46½ millions to 51½ or from a percentage per head

of 51 to 54. The progress of Ceylon was from 13,066,000 to 14,583,000 lb., or from 14 percentage per head to 16. To quote again:—

The figures below the Diagram show that the Tea consumption has nearly quadrupled during a period of forty years—since 1849.

In the ten years ending—	lb.
1859 the Consumption had increased about	26 million.
1869 do do	further increased about ... 36 do.
1879 do do	do do 49 do.
1889 do do	do do 25 do.

The quantity used annually per head of population had increased as follows:—

1849.	1859.	1869.	1879.	1889.
lb.	lb.	lb.	lb.	lb.
1·81	2·67	3·63	4·68	4·91

The increase in the actual weight of Tea used during the last ten years, was small when compared with the preceding periods. This may probably be in a great measure accounted for by the large proportion of Indian and Ceylon Teas used in the latest period. These Teas being so much stronger than China Tea, a greater number of cups can be prepared from the same weight of Tea—thus rendering British Grown Teas far more economical than China. It therefore, seems not improbable that a further expansion may take place in the Home Consumption as the displaceable quantity of China Tea becomes gradually less.

Reduction of Duty.—On the 1st May, the Tea Duty was reduced from sixpence to fourpence per lb.

The last time an alteration in the Duty occurred was on the 1st June, 1865, when it was reduced from one shilling per lb., to sixpence per lb., a reduction from 1s 6d per lb. having been made during 1863.

Although a reduction from 6d to 4d, at a time when the price of Tea is so slow as to bring it within easy reach of almost every class of the community, is not a parallel case to a reduction in the Tax from 1s to 6d per lb., at a period when the price of Tea was double its present figure; it may nevertheless be of interest to compare the average consumption during the five years just preceding 1865 with that of the five years immediately following, viz:—

Average Annual Consumption 1860-1864.	81,464,027 lb.	Average Annual Consumption 1866-1870.	109,883,329 lb.
Per head of population...	2·79		3·61

It may be mentioned that the average Consumption per head of population, has remained almost stationary during the last seven years—probably for the reasons given under the previous heading.

It is too early yet to judge of the effect of the reduction just made in the Duty, and it may be a mere coincidence that the Home Consumption during the last six months should show an unusually large advance—the whole of which is made up of clearances since the 1st May.

The immediate effect of the alteration in the Duty was to produce a strong demand for the lower grades of Indian and Ceylon Teas, and even a temporary but very transient demand for low priced China Tea. This demand was doubtless caused to meet an expected enquiry from the public for cheaper Teas.

This arrestment of the rate of progress, although undoubtedly due to the superiority of the British-grown teas, is a serious matter for India and Ceylon, which are so rapidly increasing their output of tea, and no effort should be wanting to open up new markets. It is satisfactory to learn, as we do further on, that the progress already made is promising. A diagram shows that medium Indian pekoe went down in price from 1s 6d per lb. in 1880 and 1881 to 9½d and 10½d in 1890; the downward course of pekoe souchong in the same period having been from 1s 3d to 8½d and 9d per lb. In view of a stationary consumption in Britain and lowered prices, our readers interested in tea (the great majority) will eagerly scan the

figures for exports from Britain, which are, of course, additional to exports direct from India and Ceylon to markets other than that of Britain. Here are the figures for the first half of 1890, which we trust may expand ten-twenty-thirty-fold before the expiry of the decade on which we have entered:—

Export.—Since the 1st January, the exports from Great Britain of Indian and Ceylon Teas have been shown separately from those of China Tea in the official figures. It is satisfactory to know that

lb. 1,443,994 of Indian Tea, and 651,968 of Ceylon Tea were exported from Great Britain during the six months ending 30th June.

These exports were distributed as follows:—

	Indian. lb.	Ceylon. lb.
United States of America ...	423,776	189,636
Canada ...	235,595	96,203
Turkey ...	256,634	3,121
Holland ...	173,414	85,234
*Germany ...	47,391	121,842
Russia ...	15,664	6,943
France ...	22,172	9,040
Other places ...	269,348	139,949
	<u>1,443,994</u>	<u>651,968</u>

* Probably part of the Tea exported to Germany was for Russia.

On these figures the compiler makes remarks, some of which we quote:—

United States of America and Canada.—The exports to these countries are highly encouraging. Perhaps of all export markets, these two are the most promising. It is now beyond question that Indian and Ceylon Teas have at least taken firm root in these countries, and that the development of an important and increasing trade is merely a question of time. Wholesale houses in the large Tea drinking centres are keenly alive to the change which has of late been taking place in the public taste—and are already learning that it is to their interest to foster a trade which they see is an increasing one.

Both the Associated Tea Planters, Limited, and the Ceylon Planters' American Tea Co., Limited, are doing a good work respectively for Indian and Ceylon Tea. They are both working on somewhat similar lines in so far as, in addition to a wholesale business, they have each opened retail depôts in New York. They are doing their utmost to bring their respective Teas under the immediate notice of the consumers. As prospects open, their retail depôts will probably be extended to other towns, and their means of spreading information concerning Indian and Ceylon Tea be proportionately increased.

Other agencies of various kinds are also at work and there are strong grounds for believing that both these important markets will before long become extensive buyers of British Grown Tea.

Then follow references to South America and South Africa, about which we are not so sanguine as the writer. The races of Latin origin, and especially those with a large admixture of Indian blood, seem incapable of settling down to peaceful government and commerce, and it is surely discouraging that the recent outbreaks of revolution and war should have followed so quickly on the grand pan-republican demonstration in the United States. For South Africa, Natal *could* grow tea, but the crusade against Indian labour may prevent the development of the enterprise. We turn with far brighter hope to the as yet youthful British colonies of the south. The compiler of the review writes:—

Our Anstralian Colonies already draw considerable supplies from India and Ceylon and will no doubt continue to increase the proportion of these Teas used. The exports of Indian Tea from Calontia to Australia and New Zealand, from 1st May, 1889,

to 30th April 1890, in the past three seasons were as follows:—

1887-8.	1888-9.	1889-90.
lb.	lb.	lb.
2,408,019	2,869,184	3,595,712

It may also be mentioned that the direct exports of Ceylon Tea to these places for the past six months were nearly 1,000,000 lb.

The Paris Exhibition and the markets of Russia and Constantinople are referred to. But Russia will shut out British tea if she can, and we see little ground for expecting that the effete coffee-drinking Turks will ever become good customers for tea. But who can say? The consumption of tea in Britain itself was only 1·81 lb per head of the population in 1849, while now it verges on 5 lb, the figure for 1889 having been 4·91. Of the various foreign countries and British Colonies mentioned the compiler says:—

All these openings, insignificant though some of them may appear, form an important total in the aggregate and may eventually prove of *inestimable* value to the continually increasing production which is taking place both in Indian and in Ceylon.

The progress of Travancore as a tea-producer is specially noticed. There are 4,700 acres in cultivation, and the exports have risen from 3,577 lb. in 1882-3 to 678,363 in 1888-9. It is stated that

Some forty different estates were represented in the London auctions last season, comprising a total of over 9,000 packages. In this district, Tea can be produced of good quality, well suited for self drinking, as also for blending purposes.

Of course every case of this kind reported constitutes an additional reason for the most active and persistent efforts to cultivate new markets for tea. There is a diagram showing the monthly average Home Consumption of China, Indian and Ceylon tea, during 26 years. From this we learn that China commenced in 1864 with 7½ millions of pounds per month, rose to 10½ millions in 1879, and sank to 5 in 1889. India, which began with about ¼ million in 1864, has gone on steadily and rapidly rising to 8 millions in 1889. The progress of Ceylon has been still more rapid from a few hundreds of thousands in 1884 to 2½ in 1889. The percentage of Indian tea to the whole consumption rose from 3 per cent in 1864 to 52 per cent in 1889; while the rise in the percentage of Ceylon has been from 1 in 1884 to 15 in 1889. The percentages of India and Ceylon together make up 67 per cent of British-grown tea consumed in Britain last year.

The details we have thus noticed and quoted are very interesting and in many respects important. With the progress of population, wealth and temperance, we have every right to expect a corresponding increase in the demand for the wholesome and fine quality tea we produce; and in this case we have the satisfaction of feeling that what subserves our interests as producers is entirely beneficial to the consumers.

OLD BONES IN BENGAL.

The Government of India, in their No. 67—12-1, A, dated the 4th October 1889, have invited the attention of Local Governments to the increasing exportation of bones from India, and asked the Provincial Department of Land Records and Agriculture to embody remarks on the use of, and trade in, bones in their annual reports. The following is the information which has been gathered on the subject:—

(1) SOURCE AND USE OF BONES.—Within the last few years the collection of bones from village wastes, for exportation to Calcutta, has become the re-

gular profession of a low caste of Hindus—Chamars—in the central and western districts of Bengal proper, and is gradually extending to the outer parts of Bengal, in proportion to the increasing demand of the Calcutta mills, and the extension of railway communication. Heaps of raw bones collected for transport to Calcutta may now be seen along the railway and principal river routes of Bengal. Bones are also collected by the indigo-planters of Behar for use in their indigo land. Many of them have erected mills for grinding them to dust. In Lohardugga many tea-planters make their own bone-meal, and use it as a manure for tea-plants. The bones are collected locally, and coarsely ground by the *dhenki*. The fragments are not so fine as are turned out by the mill, nor are they required to be very fine for a slow-growing perennial like tea. The bones brought into Calcutta are bought up for manufacture into bone-meal. There are four or five bone-grinding mills at the present time in and near Calcutta. With the exception of a comparatively small quantity of bone-meal sent out to tea-gardens, the whole of the output of the mills is destined for export.

(2) PRICE OF BONE-MEALS IN CALCUTTA.—The price of bone-meal ranges from R2 to R2-8 per maund. There are several sorts (about 10 in number) distinguished according to degrees of fineness and purity, the best of which resembles *sattu* or parched barley meal, both in fineness and colour.

(3) MEANS OF PRODUCING BONE-MEAL CHEAPER IN BENGAL.—Raw bones as they come from the Chamars may be bought in the *mofassil* at eight annas per maund or less. In the tea-gardens in and near Ranohi they are delivered by the collectors at the rate of five annas a maund. At Dumraon in Shahabad bones have been collected at a cost of four annas a maund, and at Julpigoree Mr. Donald Sunder, Settlement Officer of the Western Doars, has arranged with Chamars to have bones delivered at the jail at a price not exceeding six annas a maund.

A comparative trial was made in the Seebpore farm as to the relative merits, in grinding bones to dust, of the *dhenki* and an English-made bone-mill supplied to the department by Messrs. T. E. Tomson & Company. The results were that it cost two annas a maund less to prepare bone-meal with the *dhenki* than with the mill. Under the circumstances the *dhenki* can be safely recommended as a cheap and effective means of crushing bones. If ryots ever take to the use of bone-meal for manure, they will not have recourse to complicated machinery, but will use the *dhenki* in very much the same way that they grind wheat and barley flour themselves, rather than buy the machine-made article.

(4) EXPERIMENTS IN BONE-MEAL THROUGH RYOTS.—Numerous experiments to test the efficiency of bone-meal as a manure for paddy have been made in Burdwan and Hooghly. It is not always possible to show the results of the experiments in bone-meal in the form of a statement comparing the outturn of plots manured with it, with that of unmanured plots, for these reasons—(1) that in most of the experiments bone-meal was mixed with saltpetre, hide-salt, &c., so that it cannot be ascertained how much of the increased yield was due to each of these manures; and (2) that the experiments made by ryots are devoid of precision and cannot be thoroughly relied upon. The best guide to the value of this manure would be the evidence of the ryots who have tried it. In the Annual Report for 1886-87 mention was made of the steadily increasing demand for bone-meal in villages where it had been used in the preceding year. The results of the ryots' experiments in this

year were also encouraging, as the figures given in the Appendix H. show. They give an average increase of 570 lb. of paddy per acre obtained by manuring with 240 lb. of bone-meal. The money-value of the increase in a year of ordinary prices may be taken as R9-8, while the price of 240 lb. of bone-meal applied is only R6 at its present high price in Calcutta. Experiments made with bone-meal on paddy, did not succeed in 1887-88 owing to great deficiency of rainfall; and in the following year (1888-89) they totally failed on account of floods, but the ryots who made the experiments appear to be very much interested. Last year an application was received from a single person for fifty maunds of bone-meal, which was supplied and paid for by the appoiant. Inquiries were made in some of the villages in which bone-meal had been distributed in previous years. The testimony of the ryots and farmers was, according to Mr. Basu, nearly uniformly to the effect—

(1)—That bone-meal is quite as good as manure for paddy, potatoes and sugarcane (the chief crops of the village) as oilcake.

(2)—But that its effect does not last for more than a year, and according to some, a field manured with bone-meal will yield heavily in the first year only.

(3)—That better results were obtained in sandy than in clayey soils.

In Hooghly and Burdwan oilcakes (castor-cake in particular) are now being very largely used as manures not only for sugarcane, potatoes and various vegetable crops, but also for paddy, the chief staple of these districts. Although bone-meal is acknowledged to be a good manure, oilcake is believed to be superior to it in many respects. Besides that it is much cheaper than bone-meal, it is open to no objection on the ground of caste feeling. Until, therefore, bone-meal can be offered at cheaper rates than oilcake, there is no hope of its general adoption in native agriculture.—*Pioneer*, Aug. 18th.

INDIA'S POVERTY AND HOW IT CAN BE REMEDIED.

Here is the truth, plainly spoken:—

A correspondent writes to the *Madras Times*,—the poverty of India is becoming proverbial. In order to mitigate this rising poverty of India, there is a loud demand for technical institutions, in order to revive the old industries of this great empire which are now on the decay, and to encourage the arts *in esse* and *in posse*. The Good British Government, which has already conferred several priceless boons on India, is also opening technical institution for the amelioration of the poverty-stricken classes. India is thought to be the poorest country in the world. When a careful examination is made as to her real position, one is constrained to say that it is the richest in the world; but the apathy of the natives, in commercial enterprises and in agricultural pursuits, has rendered this Empire the poorest in the world. Let us therefore briefly examine the causes which underlie this poverty. There are many men here who have amassed a good deal of wealth in different walks of life. The wealth so accumulated by them is, as a general rule, spent in ways which are of very little benefit to the country. Some of these wealthy people spend a mint of money in taking long pilgrimages, in erecting costly temples, in performing the marriages of their infant sons and daughters, some in preparing costly jewels, and some in immoral ways; besides these there is another set of superstitious people who keep the money in their iron safes and actually worship it; if the money that is spent in all these ways is laid out in such commercial enterprises as opening of Banks, the opening of spinning and weaving companies, and other mechanical and engineering works, how useful and beneficial would these be in reducing the poverty of India. The mineral resources of this fertile land are great. It boasts of gold, iron and coal fields and several

other mineral products. If all the wealthy classes who say that India is becoming poorer day by day would lay out their money in opening companies for working the gold, iron and coal mines, for how many people would such undertakings provide a living? The natives who accumulate wealth either by hook or crook are naturally reluctant to lay out any portion of it in any useful undertaking, but their sole aim is to save money somehow or other, and yet we find such men sitting in their hungalows and storied houses saying that India is getting poorer.

The natives, through this apathy for such enterprises, have left this fertile soil in the hands of foreigners, who have formed themselves into many companies, and opened railways, gold mining companies, cotton mills, paper mills, and several other engineering and mechanical works, which give the working classes not only a living, but also leave a sufficient margin of profit and interest on the outlay. If the natives were to open such institutions, it would not only be a very great boon, but they would also retain the wealth of the land in their own hands; but under the present state of things, the wealth of India finds its way into the hands of foreigners. The natives, who hoard up wealth without making any use of it, are clamouring for technical institutions. No doubt such institutions would be of immense good to the people in giving them technical education; but those who have received such education would even then have to depend upon the English merchants and companies for their livelihood; agriculture is the backbone of India, but still we see that such an important source of industry is greatly neglected. When nature withholds its gifts, in sufficient abundance, the poor ryot is obliged to starve. If the well-to-do people assist the ryots at such critical times, and introduce improved machinery in tilling the soils, how much of the ryots' poverty would be averted. At present India is depending on Europe and other foreign countries for numerous articles such as muslins, matches, umbrellas, &c. If these worshippers of Mammon, who daily cry that India is becoming impoverished forgetting that it is their own apathy which is bringing about this calamity start companies for manufacturing these articles, how much would such enterprises mend the poverty of India. If all the natives would lay out the money that they have laid out on jewels, which is only a profitless investment, in other profitable and useful ways, then the poverty of India would be greatly diminished.

India is a poor country because the natives are not an enterprising nation; it is poor, not because its mineral products are less fruitful and profitable but because they are neglected by the natural sons of the soil; it is poor because the well-to-do classes do not wish to lay out their money on any profitable and useful undertaking. From Cashmere to Comorin there are wealthy rajabs, zemindars and other men who fling away a good deal of money on useless undertakings; if all the money that is so flung away were laid out in the opening of some useful and paying institution, would India then complain of her poverty? The poverty of India is mainly due to the lack of commercial enterprise on the part of her sons. The sister presidencies of Calcutta and Bombay are far better than Madras. The Baboos of Calcutta and the Parsces of Bombay are far ahead of the Madassees in commercial pursuits, and hence it is that those two presidencies are richer than Madras. Can any one in this City of Madras point out to me one mill or factory which has been opened by a company of Madrasees, besides the cotton mill at Bellary, opened by Mr. Sahapathy Mudelliar, and the rice pounding, and oil mills, opened by a native merchant of Madras on the Tiruvattoor High Road? If the advocates who suggest measures and means for mitigating the evil of India's poverty sitting in their comfortable quarters, were to follow in the footsteps of the men named above I am sure that the poverty of India would be mitigated to a certain extent. The cause of this poverty is nothing more than the apathy of the people in respect to commercial enterprises.—*Indian Agriculturist*.

TIMBER AND FOREST PRODUCE GENERALLY IMPORTED INTO AND EXPORTED FROM CEYLON.

In the appendix to the interesting report of Col. Clarke on the Forest Department, there are memoranda by the Collector of Customs showing the imports and exports of forest products for 1888 and 1889, details of which, at this juncture, will be interesting to a large class of our readers. In the imports of 1888, the item "ashwood for oars" occurs. This ashwood must have been used by some of our boat clubs, and the import, only 1 package, is not repeated in 1889. Of "cedar wood," described as white cedar wood in Col. Clarke's report, used as staves for oil casks, 141 logs and 128 pieces were imported in 1888 and 290 logs and pieces with 7 packages in 1889. Can this be the produce of the "white toon," the true *Cedrela toona*, grown so largely in the lower hill forests of Southern India? If so there is an additional reason for trying to grow this tree in the lower country of Ceylon, while the red toon receives attention at higher altitudes, where that variety, with coral red branchlets and serrated red leaves, flourishes. Of "planks not described" 324 pieces and 16 packages were entered in 1888 and 1,423 and 6 respectively in 1889. Of pitch pine wood 122 packages are down for 1888. Of sandalwood the imports in 1888 were 4,248 pieces and 7 packages, while in 1889 the imports were 926 pieces and 33 packages. This scented wood is, no doubt worked up into boxes and curios for sale mainly, like tortoiseshell articles to steamer passengers. Of timber and wood not described, 786 pieces and 881 packages were imported in 1888, and 190 tons, 264 logs, 278 pieces and 91 packages in 1889. Of teak planks and teak 2,796 logs, 3,183 pieces in 1888, and 1,217 logs, 2,001 pieces and 531 squares in 1889. Of "boards" 3,032 pieces and 500 packages in 1889. Also "Devadara" (?) wood [cannot be *Deodora*] 35 packages. "Rough oak planks" 1,200 pieces. The oak timber was probably used for the repair of vessels built of that wood. "Red wood" [? red toon] 13 packages, and actually, 1 package of our own special dye-wood, sapan. The total amount of timber of every description imported in 1888 is given at 2,937 logs, 8,769 pieces and 1,029 packages. In 1889 the figures were,—190 tons, 1,761 logs, 8,960 pieces, 702 packages and 531 squares. There appears, therefore, to have been a considerable increase in the imports of 1889 over those of 1888. In addition to timber we get horns of sorts, 23 cwt and 54 packages in 1888 and cwt 263.2.5 and 41 packages in 1889. Of orehilla weed [for export?] no less than cwt 527.3.22 and 28 packages in 1888 and cwt 210.3 and 20 packages in 1889. Of skins of sorts we imported 11,413 pieces and 74 packages in 1888, and 27,003 pieces and 71 packages in 1889.

Turning now to exports from the island of similar products, we obtain figures which indicate an important branch of our commerce. It is very unfortunate, however, that a more distinct classification of timbers is not adopted, the very largest item being described as "woods of sorts." Of such woods the exports in 1888 were 2,828 packages, 6,909 logs; with 820,247 under "number," which we suppose indicates the contents of the packages added to the logs. In 1889 the exports under the same heading were 1,862 packages; 26,779 logs; 700,536 number. It would certainly be well if the Customs could secure the naming of at least the more important "woods of sorts" sent from the island. We must express the hope that the heading did not include any palmyra timber, which constitutes the next great item. The number of

palmyra laths and rafters exported is given at 286,296 in 1888 and 296,484 in 1889. For the roofs of buildings there can be no better timber than that of well-grown palmyra palms. "Timber, dye wood and roof," chiefly sapan, no doubt (although we get cwt. 3,803-2-1 separately for sapan), was cwt. 642-2 in 1888, and cwt. 648-1-22 with 10 pkgs., and separately under the heading of sapan cwt. 1,674-0-16 in 1889. Better classification is required, to enable enquirers to discover whether any important dyewood other than sapan is exported from Ceylon. Ebony, for which Ceylon has been nearly as famous from far back antiquity as for cinnamon and pearls,* was exported in 1888 to the amount of cwt. 12,3-521-21 and in 1889 only cwt. 3,880-3-1. Col. Clarke has, in his report, explained the circumstances of export as due to a glutted market. We need scarcely remind our readers that ebony is the heart-wood of trees the outer shell of which is white, the amount of the valuable heart-wood varying with age and circumstances. Of sandalwood there was a trifling export of 5 under "number" in 1888. This was, of course, part of the sandalwood originally imported, for sandalwood is unknown in Ceylon except in the Botanic Gardens. Of our next most important cabinet wood after to ebony, that is satinwood, the exports for 1888 are given at cwt. 4,143-2-4 and 4,359 logs; in 1889 at cwt. 1,229-3, logs 1,519 and "number" 22. Of "ironwood" (including *palu*, no doubt, as well as the real ironwood, *na*) the exports were 1,475 logs in 1888 and 896 logs and "number" 10 in 1889. Of our fine and useful timber, halmilla, 349 logs were sent away in 1888 and 806 logs in 1889. Teak figures for 1 log in 1888 and "number" 35 in 1889: not likely to have been the produce of Ceylon. Of arekanut laths and rafters we exported 305 in 1888 and 415 in 1889; while coconut rafters figured for 259 and 1,718 in the respective years. Of "laths and rafters" not otherwise defined 8,290 packages and 4,809 in "number" were sent away in 1888, with 8,326 packages and 3,006 "number" in 1889. The large number of packages must surely have included palmyra laths and rafters, in which case the figures are very defective, and now that we have a forest department in full operation, it would surely be well that the customs authorities insisted on more definite information as to the nature and names of the timbers entering into the export trade of the island. Kitul (*Caryota urens*, or jaggery palm) laths and rafters to the number of 179 were exported in 1888 and 1,447 in 1889. The totals of the exports of timber for the two years were:—

	cwt.	packages	logs	and number
1888	20,941	3,26	11,121	13,093
1889	7,433	0-11	10,288	30,000

Of forest produce exported we get for "horns of sorts" in 1888 cwt. 2,341-0-16; in 1889 cwt. 2,203 and 1 package. Hides and skins, in 1888 cwt. 7,598-0-26 and 347 packages; in 1889 cwt. 8,693-2-20 and 458 packages. The value of the skins of domestic cattle in Ceylon is greatly depreciated by the excessive branding of the live animals to which their native owners resort. Of the dye material, orchilla weed the export in 1888 was cwt. 489-1-9 and one package; in 1889 cwt. 502-3-20. Of "tanning bark," not more definitely described, the export in 1888 was cwt. 747-2 and in addition

* Sir George Birdwood in a paper on the Industrial Arts of India states that the "Periplus of the Erythrean Sea," which belongs to the first century of the Christian era, notices that Omana imported from India ebony. He adds that Schlieman found carved Indian [Ceylon?] ebony in one of the mounds of the Troad identified by him with the site of the city of Troy.

"Velam bark" was sent away to the amount of cwt. 530-2. In 1889 there is no separate mention of Velam bark, only of "tanning bark," of which the export was cwt. 582-3.—There can be little doubt that the tanning bark exported from Ceylon, was mainly the produce of *cassia auriculata* and *Acacia leucophloea*. In the latest published number of the *Indian Forester* there is a paper on dye stuffs, from which we take the following extracts:—

ACACIA LEUCOPHLOEA.—The bark of *Acacia leucophloea*—the reru or safed-kikar—attracted attention at the Conference; and the leathers exhibited from various districts in India as prepared by means of this material were considered superior to any others shown.

CASSIA is referred to in the same article and it is stated:—

The leather tanned by the bark of *Cassia auriculata*—the tarwar—was considered at the Conference much superior to what could have been inferred from the examination of the highly coloured bark.

Then we have a paragraph on the *nelli* of our patanas:—

EMBLICA MYROBALAN.—A few of the tanners present were familiar with the Emblic myrobalans—the fruit of *Phyllanthus Emblica*—daula, 4mla, aonla—though they had never before seen the leaves. But the same objection exists with regard to these as has already been alluded to under *Anogeissus*. Unless a tanning half-stuff could be profitably prepared for export, it would be hopeless to expect a trade to be done in the leaves. They are doubtless good and useful tans, but have to compete with others that can be landed in the home markets at lower prices. This argument seems perfectly just and applicable to the leaves, but since it pays to export the fruits of the true myrobalans, it would seem as if the question of a future trade in the Emblic myrobalan would turn on the percentage of tannin which it possesses and the colour it imparts to the leather.

We never before heard of the acid and astringent *nelli* fruits and the leaves of the tree being used for tanning purposes.

Gamble writes of *Acacia leucophloea* (*Mimosa leucophloea* of Roxb. Fl. Ind.) that it is known to the Tamils as *velvaylam* and *vel-vaghe* and to the Sinhalese as *katu andara*. He describes it as

A moderate-sized or large deciduous tree. Bark $\frac{1}{2}$ inch thick; colour varying with age, grey and smooth when young, dark brown, almost black, and rough when old, exfoliating irregularly in patches and strips. Sapwood large; heartwood reddish brown with lighter and darker streaks, extremely hard. Pores moderate-sized, uniformly distributed in patches or short irregular concentric belts of white tissue which are prominent in, and alternate with, the dark-coloured firm tissue which separates the medullary rays. The latter are white, fine and moderate, and often slightly bent.

The weight of the wood is given at 45 to 59 lb., and it is added that

It seasons well and takes a good polish; is strong and tough, but often eaten by insects. It gives an excellent fuel. The bark is eaten in times of scarcity; it is used in preparing spirits from sugar and palm juice, to precipitate by the tannin it contains the albuminous substances in the juice. It gives a fibre used for nets and coarse cordage. The young pods and seeds are eaten, and the gum is used in native medicine.

Of *assia auriculata* the same authority states that it is a shrub of Central and Southern India and that its bark is used for tanning and dyeing leather and its seeds as an application for ophthalmia.—Of *Embllica myrobalan*, the *nelli* of the Sinhalese and Tamils, Gamble tells us, under the title *Phyllanthus Emblica*, that it is

A moderate-sized deciduous tree. Bark somewhat less than $\frac{1}{2}$ inch thick, grey, exfoliating in small irregular patches, inner substance red. Wood red, hard, close-grained, warps and splits in seasoning

No heartwood, annual rings not distinct. Pores small and moderate-sized, uniformly distributed, often subdivided or in short radial lines. Medullary rays moderately broad and broad, the distance between two rays generally greater than the transverse diameter of the pores. Medullary rays very prominent on a radial section, giving the wood a handsome mottled appearance.

Mendis gave 49 lb. as the weight of the Ceylon wood but that of Mysore is given at 67. Gamble adds :—

The wood is durable under water, and is used for well-work; also for agricultural implements, building and furniture.

The bark is used for tanning and in medicine; chips of the wood are said to clear muddy water. The fruit is the Emlie Myrobolam, and is used as a medicine, for dyeing, tanning, and for food and preserves. It gives a gum, which is not used.

PLANTING IN NETHERLANDS INDIA.

In East Java, this year's coffee crop has turned out poorly but prices rule high. The *Locomotief* mentions a firm at Samarang which last year drew sixty thousand piculs from its estates, but which expects only 112,000 piculs this year. In East Java, the tobacco crop also shows bad signs.

The Batavia *Nieuwsblad* says that the Netherlands India Government has decided upon issuing Java tea to the army there. Similarly, the Government has tried to depend as much as possible on local resources in the supply line, but the Home authorities invariably thwart these good intentions by giving preference to articles from the Netherlands. This especially seems to be a failing of the Colonial Office.

The *Locomotief*, in noticing the expansion of planting enterprise in Netherlands East Borneo, wonders why tobacco should be such a favourite in that line of business. It deems that a commercial company with a few handy steamboats and convenient trading stations on the coast could carry on a profitable barter trade in local produce. Pulo Laut, a coal island in the neighbourhood, would prove useful in supplying fuel.—*Straits Times*, Aug. 27th.

THE CHANDPORE TEA COMPANY.

The Chandpore Tea Company, Limited, has just been registered, with a capital of £32,000 in £10 shares. Its object is to acquire, on such terms as may be agreed upon, the Chandpore and Begum Khan Tea Estates, situate respectively in the district of Sylhet and province of Assam, with all lands appertaining thereto, and the goodwill, property, and assets of the business partnerships carried on by the respective proprietors thereof in connection therewith as the same stood on January 1st 1890, as going concerns, and to carry on and work the same estates. The first subscribers, who take one share each, are:—S. Cochrane, 20, Threadneedle Street, E. C.; Major-Gen. W. M. Campbell, Junior United Service Club; W. Shaw, 16, Exchange Square, Glasgow; J. R. Pedler, 9, Mincing Lane, E. C.; O. Steel, 34, Old Broad Street, E. C.; J. S. Fraser, 34, Old Broad Street, E. C.; C. Sanderson, 46, Queen Victoria Street, E. C. There shall not be less than two nor more than five directors. The first are William Maxwell Campbell, William Shaw, J. R. Pedler, and Samuel Cochrane. Qualifications, £500. Remuneration, £50, divisible, provided that the fee payable to each director shall not exceed £2 2s. each for each meeting attended.—*H. and C. Mail*.

RAMIE AS FOOD FOR SILKWORMS.

(*Boehmeria nivea*, H. K.)

We were lately surprised to find that silkworms fed on *casuarinas*. Another surprise is the statement, which we quote from the *Kew Bulletin* for August, that the leaves of the rhea plant form suitable food for the silk-yielding insects:—

It now appears that the leaves of the Ramie plant may be used as a food for silkworms, in the same

way as those of the mulberry and Osage orange (*Maclura aurantiaca*). All three plants belong to the same natural order *Urticaceae*, and there should be no reason why they should not be found equally suitable. The following account of the use of Ramie leaves for feeding silkworms in the United States was communicated to the Foreign Office by Mr. A. de G. de Fenblanque, H. B. M.'s Consul at New Orleans:—

"A discovery has been made by a lady in Columbia, S. O., that may have a marked effect upon two great industries. For a number of seasons this lady has amused herself by feeding silkworms and sending a few pounds of cocoons to the Women's Society for the encouragement of the Silk Industry in Philadelphia. The extraordinary warmth of this winter caused the eggs to hatch far in advance of the season, and as the young leaves of the mulberry and the Osage orange had not put forth, our amateur was at a loss what to do. An account adds:

"Seeing that the foliage of the Ramie in a neighbouring field was putting out, she gathered some and put the worms upon it. They fed ravenously, and she kept up the supply until the Osage orange leaves appeared. Then she divided her worms equally, feeding one set with Ramie, the other with Osage orange. She kept the cocoons separate and sent them to Philadelphia. The experts there were astonished at the size of those spun by the Ramie eaters, and wrote to the lady to know what she had done to secure them. They were not only larger, but the silk was finer."

"If further experiments should prove that Ramie leaves can be depended upon for silkworms' food, then a great impetus will be given to the production of this valuable article in the South, while it will add to the profits of those who raise that plant for its fibre."

CEYLON CACAO.

(*Theobroma Cacao*, L.)

The following article is from the *Kew Bulletin* of August. It will be seen that although the production of cacao in Ceylon is limited its quality is of the very highest:—

The cacao industry, until of late years, has been chiefly confined to the tropical parts of America, Mexico, Guatemala, Venezuela, the United States of Colombia, Brazil, and the Guianas, being the chief producers of cacao on the mainland, while Trinidad and Grenada have taken the lead amongst the islands of the West Indian Archipelago. The species of *Theobroma* yielding commercial cacao are natives of Central and South America, and it is but natural to find that the largest areas under cultivation are situated near those regions. Plants of cacao were introduced at an early period to the East Indies, and they are now found under cultivation in most tropical countries. Until quite recently, however, the best qualities (as also the largest quantities) of commercial cacao were obtained from tropical America. The celebrated cacao of Venezuela, known as Caracas Cacao, the choice cacao of Soconusco, in Mexico, and the selected sorts of Trinidad Cacao were believed to be unapproachable for quality and flavour. It appears now, however, that even the best produce of tropical America does not reach the high standard which has been attained by Ceylon Cacao. In a recent letter received from Mr. J. H. Hart, F.L.S., Superintendent of the Botanical Gardens, Trinidad, he states: "For several months I have noted in the *Public Ledger* the increasing prices obtained for Ceylon Cacao in comparison with that obtained for the best Trinidad Cacao. In the Account Sales dated the 29th March it is shown that Ceylon Cacao is actually worth more by 2s 6d per cwt. than the best Trinidad marks. The difference between the inferior marks is greater still." In view of these facts the planters in Trinidad and elsewhere are keenly discussing the merits of Ceylon cacao, and seeking for the causes which have led to the production of an article so superior to anything produced before. It is true that the quantity of cacao produced in Ceylon is relatively very small. In 1889 Ceylon produced only

17,164 cwt., while the production of Trinidad alone was probably not far short of 125,000 cwt.* The general opinion appears to be that the superior quality of Ceylon cacao is greatly due to the more careful and effective methods adopted for fermenting and curing the beans. The produce is said to be sent into the market in a bright and attractive condition and free from the dirt and mucilage which too often spoils the appearance of West Indian cacao. Again the "soil and climatic conditions" in Ceylon are said to favour the production of cacao with a delicate flavour and good colour. There is, doubtless, some amount of truth underlying all these opinions, but none of them touch upon an important element in the inquiry, and that is the character of the plants yielding the produce.

The cultivated forms of *Theobroma cacao* are broadly divided into two sorts, known in Spanish speaking countries of America as cacao Criollo and cacao Forastero. At one time cacao Criollo was largely, if not exclusively, cultivated in Trinidad, but owing to a disease (described as a "blast") which visited the plantation some time during the last century this sort was discarded in favour of a more robust and hardy sort, to which the name of Forastero (or foreign) cacao was given. The Criollo cacao is said to yield the Caracas cacao of Venezuela, but it is now comparatively rare in Trinidad and Grenada, and only sparsely found in the other West India Islands. The cacao first introduced into Ceylon and the East Indies, probably by the Dutch in the beginning of the century was the criollo sort, and if the bulk of the Ceylon produce now received in this country is derived from criollo trees that would in a great measure account for its superior quality. A Trinidad planter writes: "The Criollo Cacao is much better flavoured than any other, and requires but three days' fermentation." This aspect of the case has already been dealt with by Dr. Trimen, F.R.S., Director of the Botanical Gardens, Ceylon, in his Annual Report for the year 1885:—

"There has been some demand during the year for seed of the Trinidad varieties at Peradeniya, and the belief is general that these large growing kinds are harder than the old Ceylon sort. Since the date of my last report I have arrived at the conclusion that the various 'pale-fruited' kind (see Report for 1882) sparingly cultivated in Ceylon, as well as all the strains of these new Trinidad plants, are to be referred to the 'Forestero' class of cacao. All of them, whatever the colour of the pods—purple, dark-red, pink yellow, or pale-green—have seeds ('beans'), which are flattish in form, and purple or violet internally, and become very dark after curing. Our old cacao, on the contrary, has the pod nearly always red (occasionally bright yellow), and the seeds are more rounded in shape, and always white or yellowish on section when fresh, becoming red after preparation for the market. As to the proper name of this latter sort, I may quote a portion of a letter which I addressed to the *Observer* newspaper, in November last, upon the subject:—

"The fruiting of the selected and named varieties sent from Trinidad in 1880 and 1881 has since shown that all these names (Cundeamor, Cayenne, Verdilio, &c.) are applied to forms of what is known there as 'Forastero' cacao, and that none of the purple seeded kinds are of the 'Criollo' or 'Caracas' variety. It will therefore be well to use for the future the name 'Forastero' for them here also.

"This, being the case the question naturally arises as to the ordinary red cacao of Ceylon. What variety is it; and is there anything like it grown elsewhere? For some time I have been becoming more convinced that it is this that is the 'Caracas' or 'Criollo' cacao, and I might have taken stronger ground on the matter than I did in my last report. Mr. Morris of Jamaica, who has had good opportunity of investigation the cacaos, both in a wild and cultivated state tells me that he knows of 'only one kind with the cotyledons white or whitish, and that is what is known as Caracas cacao.' This, it is well

known, is now a rare kind in the West Indies, and scarcely to be found on Trinidad estates, having died out, though formerly largely grown there. Evidently Ceylon obtained its plants before this change had occurred. The high quality of "Ceylon cacao" is thus explained, as well as its delicate temperament."

It only remains to point out that the preparation of Ceylon cacao differs in one important point from that generally adopted in Trinidad and other parts of tropical America. In Ceylon, after the beans are fermented the pulp is carefully removed by washing, and the result is the production of a clean, bright looking sample, free from mucilage and discolouration of any kind. In the West Indies, after fermentation, the beans are generally neither washed nor thoroughly rubbed. The mucilage is allowed to dry upon them. On some of the best estates in Trinidad the mucilage is carefully removed by rubbing, and sometimes a red absorbent earth is used to assist the process as well as to give an attractive colour to the beans. The various methods adopted for fermenting and curing cacao in the West Indies are well given in a series of Essays published in the *Agricultural Record* (the Journal of the Central Agricultural Board of Trinidad) for March 1890. The present position of Ceylon cacao in the London Market is discussed in the following letter, for which we are indebted to the courtesy of Messrs. Shand, Haldane & Co., of 24 Rood Lane, E. C.:—

Messrs. LEWIS & NOYES to Messrs. SHAND, HALDANE & Co.

14, Mincing Lane, E. C., July 2nd, 1890.

Dear Sirs,—The following remarks may give some explanation of the peculiar position held by Ceylon cacao as compared with Trinidad.

The consumptive demand during recent years has caused manufacturers generally to give their attention to the making of a cocoa and a chocolate for which Ceylon is especially adapted on account of its bright chocolate-coloured break and mild flavour in preference to the strong flavoured Trinidad sought after a few years ago.

The lightness and easy fracture of the shell through the removal of mucilage renders the loss in weight less to manufacturers and likewise facilitates the working.

To the demand exceeding the supply (the largest output from Ceylon in one year being less than 20,000 cwt), together with the fact that the crop is shipped almost entirely to this port, thus creating keen competition from the markets of all other manufacturing countries, may be attributed the existing high prices.

We may mention that should the output from Ceylon be, say 50,000 to 60,000 bags, of the same weight per bag as those from Trinidad, a range of prices much on a parity with that of good Trinidad would follow.

We have recently noticed a few parcels of Trinidad cacao cured similar to Ceylon, in which the outward appearance has to some extent been obtained but the light break and mild flavour are wanting.

Any further information which you may require we shall be happy to furnish.—Yours, &c.,

(Signed) LEWIS AND NOYES.

The sample sent herewith is from North Matale estate, the property of the Ceylon Land and Produce Company, Limited.

OYSTERS IN NORTH BORNEO.—In a paper on this settlement in the *British North Borneo Herald* it is stated:—Edible oysters are also found on the rocks near the coast; these are collected and dried by the natives and sold to the Chinese traders who export them to China. The same oyster does not object to make its home on the mangrove branches between high and low water, in fact oysters may be said to grow on trees. It would thus appear that growing trees act as substitutes for the fascines used in European oyster culture. It is added Keemah or clams are also collected, dried, and exported in the same way;

* In 1885 the actual production was 122,585 cwt.

BRITISH GUIANA :

THE COLONY OF SUGAR AND GOLD.

It was natural enough that Sir James Longden should so frequently refer to "what we did in Demerara," (the Demerary of many writers), and that Sir Arthur Gordon should praise the fertile soil and magnificent nutmegs and cacao of Trinidad. We have certainly very little in Ceylon to compare with the volcanic soil of the West India Islands and the marvellously fertile swamps (when drained by deep and broad canals) of the flats which form such prominent features in our South American settlements of Demerara and Berbice,—often referred to as "those fine islands in the West Indies" during the debates which preceded the abolition of slavery. With that event the once important cultivation of coffee in British Guiana dwindled to almost nothing, while cacao is but a secondary product. But from the persevering application of science, skill and industry to the staple sugar, Demerara and Berbice have been able to hold a good position both after emancipation and during the recent crisis occasioned by the beet-root sugar bounty policy of the continental nations. But now we learn that sugar cultivation is threatened by the rapid development of an industry never so much as dreamed of when sugar was almost literally coined into gold, in the old days of slavery and protective duties. Gold is being collected in abundance amidst the alluvials of the great rivers which run up from the British colony into Venezuela and Brazil, and labour has been diverted from the production of sugar and rum to the gold diggings. In this fresh crisis we notice, from the proceedings of the Agricultural and Commercial Society, as reported in the very interesting journal *Timehri* that the colonists are not turning their attention so much to fresh labour drafts on India, as to the neighbouring colonies, especially over-populated Barbados, the Azores and, what is quite a new enterprise, to the Southern States of the American Union, where the possible solution of the problem of harmonious existence, side by side, of the whites and the negroes is in many places giving extreme anxiety. The now free negroes of America and others willing to do good work for fair wages are invited to resort to the British South American colony, scales of wages and other details being published as inducements. From an article in the magazine referred to we quote some interesting details regarding the progress of the gold enterprise in Guiana, to which, it seems to us, public attention has not been directed in a manner adequate to the importance of the results already attained and the promise afforded for the future. We quoted what was stated regarding this enterprise in *Timehri* of June 1887; and now, after the lapse of three years, the report is:—

With but scant encouragement, and suffering under great disadvantages, the industry may have said to have progressed by leaps and bounds, as indicated by the returns to hand for the different years. In 1885, according to official returns, 939 oz., were exported; in 1886, 6,518 oz.; in 1887, 11,906 oz.; in 1888, 14,670 oz.; in 1889, 29,327 oz.; and in the first six months of the present year about 27,000 oz., valued at nearly \$500,000, have been already obtained, an amount not far short of the total output for 1889, which in itself had been more than double that obtained in the previous year.

The industry has become a very considerable source of income to the Government, for the royalty (at 90 cents per oz.) within the six months, has amounted to nearly \$25,000; while but the merest nominal expenditure on their part has been entailed.

A very noteworthy feature in the growth of the industry has been the perception of the fact, that gold is to be found in paying quantities over large areas of the colony. First in the Puruni and Cuyuni river districts, then in the river districts of the north-west, and now more recently in the Potaro district, the metal has been obtained in large quantities; and it may almost be regarded as certain that the upper districts of the Mazaruni, Essequibo, Berbice and Corentyne will be similarly productive.

The constant succession of rapids, cataracts and falls along the river courses, and the serious danger of these obstructions in the height of the wet season, render the natural water-way a serious drawback; and the genius of the engineer may be said to be the great hope of the future. Following his tracks through the recesses of the forest, come the pictures of an advanced and prosperous mining industry; of the inland settlements and villages, and possibly even cities, with their farms and clearings, where a wider agricultural development may be attained; and of a trade in timber and other forest products from regions at present untapped; while the easy access to higher lands will furnish health resorts from the coast; and the gradual clearing of the land by lessening the almost continuous extent of forest; will tend to an equalisation of climatic conditions that must have a marked influence in decreasing both the great periodic and constant swamps of the interior.

Already, however, the note of labour-alarm has been sounded, for the rapid development of the gold industry within the last two years, has been the means of drawing away from the sugar estates an appreciable quantity from the staff of labourers; and with the continued advance of the industry, it is but to be expected that the labour supply of the estates will be still further lessened. The question is thus a most important one, fraught with grave issues to the material prosperity of the colony, how best to maintain the staple sugar industry in full and vigorous swing, and, at the same time, to provide for and encourage the fullest development of the mineral wealth within our reach.

The absence of special encouragement from the Government may be due to apprehensions of trouble in two directions:—the disorganization of the labour supply for plantations and the balata rubber and timber enterprises, and the danger of complications with the border countries. Venezuela, indeed, has already been indulging in tall talk of war (!) to vindicate her rights. A cautious and conservative policy may be very good up to a certain point, but there can be no doubt that the ultimate result of the gold discoveries in the British colony and the bordering states will be to connect Georgetown, Demerara, with the capitals and chief towns of the great series of Southern American States, by means of the iron bands of the railway. Besides the sugar industry and the others mentioned, labour is required for extended fruit growing for the American market, considerable enthusiasm being awakened in regard to preserved plantains. Some of our readers may not be aware that our Dutch predecessors in Ceylon were in the habit of splitting ripe plantains longitudinally and drying them in the sun on mats. Of course the great difficulty in this mode of preparation is the necessity of watching against adverse weather and the depredations of crows and other animals. The late Rev. Mr. Thurston, therefore, when at the head of the Government Industrial School, baked the divided plantains and put them up in hermetically soldered tins, in which shape they were highly prized by children sent "Home" from Ceylon for education and by absent or retired colonists. Those who have tasted the

preserved plantains (properly bananas) will agree with us that they are equal if not superior to dried figs. Those dried in the sun are probably superior, but artificial heat gives excellent results. The mode adopted in British Guiana is to provide a bed of heated sand, over which is placed a platform of laths, and on this the slices of plantains are dried in a temperature of about 150°, until they part with the moisture which constitutes 75 per cent of their weight. We have often wondered that no enterprising person has given a full trial to this industry in our colony where "plantains" are so plentiful and so good. The American Fruit Drier does not seem to have given better results with plantains in Demerara than it did in Ceylon, when tried at our suggestion a few years ago. The following extract will show that a full trial of the British market is being made from Demarara:—

The Assistant Secretary laid over further samples of two varieties of dried bananas, as well as a specimen prepared with sugar. He had received an account of the first lot sent to England, which was very much liked and arrived in first-rate condition. The specimens then on the table were moister and retained more of the flavour of the fresh fruit than the first samples. He hoped to be able to prepare them in such a way that they would keep long enough for shipment and still be moist and full-flavoured. A number of sample boxes had been sent to England by the previous Mail, and other samples had been distributed to several persons in the colony, who had all expressed satisfaction with their flavour and appearance. Again:—

Mr. Rodway laid over specimens of a great improvement in dried bananas, a sample from Trinidad, and also a box from Messrs. Finney and Lambert, who were preparing to carry out banana drying as a commercial speculation.

Of course papers on sugar cultivation and manufacture are prominent in the Journal, which opens with a discussion of "Diffusion of sugar cane, compared with double crushing in mills," by Mr. Neville Lubbock. There is also a paper on defecation by electricity. Unfortunately we in Ceylon ceased to take more than an abstract interest in sugar, long previously to the date when "failure" as regarded sugar on a large scale was repeated in the case of coffee. With abundance of rich manures, we could probably succeed in growing sugar which would properly crystallize, but in order to live planters must grow what will pay. There is a most fascinating collection of gossip about Charles Waterton (whose "Wanderings" are almost as interesting to young people as are the adventures of Robinson Crusoe) and his friend and father-in-law, Charles Edmonstone. Waterton was for six years working as the owner of plantations and slaves in Demerara, and Edmonstone, who was one of the "Keyzers" of the colony, earned the gratitude of his fellow colonists by a series of successful expeditions against runaway slaves and maroons. Waterton married Edmonstone's daughter, who was on the mother's side the grand-daughter of an American Indian, thus:—

The Indian chiefs were rather important personages in those times, (in the early years of this century,) as they received the annual presents and distributed them to a considerable extent by favour. It naturally followed, that being commissioned by the government and provided with a silver-headed stick of office, an Arrawack chieftain thought himself a somebody. In the latter half of the last century a daughter of one of these *Ouls*, as they were called, who went by the name of "Princess Minda" was married to William Reid, a Scotchman, and one of their children became Mrs. Charles Edmonstone. The gallant Burgher-Captain was therefore connected by marriage with the Arrawacks and no doubt this was one reason why he had such great influence over them. If, therefore, descendants of Charles Waterton exist,

they have American Indian blood in their veins. We do not suppose the Scotchman William Reid, who married the Indian "Princess," was connected with the Sir William Reid, Baronet, who, after long residence in Demerara as a planter, came here to engage in the coffee enterprise in 1840, and with whom the writer was associated in pioneering work in Uva in 1840.41,—but the coincidence of name is certainly curious.

In the notice of Edmonstone, we have a glimpse of a reverse of fortune from eccentricity of conduct and instability of purpose such as is not uncommon in colonies, although, in the case before us, addiction to drink does not seem to have been added to moral aberration, the result of reading the rhapsodies of a man who was undoubtedly insane:—

Near the border of the clearing at Warrow's place lived the eccentric Swedenborgian, "Old Glen." His story was a curious one. Coming to Demerara as the mate of a merchant vessel, he received a grant of land, settled down, bought a few negroes, and in seven years gained an assured position, while after twenty years he became a man of some importance. Going on board a Dutch vessel one day he found the Captain reading one of Swedenborg's books, and being taken with the new religion Glen was very pleased when the owner presented him with several works of that mystic author. From this time he became an enthusiast. His estate was neglected, everything went wrong, the negroes ran away or became careless and lazy, and every day Glen became poorer and poorer. Having ordered a large consignment of the books of his beloved author, he was unable to pay for them, and consequently the estate was sold. Being destitute he set up as a preacher to the negroes, but this not being allowed, he went to Berbice and enlisted as a private soldier. Here he fell into disgrace for sleeping on duty and was sentenced to "run the gauntlet." In pity the commanding officer would have remitted the sentence, but Glen refused, and was so determined to receive his punishment that he would not pass his comrades until they gave him the customary blows, even going so far as to chide them if they did not strike hard enough. Returning to Demerara Edmonstone found him destitute and offered him a home at Warrow's Place. Glen would not live in the house but built himself a henab in the forest. He was very gentle and kind to the Indians, many of whom came to him for medical treatment, which he practised by means of some of the forest remedies. Among other kind actions he taught the little Edmonstones their letters, and Mrs. Waterton probably received the rudiments of her education from him.

There is a very interesting paper on the Mollusca of British Guiana, from which we observe that several of the many land shells (slugs and snails) are used as food. The Revd. D. J. Reynolds contributes "Jamaica Proverbial Philosophy," which gives a good idea of the shrewdness of "Quashy." For instance:—

When snake bite you; you see lizard, you run. The burnt child dreads the fire.

Cuss John Crow "peel head" and turkey pee pee box. Offend one monk, and the lappets of all crows will flutter as far as Rome. (Spanish.)

Cow tail out off, God Almighty brush fly for her. God tempers the wind to the shorn lamb.

Quattie (the smallest Jamaica silver coin of the value of 1½d now out of circulation) buy trouble, hundred pound can't pay for it. Mischievous comes by the pound, but goes away by the ounce.

The raven cried to the crow, "avant Blackamoor." (Spanish). One ass calls another ass long ears. (German.)

Scheming men plotting—Ceitful fire roast plantain, cuncassa (soft soap) scrape it.

Youth mocking at Age—Man no done grow musn't laugh after long man.

A man who is so afraid of another man that he cannot say his soul is his own—Oow belongs to butcher, can neither say, "I berry well."

A boaster in a fix—Trubble ketch bull-dog, monkey breeches fit him.

Dog massa gib him money for buy bench, dog tek it buy bone, and say, Big Massa (the Creator) nebber ben mek him for sit down 'pon bench.

When black man tief, him tief "Quattie" (1½d.), but wheu Buckra tief, him tief whole a cstate.

When fowl drink water, him lifup him hed say "tank God, tank God;" when man drink water, himsay nothing. There is a comprehensive article on railway extension in South America, shewing wonderful progress already made in crossing high mountain ranges, from which we wish we had space to quote. But we cannot help quoting a description of labourers at the Diggings:—

We come now to the sinews of the camp, the labourer. He is never so happy as when he is grumbling, and that he is always ready to do. In the morning, the clock is fast; at night he accuses you of shifting the hands and declares that it is slow. He frequently assures you that he is devoted to your service. All he needs is a little encouragement, liberally interpreted, "grog." He is continually assuring you that if you can treat him well, that is, give him more than his allowance of food, he will indeed work for you. He abounds in honied words, commonly known as "sweet mouth" or "rattle," and at such times, beware! he is fooling you.

These remarks are intended to apply only to the creole labourer, who, after all, is the only one suited to this work. As to the others, the coolie and "Bill" are too liable to sickness, and the Chinaman is too smart. "country," i. e., the Barbadian, is too delicate, and the Portuguese and Mulatto population are physically unable to do the work. Above all, in engaging labourers, beware of the "boots man!" On no consideration engage a man who seems at home in his boots, and, generally, look for the barefoot man. "Bill" generally gives out before his time is done. He takes his advance to his uncle, and comes into the bush utterly unprovided with clothing—sometimes without even a hammock. He has to subsist on food entirely different from that to which he has been accustomed, and the poor feeding alone renders him an easy prey to malaria and dysentery.

It is about his food that the ordinary labourer is most troublesome. He is perfectly aware of the amount of his allowance, and never wearies of telling you that he knows that, though you personally have nothing to do with it, the cook is robbing him. When told that under the circumstances it will be advisable to take his raw victuals and cook them, he will find numberless objections to such a course. Many make a regular practice of begging, giving one the disagreeable necessity of refusing. These few drawbacks excepted, they are a happy lot, and generally work well.

At night when their work is done, and particularly when there is a large gang, song after song is sung, and the chorus taken up in perfect harmony and unison. Certainly the songs are frequently mere repetitions and very meaningless, but in the still nights the singing is far from unpleasant, and appears to afford the performers infinite delight. The variety of the instruments is marvellous. Besides concertinas, flageolets, violins, guitars, etc., which they bring with them from town, they invent many more. They will rattle a spoon on a pudding pan very musically, they make use of the familiar comb and piece of thin paper, they whistle very fairly, they construct flutes with old bones, violins with meat cans, and wonderful to relate, they make even violoncellos.

There is a notice of a Carib-French Dictionary, which must be of special interest, as the race has almost disappeared. There is an interesting description of the Upper Demerara river in which we see it stated that a report on this region was made, a few years ago, by Mr. C. Barrington Brown. The snakes, fireflies and birds of this region seem to be equally beautiful and one bird the HOATZIN, —*Opisthocomus cristatus*, is so singular in its formation that it is called the reptilebird, just as the Australian kangaroo is regarded, from its structure, as the reptile animal.

BLIGHT ON TEA.

Tea has not hitherto, as far as we are aware, suffered from blight, which has been the destruction of coffee, but from all accounts it appears that it is liable to it. Messrs Jardine, Skinner & Co., of Calcutta, recently forwarded to the Agricultural Society of India some samples of tea leaves, concerning which the Manager of that Company's Gardens in Assam wrote:—"By sample post I send you a tin containing samples of tea leaves which are blighted by a sort of fungus. It seems to be spreading all over the gardens, and is not peculiar to low or high land. The leaves after a time get quite brown and black and fall off, leaving nothing but the stalks. It seems to be a new kind of blight. Could you find out from the Horticultural or Agricultural Societies what it is and what remedy would be of use?" The Company therefore asked the Society to examine the leaves, and give what information it could as to the species of blight from which the leaves were suffering. The samples, owing to their being packed in tin, arrived unfortunately quite spoilt for examination, but the Society stated that the disease appeared to be one which had recently been observed in more than one garden in Assam, and seemed to be very destructive. As the blight, or fungus, seems to be new to tea, it might be possible, it remarks, by collecting and collating all the existing information about it, to learn where and when it originated, and whether it appears to be associated with any particular surroundings, soil, age of plant, or other conditions; and the information might also afford some clue to the proper method of combating it. Another correspondent wrote to the Society stating that the blight, or something like it, had long existed in some gardens in Assam without doing any appreciable injury. The proposed enquiry and analysis of the soils, &c. of tea plants might, in the opinion of the Society, throw some light on the subject, and we are glad to learn that steps have been taken to secure the services of a competent chemist to analyse tea plants, tea soils and manures and search generally into the cultivation and manufacture of tea. The inquiry once started will, says the Society, be the means of collecting and assigning to its proper place much of the information which different planters have acquired by experience, but which is not available to the rest of the community. The new tea blight referred to is a case in point. There has hitherto been no organised inquiry respecting tea cultivation and manufacture, and the departure now taken can hardly fail to benefit the industry.—*Madras Mail*, Aug. 27th.

BRICK TEA.

A curious and interesting feature of the Chinese tea trade in recent years is the extraordinary growth of the brick tea industry. Formerly the "Bods" of Tibet were the only customers for the compressed and sourish slabs that found their way across the frontiers to the Chinese dependency, but now the Tartars of Central Asia, the Siberians, and the peoples of Eastern Russia all demand their raw tea in the shape of slabs, tablets, or bricks. Consul Allen, in a report to the Foreign Office on the commerce of Hankow, recently stated that the trade in brick tea "seems to increase by leaps and bounds," so highly is the leaf in this form appreciated by the Russian and Siberian connoisseurs. The bricks are prepared by machinery latterly, and "the brick tea factories, with their tall chimneys, are the most striking buildings in the European settlement" at Hankow now. The museum at Kew Gardens received a couple of samples of this tablet tea early in the present year, and the number of the Kew *Bulletin* last issued, contains an interesting, though in some respects incomplete, reference to the subject of brick tea generally. There are two kinds of tablet tea manufactured for the Siberian and Russian markets at Hankow, the large and the small, but they differ both in manner of preparation and in the quality of the leaf used. The large bricks are made in a very simple way. A quantity of common tea dust is placed in a sort of pudding cloth or

bag, steamed for a few moments so as to cause it to adhere; it is then turned into wooden moulds, where it is beaten to the required consistency by means of wooden mallets.

In the modern steam manufactories of Hankow, the dry dust is poured into iron moulds and there subjected to "steaming" and pressure. This gives a better shaped and firmer brick, and as the Siberians set great value on the appearance of their tea-blocks, looking especially to the sharp cut of the corners and sides, the modern-made article is preferred to the old-fashioned hand-moulded slab. When ready, the bricks are placed on one side to cool, stored in drying rooms for a week, carefully wrapped in separate papers and packed in bamboo baskets, each containing 64. Each brick must weigh one catty—1½ lb. that is—and great care must be exercised to secure the desired weight, or the Siberians and Tartars will refuse them. Hence, a brick, if underweight, is rejected and afterwards remade. Green tea is prepared in exactly the same way, only that the prejudices of the buyers require it to be made up into 2½ lb. tablets, to be made of the whole leaf and not the dust, and to be packed 36 in a basket. The cost of preparation, carriage, duty, and packing is about 30s per "picul" of 133 lb., or about 2½d per lb. Hence it can be sold at a very low price in the Siberian and Russian markets for which it is manufactured. The makers being practical business men, have due regard for the prejudices of their customers in favour of a brick of nice appearance, so they take care to reserve the finer and best quality dust for the outside facing, keeping the coarser and inferior leaf for the inside core. Some years ago this kind of brick tea was shipped to London in large quantities for despatch to Russia. At present it all goes direct from China overland via Kiakhta and Maimachin.

The better class of Siberians and Mongols require a superior article, and to supply their wants a smaller brick or tablet of a good quality leaf is prepared. It is manufactured from the finest tea dust procurable from Ning-chow in Kiang-si, and Tsung-yang and Yanglutung in Hu-peh. The selection is carefully made, only the product of the early pickings or first crop being chosen. The fine leaf is not steamed for steaming has a serious drawback, inasmuch as it robs the tea of all its fragrance, and would therefore ill adapt the bricks for connoisseurs. The dust is poured into steel moulds, quite dry, and subjected to hydraulic pressure of about two tons on the square inch. In this way the tea is found to preserve for an indefinite period all its aroma and freshness. But not alone is the leaf used for the small tablets rather expensive, but the cost of manufacture is high owing to the care requisite for the proper preparation of the slabs. The original cost to the manufacturer at Hankow is over 84s per picul. Duty, carriage, packing, and so forth, will amount to at least as much in addition, so that the tablets can hardly be sold at a profit to the wholesale dealer and retailed at much under 4s per lb. With the best steam machinery the "failures" are over 5 per cent., where the old-fashioned hand moulds are used 25 per cent. of the bricks turned out are imperfect and have to be remade. It is claimed for the compressed tablets and bricks that the fragrant constituents of the leaf are better preserved than in the ordinary loose state, that the cells are broken by the heavy hydraulic pressure to which they are subjected, hence the use of the bricks is more economical, a given weight yielding a stronger infusion than the same quantity of loose tea. But though the small tablets have been introduced in this country, they have not taken with English tea drinkers.

The true brick tea of China, the unsophisticated native article, is, however, nothing like the tablets and slabs above mentioned which find their way to Russia and Siberia. The genuine brick tea of the Chinese manufacturers is that which is intended for the Thibetan market and for the Eastern Mongols. It is made of the whole leaf, stalk, flower, and all, as it is picked from the tea shrub, and is in shape and appearance not unlike a rather dirty ordinary brick. The correspondent writing in the *Kew Gardens Bulletin* states that he has never

seen this kind of brick tea manufactured, but knows "it is made by Chinese in a very simple way." Simple is hardly the word to apply to the process of brick tea making adopted by the natives. Primitive is, perhaps, nearer the mark. The leaves are chewed, and when well saturated with saliva are laid out to ferment and partially dry. They are then rolled up into little balls, with the help of some additional moisture, and afterwards moulded by hand into oblong blocks or bricks about 10 in. long, 10 in. broad, and about 4 in. thick. The leaves thus prepared acquire a slightly sour taste, due to the fermentation induced by the saliva, which the Thibetans appear to like. The trade in these bricks is a most important one, and it is the fear of interference with it on the part of the tea-growers of Assam that is at the bottom of a good deal of the hostility manifested by the Chinese and Thibetans to an attempt to enter into closer commercial relations with the Trans-Himalayan State. The trade in brick tea is a strict monopoly of the Lamas or priestly caste of Thibet, and they are very jealous of any interference with what is to them a highly profitable business. The ordinary Thibetan must have tea; it is the one thing he considers indispensable, and cannot live without, and for this commodity he depends entirely upon the Lamas. The latter know that if intercourse between Darjeeling and Thibet were encouraged, the Assam planters could, and would, supply the natives with tea at a much lower rate than the priests charge. So what with the Lamas on the one hand, who fear to lose the monopoly they now enjoy, and the Chinese planters on the other side, who are afraid of losing the Thibetan market, it is not altogether surprising that the attempt to foster commercial intercourse between India and Bodval is not viewed with favour on the other side of the Indo-Chinese frontier. Brick tea is also used as currency in Thibet, prices being quoted in equivalents of the compressed leaf. The beverage prepared from the sourish tablets is hardly likely to tempt the Western palate. The Thibetan teapot is a sort of wooden churn into which a boiling infusion of the tea-leaves is poured through a strainer; a little salt is added, and some 20 or 30 strokes are applied with a wooden dasher pierced with a number of holes. A lump or two of butter is then thrown in, and the mixture churned with 100 or 150 strokes "administered with much precision." But this is a good deal more palatable to Europeans than the brew concocted of the bricks by the neighbouring Mongols. Meal, as well as a bountiful supply of butter, is added to the decoction, and with a fat sheep's tail or two swimming about in the liquid, a dish of tea is served out which, in flavour and appearance, it is difficult to distinguish from well-thickened pea-soup.—*Morning Post*.

PERAK AS A FIELD FOR PLANTING ENTERPRIZE.

We have pleasure in giving publicity to the following extracts from a letter addressed by the Superintendent. Government Plantations, Perak, to a European firm in Penang:—

"A short report on the soil and climate of Perak, and on the suitability of the country for tea and other tropical products, is the best answer I can make to the last para of your letter.

...A glance at the map of the Malay Peninsula and Archipelago will show, better than words of mine can describe, how admirably Perak is situated. It is practically in the same latitude with, and may be said to be the centre of, the richest Spanish, Dutch, and English Colonies, which have been famous for centuries.

In most parts of the country—more particularly the Perak Valley (a magnificent tract of land of vast extent), the Kinta and Batang Padang Valleys, the Valley of the Slim and the country stretching from the British Province Wellesley to Taipeng, embracing the Krian and Selama districts—the soil is a deep rich loam, and in places where limestone mountains crop up, is truly unrivalled for productiveness.

Rainfall and Temperature.—Official returns give the mean rainfall at seven stations, occupying cent

positions in the valleys and districts mentioned, as 111.8 inches for the year 1888. Highest rainfall 171.89 inches, lowest rainfall 82.18 inches. The mean temperature at six stations for 1888 is 81°-3.

To practical men comment on these returns is superfluous. The rainfall, varying as it does, leaves the choice open to them of fields suitable to the various products: tobacco, coffee, cocoa, tea, or the different spices—nutmegs, cloves, cardamoms, pepper, &c.; while the temperature forces a growth which will tax the best soil and utmost skill of the planter to keep up with.

Labor.—It is not necessary to proclaim the virtues of the Tamil cooly as a laborer. Suffice it to say the lowest wages fixed by law are 14 and 16 cents for a male laborer, 12 and 10 cents for a female laborer, rates for food being fixed likewise. The loss on recruiting is trifling compared to what other countries less favourably situated have to suffer.

Facilities for Transport.—Perak is roughly estimated as 120 miles long by 90 miles broad. Steamers call daily at Port Weld and Teluk Anson the Northern and Southern ports of this limited area. The rivers Krian and Bernama, at the extreme North and South of the country, has been, and is being, traversed by railways, canals, macadamised cart-roads, and six foot bridge tracks, in a way which would be marvellous in a less progressive age, and under a less able and energetic administration, guided as it is by a far-seeing policy.

All that is necessary for the rapid development of the agricultural wealth of this State is that Perak should be known to Capitalists at home."—Local "Times."

THE TOBACCO PLANT.

The London *Journal of the Society of Arts*, January 3, noting that the tobacco plant "is grown and employed as a narcotic in almost every country in the world," and that about "one-fourth of the human family use it," adds:

"It is somewhat difficult to obtain trustworthy information regarding the world's trade in tobacco, because so much is used up locally in different countries. It is probable that the total area under tobacco is not far short of 6,000,000 acres. For the year 1886 certain official returns are available, which show that the United States, India and Hungary are the largest producers. The area under tobacco in acres was in

United States.....	752,520	Algeria.....	20,478
India.....	641,000	Italy.....	12,061
Hungary and Austria.	149,468	Holland.....	3,218
Germany.....	49,312		
France.....	37,156	Total acres...	2,106,213

"The consumption of tobacco in the United Kingdom is large and progressive, and the revenue derived from it last year was nearly £8,750,000. The average consumption is largest in Holland—nearly 7 pounds per head; in the United States about 4½ pounds; in Hungary, Denmark, Belgium and Germany from 3 to 3½ pounds. In the Australian colonies it is also high—3½ pounds; in France it is about 2 pounds, and in the United Kingdom under 1½ pounds.

The yearly production of tobacco in Cuba is about 300,000 bales, and 181,000,000 cigars are also exported. The Spaniards have hitherto monopolized the trade in cigars, alleging that parts of the soil of Cuba were alone suited to the production of Havana tobacco. This assertion is now disproved, for with good choice of seed, soil and leaf, and skilled manufacture, Jamaica is said now to send into the market as excellent a cigar as was ever shipped from Havana, and at a far cheaper rate. In the Philippines 100,000 cwt. of tobacco are produced. The Dutch possessions in the Eastern Archipelago ship a large quantity of excellent tobacco, which is held in high repute in Europe. The imports of Sumatra tobacco in Holland now average 140,000 bales, and of Java tobacco 130,000 bales.

"Although there are about fifty species of the genus *Nicotiana* known, only three or four are much cultivated for the leaf. The two principal commercial forms are by some botanists treated as varieties, and not as distinct species * * * Madras, where the climate is admirably suited for the growth of tobacco, stands first with regard to the development of this industry in India. Dinnigul is the great tobacco district, and cheroots are manufactured at Trichinopoly. The islands in the delta of the Godavary also yield what is called lunk tobacco, the climate being suitable, and the plants are raised in rather poor light soil, highly manured and well watered. No better evidence could be afforded of the universal use of this plant than the extensive display which was made of it in every section of the Paris Exhibition."—*Bradstreet's*.

AMHERSTIA NOBILIS.

It is now fifty years since this magnificent plant was introduced from India into England. Its name had become known from a description by Dr. Wallich, who found it in 1827 in Martaban, growing along with *Jonesia Asoca*, another splendid-flowered leguminous tree. Writing of the *Amherstia*, Wallich said: "The largest of the two trees I found was forty feet high, with a girth of six feet near the base. Both were profusely ornamented with pendulous racemes of large vermilion-colored blossoms forming superb objects, unequaled in the flora of the East Indies, and I presume, not surpassed in magnificence and elegance in any part of the world." Many futile attempts had been made to introduce this plant into English gardens before the Duke of Devonshire sent a collector specially for it, and succeeded in importing and establishing a plant in the famous Chatsworth Gardens. This plant is still alive. But the Duke was not the first to flower the *Amherstia*, a small plant in the collection of Lady Lawrence, at Ealing, flowering first in 1884. The first raceme that developed was sent to the Queen, and the second to Kew for figuring in the *Botanical Magazine*. A plant now in the Kew collection—originally, I believe, a cutting from the Ealing specimen—has produced a few flowers on several occasions within the last ten years, and it is in bloom now. The racemes, five in number, are pendulous, two to three feet long, and bearing from fifteen to thirty flowers, each of which has a drooping pedicel six inches long, bearing a pair of large wing-like bracts four inches from its base, the flower being four inches across, and composed of four spreading sepals, five unequal petals, three of them large, and in the position usually occupied by the standard in the flower of an ordinary Legume. The stamens are united at the base, and form a long curved tube. The color of the whole flower, bracts, pedicel and all is the richest vermilion or vivid scarlet, with blotches of rich lemon-yellow and a faint bluish tinge on the standard-like petals. In habit and foliage the plant resembles *Brownea* or *Jonesia*. The temperature supposed to be essential to this plant is from seventy to eighty degrees, with a bottom heat of ninety degrees, but the Kew plant is growing in a house devoted principally to Aroids and Tree-ferns, along with the largest of which it is planted out in an unheated but well-drained bed of soil. The temperature maintained in this house in winter is sixty-five degrees in severe weather, whilst in summer it ranges from seventy to eighty-five degrees. This is precisely what one keeps an ordinary stove at. Evidently, therefore, *Amherstia* may be grown and flowered in any house devoted to tropical plants. The Kew specimen is about ten feet high.—*Garden and Forest*.

MINOR PRODUCTS IN CHINA.

As an illustration of the value of some of the so-called "Minor products" in tropical countries, I may point to the fact that ground nut cakes—that is the residue or maco after the expression of the oil from the seeds of *Arachis hypogaea*—is exported from Kiangchow in China, to the extent of over 1,000 tons annually. In 1888, there was exported from this port

1,301 tons, of the value of £7,205, but in 1889 the quantity fell to 1,044 tons, valued at £5,780. In commenting on this, the British Consul says that the crop has been bad all over the island, so that a considerable amount has been imported for consumption from the mainland, whereas a surplus for exportation is generally looked for. The cultivation of this crop has given way considerably of late years to sugar, and whereas the oil expressed was formerly sufficient both for the cooking and lighting purposes of the district, it is not now sufficient for cooking alone, and the price which was formerly about 5c. per lb. is now three times that sum. Sesamum (*Sesamum indicum*), is also largely grown, but the seeds showed a decrease in value of nearly £7,000 during 1889. The crop was an unusually good one owing to dry weather, and the diminished export of the seeds is due to the fact that they have been used for expressing oil to make up for the deficiency in ground nut oil.

Betel-nuts (*Areca catechu*), seem to be another important article of export from Kiungchow, the quantity exported in 1889, amounting to 648 tons of the value of 18,333. Betel-nuts are stated to be an article both for export and import, there being a considerable demand for Betel-nuts grown in this island, as they are of superior quality, and fetch double, or more than double, the price of those imported from the Straits. These latter are, it is said, imported to be mixed with the native product, and fraudulently passed off as the genuine article.—J. R. J.—*Gardeners' Chronicle*.

PERAK SUGAR CULTIVATION COMPANY, LIMITED.

The fifth annual general meeting of shareholders in the Perak Sugar Cultivation Co., Limited, was held on Wednesday, 26th March, 1890, at the Shaughai Club. There were present:—Messrs. R. Francis (Chairman), C. J. Dudgeon (Secretary), G. H. Wheeler, A. J. How, Douglas Jones, J. Buchanan, E. Hey, S. Walker and Pow Kee, representing in all 1,303 shares and 380 votes.

The CHAIRMAN, after stating that he presided in the absence of the Chairman of the Company, said:—For reasons stated in the report it will be proposed, at the conclusion of the few remarks which I have to make, that this meeting stand adjourned until June. It is probable also that in 1890 June will be found a convenient date for the meeting but as the area of canes to be cropped in the early part of the year increases, so will the date of the meeting have to be thrown back, until, with the estate in full cultivation, it will probably be August to September before a full report of the campaign can be presented. With regard to the crop for 1889, full particulars are given in the report. The weight of sugar produced per orlong, and the proportion of No. 1 sugar have both been better than in any previous year of the Company's working. It has been somewhat unfortunate that, owing to short supply of labour, the area cropped in the twelve months has fallen short of the estimate, and consequently the accounts as made up to 31st Dec. show a less favourable result than was anticipated; it is, however, of course to be remembered that the 130 orlongs, which were short cropped in 1889 merely fall into the area to be cropped in the early months of 1890, and thus shorten the non-productive period of the present year, so that the estate suffers little or nothing at all. Labour has been a matter of considerable anxiety to the manager and directors. The increasing industries of the Straits, and the large demand for Indian labour in Ceylon, have caused a demand for labour in excess of the supply. The directors can only say that the matter is one which engages the most careful attention both of themselves, their manager and the agents in Penang. The crop for the season 1890-91 is described by the manager as the "best and largest we have had"; the crop is looking excellently well, and the only anxiety regarding it is the matter of labour already referred to. With

regard to the accounts, if the proposal for adjournment is agreed to, these will be supplemented for the meeting to be held in June, and, though at the present time there is considerable extraordinary expenditure in manuring for the coming crop, there seems no reason to fear that the estimate of a profit of Tls. 14,000 on the campaign will be disappointed. In addition to this sum it is to be remembered that the company will have paid over Tls. 10,000 in interest on borrowed capital. The Tls. 14,000 that we anticipate, and the Tls. 10,000 amounting to Tls. 24,000, will give about 8 per cent. interest on the capital, and as this is for 16 months, that will be 6 per cent for the year.

Mr. How asked if the shareholders were to understand that they might look for a dividend of 6 per cent.

Mr. Dudgeon said they were not allowed to pay a dividend of more than 4 per cent. until the debentures were paid off.

Mr. How thought the sugar account was a somewhat bald statement, and he suggested that the number of orlongs cropped should be given as also particulars of the different grades of sugar and average prices. It would be of interest to the shareholders to be enabled to follow the prosperity of the Company by means of such particulars. He asked if the contemplated expenditure on a new boiler was for an entirely new one in addition to the plant in use at the present time, or was it to take the place of one which was out of order.

Mr. Dudgeon said a new boiler might be required to take the place of one of the present ones, which had recently suffered some damage; and it was considered necessary to have a second one on the spot. The rapid deterioration of the boilers was due to the impurity of water used. The expense of a new boiler and mill roller was estimated at £500. The area cropped and averages of No. 1 and No. 2 sugar were given in the report.

Mr. How said the report only gave the gross amounts. The average prices of each grade should be given, so as to form a guide in future years.

The Chairman said Mr. How's suggestion would be brought before the Board of Directors. He (the Chairman) saw no reason why it should not be carried out.

Mr. Douglas Jones—I suppose the Board do not like to prophesy as to the length of time it will take before the shareholders are likely to get anything out of the company?

The Chairman—I think it desirable not to prophesy.

Mr. How—Unless you know.

The Chairman—If our anticipation of a net return of Tls. 14,000 is carried out, it would enable a small dividend to be paid. It must be remembered that the whole estate is not being worked; but next year or the year after, it may be expected to be in full cultivation.

It was then moved by the Chairman, seconded by Mr. Wheeler, and agreed to, "That this meeting stand adjourned until Wednesday, 25th June." The proceedings then closed with the usual compliment to the Chairman.

REPORT.

The directors, as required by the articles of association, submit their report for the year 1889. The working of the Company, however, shows that the holding of the annual meeting in March, with accounts made up to 31st December (a date almost in the middle of the crop) is entirely inconvenient, and renders it almost impossible to lay before the shareholders a proper statement of the Company's position. It will therefore be proposed at the forthcoming meeting to adjourn until June, when, the crop having been cleared off, it will be possible to submit a report with accounts, closed to 30th April, showing the actual results of the previous campaign. It will also be proposed to fix a date for the meeting in the following year which will cover the campaign of 1890-91.

Crop.—The area cropped during 1889 has given most satisfactory results both as to weight of sugar produced per orlong and as to quality. The production per orlong averages piculs 38 as against piculs 31 in the previous year, and the proportion of No. 1 sugar is 76 per cent. against 65 per cent. In price, too

the estate has been fortunate, the average obtained being \$5.75 per picul as against \$4.80 in 1888. Owing however, to a great scarcity in the supply of labour it has been found impossible within the 12 months to take a crop from the whole area of 615 orlongs, which it was stated in last report represented the crop for 1889; in addition to this the manager considered it advisable, in the future interests of the estate, to throw back the autumn cropping a month, so as to bring the cultivation more in accordance with the recognised rules of sugar planting in the Straits. Owing to these causes the area cropped has only been 484 orlongs, the short fall of 130 orlongs being left over to be cropped during the early part of the present year.

Estate Extension.—Owing to the labour difficulties already alluded to, it has only been found possible to add 35 orlongs to the cultivation during 1889. The area in cultivation is now 694 orlongs, of which it is estimated that 650 to 675 orlongs will be planted with cane for the 1890-91 crop.

Capital Works.—With the exception of the small addition to the estate above-mentioned, and some necessary additions to the coolie lines, there has been no important expenditure under this heading. It is however in contemplation to replace the present launch and sugar boat, with a larger launch which will combine the work of both. The estate is even now too large for the existing transport arrangements.

Plant.—The mill has done its work well during the year. The boilers need repair, and this will be attended to when the present crop is worked off; it has been necessary to work the boilers at reduced pressure for the past three months, which forms another reason for the short cropping in 1889. It may be necessary to supply a new boiler and a spare mill roller during the year, the estimated cost of which is \$3,500. Otherwise the whole of the plant is in good order. The additions to plant during the year have it will be seen been written off, for the most part, to depreciation.

Accounts.—These, to 31st December, show a profit of Tls. 7,113.10, in addition to which it is to be noted the Company has paid Tls. 7,512.07, in interest, a charge principally made up by the 15 per cent interest payable on debentures. These two amounts together make a total of Tls. 14,625.17, which represents the actual earnings during the year over and above the expenditure necessary for the working of the property or say nearly 6 per cent on the present capital. If the sums borrowed are added to capital, as they probably will be hereafter, the percentage of earnings is over 4½ per cent, which it is to be remembered is from a crop of only 484 orlongs. These figures, however, do not convey an accurate impression of the actual position, for on the closing of the campaign, with a crop taken from further 252 orlongs, it may confidently be anticipated that the present apparent profit on working account will be at least doubled. For the adjourned meeting a complete statement of accounts will be prepared and issued to shareholders which will show the actual results of the campaign. With regard to the debentures it is noted that the first batch falls due in December 1891, when it is hoped that they may be replaced by a new issue of capital, or by a loan on very much easier terms.

Director.—Mr. E. G. Low retires in rotation as required by the articles of association but offers himself for re-election.

Auditor.—The re-election of Mr. G. R. Wingrove as the Company's auditor requires the shareholder's confirmation.

BETEL LEAVES OIL, A POWERFUL BACTERIA POISON.

Such is the purport of a paragraph in the *American Grocer*:—

At the Naturforscher meeting in 1888, says the *Pharmaceutical Journal*, Professor Eykman reported that among the constituents of the essential oil distilled

from fresh betel leaves he had found a characteristic compound, having the odor of the leaves and the constitution of parallyl-phenol, which he designated "chavicol." About the same time Messrs. Schimmel announced that the phenol present in the higher boiling fractions of the oil distilled from air dried betel leaves corresponded completely with eugenol, though subsequently they made the modified statement that the phenol obtained by them was not eugenol but an isomer. With a view to clearing up the apparent contradiction, Professor Eykman has re-examined the oil distilled by himself from the fresh leaves and some distilled from dry leaves by Messrs. Schimmel, with the result of confirming the presence in the former of chavicol, boiling at 236° to 238° C., and in the latter of the isomer of eugenol, boiling at 254° to 255°, which proved to be orthomethoxy-chavicol (*Berichte*). It would seem probable, therefore, that both phenols occur in the leaves, and that chavicol being the more volatile had practically disappeared from the dried leaves, while the method of distillation adopted by Messrs. Schimmel favored the more complete removal of the higher boiling compound. Some experiments made with chavicol are said to have shown it to be a powerful antiseptic, it being five times stronger as a bacteria poison than carbolic acid and twice as strong as eugenol.—*Oil, Paint and Drug Reporter.*

TEA DUST.

To the Editor of the "Home and Colonial Mail"

Sir,—May I ask space in your paper to draw attention to a considerable source of annoyance and expense which tea dealers experience when dealing in tea dust. Whether it is that the ancient art of making tea chests has been lost, or that the material of which they are fashioned is now of a more brittle nature than formerly, the fact remains that scarcely any carrier will take delivery of a chest of dust unless the package is cased in canvas to prevent leakage. The reason assigned by the carrier is that the packages will not hold in their contents, and hence a claim for loss in transit is a certainty unless the aforesaid precaution is taken. The cost of casing and cording is very nearly ¼d per lb., and as the country buyer, in almost every instance, refuses to bear it, contending that the seller should deliver his goods in merchantable condition, the loss falls on the wholesale dealer, and it is out of his power to recover it from the importer. It may be contended that the dock company is paid by the importer a consolidated rate, which is supposed to cover everything, and hence to deliver the packages in good condition. But the warehouse keepers are also accustomed to canvas tea for the dealers, and as they make a profit on the operation they are interested in the system which renders casing necessary. The carriers are also engaged in the same business, and the consequence is that when a carman appears at the tea warehouse to take delivery of a lot of tea, and the delivery foreman calls out "It is dust," there is an immediate halt in the proceedings. The carman drives off without the tea, and sends to the wholesale dealer the following notice of "stop." "We find these packages contain dust, so we cannot take delivery unless they are cased." The dealer may insist on delivering the tea as it is, but in that case the carrier declines to give a binding receipt, and thus secures himself against claims for loss in transit. This state of affairs has been on the increase for years past, and makes it impossible to deal in tea dust without constant annoyance and expense. The wholesale dealers naturally admit the force of the country buyers' contention that it is incumbent on the seller to provide a merchantable package for his goods. It is now time that planters would look to this matter. It is no part of my present design to advocate the use of anybody's patent metal oistern or *papier maché* casket, although I decidedly think those packages will answer the purpose of holding dusty tea far better than the ordinary lead lined wooden chest. All I wish to say is that the package in which tea dust is sold ought to be fit to hold it in till it reaches its destination. Planters

might easily ensure this by a little more care in selecting strong chests for their dust teas. If, however, they continue to neglect it, they may, perhaps, find that buyers in this market will give dust teas less attention in the days to come.—I am, &c. D. F. SHILLINGTON.

[If, as we have seen it stated, 150 lb of dust are sometimes crammed into a single chest, we cannot wonder if such chest gives way.—ED. T. A.]

THE JAVA COFFEE CROP.—The Amsterdam correspondent of the *London and China Express* writes under date Aug. 13th:—The reports regarding the Java coffee crop for this year continue to be very unsatisfactory, for the Government as well as for the private planters. There are districts in which the crop will not be more than 10 per cent. of the quantity harvested in the past year.

PEPPER & CO. IN PERAK.—A report from Kuala Kangsa district states:—

The cultivation of pepper is not making so much progress as might be wished, owing to the want of capital, and the difficulty in procuring plants. There are still a number of applicants, principally Achinese, for pepper land, but the majority of these people are only able to take up from one to three acres each, and they are very often unable to bring even one acre under cultivation, unless they can obtain advances. Kong Lin, however, is making good progress with his estate. He has cleared thirty acres of land in addition to the original clearing of ten acres, which is now almost planted up; but he, also, has experienced difficulty in obtaining pepper cuttings, and informs me that about 50 per cent of those sent over from Penang are not worth planting. He is now clearing ten acres of land near his pepper estate, which he intends planting with orange trees from Kelantan. The fruit of these trees, he informs me, is superior to any produced in the Straits, and commands a ready sale. I have not lately been able to visit the pepper estate at Pasir Panjang, but Syed Musa informs me that it is progressing favourably, and is now partly in bearing. He has about 20,000 dedap cuttings for sale, and can also supply a few pepper plants.—*Perak Government Gazette.*

THE PEARL FISHERIES of Mexico are about to be prosecuted with greater energy, and the Government has just granted a concession for fifteen years to Senor Quaglia for the exclusive right to fish for pearls in the Gulf of California and off the coasts of Lower California. Hitherto the average annual value of Mexican pearls sent to Europe has been about 80,000 piastres, and of mother-of-pearl about 25,000 piastres. The divers (mostly Sonora Indians) are remunerated according to results, and there is a wide margin between the prices fetched on the spot and those obtained in Europe; for instance, a pearl which is bought in La Paz for 500 dollars will fetch about 25,000 francs in Paris. Mother-of-pearl shells, again, which may be bought in La Paz at from 8 to 12 centavos per pound, are worth three times as much in Europe. Mexican pearls take the next place after the Indian for beauty; they are mostly small and irregular in shape, but very hard, and of exceptional brilliancy. In the year 1881 a pearl was found weighing 28 carats, and this fetched 90,000 francs in Paris in 1883, again one of the divers brought up two pearls weighing together 76 carats. Mexican pearls are mostly white, and these are of less value than the brown, black, or pink the latter being the rarest. The finest specimen has been set in the Spanish Royal crown; it weighs 100 carats, and although it dates from the 17th century, it still preserves its ancient brilliancy. The pearl fishery is a very lucrative business in Mexico; the oyster shells brought up sell at the rate of 10 to 12 piastres per 100 kilogrammes, which of itself is sufficient to cover all expenses, everything else being clear profit.—*Times of India*, Aug. 15th.

THE MONGOOSE IN JAMAICA, introduced to destroy rats on sugar estates, has largely effected this object, but unfortunately "this strange bird" as Mr. Whymper called it, did not confine his attention to rats, but has been so destructive in the fowl yards and otherwise that a commission has been appointed to decide the question whether these Indian representatives of the ferret and weazel are not more mischievous than useful and whether they ought not to be exterminated and how.

"CARAVAN TEA."—"Miss Mantalini," writing in the *Pall Mall Budget* of 31st July on various delicacies to be had at Morel's in Regent Street, London, says:—

"Talking about tea, Morel's manager told me he had many customers for 12s 6d tea. This tea isn't packed, and its qualities are that it is weak and scented. The taste for this tea is acquired; it wouldn't suit the general English palate, which likes something rough. It is well known that Russians take all the best of the China teas."

No doubt the wealthy idiots who pay 12s 6d a lb. for "weak and scented" Chinese trash consider good wholesome Ceylon and Indian tea far too vulgar for their delicate palates. We hope that their number is not large.

USES OF THE COTTON PLANT.—Two more have recently been added to the many uses of the cotton plant. A report comes from Germany that a process has been discovered by which sugar is extracted from cotton seed meal. It is said to be very much sweeter than cane sugar but having a peculiar fermenting quality cannot be so generally used. For some purposes however it will be greatly preferred to the ordinary product. The other use is that of making felt from the lint which clings to the seed after it has gone through the "gin." This cloth, it is claimed, will come into wide use for hats, etc., as the process is inexpensive and the material has hitherto been counted waste! What a feature of these modern days is this utilization of so called "waste!" Material that like the cotton seed were but yesterday considered a nuisance and some that were a menace to public health are today by the touch of chemistry and mechanical ingenuity transformed to articles of use and beauty. It surely looks as though those were right who claim that there need be no waste and there will be none when men come to understand nature's forces better.—*Indian Agriculturist*, Aug. 16th.

A NEW INDIAN INDUSTRY.—The Pioneer Glass Manufacturing Co., Limited, has recently been formed in Calcutta to manufacture glassware from indigenous materials, which, it has been found exist in abundance in Bengal and with which experiments on a large scale have already been made by a leading London glass factory. The first experiments were made in the presence of Mr. James Watson (well-known in Calcutta as the inventor of the hydraulic press now in use here) and Mr. Malcolm, of Messrs. May Malcolm & Co., of London, and these, as well as subsequent trials of the Indian materials, proved their suitability for the making of all classes of glassware in use in this country, including window glass. The Company has for the present been formed on a comparatively small scale, but it is intended that the work should be extended in due course. The cost of manufacturing glass articles here is estimated at from forty to sixty per cent, less than in Europe. The Company has secured the services of a highly qualified English expert as manager, and suitable land and buildings have been secured in the neighbourhood of Calcutta.—*Indian Agriculturist*.

THE FUEL QUESTION IN CEYLON.

With reference to the very natural desire of the Uva planters to see the planting of patanas with timber trees on a large scale, reference may be made to Col. Clarke's remarks on the heavy expense of afforesting or re-afforesting processes. We can speak from personal experience of the cost of obtaining seeds which perhaps do not germinate or when they germinate are destroyed by insect or fungoid pests. Plants put out are also too often killed by unfavourable weather, and then, when the planting is successful, there is the long waiting for returns. Nevertheless, tea planters ought to plant trees. One who deserves to be listened to writes to us:—"This is a most important question for the Forest Officers who have to keep up the railway supply, and are looked to to meet the wants of the planting community. The Government will doubtless do all it can, but the planters must look to their own resources. I know an estate on which the other day I strongly advised the planting of the available patana and waste spaces with teas, but the gentleman charged with looking after the interests of the estate *opened the remainder in tea*. I suppose to get a little money for the present, Planters upcountry ought to keep at least 25 per cent of their land in forest if they desire to making their own tea. Damba, the tree you mention as being liked on high estates, belongs to a family very numerous in this country,* almost all of which yield excellent building timber. *Wa*, as you say, is esteemed by the railway; but, I apprehend, it was only mentioned by Mr. Strong owing to its foliage and flowers standing out so prominently on the land bordering the Railway. There are *many many* other woods equally good for fuel with *wa*, which, indeed, is too good for fuel, being quite a cabinet wood." This agrees with what we heard about beautiful articles of furniture being made from an old *wa* tree (*Cassia stamca*, or *C. florida*) at Negombo. The timber is hard and beautifully mottled,

A VISIT TO THE COLOMBO CIGAR FACTORY.

(From a Correspondent.)

I recently paid a short visit to the Ceylon Tobacco Manufacturing Company's premises at Messrs. Cumberbatch & Co.'s mills in Vauxhall Street, and was much interested in what I saw. The cigar factory is an upstairs building, formerly a coffee store. Upon reaching the top of the stairs a busy scene was observed, men, women and children all actively engaged, each one at his or her own special task in the making of a cigar. First were a number of men stripping the ribs out of the tobacco, all seated in line on the floor. Then came a lot of women cutting it up and piling it in heaps ready for the packers. These were mostly boys, who are very expert in gathering up a handful, arranging it and quickly seizing a leaf rough wrapper, he places one end between his toes (not a very agreeable sight for those who smoke the cigars), stretches the leaf, and holding it by his right hand he rolls it into a sort of ship shape, which concludes his work. It is then passed to another who places it in a mould, which is put under a screw press. The mould holds about 15 cigars, and they are pressed in shape, and have to remain in the mould till partly dry. They are then taken out and another wrapper of the finest tobacco, which is imported in boxes and bales from Sumatra and Borneo, is put on. The cigars, after passing

through all the hands who have to do with manufacturing them, are passed on to another part of the room where they are packed into boxes, after having been tied into bundles with a pretty yellow silk ribbon.

The boxes are all labeled "The Ceylon Tobacco Manufacturing Company, Limited," and passed downstairs into the drying-room, which is built airtight, with an iron hot-air tub about 18 inches wide running through the centre of it. The thermometer usually registers more than 100 degrees in the room, so that the cigars are soon dry, and ready to be exported. The market usually chosen is Australia, where there is a ready and profitable sale for them. In the drying-room a lot of bricks are used to place on the top of the boxes to keep them from warping. There is also a room where the tobacco is steeped in vats, and placed on a sloping cement platform to drain off the water. This must be done before it can be worked with.

The manager of the factory, Mr. Boyd, has great trouble with the coolies, who are very much addicted to chucking up their billets after they have been taught the art of manufacturing cigars, so that he has to teach fresh hands almost daily. There are about 60 hands in the factory at present, but they sometimes exceed 100.

There is plenty of coarse tobacco in the country to be got cheap, which would do very well for manufacturing cavendish, and I don't see why it should not be tried; there is plenty of sale locally for good black cavendish. The manager says that the ribs taken out of the leaves are all wasted here, whereas they are used up at home for snuff-making, but the heavy duty on tobacco at home prevents its being sent to the London market. Why not start a snuff factory as well? I am sure the natives here are large consumers of snuff, which is all imported, I presume, at present. I love a good cigar, and I must say I have smoked some of the finest to be had in the East, and they were turned out of the Ceylon Tobacco Manufacturing Company, Limited.

COFFEE IN GUATEMALA.

Coffee is the principal staple commodity of the Republic of Guatemala, and its chief article of export. The topographical features of the country are such that climatic influences are favourable to the growth of the berry, varying only according to altitude and care in cultivation, or as the degree of tropical heat may be tempered by copious rainfall, and precautions as to shade during the early age of the tree. The United States Consul at Guatemala says that in cultivating coffee, a nursery is formed by the choice of a level piece of virgin ground, in proximity to water, where the earth is rich. The land must be thoroughly cleared, and the soil dug to the depth of at least nine inches, and made as friable as possible. It is then divided into beds, with narrow paths between. The seed, carefully selected from the soundest grains, either in parchment or with their outer husk, should be sown, row by row, about ten to twelve inches apart. A rope, the length of the beds, stretched from one end of the same to the other, is used for this purpose. The seed, if sown in suitable weather (April being the best month,) makes its appearance in the tender blade above the surface after thirty-five to forty days; so that a nursery formed during the month of April of one year has plants sufficiently matured to be set out during May or June of the following year. Preliminary to the all-important progressive step in coffee culture, that of transplanting, is "holing." The field is prepared in advance for the reception of the nursery trees by digging holes (five yards apart when above 3,000 feet above the sea,

* The *Eugentias* are referred to.—ED. T. A.

and three yards when at the lower level of from 2,000 to 1,000 feet above the sea) to depths of about twelve inches by twelve inches in width. It has been demonstrated, by frequent experiment, that leaving the holes open for three or four months is chemically beneficial to the soil. In the matter of transplanting, the actual placing of the infant trees into the holes prepared for their reception is one that requires the most care and attention of all the operations in the formation of a coffee plantation. Early planting, during the month of May, June, and July, is desirable because the tree have the benefit of the entire rainy season, and are sure to give a larger maiden crop. Coffee trees usually bear abundantly one year and lightly the next. Judicious pruning helps to increase the crops, although no definite rule can be given for pruning old trees further than that no branch should be allowed to yield more than three crops. The average product per acre in Guatemala of coffee cultivation is 1,800 lb. In the preparation for market, the berries are always picked by hand and carried to the curing house, where the pulp is removed by machinery and placed in a water-tank, where the bean is never allowed to remain beyond a period of twenty-four hours. After the saccharine scum which covers the bean is washed off, the contents of the tank are turned out upon large drying grounds of cement, called *patios*, upon which the coffee beans are thinly spread. It is important that the coffee shall be constantly turned until all the surface is dry, and the beans cease to adhere to each other, while care is taken not to break the parchment whilst exposed to wind or sun, as every hour's exposure to the atmosphere, after removal of the parchment husk, takes away both the colour and aroma of the bean. When the beans are thoroughly dried and hulled, the sorting operation commences. Generally "firsts," "seconds," and "thirds" are prepared for packing into Dundee or Calcutta sacks of 130 to 135 lb. net each, and upon its completion the coffee is ready for transportation on the backs of Indians or mules, or in carts drawn by oxen, to the nearest railway station for the most convenient port of shipment. The largest bulk of the "firsts" finds its way to London, the "seconds" to Germany and France, and the "thirds" to the United States. The labour on the coffee plantations is performed by the Indians of the country, whose remuneration varies from 19 to 25 cents in Guatemalan currency. The Indians subsist on *torillas*, a corn cake and *frijoles*, the bean of the country, both corn and bean being grown by their own labour on patches of ground on the squatter system, which belong to either the owners of the estates where they are employed, or are unsold Government lands which are thus gratuitously appropriated.—*Journal of the Society of Arts.*

SCIENTIFIC GOSSIP

on the kola and areka nuts, on tea, camphor and other substances, as given in the Melbourne *Leader* is interesting. It is specially important to learn that tea grown under shade, so as to be partially blanched, possesses nearly one-third more theine than tea grown in the open. It is, however, startling to learn that theine is a poison! We quote as follows:—

The Kola nut of South America and the areca, better known as the betel, nut of India have had much attention paid to them of late, because there is a disposition on the part of Europeans to give them a trial on the supposition that the South Americans and Indians must have really derived advantage from the virtues they are supposed to possess. The Germans have resolved to give the Kola nut to their soldiers when on service in a campaign, because it is at once a food and a stimulant, containing within a small space more nutriment and more capacity for maintaining strength than any other condiment. The consumption of this nut may have its drawbacks, but they have yet to be found out, and the experiment is

at least worthy of being made. The nut contains a large proportion of theine and of theobromine, so that it is at least probable that it has some sustaining properties, although these are probably exaggerated. The chocolates sold as sweetmeats may have similar properties, and we may hear of their being added to the commissariat of the French army, so that the virtues of the two stimulants may be tested in future warlike encounters. The Indian areca nut is regularly eaten every day in the year by 100,000,000 of the population. There is an annual importation of upwards of 30,000,000 lb. from Ceylon, the Straits Settlements and Sumatra, and they are exported in considerable quantities for the use of Indians living in Zanzibar, Mauritius, Aden, China and other countries. The fresh nuts have intoxicating properties and produce giddiness. These objectionable properties are much diminished by heat and by drying, and many cautious people decline to use any except those nuts which have undergone a process of cooking and are known by their color. The original wild nut was intoxicating, but the only nuts now used are from cultivated trees, and these are milder. They are only intoxicating when unripe, and then but slightly. The nuts are eaten with the betel leaf, the praise of which is sung in the ancient books of the Hindoos, which attribute to it no less than 13 valuable properties which are duly enumerated. Modern medical men vouch for the fact that the essential oils of betel leaves are highly beneficial in catarrhal affections and throat inflammations. Further researches into the properties of the nut and leaves are evidently called for, because their preparation by native methods are a good deal regulated by superstitions. The betel leaves are mixed with other spices and with lime to form *pan*, with which the nuts are eaten. An organic poison can be extracted from the nut, and when this is injected under the skin of rabbits and cats they die in a few minutes: but the same may be said of a great many other vegetable productions, the Kola nut inclusive, which are usually regarded as harmless. Even the lettuce contains such a poison. The arecanut grows on a palm which is supposed to have been indigenous in the Malayan Peninsula and Islands, but is not now found in a wild state. The Indians no doubt indulge too freely in the use of the arecanut and betel leaves but for exceptional use they may be found to be medicinally beneficial. If the reverse be the case, further investigation is demanded on behalf of the 100,000,000 betel eaters.

The finest tea, in oriental estimation, is gathered from shrubs which have been kept shaded for three weeks, so that the leaves are partly etiolated or blanched. It is called "flat tea," because the leaves are not rolled; they are merely steamed, and are never touched by the hand but turned over by the aid of a bamboo stick. After steaming they are merely dried. There is nothing in this process to justify the high price demanded for the tea. A Japanese chemist, Y. Kozai, assistant in the Agricultural Chemical Laboratory, has analysed this tea and found that it contains 30 per cent. more theine than the tea made from leaves grown in the sun. The work done by the chemist appears to be reliable. He analysed the natural leaf and the same manufactured into black and green tea. The chief difference he found was in the quantity of tannin, which was large in the natural leaf and in the green tea, but very much smaller in the black tea. He maintains that there is nothing injurious in faced tea, the Prussian blue being only 1000th part of the weight; but he is severe in his condemnation of the practice of mixing with the tea the leaves of other plants which

contain tannin but no theine, although he admits that none of them are injurious to health. He supplies some hints about the making of tea which have at least novelty to recommend them. The very fine teas are ground to powder, and this is infused in water not much more than lukewarm, the temperature ranging from 120 to 150 Fahrenheit. Medium quality tea is infused for one minute only in water at the boiling point, while inferior black tea requires to be absolutely boiled. What tea drinkers want is a combination of quality with cheapness, and this should not be unattainable.

Theine is a rank poison, but it does not follow that tea, coffee, cocoa, maté, and many other kinds of foliage and fruit are fatal to life or even in any marked degree injurious to health. In like manner prussic acid kills instantaneously, and yet bitter almonds and apple-pips may be eaten with impunity. Vegetable poisons may, as a rule, be taken in small doses, not only without much risk, but medicinally, with advantage. It need not, therefore, be looked upon as surprising that the Americans have made the discovery that strychnine lozenges may be taken without any immediate lethal consequences. It is contended that a lozenge containing the 13th of a grain of the alkaloid serves as a tonic, bracing the system and banishing languor. But who says so? Any eminent physician? No. Somebody has said so, and rumor keeps up the fallacy. The practice is dangerous, and should be discountenanced. The habit of taking strychnine lozenges may become confirmed, and may lead to a craving for larger doses, as opium eating does. Not only is strychnine poisonous, but so also is the plant from which it is extracted. Daturin is an allied alkaloid, and medical men not infrequently advise patients suffering from asthma to smoke the stalks of the thorn apple or datura stramonium, but it may be questioned whether the alkaloid is not destroyed during the combustion. The strychnine lozenge is a more serious affair, and its consumption has its analogue in tobacco chewing, although no one has yet taken to the use of nicotine lozenges. Those who take drugs of this kind, in any form, unless in obedience to the orders of their medical advisers, are not deserving of sympathy when their indiscretion leads to suffering.

There is a scarcity of camphor in Europe, and it has gone up enormously in price, which has advanced from 1s to 3s 6d per lb. The explanation given is that camphor is used in large quantities in the manufacture of smokeless gunpowder. It is just as likely that a camphor ring has been formed, and that large quantities of the drug may be stored somewhere awaiting a further rise. In the meantime a Paris physician recommends it as a specific in cholera—a very old idea which may have little but its age to recommend it. —Melbourne Leader, Aug. 2nd.

SELLING QUININE FOR FUTURE DELIVERY.

For some weeks past there has been a revival, on a rather modest scale, of the speculation in quinine, which at irregular intervals lends a temporary flicker of excitement to the dealings in that unfortunate product. In spite of the oft-repeated lessons of former years, it seems that there are still persons sanguine enough to believe that a good thing is to be made by investing money in quinine. There are never wanting intermediaries who with an eye to brokerage, are ready to prove with the aid of statistics that the market *must* soon take a turn for the better, and that if facts hitherto have unfortunately failed to

agree with their predictions, so much the worse is it for the facts. Any spasmodic revival of speculation brings grist to the mill of the brokers who are manipulating the purchases on behalf of investors, and the kernel of whose philosophy may be considered to lie in the axiom *après moi le déluge*. Outsiders have been drawn into the stream by relying on the slender knowledge displayed in certain "financial" journal which have permitted the columns to be used for the furtherance of some operators' views. The communication which we print on another page of this issue from an Amsterdam cinchona broker of standing may be studied to some advantage by people who are always ready to allow themselves to be drawn by the infallible statistic system. Our correspondent propounds the theory that the quinine price cannot permanently advance so long as one or two "speculative" manufacturers are able to depress it to their own immediate advantage, and with complete impunity so far as they themselves are concerned, by a simple but efficient system of contracting with the Java planters to supply them direct with their bark at a price to be dependent on the basis of the quinine unit existing at the time when the bark shall be delivered. The planter thereby saves auction expenses, brokerage and warehouse charges; he knows that, come what may, he is sure to be able to dispose of the whole of his produce at the market price of the day; and preferring modest certainty to capricious chance, he delivers himself into the hands of the speculative manufacturer. Now what is the position of the latter? He has to face a keen competition, and can only keep his head above water by either forming a "combination" with his rivals, or elbowing them out. "Combination" has been tried and found wanting, and the other alternative is therefore being pursued with vigour. The manufacturers' mode of procedure is sketched as follows: Having made his contract with the planter, and knowing that he can depend with certainty upon a supply of bark equal to, say 300,000 oz. of quinine in the course of the season, he proceeds to attract buyers by offering quinine at an exceptionally low figure, to be delivered, say in four or five months' time. Being the lowest in price, he secures orders, and his rivals, who have to buy their material mostly at the public sales, are bound either to follow suit, handicapped by the want of a certain cheap supply of cinchona in the future, or to give up the competition and trust to the established reputation of their brands for the preservation of certain channels of consumption. When delivery of the quinine is due, the "speculative" manufacturer is in possession of the cinchona from his Java planters, and as he pays them upon the basis of the quinine unit ruling at the time of delivery—which, in a period of abundant supply, he is able to influence towards depression by underselling his competitors in advance—he is sure to make a profit, small may be, but absolutely certain, the Java man paying the piper. The names of the clever operators referred to will occur at once to anyone familiar with the London drug market. As a matter of fact there are and have been for a long period, only two or three so-called "speculative" quinine makers. The others have ceased to "compete" seriously in the "future delivery" business, and are waiting for the time when the system, which must naturally be a hazardous one, shall be relinquished. In confirmation of our correspondent's theory, for which we disclaim any responsibility ourselves, but which is certainly an ingenious one, we may point to two items which were published in our journal about a year ago. At a meeting of the Soekahoeimi Agricultural Association of Java (to which most of the cinchona planters of the island belong) held early last year, a letter was read from Messrs. Zimmer & Co., of Frankfort-on-the-Main, expressing a desire to enter into negotiations with Java cinchona growers for the purchase of their entire production of bark outright, to save charges. At the annual meeting of shareholders in the Sekanegara Company held in Amsterdam last June, it was announced that the whole of the cinchona produced on that company's plantations had been consigned to the Brunswick Quinine Works at an average price (for 1888) of about 10½d per oz. for its equivalent of quinine sul-

phate. The Soekanegara plantations produced in 1888 104,000 kilos. bark, equal to 4,680 kilos. quinine; in 1889 132,000 kilos. bark, equal to 5,610 kilos. quinine; and their estimated crop of 1890 is 100,000 kilos. bark, expected to yield 4,500 kilos. quinine. They rank among the three or four largest private plantations in Java.—*Chemist and Druggist*, Aug. 16th.

GOLD IN MADAGASCAR.

The discovery of gold in large quantities in the great African island of Madagascar just at the moment when Europe is turning for fresh fields of enterprise to the dark continent, is an event of more than local importance. Silver has long been known to be a pretty whispered mineral in the island. But hitherto the Hovas Government has discountenanced any attempt on the part of adventurers from Europe to exploit the island in quest of precious metals. With the establishment of the French protectorate a few years ago the country has been to some extent opened up to foreigners. Already a "gold rush" on a small scale has commenced to the island, the adventurers hailing from the French West Indian Colonies and the Hovas are beginning to see that it is impossible to keep white men out of the country, once the existence of the fatal metal becomes known. Possibly the Malagasies will share the fate of the Australian aborigines and the Maoris within our time and the output of gold from the once most exclusive island will begin to exercise an appreciable effort upon the world's store of the precious metals. But the climate of Madagascar, which is not favourable to Europeans may save it for a time. The country is one eminently adapted for mining industries, labour is cheap, and the gold-bearing reefs are not far from the coast. Indeed the metal appears to be pretty generally distributed all over the island though it is found in greater quantities along the west coast. Already a good many speculators are buying up likely land in the island and an influx of miners from America, Australia and South Africa is expected to commence.—*Indian Agriculturist*, Aug. 23rd.

TEA IN JAPAN.—The *Japan Weekly Mail* of Aug. 16th says:—"Nothing new in tea; sales and prices about the same as for the last few weeks, though fully five and a half million pounds more have been shipped this season than last year at same date." The *Mail* in its issue of Aug. 22nd says:—"The tea trade is steady, and values are unaltered. The receipts of leaf here are already 5,000 piculs more than the total last season, and there is doubtless a good deal more to come in if present rates are maintained."

ODESSA is doing a large and increasing trade in China tea. In the month ending the 15th July, seven tea-freighted steamers were timed to arrive at the Russian port, five of which belong to the Volunteer Fleet, the other two being specially chartered English vessels. The tea freight is chiefly destined for Moscow and St. Petersburg houses, the consignors in those cities having engaged three hundred wagons on the South-Western Railway for transport. A correspondent thinks, however, that the prospect of the Chinese tea trade is on the whole anything but encouraging for the Chinese themselves. "For some time to come Russia will probably continue to be a chief buyer of Chinese teas, but the amount of her purchases will gradually diminish with the rapid propagation and development of the new tea plantations in Russian Central Asia." The writer adds that undoubted preference is now being manifested alike in England, the British colonies, and the United States for Indian and Ceylon teas.—*Indian Agriculturist*, Aug. 23rd.

THE WORDS FOR SUGAR IN DIFFERENT LANGUAGES are quoted by the *Sugar Cane*, in a review of an elaborate work on sugar by a Dr. Lippmann. We quote the curious paragraph:—

In the next section, that entitled "Sugar at the time of the Crusades," is an interesting dissertation, founded on the studies of Littre, Diez, Grimm and others, on the word sugar in various European tongues.

From the original Indian form *çarkara*, which in Prakrit became *sukkara* (the habit being to drop the letter r before a consonant, and replace t by reduplication of the following consonant) was formed the Arabic *sukkar*. This word naturally became the parent of all the different forms such as—asucar (Spanish, from *alsukkar*, pronounced *assukkar*), *assukar* (Portuguese), *zucchero* (Italian), *chuehre* (Proveçal), *chueure* (old French), *sucre* (French), *zuckra* (old German) *zucker* (German), *zocker* (Flemish), *suiker* (Dutch) *sokkar* (Swedish), *syker* (old Norse), *sukker* (Danish) *sachar* (Russian), *cukier* (Polish), *cukorus* (Lithuanian), *cukra* (Bohemian), *czukor* (Hungarian), *shicker* (Mongol), *shakara* (Tibetan), *shakar* (Persian), *shachara* and *shukar* (Armenian) *sheker* (Turkish). The middle Latin contained as many as 28 forms, varying from *chuchra* to *sachara*, *zockra*, *zaccarum*, and *zukurum*, the last agreeing most nearly with the usual Latin form *saccharum*.

ELEPHANTS AND IVORY IN AFRICA.—From reminiscences of Equatorial Africa, which are appearing in the *Pioneer*, we quote a sad passage:—

We also came across traces of the wild elephant during this march, the spear being quite fresh, and the broad track they had made for themselves proved the herd to have been a very large one. There was a freshly beaten path through the jungle, with the saplings bent and twisted down, branches of trees torn off and denuded of their foliage, and an occasional uprooted bush lying about the track, looking as though a battery of heavy guns had been forcibly dragged through the place, cutting up the soil into deep ruts and damaging the trees by its transit. That the herd could only have passed but a very short time before was evident; but we followed up the path for some distance we failed to get a glimpse of them. The natives have a very barbarous method of killing these huge animals which they described to us with great gusto, evidently considering it to be very ingenious and not seeing anything cruel in it. They did not dare to face them in the open, but used to carefully mark out the spots near the river where the elephants were accustomed to come to drink. Selecting some tall tree overhanging the path, they would conceal themselves among its thick foliage for days together in the hope of seeing the huge beasts pass underneath their hiding place. The weapon they employed were very heavy barbed spears, having long pliant shafts attached to them, and these they hurled with great force upon the elephant below. The animal immediately dashed off at a tremendous pace through the jungle as soon as he felt the wound of the spear. The long handle kept striking against boughs or catching in thickets, making the terrified animal still more mad with pain and fright, and causing the iron barb to inflict a wider gash. The cruelty of this plan was not merely in the self-inflicted agony of the moving barb, but in the length of time that generally elapsed before the poor beast would slowly sink from exhaustion and loss of blood. They told us that they had followed up the track for as many as four days before coming up with the wounded elephant; and the horrors of its death seem (as they vividly described it to us), with a circle of tormentors hurling their spears from a respectful distance until its carcass resembled a huge pin cushion, were enough to make one look on ivory with mingled feelings ever afterwards. Yet one could not blame those savage hunters, for, as they themselves said: "We have no big guns such as you possess, and one would much rather kill them quickly than slowly." It is to be hoped for the poor elephants' sake that they may soon possess the needed rifles, for as the competition among the East African Companies will increase the demand for tusks, and for every other saleable commodity those forests can produce, the probabilities are that the native hunters will have a busier time of it than ever. How long the ivory will hold out is another question.

LUPINS AS BINDERS AND REGENERATORS OF SANDY SOIL.—There is an interesting paragraph on this subject quoted from the *Madras Mail*. The only question is would lupins thrive at sea level in the tropics. Von Mueller describes the white lupin as common to countries on the Mediterranean Sea, also in the orient. Of *Lupinus arboreus*, which is referred to California, he writes:—

This has been used there for reclamation of sand, on account of its long tap-roots, the latter having been traced to a depth of 25 feet, while the stems were only 8 feet high. The germination is easy and the growth rapid on the sand-downs. For aiding the young lupines during the first two months, to get hold of the sand, barley is sown with them, as the latter sprouts in a few days and holds the sand in the second week; the lupine subsequently covers the sand with a dense vegetation in less than a year.

And of the lupin specially referred to, *Lupinus intus*.

The Scented Yellow Lupine. Countries in the vicinity of the Mediterranean Sea. Can be grown in Norway to lat. 70° (Schnobler). This annual species is predominantly in use as green manure through Middle Europe; to improve sandy soil, it is the best of all yet tested, and will do even on coast-drifts. It can also be employed like some other lupines as a fodder-herb, green as well as for hay; some lupines are also very valuable as pasture-herbs. Lupine-seeds are very fattening, when used as an addition to ordinary fodder, and are in this respect quite equal to oil-cake, while the foliage is said to be not inferior to that of clover and more bulky. Nevertheless some lupines have proved poisonous to sheep. About 80 lb. of seeds are required for an acre. Langelth observes: "What the Sainfoin does for the poorest-limestone or marly soil, that the Yellow Lupine carries out for sand-land." Lupines are not adapted for wet or moory ground, nor for limestone formations, where most other leguminous fodder-plants do well. Mr. Joseph Augustin speaks of a yellow-flowering lupine, which sometimes in the Azores attains a height of 12 feet in three months. Plants native to California ought to succeed fairly in Ceylon.

AGRICULTURE IN JAVA is thus noticed by a writer in the *Pioneer*:—"The hamlets look like green islets in a sea of golden rice. Immediately outside the ring fence which has been described commences the rice or other cultivation. Not a square yard of ground seems to be wasted, and the care and evident labour with which each bit of slope is terraced and supported, the greatest area thus being obtained for the rice crop, is most admirable. These terraces are carried up the sides of the highest mountains, the mighty volcanoes themselves allowing the cultivation to creep up within what looks a dangerous distance from their craters. The water for irrigating the crops is brought from the hillsides and is unfailling. This enables the cultivator to get two rice crops off the same field, and this staple appears on the village lands in the month of April, in all stages of growth from sowing to harvest. The main crops are rice, Indian corn, beans, sugarcane (eight kinds), coffee, pepper, indigo and tobacco. During the past three years a blight has affected the sugarcane, stunting the growth and seriously diminishing the output. This has been a severe blow to the factories. Rice is still an article of export, so that, in spite of the enormous increase of the population, which now is said to reach twenty millions as against five millions in Radja's time, the island more than feeds itself. The cocoa tree, with its beautiful blossoms and fruit, both on the tree at the same time, is to be found in many of the peasants' gardens, and the coconut and the sugar palms abound. All the Indian fruits are to be seen in the bazars, together with the dorian and the mangosteen."

TREES IN WESTERN AUSTRALIA.—The following is from a "Naturalist." Mr. A. J. Campbell, F.L.S., writing about Western Australia in the *Australasian*:—

Leaving Perth midway on the 30th December—a sultry day—we proceed through open timber and scrubby country. Christmas trees, in golden bloom arranged, lift their heads above the "stinkwood" scrub. There are *Ranksias* great and small and healthy patches where sheoaks and grass trees give figures to the landscape. I never look at a sheok (but why "she" when half the trees are males?) without thinking of its far-removed, although euhomous, botanical name, *Casuarina*. *Casuarina* (*Casuarina*) signifies the cassowary, a large bird, whose hair-like plumage is the equivalent of the more perfect feathers in other birds; and it has been thought that the wiry foliage of the sheok stands in like relation to the better-formed leaves of other trees.* The general nature of the soil is sandy, but dark and loamy, especially where twisted white-bark gum-trees stand out in bold relief. Passing Guildford, eight miles from the coast, some fine orchards are seen in the stiff reddish soil. Figs almost grow wild here, judging by the large trees bearing prolific crops. Now we are winding among the ironstone spurs of the Darling Ranges. Having crossed that natural barrier and descended into the level country, we leave the rough-barked jarrah and smooth silvery barrels of the wando in the rear, and York gums with rough dark-grey stems, commence to assert themselves. The cultivated soil grows good wheat; of strange to say, although the population of Western Australia is only 43,000—exactly one-sixth that of Melbourne—energy is lacking to raise sufficient grain for local wants. At 8 a. m. we leave Beverley, and are soon speeding south over the West Australian Land Company's section—242 miles of railway, with its 3,000,000 acres. This is undoubtedly the largest land syndicate in Australia. There is plenty of open genera scrub around. "The land of the sheoak" would in fact fitly apply to Western Australia, because out of 300 Australian species about two-thirds have been recorded for this territory. The most conspicuous is *Acacia acuminata*, vulgarly called raspberry jam wood, for when its dark-brown timber is worked a scent is given off exactly like that of the well-known preserve. One of these trees at a distance resembles a balloon without a car, having a crown of narrow light-coloured leaves, supported by numerous long stems branching from near the ground. At a wayside station, I examine one of the stems and find it a perfect conservatory for lichens. One piece of bark only 6 in. x 2 in., which I subsequently submitted to a lichenologist, supported no less than eight varieties. Many of the jam-wood trees, which are about 10 ft to 20 ft. high, bear the mistletoes. On reliable authority I learn that the sweet little swallow *Dicaeum* feeds on the mistletoe berries when they are in season, as this bird does in every other part of Australia. From the jam-wood, which is very durable, blackfellowa manufacture their woomeras and boomerangs, while a dwarf tough mallee, which they call "marlock," is suitable for slender spears. Now and again we get a glimpse of the pendulous foliage of a small sandalwood tree (*Santalum eggnotum*). All the marketable specimens seem to have been cut except on the back block from whence they are carried to the different railway stations where their wood of delightful fragrance may be seen in great heaps. It is valued at about £8 per ton. During 1888 £33,525 worth was exported to China, where it is used solely to burn as incense before idols. I understand a company is about to distil oil from the wood, as sandal oil is frequently used for medicinal purposes as well as for blending in the manufacture of perfumes. The sandal-wood tree closely resembles the quinquina of Victoria.

* Absurd as "sheok" is (the grevillea is called silk oak, the term "leaf wood" is still worse). In driving Mr. Hemiker Weston and a party of friends along the the avenue of eucalyptus which leads to the Tamatie Asylum, that was the term we heard applied by the Australian colonists to this graceful pine-like tree.—Ed. T. A.

PETROLEUM AND OTHER LIQUID FUELS
FOR USE IN THE WORKING OF
STEAM ENGINES.

We have always taken a great interest in the question of utilizing petroleum as a source of steam production in engines and, also, if that should be found possible by the repression of the odour as fuel for drying furnaces in tea factories. We have written often and quoted largely on the subject, and latterly we have been waiting for more light on the question before noticing some important papers with which we have been furnished, in order that we might deal with them. We are disappointed that a reliable authority to whom we sent a paper on the Priestman oil engine should return it with the statement that he had not seen a Priestman's oil engine or heard any definite particulars about its working; but he has promised to make inquiries and communicate the result. Meantime he writes—"If what the makers say about it is correct, it is just the thing we want for estates with no fire-wood left." As our readers are aware, this is the only oil engine which has yet been put to the test of actual trial in Ceylon, and it has been favourably reported on. The serious questions here in Ceylon of course, will be the cost of the oil and the quantity required per horse-power. We have always felt that the prospect of a large use of petroleum in Ceylon, for engines or furnaces, depended on the possibility of using the waste or refuse product resulting from the refining of the crude oils. To admit of the import of such waste substance, we suppose the Ordinance No. 6 of 1887 would require to be amended, for by that Ordinance petroleum is held to be dangerous when the flashing point is below 76 of Fahrenheit's thermometer. We cannot doubt that means could be devised, by chemical treatment or mixture with other substances, whereby waste petroleum could be rendered safe (the danger of explosion and contaminating odour being equally obviated), and the prospect is that we need not be dependent on America or Russia for this class of engine fuel. It has been found and is being constantly discovered in various parts of India and Burma and is used in locomotives on the Indian State railways. Meantime, with reference to our Ceylon standard of safety, it is curious to find in the description of the Priestman engine the statement that there can be no danger, because "oil can be used, having 800 specific gravity and upwards, with flashing point from 75deg. (1deg. below our safe point) to 150deg." But we suppose 75deg. as flashing point is safe enough, because our Petroleum Ordinance provides "That when all or any of the petroleum on board a ship or in the possession of a dealer is declared by the master of the ship or the consignee of the cargo, or by the dealer, as the case may be, to be of one uniform quality, the petroleum shall not be deemed to be dangerous if the samples selected from the petroleum have their flashing points, on an average, at not less than seventy-six degrees of Fahrenheit's thermometer, and if no one sample has its flashing point below seventy-three degrees of that thermometer." As to cost of petroleum and kinds of oil or fuel which can be used, the paper on Priestman's engine states: "Oil used is about 1.25 pints per actual h.p. per hour for the larger, and about 1.6 pints for the smaller engines with full load. Mineral oil can be purchased in England at about 6½d per gallon, costing from 1d to 1½d per actual h.p. per hour. Any ordinary mineral oil suitable. Royal Daylight, Russian, Orient, Teareso, King's County, Water White, White Camelia, Pipe Line, Scotch Paraffin, Prime White, American Fuel, &c." We suppose that the quotation "1d. to 1½d per actual horse power per hour" for petroleum oil would have to be increased by at least 50 per cent

for Ceylon, say 1½d to 1¾d, or say to 2d per h.p. per hour. If crude oil or waste product could be used, the cost would, of course, be less. It is claimed for the engine that it is perfectly safe, because "Oil and not spirit is used." Amongst the merits claimed for this engine are:—"No gas, no steam, (?) no danger, no chimney, few working parts, no extra insurance, piston self lubricating, quickly started, no coal, no boiler, no fire, no driver, (?) no water consumed, repairs very small, little space required, works anywhere." And then as to mode of working:—

"The working of the Priestman Oil Engine is so simple that an unskilled person can give all the attention it requires. The motive power is obtained from Mineral oil, one or two days' supply being placed in a closed iron vessel inside the foundation of the engine. The oil having been mixed with air under pressure, is drawn into the cylinder and ignited by an electric spark from a small ordinary battery supplied with the engine. To start the engine, after heating the vaporizer a few minutes, it is only necessary to admit a small quantity of oil into the cylinder by taking a turn or two of the fly-wheel. Little or no attention is required in working the engine, and there is no risk in leaving it unattended, as, should the oil become exhausted, the engine will then only cease to run. Detailed working instructions are sent with every engine."

There are certificates from such scientists as Sir Wm. Thomson, and testimonials from persons who have used the engines for widely differing purposes, one gentleman stating "In a place like mine where water is scarce, and a high pressure engine unsuitable, your engine is indispensable." The prices seem fairly moderate, but these the local agent can supply. We may, however, quote a note to the effect that

"These prices include, besides the engine, all the plant required for creating oil vapour, making the user entirely independent of boiler or gas works. There is little or no expense in fixing these engines, as they are self-contained."

So far in regard to Priestman's engine, in which oil only is used. But we have also before us a paper on

"Holden's Patent System" of using liquid fuel as auxiliary to solid fuel in the fireboxes of locomotives or boilers of similar type.

The advantages here are that a mixture of fuels, or a particular fuel alone, can be used according to circumstances, the calorific value of coal or wood being apparently greatly increased by a mixture of "green oil," (?) or coal gas tar. We quote as follows:—

"By this system, liquid fuel and air are introduced into the firebox above a thin layer of solid incandescent fuel by means of a special injector, and but in combination with the solid fuel, without any alteration of the firebox, other than the insertion of one or more tubes through the casings, the boiler so fitted being equally suitable for the use of ordinary fuel. The use of this method results in efficient combustion, entire absence of smoke, intense and regular heat, and great economy of fuel. Slack, inferior coal, lignite, cinders, wood, peat, or sawdust may with equal good results be used as solid fuel. The air necessary for combustion, not having to be introduced through the fire, a very small amount of draught is required, and in the case of locomotives the orifice of the blast pipe may advantageously be enlarged from 50 to 60 per cent, reducing the wear and tear of the firebox, tubes, smokebox, and chimney, preventing the emission of sparks and ashes, and conducing to economic and efficient working by the diminution of back pressure.

From a description of the patent in *Engineering*, we learn that

"The first experiments of Mr. Holden on liquid fuel burning were made at the Stratford works of the Great Eastern Railway Company on a boiler in the

department where oil gas is manufactured for lighting trains. At these gas works one of the products is a tar which it is difficult to dispose of at any price, but this is now burnt under the boiler, which was fitted with the liquid fuel apparatus early in 1886. The boiler is a small one of the Cornish multitubular type, 10 ft long by 4 ft. in diameter, with a furnace 7 ft. long by 3 ft. in diameter, from which 122 iron tubes 1½ in. in diameter by 3 ft. long extend to the back of the boiler. The boiler is worked at 60 lb. pressure, and when coal was used the consumption per week (79 hours in steam) averaged 68 cwt. 1 qr. 16 lb. or 97.1 lb. per hour. With the liquid fuel apparatus the consumption per week, with 69 hours in steam has averaged 454½ gallons of tar and 2 cwt. of coal, or an average per hour of 65.9 lb. of tar and 3.3 lb. of coal."

The question is whether the tar referred to, as "difficult to dispose of at any price," could not be imported and used here more economically than petroleum, or coal, or coke? In the case of a printing office boiler

A comparison of the cost of working with coal only in 1887, and with coal and liquid fuel during the present year [1888] (the comparison being made for a week in each case), gives the following result:

Coal only Used.

1887. Consumption during one week from August 15th to 20th (inclusive), 74½ hours' work, including lighting up=80½cwt.=121.3 lb. of coal.

Cost for 100 hours=12,130 lb. of coal at 11s per ton =2l. 19s 7½d.

Coal, Coke, and Tar—"Holden's System."

1888. Consumption during one week from June 25th to 30th (inclusive), 87½ hours' working including lighting up

=coal 15 cwt.=19.2 lb. per hour
 =coke 11½ " =14.7 " "
 Gas tar 280 galls.=35.1 " "

Total 69.0 " "

Cost for 100 hours

			s.	d.
=1920 lb. of coal at 11s 0d per ton=			9	5½
=1470 " " coke " 9s 6d "			=	6 1½
=3510 " " tar " 12s 6d "			=	19 7½

Total£1 15 2

Again:—

Various kinds of liquid fuel have been used, and the apparatus appears capable of dealing with any of the ordinary marketable qualities. On the occasion of our making a trip on the engine there was being burnt a mixture of one-third "green" oil with two-thirds tar, and this was burnt entirely without smoke or trouble of any kind. Roughly speaking the consumption of fuel on the engine above referred to is one gallon (or 11 lb.) of liquid fuel (a mixture of two-thirds ordinary gas tar and one-third creosote or furnace oil) to about 14 lb. of coal per mile.

Engineering, in summing up, states:—

"It will be seen from the facts we have stated above, that Mr. Holden's system of using liquid fuel is one of very great promise, and it appears to us of especial value for use in cases where it is of importance to be able to at once revert to burning coal alone, as may occur in consequence of fluctuations in the market price of oil or other circumstances."

Whether the Priestman engine is adopted or not, our readers will see that great benefits can be derived from a mixture of liquid with solid fuel in furnaces.

As might have been anticipated, Messrs. Marshall of Gainsborough, so well known as the manufacturers of tea machinery, have not failed to lay themselves out to meet the demand for appliances wherewith to burn petroleum as engine fuel. In papers with which we have been furnished we find the following notice:—

"Petroleum as fuel in locomotive and Vertical steam boilers. In many parts of Ceylon, India, &c., where coal and wood are scarce or costly, we beg to draw the attention of Planters and others to Petroleum and

other mineral oils for use as fuel in the Boilers of our Steam Engines. We can supply the necessary Apparatus and Fittings, which can readily be attached to our Locomotive and Vertical Boilers, for using this class of fuel, and they can quickly be removed and the Furnace used for burning wood or coal if required. The apparatus is simple and efficient, and we shall be happy to furnish full particulars and prices on application."

In reply to a Firm who had written to them on the subject, it was stated:—

"In reply to the last paragraph of your letter re Petroleum burning we have supplied an arrangement for this purpose to a number of Locomotive Boilers from time to time, and we see no difficulty in its application to Boilers of the Vertical type also. We give you at foot, prices of the necessary plant in connection with existing Boilers.

"This would consist of a tank to hold the oil-coil to heat the same from the exhaust steam—the necessary injector and pipe—and also the firebrick material for the inside of the firebox. The refractory material for the grate we do not supply, as of course anything of an imperishable nature would suffice for this, road material or any kind of clinker that is available would do very well for this purpose.

"With regard to the quantity of oil consumed so much depends upon the kind of oil used, but we may explain that in our experiments at the works we used about 3 pounds (3 pounds) of oil per indicated horse-power per hour, that is about one-third of a gallon.

"From the above explanation your Managers will readily be able to ascertain the quantity used per day, as each will have an idea what indicated power his engine is giving off, and will then readily be able to calculate from the above what quantity of oil it would consume. Our experiments here were conducted with what is called "Refuse Oil" but if the oil is of better quality the consumption would be less.

"Cost of Petroleum Burning apparatus to existing Boilers including oil tank and coil, injector and piping, firebrick lining for firebox.

6 H-p. £20 10 H-p. £24
 8 H-p. £22 12 H-p. £26. Subject to usual terms."

Our readers will thus see that they can, if destitute of an engine and requiring one, obtain a Priestman engine for the consumption of oil alone; or engines in use can be supplied with the needful apparatus for the consumption of petroleum; or finally they can get increased heat with increased economy by using as fuel a mixture of liquid and solid substances having calorific properties. The curious point in the whole matter is that even Messrs. Marshall, who ought to know much about the delicate character of tea and its absorbing qualities, express no apprehension and suggest no caution as to prevention of petroleum odour coming in contact with the tea in the store. We suppose the danger has been calculated and thoroughly provided against.

PLANTING IN WYNAAD.

Aug. 27th.

After two months, during which hardly a single day passed without a considerable rainfall, we are now enjoying a delightful break in the weather. This was very greatly needed, as the constant damp not only checked growth, but it did an infinity of mischief to the coffee by rotting the leaves and, worse still, the berries. This is really a case of adding insult to injury, for surely our crops need no diminishing and it is cruel work to see the very little we have falling from the trees. I am sorry to have but a bad report to give you on ant leaf disease and borer, both of which are simply ravaging the estates all round. The appearance of some of our finest properties is shocking, and so severe an outbreak of both these terrible epidemics, must seriously affect the trees. Possibly under such circumstances, the fact of little or no crop may be an advantage, as the coffee has one less drain on its enfeebled constitu-

tion. But I believe a discouraging view is held generally of the future of Arabica, and this is sufficiently proved by the large and steadily increasing demand for Liberian seed. In fact, the time has evidently come for planters to depend no longer on the old broken reed. Arabica will give crops in perfectly new clearings, if heavily manured, for a few years, just long enough to allow its sturdier relative to come into bearing, but we can never hope to see those clearings healthy fields fifteen years hence, as we should have done in the good old times. The species is so thoroughly and hopelessly impregnated with leaf disease, that it is impossible for it ever to be eradicated, so nothing apparently remains for us but to bury our old friend, and regard him only as a fragrant memory. It is thought that Liberian has a fair chance, and this, as I said before, is being largely planted throughout our district. Pepper is the next hope. So far, this gives every promise of growing well, and we are assured that though at present, the prices are depressed, there is a prospect of a good rise before long. This year the vines do not appear to be fruiting as well as usual; this is probably due to the weather. But the plants themselves look exceedingly healthy, and are growing very fast. There can be no doubt about the suitability of our climate for tea. That which has already been planted grows splendidly, and at considerable profit. The great difficulty—and this a serious one, is the labour. A tea—unlike a coffee plantation, must have labour all the year round and it is especially needed during those months when our coolies are accustomed to return to their country. It is a decidedly unhealthy time in Wynaad and this being well known, makes another difficulty in procuring permanent labour. The labour question, even with regard to ordinary cultivation, is becoming a worrying one to us all. This year having no crops to pick, it will not so much affect us. But should next blossoming season be successful, and our labour be as failing as it has been this year, I don't know what will have to be done. Considerable losses have been incurred by the vile and apparently unalterable system of advances. The coolies do not now take the trouble to invent excuses for their absence; and they even in some cases send out scouts to view the land, and if the report is, "plenty of weeds,—bad crops and no chance of present at the end of the season," they remain at home happy in their minds that they have secured a good advance, and need not fash themselves to work it off. Cinchona is another trouble. We know quite as well as anyone can tell us, that at this elevation, high cultivation is absolutely necessary for the well-being of cinchona. Where we have planted it with coffee thereby enabling it to benefit by the manure, our fields look healthy enough. The hitch is that it is impossible for us in these exceptionally hard times, to cultivate cinchona *by itself*, as it requires. A rise in the price of bark would enable us to go in for high cultivation, but at the present market rates, it is barely remunerative without any cultivation at all.

Verily, "these be parlous times," the planters' burdens are pretty heavy all round. The rise in exchange which makes so many fathers of families rejoice, is to us a dust and ashes, and means a woeful decrease in our already attenuated incomes. And here, comes in another pinch. The subject being our taxation.

By the old arrangement planters were called on to pay R2 per acre on all coffee or cinchona which was of age to give a return—i. e.—3 years old; and if at any time a field or coffee was found unremunerative it could be abandoned; and Government claimed no more of it. Unfortunately, for all who have middle aged or old properties, the case is quite different; since the settlement introduced by Mr. Castle Stuart, two years ago. Our assessment was then fixed, once and for all; and whether the coffee is since dead or not our dues must be paid, or the whole property will be sold up. An owner of 800 acres, let us say, of old coffee, may find now that only fifty acres of this can pay its expenses, and let the other 250 go back into jungle. But he will have to pay R600, a year in tax on his 50 acres, or failing

that lose his little all. Government will put his whole property up to auction, if he does not pay sharp, and probably buy it in itself for a few rupees. In fact, the greater part of Wynaad is being so bought up by Government; on account of arrears of taxes owed by natives and I am told on good authority, that batches of 60 and 70 holdings, are sold off every month, Government in most cases buying them in. Needless to say, this is causing much suffering amongst the small cultivators, whose little all, and sole means of maintenance depended upon their miniature estates.

It is all very well gaining *kudos*, for raising an enormous apparent revenue, out of a poor country like this, but the end of it will be, that the cultivators, European as well as native, will soon be driven forth, and Government itself will have no revenue; let us hope that this will be compensated when it finds itself the proud possessor, as far as eye can reach, of limitless fields of lantana, and ruined bungalows, once the pleasant homes of hard working Plauters. It is a kind of vicarious suffering, which amidst our other troubles we find it rather difficult to bear with equanimity.

The best proof that coffee is not quite defunct and that some yet live who believe in it, is that there have been some extensive robberies of nurseries, and in one case, an entire new clearing, just planted was systematically cleared of every plant it contained.—*Madras Times*.

ADVERTING to the speedy growth of bamboos, which formed a subject of discussion some time ago in the papers, Mr. W. J. Addis, C.E., now in Burma, writes to say that he measured bamboos near the Western coast of India and in the Annamally forest, and found them grow at the rate of 15 to 16 inches in 24 hours. A great deal, he says, depends on the soil and species of bamboos; and the growth is slower after they attain the height of 10 or 12 feet.—*S. F. Press*, Aug. 28th.

SUBSTITUTE FOR COFFEE.—We hear that natives who have become accustomed to coffee from having served as domestic servants with Europeans, make use of the beans of the yellow wattle, called by the Tamil "thumba chedi," as a substitute for the coffee berries. Treated in the same way as coffee berries, the thumba bean makes a beverage closely resembling coffee in taste and smell—only slightly more bitter. The pariahs mix it with burnt rice and say it is quite as palatable as coffee.—*Bangalore Spectator*.

WATER-RAISING APPLIANCES.—In a Madras Government Resolution on a recent agricultural show in the district of Salem, occurs the following passage:—

The results of the water-lift trials in competition for the prize offered under G. O., No. 650, dated 12th September 1888, were recorded in G. O., No. 2,263, dated 10th April 1890, and the present report confirms His Excellency the Governor in Council in the opinion that for moderate heights the superiority of later inventions over the common picottah has not been demonstrated. For greater lifts the leather bag worked by bullocks is very effective, and the practical difficulties involved in using iron, viz., its weight, expense, and the absence of facilities for its repair, detract from the utility of nearly all Western improvements. These objections apply with equal force to most improvements of improved types, with the exception of sugar-cane mills; of these there was a fair show, and the Collector points out that the fact of a very large number of Massey's mills having been sold proves that the ryot is fully alive to the advantages of using a modern machine.

The "picottah" is the lever beam working between two uprights, the working of which is occasionally helped and accelerated by men or boys running up and down the beam. Its use in raising water from wells is common in Ceylon, especially in Jaffna where hundreds may be seen in operation raising the water impregnated with fertilizing salts, for the garden culture of onions, chillies, brinjals, tobacco, &c.

Correspondence.

To the Editor.

HOW TO INTRODUCE CEYLON TEA INTO RUSSIA.

DEAR SIR,—Your newspaper containing letter from an Anglo-Indian Major respecting the chances of introducing Ceylon tea into Russia through St. Petersburg I have read with great interest.

I think the Major writes a good deal sense and agree with him that it is possible to introduce Indian tea not only into the capital of the great tea drinking people but also into the other towns of the Russian empire. The first step toward attaining this object is to remove the prejudice existing in the minds of the Russian grocers and tea dealers who are under the impression that Ceylon tea is scented by artificial means and is unfit for Russian consumers. Secondly, the planters should only send those qualities which would suit the Russian market either in that pure state or mixed with the weaker brands of Chinese tea. The writer has found from experience that the Russian public will not drink Ceylon tea in its pure state on account of its being too aromatic and strong in flavour. A Russian grocer to whom I sold several chests in Moscow made a handsome profit by mixing the superior brands of Ceylon tea with the inferior qualities from China. The best plan for the Ceylon planters is to be independent of the Russian grocers and the Russian tea merchants and open a *small* shop on their own account in St. Petersburg on the Nevski Prospect. They can then sell the tea in its pure and natural state as mixed with the Chinese brands and let their article stand or fall on its own merits. The writer is convinced that the only obstacle that prevents the Russian public from drinking Ceylon tea are ignorance and prejudice, and also because they have not yet accustomed their palates to the taste. Tea drinking, like many other things in this world, is a great deal a matter of imagination, especially among a people whose palates have not yet been educated by the questionable benefits of civilization. The Russian peasant who pays Roubles 2 a lb. for rubbishy tea has not much idea of aroma or qualities. So long as he is told it is "tehai" (tea) by the grocers, he believes them, and drinks the rubbish which they supply him with in blissful ignorance of what it is composed. It may be tea or it may be kapree grass for little he knows. It would not be difficult for the Ceylon planters to give him the genuine article at the same price as he is now paying for adulterated and rubbishy mixtures.

In case the writer, who has himself sacrificed money and time on this object, can be of any use to the Ceylon planters by means of his influence with the Russian press, the merchants, or with the authorities, he is willing to offer them his services, provided that he is fairly remunerated for his exertions on their behalf.

If Indian tea is to be introduced into Russia there is no time to be lost, for the Russian merchants in China have already opened large shops in Moscow and St. Petersburg where the genuine tea is now being sold at a fair and just price. One of the principal shops was only opened this spring. It is fitted up in the Chinese style, and the assistants are Celestials. I hear they are doing a good business and I do not see why the Ceylon merchants and planters should not follow their example.—Yours respectfully,

WM. BARNES STEVENI,

St. Petersburg Correspondent for the *Daily Chronicle*.

PLANTS AND PESTS.

Franklands, Wategama, Aug. 4th.

DEAR SIR,—I have sent you by this train some cotton seed with numbers of red poochies taken out of an open box standing in an open shed near the store of this estate, also a branch of a tree called by the Sinhalese *godakirilla* growing on this estate. Wherever this tree grows you will find numbers of these red poochies swarming around and crawling all over the young branches living on the sap of the young shoots and flowers; the tree is nearly always in flower more or less. I have found by experience that whenever these poochies scent any of my cotton plants having flower and young pods they leave the *godakirilla* tree and at once attack the cotton flower and young pods. To test it further I placed some cotton seed sent to me by Mr. Joseph of Matale in a box as above described, and within a week the seed and box were covered by these poochies and only a few remained on the *godakirilla* tree. The distance from tree to the box is $\frac{1}{2}$ mile. The Revd. S. Lindsay calling here yesterday: I showed him the box with cotton seed; the box and seed were covered with poochies. Though we have this enemy to destroy more or less our cotton crop, yet at times we will be able to secure a good crop, but we must not plant again the same land or land near it for a few years. It is only yesterday I met a planter who secured one good crop and obtained 40 cents per lb. from the Company, cleared some forty rupees per acre and in this year planting again in another district among cacao, and I have heard of others who could not clear their expenses. Cotton wants a good rich soil and good rains up to crop time. Insect pests will come and go; the home of the black bug was originally the *mililla* and *rukattana* trees, it afterwards took to our coffee; the croton bug and caterpillar had its home on the *keppetree*, afterwards destroyed the croton oil plant. Even the rats sometimes come by hundreds. I remember once, in a week about twenty acres fine coffee was destroyed by them on an estate I had charge of. We must ever be on the watch, and when we find an insect pest coming we must at once do our utmost to eradicate it before it gets too large a hold on us. The *godakirilla* tree on this estate is about 15 ft. high with a great spread of branches leaf oblong shape. I understand from natives they grow much larger in the jungle.—Yours truly,

J. HOLLOWAY.

[The tree of which Mr. Holloway sends us a specimen is the *Holoptelea integrifolia* of botanists, and the Tamil name is *ail*, *aigilli*, or *kancha*. There does not seem to be any affinity between it and cotton. The little red bugs or beetles, which, on the box being opened, ran about after a very lively fashion, are amongst the most common and most annoying pests of the cotton plant. We remember seeing them in multitudes on cotton cultivated in the Jaffna Peninsula in 1842 by the Messrs. Whitehouse brothers (who came to Ceylon from Demerara, by the way) and Mr. Hardy, and which cultivation was apparently not a success, for it was not persevered in.—ED. T. A.]

KINO.

Nuwara Eliya, Aug. 18th.

SIR,—Will you kindly inform me, what is kino? How is it prepared? What is it used for &c.?

I have repeatedly been asked these questions.—Yours faithfully,

T. P.

[Kino is a general name used in the drug market for the astringent gums or inspissated juice of several trees, such as *Eucalyptus resinifera*, *Butea frondosa*,

and *Pterocarpus marsupium*. It is used medicinally, and also in the arts, especially in dyeing. The London market rate for gum kino is given each month in our *Tropical Agriculturist*.—Ed. T. A.]

CACAO IN CEYLON.

Kandy, Aug. 18th.

DEAR SIR,—Your Uva correspondent "102s 6d," does not seem convinced of the accuracy of my statistics that, up to the season 1883-84, cacao went on increasing its yield to 5 cwt. an acre, but he admits that the best returns he knows of from cacao last year, are crops of 2 at 3½ cwt.

I suppose he did not understand my table, which for that period is as follows:—

235 acres	1876-77	@ 5 cwt.	1,175cwt.
191 "	1878	" 4 "	764 "
1,953 "	1879	" 3 "	5,84 "
2,065 "	1880	" 1 "	2,065 "

4,444 " in clearing gave the crop 9,863 "

The computation of this acreage can hardly be contested in the face of yours, that, in March 1881, 5,460 acres were in cultivation; for it assumes that only about 1,000 acres have been planted in the season 1880-81, which is rather below the mark, as the general very successful results were then giving an increasing impetus to this cultivation which, but for the mysterious root disease that made its appearance in 1881, would have been an

ELDORADO.

THE PACKING OF TEA DUST IN CHESTS.

Colombo, Aug. 25th.

DEAR SIR,—I wish to caution planters through the medium of your columns against packing tea dust in chests.

Some short time ago I purchased in local sale a break of dust the packages of which each contained 150 lb. of tea. Although they were doubly hooped before shipment they were landed in very bad order at the port to which they were shipped, some 6 lb. per package having run out in transit.

The maximum weight for dust should be about 70 lb., the greatest possible care being taken to see that the packages are not slack packed, lead linings free from holes and the lead of the thickest quality. The nails used by some planters are unnecessarily long: nothing is gained in strength by using nails longer than 1½ inch, the probability being that if they are longer than this that they puncture the lead in being driven in.

I would warn planters against using planks of a less thickness than ½ inch, anything under this being insufficiently strong to stand the numerous movings the packages get between the estate and the retailer. —Yours faithfully, F. F. STREET.

NEW PRODUCTS IN CEYLON:—THE NEED FOR CULTIVATING A GREATER VARIETY OF PLANTS:

ARECAS—NUTMEGS—CLOVES.

DEAR SIR,—It is a matter of surprise to me that the cultivation of products other than tea is so much neglected by my brother planters. No doubt tea must be our main staple, but there is no reason why we should not derive auxiliary help from the cultivation of products suitable to the various climates and altitudes of our tea estates. Seeing, for instance, that land in the low-country, which has been proved by results to be well adapted to the successful growth of tea, will,

in the majority of cases, be found suitable also for the development of other important industries, surely more might have been done in the direction of supplementary cultivations, especially by the large companies which have associated themselves with tropical agriculture in Ceylon of recent years. With the exception, however, of a few arecanuts alongside roads and boundaries the tea bush still enjoys an undisturbed possession of the soil on nearly every estate, and if a solitary nutmeg or clove tree encroaches upon the otherwise well-established monopoly it is more likely to be the result of accident than design. And yet there are few things that pay better than nutmegs if properly cultivated, and they can be combined with tea in moderate numbers (say 1,000 for every 100 acres) without fear of their ever materially affecting the yield of the tea. At present prices the annual return from a well-nourished nutmeg tree ranges from R20 to R50, and there is no early prospect of the cultivation of this valuable spice being overdone; for the reason, probably, that the trees take some considerable time to reach maturity, and planters in the West Indies as well as in the East look to quick returns first and permanent ones afterwards. In the district of Udagama some years ago a number of nutmegs were planted, but the conditions under which the cultivation appears to have been carried on would account for the disappointing result which followed. More recently, and under circumstances which justify the hope of a successful issue, the enterprising proprietor of an estate in the near neighbourhood of Awisawella has succeeded in establishing a large number of these trees, nor is it the first time that this gentleman has taken the lead in planting matters, though his professional duties give him but little time to follow up the experiments he initiates. On an estate in Matale where the climate, one would have thought, was rather too dry for nutmeg cultivation, the growth of several hundred five and six year old trees is excellent, and a maiden crop is now being gathered, which gives every promise of being followed by an abundant yield next season. In the Kelani Valley there should be little or no difficulty in establishing this very valuable tree, but I would advise wide planting, not more than 10 or 12 trees to the acre, or thinned out, at any rate, to this number after the sexes are determined, and all sickly trees should be promptly removed. For further particulars of this interesting cultivation permit me to refer my brother planters to the excellent work compiled by yourself "All About Spices," which should have a place in the library of every planter. —Yours faithfully, NUTMEG.

NEW PRODUCTS IN CEYLON—THE NEED FOR CULTIVATING A GREATER VARIETY OF PLANTS—NUTMEGS &c.

DEAR SIR,—Your correspondent "Nutmeg" in your issue of September 2nd, will be doing good service if he elicits any further information from planters of experience in the lowcountry and who may have more to say on the subject.

Despite the Udagama failure, it would appear that the Matale and Awisawella trials afford grounds for a good deal of expectation, though I much doubt the accuracy of the statement that so much as R50 annual return could be got out of a single tree,—and one of a species which in the Straits thrives in moist climates, yet in Matale, which is a dry climate, can, he says, be brought into bearing in 5 years!

The professional gentleman who is proprietor of the Awisawella estate may be congratulated upon his foresight, for if he has but 3,000 of such productive trees as your correspondent names, he has Rs15,000 as an annual return. So let us hope he is a lawyer and that nutmegs will win him from the pursuit of that baneful following.

Your correspondent "Peppercorn" once referred to nutmegs on a place not very far from the town of Kandiy. Can you rouse him to tell us the age and powers and profits of the trees?—not however such profits as are derived as seed-bearers, but counting the profits at the ordinary market rates of nutmegs?

MOSCHATA.

LOCAL TEA SALES AVERAGES.

Sept. 3rd.

Sir,—After a very strange fashion the editor of the "Times of Ceylon" under the above heading seeks to console local sellers by telling them that in getting 41 cents per lb. for their tea at the local sales on the 27th ult. they were very fortunate inasmuch that, compared with the local sale held on Jan. 8th, they were taking all things into consideration better off by 11 cents!

The view thus given to his readers is an altogether distorted one—what are the true facts of the case?

On Jan. 8th sellers locally instead of receiving as they did 45 cents only ought to have received 58 cents (a difference of 13 cents), this rate being the equivalent of the position of tea at that time, viz.:

Reuter's London average .. 1s
Demand rate of exchange .. 1s 5 5-32d

(These are the figures given by the local "Times!")

In the same way sellers locally on the 27th ult. instead of receiving 41 cents should have received but 40 cents or the equivalent of

Reuter's London average .. 10½d
Demand rate of exchange .. 1s 8 7-16d

(Figures given by "T. of C.")

so at this latter sale the sellers actually got 1 cent per lb. more than the quotations then current sanctioned as a "set off" against the clear loss of 13 cents on 8th Jan. sale.

The difference between the true value of Ceylon tea on the dates mentioned is no less than 18 cents and not 4 cents as has been insinuated, for, on 8th Jan. local sellers were unfortunate by 13 cents 27th Aug. local sellers were fortunate by 1 ,, and this, and in no other way, can the difference ("the little difference") referred to by the editor of "T. of C." between the two sales be truly accounted for, viz. only.. 4 ,,

18 cents

In your issue of the 21st Aug., you give Messrs. Watson, Sibthorp & Co.'s report of the 12th idem, on the Calcutta local tea sales—we find there that at the sale held on 8th Aug., annas 6 and 8 pies was the average price obtained for 16,267 packages—six annas and eight pies equal 80 pies—and as there are in a rupee 192 pies against Ceylon cents 160—it follows that if we half the 80 pies we get very close on the Ceylon valuation of sales in Calcutta. In the case referred to about 41½ cents in the true equivalent, for in every 4 annas in the Calcutta price an additional Ceylon cent must be added after the half has been arrived at, to make up for the difference between 192 pies and 200 half cents = 1 rupee.

These Calcutta reports (they should appear regularly) are most INTERESTING, giving as they do the prices current locally and at the same period for

the previous two years—thus your readers can compare the Calcutta local market with their own and draw their own inferences—true ones—not DISTORTED.

P. S.—I have not a file of the *Observer* to refer to. May I therefore ask what the Calcutta average price was about the 8th Jan. last, and also, if you have got the report, on 27th Aug. last, I have seen no report since 12th Aug.

[The average price given in Messrs. Watson, Sibthorp & Co.'s report of 7th Jan., for the sales of 2nd Jan., was As. 7-1, or about 9½d per lb. The average given in their report of 26th Aug., for the sales of the 21st, was 6 as., or about 10d per lb.—Ed. T. A.]

CEYLON TEA IN RUSSIA.

LETTER FROM THE COMMISSIONER.

Kandy, Sept. 4th.

To the Editor, *Tropical Agriculturist*, Colombo.

Sir,—I beg to enclose copy of a letter received from Mr. Maurice Rogivue, Ceylon Tea Fund Commissioner to Russia giving interesting particulars regarding his mission.—I am, sir, yours faithfully, A. PHILIP, Secretary.

St. Petersburg, 23rd July to 14th Aug. 1890.

A. Philip, Esq., Secretary of the Ceylon Planters Association, Kandy.

TEA FUND.

Dear Sir,—I wrote you last from London on the 14th July, and arrived here safely on the 11th and 23rd same month.

BERLIN.—Passing through that place, where I remained two days, I visited Messrs. _____ a first class firm, who are willing to take up my agency for the sale of Ceylon Teas *exclusively* in Berlin, and with them I visited the two most important tea merchants of the place, viz. Messrs. _____ who are both prepared to *taste* and *try* our teas. Messrs. _____ my agents in London, have therefore been instructed by me to send, as soon as possible, to Messrs. _____ an assortment of tea samples, in small tin boxes, with prices of the different sorts and qualities, c. i. f. Hamburg and f. o. b. London.

They will also do the same for Mr. _____ in Konig-berg (Prussia), a good and active man, with whom I have also arranged to act as my agent there.

Both firms might be able to secure large orders for Ceylon Teas on their respective fields, and it is most important that they should receive samples with full particulars as regards quality, flavour and prices. Samples should be selected in all grades, from the commonest *pekoe souchong* to the best broken and orange *pekoe*.

ST. PETERSBURG.—From all the information I have been able to collect since my arrival here, I come already to the conclusion that there is a *great future* for Ceylon tea in Russia, where it is already pretty well-known, to a *very small extent* it is true, but still *appreciated* for its *purity and cleanliness of manufacture*, and it is not quite true what I have heard in London, that our teas are found too *strong* and too *dark in infusion*, the generality of Russians like a somewhat strong tea and do not at all object to a dark reddish colour, but, what they do not like, at least in St. Petersburg, is the sweet raspberry taste given to Ceylon teas by the water of the Neva!

I have already visited all the most important tea warehouses of this place, who *wholesale* and *retail*—such as _____ &c. all very large tea houses, I have been very well received everywhere and every one of them have told me the same thing as above, but they are all desirous of seeing and tasting my samples, which unfortunately have not been cleared yet at the Customs.

The steamer "Viaka" bringing them over from London arrived here only last Tuesday the 17/29th

July and with all the difficulties, formalities and *bother* of Russian Custom-house, I have been yet unable to clear them, but hope to get them tomorrow when I shall store them in a small warehouse got by me for the purpose and pack them in $\frac{1}{4}$ and $\frac{3}{8}$ lb. packets, label these packets with labels, *as per enclosed patterns*, and distribute them to the several tea merchants, dealers, &c., here in Moscow, Nijni-Novgorod or otherwise, along with a short circular printed in English, German, French and Russian languages, of which I herewith hand you a facsimile.

Moscow and Nijni-Novgorod, I would like to visit shortly as soon as I can get away from this place to be in time for the large fair of the latter place.

Please note that I have to pay for *duty alone* of these tea, *roubles* 650 or a little over £70! other charges for warehouses, packing, petties &c., will amount to over £10. I should like to have the teas analysed by the Government Police analyst, another 50 or 100 roubles—advertised in the Press &c. or otherwise &c., &c., all most important matters, which cost a lot of money. I must live and this is very expensive in Russia, a voyage to Moscow and Nijni and stay there for a couple of months is another expense of at least 1,000 roubles? In Russia, the most autocratic country of the world, everything is done “a coupe de roubles” by “réclame” favors and tips and you can do nothing without tips; to get the key of everything, of every door, of success in business or otherwise, you must tip everybody from the lowest “moulique” to the most influential swell, and it is only in doing so that we shall introduce our Ceylon teas in this country. I have been told that a Chinaman last year has spent likewise over 30,000 roubles in opening a large Tea Retail Warehouse on the Nevskie Prospekts (the largest and most central street here); he has now made his fortune; the Brazil Coffee Company has spent 3 years ago roubles 60,000 to introduce their coffee here and are now doing all over Russia a very considerable paying business as their coffee is now to end [*sic* ?] and drunk by almost everybody.

Another coffee company of some kind, who would not spend the necessary currency in tips or otherwise and tried to do without it, did nothing at all and failed. This is Russia, and it is the same for everything and everybody!

Everyone I have seen here, with my numerous letters of introductions, tells me the same thing. Ceylon teas, with their superiority over Chinese teas, have here a *great* future, but it is no use of thinking introducing them in Russia if your Association is not prepared to spend money largely for the purpose.

His Excellency _____, Director of the Mining Department, with whom I had a few days ago a long conversation on the subject, and who gave the same valuable introductions for Nijni Novgorod, viz: His Excellency, &c. told me that it is most important that I should go there where *everything* connected with business and trade in *general* is done every year. There I must get my teas tasted and compared with Chinese teas, heat the big drum, and from my visit there will mostly depend our success. Captain _____, the Hon'ble Inspector of the Russian Volunteer Fleet, and Mr. _____, Government Engineer (brother of the former), whom I also visited, told me the same thing and gave me also some valuable letters for Moscow and Nijni. The fair has already opened officially a few days ago, but it is only about a fortnight, that all the “haut commerce” will be assembled there and treat real business. My idea would be to leave St. Petersburg in a few days, after I have done here all the necessary; stay a few days in Moscow and then go to Nijni for a few weeks, coming afterwards back to Moscow, but this, after all my expenditure here, will necessitate a new grant of funds! All this is to show you that the work and undertaking are very difficult and that the success of my mission in Russia depends entirely on the amount of money “The Ceylon Tea Fund” is prepared to spend for the purpose, and I should like their committee to bear in mind that unless they are willing to make a real sacrifice of money to do the advertising properly and on a large scale, it would be of no use to do it at all,

to throw away any more money, and I had better clear out of this country and return at once to *less expensive shores*. I have spent already in travelling expenses from London, duty of tea samples, hotel, carriage hire, &c. a great deal over £100 (of which I received only £66 up to the present time, from the Association and you can easily understand that with the £100 granted to me, I cannot go very far. It is not £100 which will be required, but *several one hundred pounds sterling*! Then I can almost guarantee the success.

All the foregoing remarks and reflections induced me to send the other day, on the 20th July-1st August, to Messrs. Malcolm, Kearton & Co., London, the following telegram:—“Beginning encouraging, large orders sure to follow, success depends entirely, large expenditure and voyage (to) Moscow (and) Nijni, duty paid (on) samples, Tea 60 pounds funds require immediate communicate Leake (to) open credit (with) credit.”

M. R., Hotel Europe,” which has been no doubt communicated to you by Mr. Leake, and I trust you have been good enough to place the matter before the Committee of the “Tea Fund” for their *immediate* consideration as there is no time to lose in order to be *in time* for the Nijni fair.

I shall at any rate require at once the balance of £33 due to me on the £100 granted, as I do not like the idea to be left here without money.

1. CUSTOMS DUTY AND WEIGHT OF TEA PACKAGES. Customs as a ready mentioned is most bothersome in Russia. The amount of papers, formalities of any kind, and time lost is simply *awful*, and here again you must tip every one from A to Z otherwise you can do *nothing*.

2. DUTY ON TEA is 21 *Gold Roubles* per pood or 40 Russian Pounds of which 124 equal 112 English Pounds (1 cwt). Payments at the customs must be made in *Gold Roubles* or Government *Coupons*.

The exchange at present is, about Roubles (silver or paper) 83, 75 to 84 for £10, 100 gold Roubles = 135½ to 135¾ silver or paper roubles.

3. WEIGHT OF PACKAGES.—It is most important in making up an Invoice for Russia that the *gross, tare, and net weights of each package* are given *exactly and separately* for each Invoice. There are two ways of passing an invoice at the customs for duty, viz.,

a. As per Invoice sent by the shippers showing *gross, tare and nett weights* which are taken with an addition of 3 per cent on the *net*.

b. With 2 per cent allowance for *tare* on the *gross verified weight*; so that it is important that the tare should be less than 2 per cent of the *gross weight*.

The former entry is somewhat more favourable but requires a great correctness in weights, and would lead to serious difficulties and trouble, if the weights were found here, on verification, not quite accurate.

This is all what I have to report for the present, and I remain, dear sir, yours faithfully,

(Signed) M. ROGIVUE.

LETTER FROM THE COMMISSIONER TO MR. W. MARTIN LEAKE.

We have received for publication the following letter which has just reached the Secretary of the Planters' Association through Mr. W. Martin Leake:—

St. Petersburg, 1st-13th Aug. 1890.

Wm. Martin Leake, Esq.,

Secretary, Ceylon-London Association,

4, Mincing Lane, London, E. C.

Dear Sir,—Confirming my last letter of the 24th July 5th instant, I herewith beg to draw again your serious attention on the very important question of the “*Nijn Novgorod Fair*” on which, as already mentioned, will chiefly depend the success of my mission to introduce Ceylon Tea in Russia. The fair will last only till the 20th instant (1st Sept.), and, as it takes 3 to 4 days to go there, it is now ample time to decide whether I have to go there or not, and in the affirmative whether the Tea Fund is prepared to defray my expenses for the purpose. I shall therefore thank you to send me soon, on receipt of this letter,

a telegram on the subject with positive instructions regarding "Funds" as I shall not leave St. Petersburg at any rate, before the 6th-18th instant. The Nijni Fair is the place where every year all the Russian merchants from St. Petersburg, Moscow, Odessa, in fact from every place in Russia, from Finland, Caucasus, Siberia &c., go to make their yearly purchases, fix the prices of produce, goods, Tea, &c., and transact all kind of business, and it is only after the fair that a merchant would be persuaded to give an order for any kind of goods. Everyone tells me and it is also my firm belief, that there is to be made our first *Reclame*. There our tea must be tasted and compared with Chinese tea; a capital idea would have been to open there a Kiosk for the sale &c. or gratis distribution of tea in cup and in packets, it is still feasible in the shape of a small shop or a tent (easy to be got there) but we ought to start at once. The advertisement would be splendid.

Going there I would take with me a first rate man, well recommended to me by the Swiss Consul. A man (Swiss) of 25 years' business experienced in Russia, speaking Russian fluently, who has been already several times in Nijni during the fair.

I estimate my expenses to go there with a stay of about 12 days, at about 30 Roubles a day, with the most strict economy, or say about 400 Roubles roughly speaking £50st for the trip, all charges of advertising, rent of a local [?] travelling and hotel expenses for two, included, and I think, for this amount, we ought not to lose our chance there.

Kindly consider the question with the committee of your Association, send a wire to Ceylon if you think it necessary and let me have a wire reply without delay.

My samples tea have been landed and cleared at the customs. I had to pay 668 Roubles or nearly £80st for duty and other charges. I have packed it in $\frac{1}{2}$, $\frac{1}{4}$ and $\frac{1}{8}$ lb. packets as per enclosed label in Russian language which I have found more suitable than the one adopted previously; and have already distributed them to a large number of merchants, hotels, restaurants, public bars and private people. The tea has been tasted now by many and, I am glad to say, that the general report and opinion is in favor of its good quality, wanting however more strength and delicacy in flavor and somewhat too dear to compete with Chinese tea. Contrary to what I have been told in London, Russians do not object to a strong and rather reddish dark coloured tea. They make it in the usual way, fill half of the glass or glasses (very seldom they use cups) with made tea, and, with the Samovar (hot-water bottle) always at hand, they fill up the glasses with hot-water, thus making a rather real [?] beverage of very little taste and flavor. The tea pot is again re-filled 3 or 4 times with hot-water until the infusion is quite exhausted and contains no more of aromatic particles. I really cannot say they drink good tea in Russia. What they look for here is more the appearance of the tea before the infusion and most of the people who have tasted my samples complained that they are too dark and have too little of that fine and sweet aroma, the smell before the infusion, which the Chinese Teas have even in the very inferior qualities. Strong, not too dark, high flavoured aromatic and coloured Teas, will I believe, always sell better here than others.

They also complained of our Ceylon packing in $\frac{1}{2}$ and full chests which they qualify as being rough, rustic, coarse and defective, packages without appearance and neatness, most of them broken and made up with old pieces of all kind of wood, as it was the case with my 10 chests samples. This is a most important question and I think a little more care and attention could be paid in Ceylon as regards packing, there is no doubt that the generality of our chests are made too roughly, with all kind of bad wood, and are not strong enough to bear a long voyage and sometimes several transshipments. Would it not be possible and preferable—at least for Russia—to adopt a somewhat similar packing as in China, mat, &c., well made chests of about 25 to 50 pounds nett, not larger of tea with a sliding lid (the top plank cover instead of a nailed one and the whole chest wrapped in some kind of coloured paper, with printings of some kind

(common) representing Ceylon views and or native subjects characters and prints, and again a light gunny wrapper to cover the whole chests. Appearance and neatness for a produce of this kind is a great thing for Russia, and there is no doubt that a well made, neat and well presented package will improve its contents at the eyes of the buyers. It will be, I know, a little more [?] experience for the Ceylon planters, but would greatly facilitate the introduction and sale in Russia, at least for the beginning when all kind of sacrifice has to be made, later on, it will be easy to revert to the old system.

In a long conversation I had again the other day with Captain Vachtina, Director of the Russian Volunteer Fleet, he told me that another good plan for our success would be to have in Odessa a stock of tea of some importance ready to be cleared at the Customs in small quantities proportionally to our sales, there and or in the interior of Russia, and he offered and [?] if these teas were sent direct from Colombo to Odessa by their Volunteer Fleet steamers to place at the disposal of Tea Fund and [?] of their loaded warehouses and to store the tea there in bond free of rent, for any length of time, until they are sold by me. This would be of great advantage considering the heavy duty and exorbitant charges of any kind of a Russian Customhouse. This question has to be seriously considered.

FUNDS.—Messrs. ———, my agents in London, have remitted and [?] a cheque for roubles 166.95 equivalent of £st20 being the balance of £33 6s 8d for the last instalment of the £100 grant and I am much surprised to see that they have deducted from that balance (33 6/8) the excess over £30 grant of tea of their invoice for samples, although you had positively told me in London that you would take it upon your own responsibility to settle this difference on account of the Tea Fund.

It is useless to think that I can sell my tea samples, thus my costs allowance is reduced to £90 or rather £86 only, viz. :—

£33 6s 8d received in Colombo

£33 6s 8d received from you in London

and £20 received from Messrs. M. K. & Co.

who are even out of pocket for £2 10s 4d to my debit.

My expenses up to the present time amounts now to over £150 of which at least £140 are on account of the Tea Fund as per enclosed extract, leaving over £54 out of my own pocket and it is easy to understand that I am spending more and more daily.

I therefore leave you and your Committee judges of the situation which is to become very critical for me, as well as for my mission, if I am not placed immediately in funds. If I had known before all what I know now and what a country Russia is for expenditure, I would have never started on such condition as I did.

I shall be very thankful to you if you would kindly weigh very carefully the foregoing questions and place them without delay before the committee of the London Association for an immediate decision in all the matters. I repeat it, there is no time to lose and I shall wait here your wire reply up to the 6-18th instant, on that date I hope leaving for Moscow where my address will be

"Hotel Dussan, Moscow"

You may communicate this letter to Ceylon, having no copying press I am unable to take more than one good copy of my letters.

It may interest you to hear that two Volunteer Fleet steamers have arrived the other day at Odessa from Vladivostok, with 800,000 pouts equal to about 29,000,000 English pounds, of Chinese tea, of which 40,000 pouts remained in Odessa and the rest is to go into the interior of Russia. Hoping to hear soon from you,—I remain, dear sir, yours faithfully,

(Signed) M. ROGIVUH.

M. R.

EXPORT OF COFFEE AND PEPPER FROM THE MALABAR COAST.

Tellicherry, Sept. 8th.

DEAR SIR,—Accompanying this we have the pleasure to hand you our annual statement of exports of coffee and pepper from the west coast for the year ending June 30th last.

Coffee.—Although from the figures given it will be seen that the total exports of coffee for the past season exceeded those of the previous year, the result taken all round was disappointing and it was a fortunate thing for all concerned that such excellent prices were obtained. Mangalore still continues to receive an appreciable quantity of coffee from North Coorg and Mysore. Tellicherry on the other hand, which may be said to be the central market for coffee on the west coast, drawing a considerable quantity from other ports, is falling off considerably in its actual receipts from upcountry owing to the almost complete extinction of estates in North Wynaad and decreasing crops in South Coorg. Calicut and Beypore both show an improved export as compared with the previous year.

Prospects for the coming crop are decidedly gloomy, and it is very evident that whether owing to want of labour, abnormal seasons, or leaf-disease, it is a recognised fact that crops generally even in the most favored districts are gradually decreasing and this in spite of a larger acreage coming under cultivation, and we anticipate that we shall see a very considerable falling-off in exports for the coming season as compared even with the past.

Pepper.—It will be seen that last year's exports exceeded those for the six years shown in our statement, and we may add that a very considerable quantity of last year's crop is still being held. Prices fell very considerably, and with the reported increase in Singapore, Penang and Java yields and a rising exchange, growers will have to accept still lower prices if business is to result.

The coming crop is reported to be an average one.—We are, dear sir, yours faithfully,

RALPH TATHAM,

* Including the following:—For Ancona, 1,000 cw Tellicherry Pepper, and 100 cwt. Calicut Pepper. For Veni

A PROLIFIC TUBER.—Some time ago a Montrose gentleman received from a friend in Minnesota, United States, a potato which, for curiosity, he planted whole. On being dug up it was found to have yielded no fewer than forty-six potatoes.—*Inverness Courier.* [The other day at Albion estate, New Galway, we saw between 20 and 30 potatoes gathered from one stem.—*Ed. T. A.*]

MINOR AILMENTS AND THEIR CURES.

I

AGUE.—Ague, or intermittent fever, is a common ailment and results from the decomposition of vegetable matter. It is what is called a periodical complaint, the attacks coming on at stated intervals, the patient meanwhile being to all appearances perfectly well. An attack of ague is usually divided into three stages: the "cold" stage, during which the sufferer shivers violently; the "hot" stage, in which he or she complains of a burning heat; and the "sweating" stage, in which the patient perspires profusely.

This complaint untreated, shows no tendency to get well. Its medicinal treatment is perfectly simple, and in acute cases there is no difficulty in obtaining relief. An excellent remedy is quinine, which is best administered in the form of Tabloids of Bisulphate of Quinine, each containing five grains. It is customary to administer three of these Tabloids between two successive attacks of the disease.

ANEMIA.—This is the medical term for poorness of the blood, a condition which occurs most frequently in young and badly nourished females. There is always more or less pallor of the face and lips. The appetite is poor; the patient has great difficulty in doing her work; has puffiness about the face, legs, and ankles; the circulation is weak; and not infrequently palpitation of the heart is a common symptom.

This condition goes on progressively increasing unless remedial treatment is resorted to. A most useful preparation of iron, which is the best remedy in these cases, is the Wyeth Dialysed Iron, ten drops of which are usually administered on a lump of sugar five times daily. It has a great advantage over most other preparations of iron from the fact that it does not tend to constipate. A course of this treatment, extending over three or four weeks, will usually effect a cure.

To prevent a return of this complaint Elixoid of Calisaya Bark will be found useful, a table-spoonful or more being taken three times a day. The patient should take plenty of exercise in the fresh air and should be well fed, a little stimulant in the form of stout being taken at meal times only.

BURNS AND SCALDS.—One of the best remedies for a burn is Carron Oil, a mixture of equal parts of linseed or olive oil with lime water. Another admirable remedy is bicarbonate of soda (cooking soda), a small box of which should always be kept at hand for immediate use. Cover the burn with it, and bind up with a dry and soft pocket-handkerchief. Hazeline may be applied to the part to allay pain; it also promotes the healing of the injured surface.—"*Health,*" London.

THE TIMBER TREES OF NEW ZEALAND are mostly pines, and very slow of growth, especially the kauri pine, which only grows in the extreme north of the North Island. I saw a kauri sapling (in a government garden in Wellington) which is thirty years old and which is not more than twelve feet high.—*Dunedin Cor.*

ACCORDING to a note in the June issue of the *Revue de l'Horticulture Belge et Etrangere*, there is in the gardens of the palace at Versailles an orange tree more than 450 years old. It is said to have been the first introduced into France, and is known as the "Grand Connetable." The seeds from which it grew were sown at Pampelune about 1416 by Eleanor of Castile, wife of Charles the Third, King in Navarre. Later the tree was brought to Chantilly, then to Fontainebleau, and finally, in 1864, was added to the collection of Versailles. The handsomest Orange-trees, grown in tubs in France, are those in this collection and in those of the gardens of the Tuilleries, and of the Luxembourg Palace in Paris. The gardens of the Palace of Compiègne still contains fifty large specimens, brought there during the reign of Napoleon I. There are also collections of these curious old Orange-trees supposed to be several centuries old in a number of private gardens belonging to various French chateaux. They are always carefully tended, and produce year after year surprising crops of flowers and a good deal of fruit, considering how long their roots have been cramped within narrow quarters.—*Garden and Forest.*

The following pages include the contents of the *Magazine of the School of Agriculture* for October:—

LIQUID MANURES.

WHAT would you say," remarked a well-known agriculturist, speaking to a body of farmers, "if, instead of serving up the liquid portion of your morning beverage of tea, the good wife poured it into the sink, and set in front of you nothing but the tea leaves with a little pepper and salt to aid digestion? Go where you will, you will see running to waste the very essence of what would, if properly stored and utilized, turn a loss account into a profit account at the end of a financial year." The simile quoted above, though it helps to impress one with the ignorance displayed in the ordinary treatment of the excreta of farm animals, is, however, not quite correct; for while the value of tea leaves after the essence has been soaked out of them is practically *nil* to the tea drinker, the solid excreta of stock not only possess, if properly handled, a high fertilizing value, but also serve to improve, in a marked degree, the mechanical condition of the soil. But the fact remains that the urine of animals is really the richest part of their voidance. The urine not only contains a large proportion of nitrogen, phosphoric acid, and potash resulting from the disintegration of animal tissues, but these most valuable ingredients are held in solution, and are most readily assimilable by plants. And yet in this country it is the rule to find the liquid manure from cattle sheds and the dark-coloured drainings from the dung heap allowed to drain off or be washed off, so that it is lost to the cultivator altogether. On the other hand, scientific agriculturists and a few who perhaps know very little of science, are showing a just appreciation of the great value of liquid manure.

Some years ago the Highland Agricultural Society of Scotland offered a prize of £400 for the best scheme of utilizing the urine of house-fed animals. It is evident, however, that the best method of utilizing liquid manure will depend on the different circumstances of each individual cultivator. Where cattle are fed in covered sheds, and where litter is plentiful, the urine is best secured by being absorbed by the litter, so that both liquid and solid excreta are carried off together. Again where urine can be conveniently stored in a tank, soil, leaves, sawdust and various forms of refuse matter should be put in the tank, for in the course of filtering through these substances the liquid deposits a large proportion of the valuable materials it holds in solution, and the contents of the reservoir become a useful manure. Again, there is the option, where convenient, of distributing the manure in the liquid form without using any absorbents, but care must be taken in adopting this method. Fresh and undiluted urine, as is well known, has a caustic and injurious effect on vegetation, but when diluted to any appreciable extent, its application never fails to cause a great increase in the crop. Of course, the diluting of the liquid increases the labour and cost of application, but the undiluted liquid cannot be safely applied until it has fermented and decomposed, which will cost a loss of its ammonia unless care be taken to prevent that. The best way of fixing the ammonia in the case of either solid or liquid manure is to add a little gypsum, a very cheap fertilizer, which converts the volatile ammonia into non-volatile sulphate of ammonia.

The most inexpensive method, and that best suited for small landowners, is perhaps the using of absorbents to soak up all the liquid part of the excreta. The urine might be led off into a pit containing these absorbents, or what is still easier the cattle sheds should be strewn with them. Cattle belonging to natives seldom have any form of litter given them, and are generally allowed

to lie on the ground, cold and wet owing to absorption of liquid. Thus the use of litter will not only secure the urine for manurial purposes, but will also benefit the cattle. Straw, sawdust, wood-shavings, coir fibre and coir dust are admirably suited both as bedding and absorbents but where none of these can be conveniently used, even dry leaves, or dry powdery earth should be made use of, so that at least some of the valuable ingredients of liquid manure may be secured instead of being wantonly allowed to run to waste. Care should be taken that whatever absorbents are used, they should not be allowed to lie and decompose in the cattle-sheds, but should be regularly swept away, and new stuff laid on.

Even where cattle are indiscriminately herded together for the night, provision should be made for absorbing the liquid manure. If some such means are adopted by small cultivators, the result will not only be beneficial to the health of cattle as giving more comfort and warmth and securing better sanitation, but also when the refuse with the absorbed liquid is applied to the land, will prove to be of material advantage to their sadly-neglected soils. Those who own cattle but no land to speak of, should also be encouraged to adopt the methods indicated so as to dispose of the resulting manure to some advantage, for undoubtedly it will possess some money value.

OCCASIONAL NOTES.

We are in receipt of the first annual report of the School of Industry, Haputale. It is needless to dwell on the good work done by this institution, the success of which is secured under the superintendence of so able and energetic a worker as Mr. Langdon. "For the farm-work and agricultural teaching," says the report, "the Government has kindly granted us a large reserve of land surrounding the school, on which we hope, by and bye, as the institution develops to cultivate some paddy, potatoes, perhaps cotton, and possibly do some pasturing." According to the Government Inspector's report, dhall, tobacco, cotton, tea and coffee are being cultivated. The students above 9 years of age are instructed in theoretical and practical agriculture by Mr. E. T. Hoole, the enthusiastic Agricultural Instructor, who is an old boy of the Colombo School of Agriculture. We wish this worthy institution all success, and earnestly hope it will receive the support which it deserves.

A visit to the Colombo Lunatic Asylum lately, impressed us with the idea of how much could be done with the mentally-afflicted by tact. It is only one who has made a long and careful study of the insane that can superintend an asylum for this class of unfortunates with any success. One has to study carefully the peculiar traits of the inmates and the inclination and aptability of each individual, before he can utilize the manual power which lay in them, so that labour may at the same time be a source of pleasure to the workers, and, secondarily, a source of income to the establishment which does so much for their support and comfort. The labour of man has been divided by some into (1) purely mental labour, (2) labour with reason, and (3) purely manual labour.

The labour got out of the insane would of course come under the third heading of purely manual labour, or labour which calls for no exercise of the reason. It is this kind of labour which is generally allotted to those whose intellects are dull and undeveloped, with a tendency to a minimum of sound reasoning. In the insane, on the other hand, the tendency is (in addition to a minimum of sound reasoning) a maximum of false and eccentric reasoning, which of all conditions associated with manual labour must assuredly be the most difficult to deal with. It is, therefore, very pleasing to note that at the Colombo Lunatic Asylum about half the vegetables required for the dieting of over 300 patients is supplied by the labours of the inmates, while a handsome return is got as a result of the various forms of industrial work which the different classes of lunatics effect.

The *Evening Despatch*, the evening edition of the *Scotsman*, gives the following racy account of the latest product of Yankee inventiveness:— One of its singular features is that it has cost only 2,000 dols., the amount of an appropriation by Congress to the Forestry Division of the Department of Agriculture "for experiments in the production of rainfall." By means of this sum, it has been ascertained that nature's method of raining on the just and unjust is antiquated, and can be vastly improved upon. In future, all that will be required of the agriculturist will be to set his rain apparatus in order, and go and enjoy himself. There are certain preliminaries, of course, but the Forestry Department of the United States thinks they are of comparatively little consequence, and may be left to the hired boy or orra lad. The first essential thing is to get the clouds together over the dry spot and then blow them up. The precise method is still left in some little doubt, but that is of no great consequence,—the result's the thing. Anyhow, it is accomplished by means of a rain-gun, and an arrangement of electric wires which catch and 'locate' the cloud. The advantages of this will be apparent to the meanest capacity. All agricultural grumbling and writing to the papers will cease, farming will become chiefly a thing of cloud catching, and a new and intensely interesting sport will be devised. After the necessary operations of the day the thrifty farmer will open a gentle rain in the necessary quarter for the night (having previously fired some Paris green into the cloud, for the benefit of the bugs or other insects). The hearts of rural ministers will rejoice at this news. There will be no longer any necessity for their praying for rain, which, when it comes, may prove the salvation of one farmer and the ruin of another. The rain-gun and cloud-catcher will leave nothing to chance, and the ministerial rain doctors will no longer be called upon to address perplexing appeals to Providence.

The medical celebrities assembled at Berlin last August had before them some particulars respecting two alleged discoveries, which, if they stand the test of experiment, may prove to be of inestimable value. One of these is the alleged discovery, by the eminent bacteriologist, Dr

Koch, of a germeide which can destroy the bacillus of tuberculosis. If this discovery prove to be genuine it may well be hailed with feelings similar to those with which the blind man hails the surgical operation which restores him his sight. Tubercular consumption in the human subject has always been regarded as an incurable disease, which condemns thousands every year to a lingering death; and nothing but a change to a very dry climate, in a foreign country, has ever been known to check, even for a time, the progress of this fell disease. Among cattle and poultry, tuberculosis is a deeply-rooted and widely-ramified disease, which slays its tens of thousands every year. The feeling of fear that haunted the public mind on account of the prevalence of this disease was intensified by the confessed impotence of veterinary and medical science to ward off that danger, or even to form an accurate estimate of the extent of that danger. It was known that the disease was hereditary; that it was communicable from man to animals and from animals to man; and that was about all that was known about it. Our "expert" friends were always wrangling with each other as to whether the milk or meat from a tuberculous beast could be safely used as an article of diet; and while the meat inspector tried to guard the public against eating of the tuberculous flesh, no one could ever be sure that the milk he was drinking was not loaded with the germs of this deadly disease. But if Dr. Koch's discovery proves genuine, all this waste of human health and life, and all this loss to dairy farmers and stock breeders in general, will be saved for the time to come. The other discovery is that by M. Roux, and is to the effect that broth made of brewers' grain kills the microbe of Asiatic cholera. Should this discovery also stand the crucial test, it will certainly prove a valuable one too. Medical Science has made vast progress during the last half-century, but these most recent discoveries, if genuine, will prove equal in value to any discoveries that this science has made in the whole course of the Victorian era.

INDIGENOUS FOOD PRODUCTS: CULTIVATED AND WILD.

By W. A. DE SILVA.

Leguminosae.

28. *Adenanthera Pavoniana*, L.; Sin. Madetya.

This is a tree growing in the warmer parts of the Island. It attains to large dimensions and has few branches. The bark appears to be of a scaly nature with indentations all throughout. The leaves are compound (pinnate) and are of a light green colour. Like most other leguminaceous trees, the leaves close towards sunset and return to their natural position at daybreak. The flowers are borne in clusters and they are of a whitish colour, especially the stamens, while the calyces are green. The pods are from 3 to 4 inches long and curved to a slight extent. Five to six seeds are found embedded in a somewhat leathery pulp. The seeds are round, convex on both sides, and of a bright red colour. When fresh they are soft, but the dry seeds are hard with a glazed appearance.

This plant is, correctly speaking, not a food-producing one, except in so far as the seeds are sometimes roasted and eaten. The roasted seeds are sometimes sold in the market, but are considered to be heating, producing, as is popularly believed, a defect in the hearing powers of those who eat them.

In India it is said that the dry seeds are worn as ornaments, made into necklets and bracelets. Locally these seeds are used for weighing precious metals and medicines. It is the weight known as a *manchadiya*, and 20 *manchadiyas* form a *kalan*, the weight of a 1-cent piece; a hundred of these go to form a pound. The almost uniform weight of these seeds makes them suitable for this purpose.

The *Adenanthera* yields a good light-grained timber used for building purposes.

The leaves and bark are locally used for external application in cases of swellings and sprains, and the leaves are said to possess a peculiar property of extracting poison caused by snake bites.

29. *Tamarindus Indicus*, L.; Sin. Siyambala.

This is a large tree growing to a great extent in the warmer parts of Ceylon. The tree attains to very large dimensions, sometimes 20 feet in circumference and nearly 80 feet in height. The stem is erect and much branched towards the top. The leaves are compound (pinnate) with small oblong leaflets arranged in pairs. The flowers which are borne in clusters have white petals dotted purple. The fruits are somewhat cylindrical from three to twelve inches in length, and contain from two to six seeds. The pericarp of the fruits, when ripe, is of a greyish colour, thin and brittle. Previous to ripening they contain a white coloured acid substance, which, when ripe, turns into a brown-coloured soft pulp, which is of a sweetish acid taste.

The seeds are flattish and smooth, and the brown red outer coating is hard and has a glazed appearance.

The young leaves of the tamarind are made into a curry of a rather acid taste, reputed to be a very cooling food.

The pulp of the fruit is used as a condiment generally among the Tamils, and hence it is collected and sold in the bazaars. It is also made into a jam by the addition of a large quantity of sugar.

The ripe pulp mixed with sugar has slightly purgative properties. The kernel of the seed is also sometimes roasted and eaten. As a medicinal plant the tamarind is in high repute among native medical practitioners. The tender leaves are used to reduce inflammation in sore eyes and as a poultice in boils, &c. The seed is employed in toothache and diarrhoea. The timber is used for cabinet work.

30. *Dialeum Orideum*, L.; Sin. Gal Siyambala.

This is a tree growing in districts north of Kandy at no great elevation. It has lanceolate smooth leaves, and bears panicles of flowers. The epicarp of the fruit has a pretty velvet appearance. The fruit is of an agreeable acid flavour and is sold in bazaars. The timber is strong and handsome, and is used in making ornamental furniture.

LIFE HISTORIES OF INSECTS INJURIOUS
TO VEGETATION IN CEYLON. VII.

BY ABA.

THE WIREWORM—(Continued.)

Prevention and Remedies.—The only good thing in connection with chena cultivation is that it prevents to a great extent the increase of noxious insects, for in the act of burning a clearing not only are the insects that found harbourage in the trees and shrubs of the jungle, but also the eggs and larvae of those that are found in the soil are destroyed. To this fact may be attributed the immunity our chena crops have always enjoyed from the attacks of the wireworm and other such insects.

In England it is said that the wireworm does great damage to corn, hops, and other crops, and there is every reason to believe that when we give up chena cultivation and grow our crops on ploughed and manured land, the wireworm will be as troublesome here in Ceylon as in England.

When grass land is newly broken up for cultivation, it is always advisable to adopt some means beforehand to diminish the number of insects and prevent their further increase. This is effected by an application of lime, ashes or any other substance obnoxious to insects. Paring and burning should be practised not only for destroying the grub, but also as a means of getting rid of the weeds and roots of grass that might feed such grubs. The burning of all rubbish on the ground is also recommended. Strips of grass should not be left growing in or at the sides of fields, lest the wireworms feeding in these spread and damage the growing crops.

It is said that wireworms injure and weaken a great deal more than they actually destroy. Therefore it is necessary that such methods of cultivation as will ensure a vigorous growth be adopted, so that the plants may be in a fit condition to use all the available plant food and push forward and get over the attack, without sinking under it as in the case of weak plants.

In England drilling manure with the seed has been found useful. A mixture of guano with superphosphate of lime, drilled with the seed says Miss Ormerod "brought a good crop, whilst the rest of the plants on the field perished by wireworm: in this case wireworm was found between the drills, which seems to point to the safety of the crop being from the dislike of the grubs to the manure, as well as to the increased strength of growth. Dissolved bones drilled with the seed also do good."

Soot applied during rain, so that it may be washed down into the soil, has been found to be useful both in driving away some of the wireworm and stimulating the vigorous growth of the crop. Nitrate of soda and common salt mixed in the proportion of one hundredweight of the former to two of the latter have proved useful.

The following is taken from Miss Ormerod's "Manual of Injurious Insects:"—

"With regard to *mechanical* applications, one of the common remedies used among corn crops is, rolling with a heavy roller so as to solidify the surface and thus prevent the grubs from travelling through the ground. The remedies used amongst root-crops are drill-hoeing and horse-hoeing twice

in a place, hand-hoeing close to the rows, and chopping out to stop the progress of the wireworm along the drills; here the object of the treatment is by stirring the soil, to encourage the growth of the plants, and to harass and disturb the wireworm.

"In attack of wireworm on young beds of year-old seedlings of forest-trees, it has been found of use to scrape the earth back from the collars of the young plants to a distance of about six inches, so as to lay bare the larger roots, and hand-pick and destroy the grubs. The roots were then dusted freely with equal parts of lime and fresh dry soot, and fresh soil used to cover them; the old soil being removed and charred, to kill any wireworm that might remain in it."

(To be continued.)

THE LAWS OF CEYLON RELATING TO
AGRICULTURE.(1.) *Cattle Trespass, No. 9 of 1876.*

I. The word "cattle" when used in this Ordinance means bulls, cows, oxen, heifers, calves and buffaloes.

The word "animal" means except when it is otherwise expressed: cattle, sheep, goats and swine.

The expression "irrigation works" means tanks, bunds, canals, sluices, channels and other works used for irrigation purposes.

The expression "duly authorized person" means any person specially or generally authorized to act under the provisions of this Ordinance by the Government Agent for the Province or the Assistant Government Agent of the District wherein such person resides.

II. Any proprietor or occupier of land (or any other person by his direction) may seize, tie up and detain animals trespassing thereon. Such land shall be fenced according to local custom, or may be unfenced if, by the established custom, no fence is required. The detention of such animals shall be until the damage, if any, and the fair expense of their keep (assessed in manner herein-after stated) shall be paid or recovered.

III. Animals found trespassing on irrigation works may be seized or pursued off the works and seized by any person duly authorized.

IV. The owners of any stray cattle shall in the case of trespass on private lands be liable to pay to the proprietor or occupier, and in the case of trespass on irrigation works to the Government Agent or the Assistant Government Agent the full amount of damages arising by reason of such trespass; and if such trespass was committed in the night time, he shall be further liable to pay to the Crown a fine equal to the amount of the damages awarded.

V. *Procedure.*

(1.) Notice of seizure or trespass shall, with as little delay as possible, be given to some Police Constable or local Headman having jurisdiction in the District. All rights under this Ordinance shall be forfeited if such notice be not duly given.

(2.) Such Constables or Headmen shall thereupon inspect the land and animals, and with three or more respectable persons of the neighbourhood, if available, (otherwise alone) shall (a) Ascertain

the owner or owners; (b) Assess the amount of damages; (c) Furnish a report stating (1), the particulars relating to the nature of the trespass; (2), the names of the owners (if ascertained); (3), the amount of damages; (4), the names of the assessors.

(3.) The Police Constable or Headman shall take charge of the animals if the amount of assessment be not immediately paid.

(4.) Forty-eight hours shall be allowed for such payment of damages and expenses of keep.

(5.) On failure of payment within such time, the proprietor or occupier of the land so trespassed upon shall produce before the Police Court or Village Tribunal the report which, if verified by oath or affirmation in open Court of the Constable or Headman who furnished it, shall be received in evidence.

(6.) Notice shall issue to the owner, which notice, when the owner has been ascertained, shall be served on him or left at his last known place of abode.

(7.) The Court shall then summarily make inquiry and take such evidence as it thinks fit, and if it thinks fit, award the aforesaid damages, charges for keep and penalty to the Crown. Such summary inquiry may be made even without such notice as aforesaid, provided after reasonable inquiry the owner has not been ascertained.

(8.) Twenty-four hours shall be allowed for the payment of such awarded damages, charges and penalty.

(9.) On failure of payment within such time it shall be levied by sale of the animal, and if necessary by distress on the other property of the owner of the animal.

VI. In any case when any trespass shall be proved, whether any damage shall be proved to have been sustained or not, the Court may award a fine not exceeding Five Rupees for each animal. And in case of trespass on private land, the Court may, at its discretion, order a share of such fine, not exceeding one-half, to go to the owner or occupier of the land, the remainder to the Crown.

VII. Even if animals be not seized, yet on proof of trespass, and on notice and procedure as above indicated, the owner shall be liable.

VIII. (1.) All cattle over eighteen months old shall be branded, and the owners shall in the month of January every year furnish the Chief Headman with a correct description of the brand marks.

(2.) Each Headman shall make a return to Government on or before the 1st March every year.

(3.) On default of branding and furnishing such report, the owner shall be liable to a penalty not exceeding twenty-five cents for every head of cattle not branded, and to a penalty not exceeding Two Rupees for every omission to furnish such description.

(4.) The moiety of any penalty shall go to the informer.

(5.) Nothing herein contained shall extend to any Chief Headman's division, which shall be within the operation of the Village Communities Ordinance, 1871.

IX. Any person unlawfully removing cattle detained for trespass, or causing animals to trespass upon the land of others, or driving the animals of others, or conniving at such animals

being so driven, upon his own land with intent to take proceedings for cattle trespass, shall be punished by such punishment as a Police Court has jurisdiction to award.

X. (1.) When cattle committing trespass cannot be seized or identified, so that the owners may be ascertained and proceeded against, the Government Agent or Police Magistrate of the District may grant a license to shoot.

(2.) He may also on granting such license appoint a fit person to endeavour to seize or identify the cattle, so that they may be shot only on failure of seizure.

(3.) They may be shot even when driven off the land or irrigation works in the endeavour to seize.

(4.) The license shall be in force only for one month from the date thereof.

(5.) Pigs trespassing may be shot without license, so also elephants and wild buffaloes trespassing on irrigation works.

XI. The carcase of any stray animal shot shall be the property of the owner of such animal, but if the owner cannot be found nor any claim made therefor, it shall be sold by the local Headman, and the proceeds paid to the Kachcheri.

XII. A Police Court or Village Tribunal may impose the full amount of damages or penalty under this Ordinance, notwithstanding that such amount might otherwise be beyond the jurisdiction of such Court or Tribunal.

XIII. This Ordinance shall not affect any common law right in respect of damage sustained by trespass of animals.

H. A. J.

BASIC CINDER.

Basic cinder or slag, known chiefly as Thomas-slag (after the name of one of its inventors) on the Continent, and sold under the name of slag-phosphate-meal, is a manure, the merits of which have been much discussed of late, and one that is gradually coming into favour. Thomas-slag is a substance formed as a bye-product in the manufacture of steel from pig-iron by the "basic" or "Thomas-Gilchrist" process. Steel is a compound chiefly of iron and carbon. It may be made from pig-iron, which is also a compound of iron and carbon, but containing a larger proportion of the latter element than exists in steel. Hence in order to convert pig-iron into steel, a part of the carbon must be oxidized. Besides carbon there are other impurities in pig-iron which must be got rid of, and one of these is phosphorus. A great many iron ores contain phosphorus to an extent which makes them unfit for the manufacture of steel of good quality, and owing to the difficulty which was experienced in ridding the pig-iron of phosphorus, only the purer varieties were used, and steel was a dear commodity. But in 1879 Messrs. Thomas and Gilchrist discovered a method by which the phosphorus could be removed from pig-iron, the result of which was a revolution in the steel trade, and steel came to be much more widely used than it had been before. The new process consisted chiefly in adding lime to the pig-iron, and lining the "converter," in which the iron is heated, with lime instead of bricks composed largely of silica. That is, lime which is a base was used instead of silica—an

anhydrous acid—hence the name "basic" cinder. A blast of air is sent through the iron in the converter, which is raised to a very high temperature for the purpose of oxidizing part of the carbon and other metallic and non-metallic impurities. Among the latter is phosphorus which is oxidized into phosphoric acid. This unites with the lime and forms a kind of phosphate of lime. When the blast ceases, the oxidized impurities together with the phosphate of lime rises as a scum to the top of the converter, and constitutes what is known as basic or Thomas-slag. The slag is tilted into boxes and left to cool, and for some time was cast aside as a refuse material. Many attempts were made to extract the phosphoric acid, but though some succeeded, it was found that the processes could not be worked at a profit. Sometime later it was ground to a fine powder and applied as a manure with much advantage. The phosphate of lime in basic cinder was found to be not the ordinary tri-basic phosphate of lime found in bone and natural mineral phosphates, but a tetra-basic phosphate which contained 224 instead of 168 parts of lime. This compound has an advantage over the normal phosphate to the agriculturist, for owing to the phosphate being supersaturated with lime, the lime and phosphoric acid are in a somewhat feeble state of combination, so that the compound can easily be decomposed by the carbonic acid in the soil, and by the acid juices in the roots of plants. Therefore crops can without difficulty extract the phosphoric acid from the manure. The amount of phosphoric acid will, of course, vary with the amount of phosphorus in the pig-iron,—from 14 to 20 per cent, equal to from 30 to 40 per cent phosphate of lime. Basic slag must be used in the form of an exceedingly fine powder for appreciable effect. It has been found suitable for leguminous crops, turnips, clover, and grass, secondly for cereals; and is well adapted for application to marshy land, stiff clays, and wet land generally, owing to the caustic lime which it supplies. It should be well incorporated with the soil and applied early for effect. No harm is said to result even when applied in large quantities, but 4 to 10 cwt. per acre, according to circumstances, is a fair dose. There is an abundant supply of the substance, which is a valuable manure with a future in store for it if it could be purchased for about R22—R25 per ton ground to an exceedingly fine powder. It should have a guarantee both of fineness and percentage of phosphate.

CRUDE THEORIES REGARDING THE ORIGIN OF CERTAIN PLANTS. III.

BY W. A. DE SILVA.

My subject in this paper is the sweet-potato, *Batatas Edulis* (Sin. Batala). This yam is a common food-product in villages, and ranks perhaps next to rice and kurakkan in the extent to which it is eaten. The poorer inhabitants of the rural districts live on nothing but this at times, and truly they need have no cause of complaint against the force of circumstances. The original home of the plant is supposed to be America, whence it was evidently introduced at a very early date, as apart from the plant being quite

naturalized here, the natives look upon it as an indigenous product. There is, moreover, no such affix as *Rata*, signifying foreign, which characterises a comparatively modern importation, while the fact of its being a subject of folk-lore is sufficient to prove that it has existed for a very long period in the island.

Our story starts with a widow and two daughters who lived together in comfortable circumstances, till the marriage of the two latter, one to a man of wealth, the other to a husband of moderate means. Bad times coming upon the widow, she paid a visit to her rich daughter, hoping to get help from her, but though she arrived faint and hungry, her ungrateful child offered her no refreshment; and even when a request for food was made, the answer was that there was nothing in the house to eat. At first the old woman was inclined to pity her daughter who, she thought, must have become poor like herself, but again she became suspicious of her child's ingratitude, and when the latter left the house for a while, she looked about and discovered that a pot full of rice had been hidden away. Full of sorrow at the thought of her daughter's ingratitude, she wept bitterly, with the result that some of her tears fell into the pot of rice. Then she left, and sought her other child who received her with all hospitality. The ungrateful daughter was pleased on her return to find her mother gone, and proceeded to partake of her meal alone, when, to her astonishment, she found the rice reeking with blood. Such was her punishment for her want of filial affection. But the strange sequel is the important part of this account, for when the bloody meal was thrown away, an unknown plant sprung up from the place whereon it fell, which in course of time developed a tuber to which was given the name Batala, derived from *Bata* rice, and *la* blood—an unpleasant enough etymology for so estimable a food.

BUILDING MATERIALS.

SECTION I. STONE.

BY A FACTORY APPRENTICE.

The names of the various sorts of stones are derived either from the places where they are quarried, or from the substances which principally enter into their composition. The term "Free-stone" is, as its name implies, that sort which can be wrought with the mallet and chisel or cut with the saw, an operation which cannot be performed on granite, whose hardness requires it to be dressed with pointed tools of different weights and sizes. It includes the two great divisions of Limestone and Sandstone.

Hardness, tenacity and compactness are the three chief qualities requisite for a building stone. It is not the hardest stone which has got the greatest tenacity or toughness, for limestone, though much softer, is not so easily broken as glass.

Nearly the same causes, which destroy the rocks on the surface of the globe, accelerate the decay and destruction of stone. Such causes are of two kinds, those of decomposition, and those of disintegration. The former effects a chemical change in the stone itself, the later a mechanical

division and separation of the parts. The effects of the chemical and mechanical causes of the decomposition of stone in buildings are according to their situation, as in the town or country. In populous and smoky towns the state of the atmosphere accelerates decomposition more than in those placed in the open country.

A great advantage which a country building appears to possess over a building situated in a populous and smoky town, is owing to lichens, with which the country building is almost invariably covered, and which seem to exercise a protective influence against the ordinary causes of the decomposition of the stone upon which they grow.

Mineralogists and Geologists enumerate a great variety of stones, but the Architect and Engineer recognise but three great divisions, known as "Freestone, Slabstone, and Rubblestone."

Freestone.—The name of this stone is derived from the freedom with which it is worked, one of its leading characteristics is, that though durable against weather, it is yet soft enough to be worked with the mallet and chisel. It is therefore particularly valuable for purposes, such as columns and their capitals, cornice, frieze and mouldings, or for the building of walls, where external surfaces are desired. The following are the different varieties of Freestones:—

1. *Marble* is one of the primitive limestones, being a carbonate of lime, and when pure is perfectly white. On account of its durability, its non-absorption of water, the ease with which it is worked and the high polish it takes, it ranks first amongst the freestones.

2. *Alabaster* is a fine white stone resembling statuary marble; it is a sulphate instead of a carbonate of lime, therefore not a marble, being very brittle and not durable in the open air is used for interior ornamental purposes.

3. *White Sandstone*, next to marble in point of grain and durability, is the fine white sandstone, which is composed of a fine silicious sand held together by a peculiar natural cement, so fine that it cannot be perceived between the grains. It bears fine carving, is strong and durable, and not affected by the weather.

4. The *Oolite*, so called from its resemblance to the roe of a fish, is of a yellowish white colour, its grains vary from the fineness of sand to the size of peas, united by a natural cement quite visible to the naked eye, it is very soft at first but hardens from exposure. It is used for building purposes solely on account of its fine grains.

5. The *Ferruginous or Red Sandstone* consists of a coarse silicious sand, cemented by an oxide of iron. This stone likewise acquires hardness by exposure to the open air; it is well adapted for bridge building, especially in arches of large span.

6. *Soapstone* will stand great heat, and is therefore applicable for fire places and chimney pieces, &c., but is too soft for building with.

7. *Granite* ranks amongst the most hard and durable stones. It bids defiance to the saw and almost to the chisel, but still it can be worked, with expense, to any form, to a fair but not a smooth surface.

Slabstone is of a character which splits into parallel plates; it possesses great strength in the direction of its laminae. This stone must always

be used with its natural joints in a horizontal position. It is especially used for flooring and covering of roofs, or in the foundation of extensive buildings, as being flat and affording equal pressure on a large surface of ground.

Rubblestone is of a character which splits into from their hardness cannot be sawn, and from their brittleness and irregularity of grain resist all attempts to reduce them to regular shapes, save by very expensive processes. These stones are only used for rough work in foundations, or filling in walls of more than ordinary thickness, backing and strengthening them in parts not exposed to view.

(To be continued).

THE GARDEN SPIDER.

The Spider belongs to the class Arachnida of the sub-kingdom Annulosa. The true spiders (Araneida) is distinguishable as having no true antennae, and the head and thorax amalgamated into a "cephalothorax." The spider after birth undergoes no transformation, and merely increases in size, though it changes its skin repeatedly before attaining maturity.

The web of the Garden Spider, though very wonderful in construction, is so familiar that a description of it would be superfluous. The material of which the web is made is the secretion of a special gland, and it is moulded to its proper shape by being passed through certain conical little organs which are placed at the extremity of the abdomen, and are termed the "spinnerets." The apex of each spinneret is perforated by a large number of little holes. The silk is at first fluid, but hardens rapidly on exposure to air. A single filament of silk is thus produced by each of the perforations in the spinneret, so that what is called a single "thread" in a spider's web is really a cable, composed of a great number of the most delicate fibres agglutinated together. The webs of the Garden Spider are almost always spun between the leaves of a plant or in the space between two or three plants situated in close proximity. The elasticity and strength of the material of the web is proved by the fact that it is uninjured by a strong breeze. Should a thread be broken by a violent gust of wind or some other unlooked-for accident, the spider effects the necessary repair almost immediately. By a singular instinct the spider prevents the web from being unduly stretched with the chance of snapping, by hanging pieces of wood or pebble to give it weight. The spaces in the web contains a sticky substance which is intended to entrap insects by their legs or wings. The spider kills its prey not by a sting like that of the scorpion, but by a pair of strong hooked jaws (poison jaws) which have their points perforated for the escape of a poisonous fluid secreted by special glands. As is generally known all spiders are carnivorous, but the point of interest about the Garden Spider is that the flies and insects it captures and kills are nearly all injurious to vegetation. Langsdorf goes the length of saying that *Mygale aricularia*, a Garden Spider, only eats insects injurious to vegetation! At any rate there seems sufficient reason for

believing that the Garden Spider is a friend rather than an enemy to the agriculturist, and as such should be treated with due mercy.

V. KUMARAVELU.

GENERAL ITEMS.

The strawsonizer, apart from its value as a distributor of manure and seed, has proved a most effectual means of keeping off insects from certain crops by the perfect way in which it distributes insecticides. Already it has been found that paraffin oil, as sprayed by this machine, is a specific for the turnip fly pest, and now it is coming to be recognised that the strawsonizer may be effectually used for combatting the potato disease fungus. This latter use of the machine opens up a field of the widest possibilities.

Great distress must be anticipated if, as is reported from Cairo, 9,000 acres of rice and cotton have been entirely destroyed, in the province of Garbieh, by an inflow of salt water.

The *Indian Agriculturist* notes that of the eleven Indian students who have since 1880 studied agriculture in England, only two have adopted an independent line of employment, and one is engaged on enquiries on sericulture, the rest holding appointments in no way connected with agriculture; and suggests that these men should be utilized by the Government for taking charge of Crown lands which are in the hands of those who have no special knowledge of agriculture, so that the interests of the Government may be better looked after than they are.

The taste for agricultural education is evidently spreading. We lately referred to the forming of an agricultural department in Egypt, and now the news reaches us that the Government of Monte Video have resolved to found a Superior School of Agriculture and National Stock Farm, and with that view have set apart a large tract of land at Toledo. In the school theoretical and practical education to qualify students for the title of agricultural expert (*perito agronomo*) will be given.

The Kandesh Experimental Farm in India is said to have given most satisfactory results

during 1889-90. Full details of the cost of cultivation have been published, and the following (in Ceylon currency) shows the profit per acre in the case of some of the crops cultivated: Cotton, R12'86; Wheat, R14'80; Sesamum, R5'52; Linseed, R4'85; Rice, R7'00 and Sugar-cane R32'82. The profit per acre on all crops cultivated amounts to R10'66.

According to the British Vice-Consul, at Athens, the Greeks do not show any great aptitude for agriculture, though they are eminently adapted for trade and speculation. The rural districts are thinly populated—cultivation being mainly confined to fruits and vegetables.

Some of the natives of India are said to use, as a substitute for coffee, the beans of the yellow wattle (Tamil *Thumba Chedi*) after roasting them, and in some cases mixing with roasted rice.

A flower is reported to have been discovered in the Isthmus of Tehuantepec which in the morning is white, at noon red, and in the evening blue, and only gives out a perfume at mid-day.

The following subjects were treated of and discussed at meetings of the Agricultural Improvement Society held at the School of Agriculture during the past month. "The Relation of Geology to Agriculture," "The Improvement of Dairying in Ceylon," and "The Need of Technical Education in Ceylon."

The August number of the "Agricultural Gazette" of New South Wales to hand consists of an exhaustive report on the *Pylenchus* worm. The Minister of Agriculture lately announced that he has completed a scheme of education and has secured qualified men to instruct students in the various branches of agriculture. A library and museum are also being formed for the instruction of the students.

The International Congress of Forestry and Agriculture in Vienna was opened on September 1st. The members of the Congress numbered nearly 900, delegates being present from Great Britain, France, Belgium, Denmark, Italy, Germany, the Netherlands, Norway, Russia, Roumania, Servia, Sweden, Switzerland, Australia, India, Brazil, and Japan.

THE TROPICAL AGRICULTURIST MONTHLY.

Vol. X.

COLOMBO, NOVEMBER 1ST, 1890.

[No 5.]

"THE MAN AND THE ANT."

THE above title is not intended as a plagiarism on our old friend *Æsop*. It is meant only to indicate the warfare which has raged from time immemorial between the most intelligent of mammals and almost the smallest—albeit the most highly gifted as to mental power—of the insect tribe. In that warfare man, with all his great gifts of intellect and his vastly superior strength, has been heavily worsted by his relatively insignificant opponent. There are few of us, we imagine, who can fail to share Sir John Lubbock's appreciation of the extraordinary capacity of our tiresome little enemies, for as such we are certainly justified in classing the ant tribe. It is unfortunately the case that in all tropical countries—and in none more so, we should say, than in Ceylon—the opportunities for observing and for appreciating, —after a left-handed fashion,—the qualities of the ant are particularly and regrettably wide. They invade our meat safes, they disturb us in our beds and even extort cries of pain from us when met with in their jungle habitats, and they cap all their aggressions upon their human foes by eating our houses over our very heads. Truthfully may it be said that hitherto no adequate, inexpensive remedies have been devised by which the balance of advantages now so largely in favour of the ant may be redressed in our favour. In spite of all attempts, of the many suggestions which have been put forward, the little insignificant-looking insect continues master of the situation, and daily, in one form or other, makes us feel his power. Has not the so-called ant of the white epidermis almost succeeded in eating a whole Colony—that of St. Helena—practically out of house and home, and rendered it at one time a matter of serious consideration whether it would be practicable for

Great Britain to remain the tenant of that isolated island! We know that the ravages of the white-ant not many years ago, did render such an evacuation within the "range of practical politics," and all methods of treatment tried in other Colonies have failed to keep under this ravaging little intruder on domestic comfort.

We are, therefore, inclined not altogether to pooh-pooh a suggestion offered to us as to a possible method of largely exterminating these little pests which has at least, so far as we know, the recommendation of novelty. It is known that a low range of temperature is as fatal to insect life as a higher range is to its production and maintenance. The numbers in which ants swarm, and the extent of their wonderful subterranean galleries, render it most difficult to reduce their numbers. To get at the "Queen Ant" without the destruction of which all efforts at exterminating are fruitless, is a work often of great labour, and very frequently is wholly unsuccessful. Chemical solutions, to be used in the large quantities necessary, are costly and sometimes difficult of application. Well, it is now suggested to us that we might freeze our foes out of existence in the neighbourhood of our dwellings! We have heard how quicksands are now passed through, in excavations, by the use of freezing mixtures which suffice to turn the moisture of large cubes of soil into solid blocks of ice. The idea now is that a cask of such freezing mixture should be fixed over the main entrance to an ants' nest—the others being closed up with clay, as they become apparent—and that a tube from it should be placed into the hole and also well "luted" with clay. The pressure due to the head of liquid in the cask would suffice to drive the freezing mixture into the inmost recesses of the galleries, and these, it is expected, would almost instantly become lined with solid ice, or at all events would have such intense cold produced in them that no ant, however tenacious of life, could long survive exposure to it. Such freezing mixtures are, we are told, exceedingly cheap—they could not otherwise be used on the large scale they now are in engineering operations—and it may be found that the progress of science in the latter part of the nineteenth century has achieved a victory for which so many past generations have contended though in vain.

WATER IN LANDSCAPE GARDENING.

From an article so headed in the American periodical *Garden and Forest* we quote a passage, which we commend to the notice of those responsible for the upkeep of the pretty grove and sward in "Victoria Park" in which the Band of the Volunteers plays once a week. The fountains in the "Gordon Gardens" prove how greatly water in motion adds to the attraction of a pleasure ground. A nice fountain and fernery with a *Victoria regia* tank would give fresh beauty to a spot already beautiful in "Victoria Park." The amount of water required would not be large; and much of it, by proper arrangement, could be used over and over again. Daniel D. Slade writes:—

"Where the supply is limited, a weeping fountain, which consists of an upper basin into which the water is brought with just sufficient volume to overflow on every side into a large basin below, is perhaps to be preferred. By carrying the pipe to a level with the outer edge of the upper basin the water may be thrown a little above the surface in a jet, or it may be allowed to boil up in the basin. In material and design such a fountain may be infinitely varied. An inexpensive arrangement was carried out in this way. The vase, or upper basin, was formed of an irregular shaped block of freestone, nearly circular and some three feet in diameter. This was supported upon three blocks of the same kinds of stone placed with apparent carelessness one upon the other, the lowest resting in the centre of a lower basin, which was circular and some five feet in diameter. The blocks were drilled for the passage of the conduit pipe and the whole was rough-hammered. The spray of the water which dripped from the upper basin quite sufficed to moisten the ferns and aquatic plants set about its base and the colour of the freestone was quite in harmony with its surroundings."

CEYLON UP-COUNTRY PLANTING REPORT.

THE WEATHER AND PLANTERS' WARDROBES—THE 'TROPICAL AGRICULTURIST'—A NEW DEPARTURE—PRICES FOR CACAO AND CACAO CROPS—COFFEE—TEA—LABOUR.

September 15th.

The continuous rain we are having is rather monstrous, and is trying the capabilities of the planter's wardrobe. The wet clothes accumulate; for the green firewood in the kitchen—and whoever saw any other kind than green firewood in wet weather—can't keep up with the armfuls of splashing "duds" that require to be dried and which are handed back in the morning, warm but moist, and decidedly redolent of wood smoke. With rain night and day, even a good stock of clothes soon gets all wet, and it was not a matter of any surprise to me when I heard that in one district the indoor rig of the planter is at present the dress suit! To the stranger visiting, this style of things would give an idea of there being a high standard of civilization abroad, and doubtless there is; but that it should blossom at this time, and so generally, would be puzzling to account for, but for the weather. All the same: a planter with a healthy appetite does not mind much even if he has a swallow-tailed coat on at breakfast, and sits down to his solitary dinner in full evening dress.

The *Tropical Agriculturist*, which keeps up its character as a practical and thoroughly useful planter's magazine, is certainly improved by having had of late its edges cut at the publishing office, instead of leaving that to the reader. It is a small matter of course, but it is a comfort all the same. It stumps the critic who only cuts a page or two, smells his paper-knife, and then proceeds to review!

Besides this it is evident that the publishers keep abreast of the times, and in small matters as in great are bent in doing all they can for their readers.

The September number, which is before me, is as full of information as any of its predecessors, and the sweep of the editorial net is about as extensive as it possibly can be. Except that it would take up too much space, I would like to jot down all the sources from which the information in its pages have been drawn. To do this one would have to begin with *Punch* and the *London Times*, and end up with the *Japan Weekly Mail*.

Cacao planters, who have of late been realizing the handsome figures of 110s to 115s for their produce, do not quite appreciate the decline in rates, albeit 100s per cwt. for "bright bold" is still a very good price. I am told from home that the absence of American buyers from the market is one of the reasons for the fall, and the big gap between the West Indians and our own is perhaps another. Cacao, too has better prices in the winter months, somehow, than obtains at other parts of the year; so it is to be hoped that ere the bulk of the crop goes home prices may strengthen. I do not know of any produce in the island which has its gingerbread so thickly gilt as a good cacao garden: but that makes it all the harder to bear when some of it comes to be rubbed off. It is like the widow and her mite; where one is so "down on his luck" as that, to part with the coin is easy; the difficulties and trials come in when you have more.

Cacao is looking wonderfully well, and all that I have seen promises a decent crop. Already fair gatherings of pods are to be had, but better tasks will be selected later on. The Moormen who were so anxious a few months ago, to buy up any black rubbish in the shape of cacao that could be got are "easing off" and want now to be tempted. Perhaps their little game of improving the colour by means of the annatto dye may be played out, and they may be considering what next honest employment to turn to.

There is a sprinkling of ripe coffee about, which will need a good price for its parchment to pay for the gathering. "Still, there is more to follow"; and the trees seem as if they would run through the season, and not be very much the worse of it at the end. A nursery of Coorg coffee which I saw the other day, had come up very well, but there was leaf-disease on it pretty bad, although it might have been worse.

A good deal of tea is cut down just now, and the flushing is nothing to boast of. Some of the districts which are cold and wet are anxiously waiting for the genial sunshine, which has not been seen since June or July, so as to encourage the flush and put life into the coolies. The tea-house working at half time is never a very paying concern, and a good many have of late had to be content with that.

Coolies are sufficient, and more, for the planter's wants, and seem rather to enjoy a short time of enforced idleness. If Ramaswamy has been working steadily before, he is like a man who has lost his sleep, and has a good deal of resting to make up. That he does with pleasure, and both the planter and cooly are content.

PEPPERCORN.

NOTES ON POPULAR SCIENCE.

BY DR. J. E. TAYLOR, F. L. S., F. G. S., &c.,
EDITOR OF "SCIENCE GOSSIP."

A French chemist, M. Aimé Girard, has drawn special attention to the employment of copper salts as a remedy for the potato disease. The notion is not new, for Dr. Griffiths published his own experi-

ments with both copper and iron salts as a manurial remedy for the same diseases, and the fungoid diseases of cultivated plants generally, nearly two years ago. M. Girard, however, shows that a solution of sulphate of copper used as a preventive of the potato disease is not only very efficacious, but that it results in a gain to the crop such as more than pays for the expenses of the treatment. Even when used as a purely curative agent, he says the yield of healthy potatoes is increased from between twenty to twenty-three per cent.

It has been found that when leaves, or rather plants, are grown in unhealthy situations, such as where there is a deficiency of light or nutriment, the green chlorophyll becomes degraded in its functions, and assumes another colour indicative of this fact. The commonest of the degraded colours of leaves is some high tone of yellow. This is due to the presence in the cells of carotene, instead of chlorophyll. Moreover, our orange and deep yellow autumn tints are due to the change of the latter into the former.

Somebody spoke of the present as the "age of iron," until a recent writer termed it the "age of steel." But wood is not yet disused, although as regards house-building it is no longer an "age of timber," builders having discovered with how small a quantity of wood a house can be built. But wood is not timber, although many people confound the two. Tree ferns and palm trees have large woody stems, but nobody uses them as timber. They would rot directly.* The simple structural forms of timber are coniferous trees, such as larch, pine, &c. They possess the loosest tissues, which soonest decompose (in spite of their natural turpentine), and consequently are much employed under certain conditions. In them the woody bundles run the length of the stem, and produce "grain;" but we do not find in the structure of such timber the horizontal bars of wood we see in a section of oak, ash, beech, &c. The real timber trees were those used by our forefathers in the old-fashioned houses, built when real timber was as abundant as "wood," so they helped themselves to it, as the beams and rafters of our old houses prove. The oak and ash and other real "timber trees" are built up naturally into a solid woven fabric, consisting of vessels and woody bundles running lengthways of the trees, whilst such extra additions as the "medullary rays" (absent in cone-bearing trees) are interwoven into them from the core to the bark. Generally they increase at the rate of one added ring of growth per annum, but this is not necessarily so, especially in young "timber trees," in which the rings represent merely a fresh spurt of growth, annual or otherwise. The seasons are now known to exercise a wonderful influence upon the nature of the rings of woody growth added in the older timber trees annually. We have dry summers and wet ones. Nobody can prophesy (until afterwards) which will be the case. It is only in summer, when the leaves are crowding the trees, that the timber of the woody trunk can grow exogenously. Therefore it is evident the nature of that growth must largely depend on the character of the season. One of the worst things which can happen to wood (considered as "timber") is when there has been a succession of dry seasons followed by wet ones. During the latter the tree forms what is known as "weak wood"—so weak, that not infrequently, as the growth progresses outwardly, it is detached at the weak part of the ring from the previous growths. This is technically known as a "ring-shake." Coniferous trees can grow on scanty soils. They are the oldest trees in the world, geologically speaking, and are used to the poor soils of a primeval world. Oaks, beeches, ashes, &c., are among the latest introduced of trees. They cannot live on a vegetable pauper diet, but require the rich subsoils of the latest geological formations—clay, marl &c.

It is a well-known fact that the more we cultivate any particular crop the greater is the number of diseases to which the latter becomes liable. Is it due to overcrowding—to increasing the individual plants we denominate a "crop"? The potato disease was hardly known until Ireland scarcely grew anything else but potatoes. Vire diseases (animal and vegetable) have accumulated with extended vineyard planting. It is the same with orchards, olive-yards, orange-groves, &c. The cultivation of oranges all over the warm temperate parts of the world has mightily increased within the last few years. People have learned to love them, and increased transit has brought the producer and consumer nearer together. Oranges are no longer the sole luxury of the rich, and the objects of envious desire to the sick poor. But with increased cultivation have come increased diseases to the fruit. They are attacked by blue and green moulds, which destroy nearly half the quantity that arrives in Great Britain. They are also subject to extensive ravages by a peculiar species of small fly, whose pupa-cases may be seen embedded in the outer skin of most oranges by thousands, looking like so many caraway seeds. The name of this minute insect is *Ceratitis citriparda*. Recently another entomological enemy to the orange tree has been discovered in the larva of a beetle (*Cerambyx neles*), which bores into the lower part of the stem and down into the roots. This grub seems to be either identical with, or nearly allied to, the *Cossus* of the ancient Romans. A species of *Praya* has also this year been found feeding in the buds of orange and lemon trees in the south of Europe. Let Australian orange-growers, therefore be on the look-out for this new arrival of enemies.

Microscopy has done a good deal for practical and technical science, and it promises to do a good deal more in the future. An interesting paper has just been read before the French Photographic Society on microscopic sections of wood. The French Inspector of Forests pointed out that such photographs permit the trees which furnish the woods to be classified, owing to the microscope bringing out the structure of the cells and fibres, so that thin cuttings of any wood can be compared with standard photographs so as to enable them to be identified at once.

Messieurs Gayon and Dubourg have been exploring the mysteries connected with the important subject of the alcoholic fermentation of invert sugar, and have laid the results before the French Academy of Sciences. In brief, the following are the conclusions they arrived at. They followed the progress of the fermentation by means of the polarimeter, and they prove that the two components of invert sugar are attacked with different degrees of rapidity, and that different ferments do not act in the same manner; some attack the levulose by preference, and others the remaining component.

At the risk of repeating what you may have already heard of, I do not hesitate to give the following important bit of news connected with the banana plantations. The discovery was made accidentally in Fiji—the paradise for Australian bananas. There can be little doubt the discovery will prove valuable in all tropical countries where bananas are cultivated.

The banana disease had broken out virulently on a plantation at Vanua Levu. Near the seashore a banana patch was very much diseased. Some time ago the sea broke over into it, the salt water remaining there for about an hour. All the plants were killed as far as the standing stems were concerned; but vigorous young shoots came up freely from the roots, and were not only quite free from disease, but soon began to bear much larger bunches of fruit than the parent plants ever did. The planters noticed this effect, and immediately tried an experiment upon a number of diseased bananas which the water had not reached. They cut down the diseased plants, stirred the ground about them, and then poured three or four buckets of sea-water about each plant. The parent stems withered, but vigorous young shoots sprouted in their place without a sign of disease.

The question of a scientific investigation into the aeration of soils must commend itself to all agricul-

* Dr. Taylor had in view the general run of palms. There is no better timber for rafters and reapers of house roofs than that of the palmyra palm, whilst selected coconut trees are good for similar purposes.—Ed. T. A.

trists. The French chemists have long been to the front in the investigation of matters of this kind, although their English brethren are fast overtaking them. M. Schloesing has been experimenting in the matter, and has recently made known his results. He shows that ploughed land contains a relatively larger amount of oxygen to a certain depth. The carbonic acid generally increases with the depth, but in two cases the reverse occurred. This was when a high wind renovating the upper soil had been followed by hot and calm weather. Then more carbonic acid gas was generated in the surface soil than in the subsoils. In sloping pastures the most carbonic acid gas was found at the bottom.

At the recent annual meeting of the Society of American Microscopists an interesting paper was read by Dr. Thomas Taylor, on the adulteration of tea. Can any philosopher in the world explain why a man's drinks should be more liable to adulteration than his solids? Perhaps it is because he takes more of them. Therefore, both drinkers, and teetotallers, are hereby liable to the same imposition. Dr. Taylor showed how Japanese teas are "faked" to resemble the Chinese green teas, the materials used in the process being indigo and plaster of Paris. It so happens that this is the kind of tea the Yankees prefer. Neither of the adulterants is harmful, only there is no necessity to drink tea with any other adulterants than cream and sugar. The Japanese are a wise people, and by them coloured tea is regarded as an abomination. He taught that a return of the consumers of teas to Japanese habits would certainly result in the preparation of the tea-leaves in Japan, and would thus afford customers better teas at lower prices.

At Keswick, in our well-known lake district, there is now taking place the first essay in England to utilise natural water power of the hills for the purpose of public electric lighting. The river Greta supplies the motive power. About three-quarters of a mile from Keswick town it has a head of twenty feet, and this has been selected as the site for the works. The light has been received with much favour, and already the demand is equal to the supply. One man and a boy have been found sufficient to manage the machinery.

The oil wells at Baku, at the Caspian, are said to be drying up again. Out of four hundred wells less than two hundred are now working. This may cause much inconvenience to the Russian navy on the Caspian, many of whose vessels have been specially fitted up to consume petroleum. If the world's supply of coal is limited, and will only last a certain time, it is very certain its mineral oils are more limited, and will be exhausted in a much shorter period. The craze for oil-well boring cannot be too carefully watched.

Another well-known French chemist, M. Muntz, has published his experiences on the part taken up by green manures as nitrogenous dressing for soils. His experiments show that the efficacy of green manures as nitrogenous dressing materials depends especially on the facility with which the fresh vegetable matters allow the nitrification of the proteids, and on the favourable influence they exercise on the physical properties of soils.

A singular confirmation of the theory that certain kinds of insects have become specialised to visit certain kinds of flowers or rather that the latter have been specially adapted to the former, has just been proved by a German botanist. The highest organised and specialised of the numerous members of the buttercup family (*Ranunculaceæ*) is the aconite. On the other hand, it is granted that the bees are, perhaps, the most highly celebrated of insects, and know their way about. It has been shown there is a biological relationship between the aconite (*Aconitum*) and a genus of bees (*Bombus*). The aconite is dependent upon this bee for fertilisation. On comparing the geographical area of the two it has been found that the area occupied by *Aconitum* is entirely covered by the area of distribution of *Bombus*.

You in Australia know what it is to disturb nature's zoological balance by your rabbit pest. They are suffering from a similar disturbance in the Southern States

of America. The alligators have nearly all been killed off for the sake of their hides, which are manufactured into a special kind of leather. It seems the alligators are the specific foes of the musk-rats, which have multiplied accordingly since the almost complete extermination of their natural enemies, inasmuch they are now a great scourge to the farmers in Louisiana and elsewhere. The consequence is that a fine of 24d. is now imposed upon any one who shall slay an alligator.—*Australasian*.

A TEA PLANTER'S ROMANCE.

In "The Dead Man's Gift: A Tea Planter's Romance," just published by Messrs. W. H. Allen & Co., Mr. Herbert Compton has written a capital Anglo-Indian novel, dealing with a phase of English life out here that has scarcely been attempted before. The plot is ingenious and exciting, the scenery is admirably described, and the characters are wonderfully lifelike. With the plot we need scarcely concern ourselves here; it will be enough to know that a very pretty love story and an atrocious scheme of commercial villainy are gradually revealed in a novel and picturesque frame-work of Himalayan scenery. The interest of the book from our point of view lies rather in its characters, vivid enough to be transcripts of actual individuals, and in its faithful, unvarnished descriptions of tea-planting life. Dennis Durand, the central Tea Planter of Mr. Compton's romance, is a frank, straight-forward young University man, who after having had a good time at home invested what he had left, some four thousand pounds, in a tea garden at Dulgoorie (for which perhaps Darjeeling may be read), and then proceeded to learn the business. A kindly neighbour, old Pekoe Puckle, fortunately took him in hand. When Puckle first came to Dulgoorie, the process of tea-manufacture was a Mystery tempered with Ignorance. The manufacture of the leaf was in the hands of a few Chinese charlatans, who had been imported from the Flowery Land, and distributed over the new tea districts to disseminate a knowledge of their reputed craft. They concealed their ignorance under a cloak of pride and impenetrability, and did all their work in carefully secluded corners. Puckle put them down as gigantic humbugs, and evolved a process of his own that gave his teas a very profitable price. Unlike most of the old-fashioned tea-planters, he was always ready to give everyone the benefit of his experience.—"The sooner we can all make good stuff," he would argue, "the sooner we shall sweep the rubbish from China out of the market. It's bound to go if we pull together." Strolling for five minutes through a friend's factory, he would point out all the errors and mistakes he noticed, and rectify them at once. The smell, the colour, the look, the touch, the feel of the leaves in the process of manufacture told him everything at a glance.—"In short, he was a Tea Expert." Things, we are told, have altered since those remote times when the sixties were young.—"Everything is done by machinery in a tea factory nowadays, and Puckle's tea-house operations slowly and laboriously, and it is to be feared dirtily, performed by hand by a large staff of specially drilled coolies, can now be conducted by half a dozen intelligent men in charge of a variety of withering, rolling, drying, and sifting machines and with a facility and precision and cleanliness which would crumple up some of the old dead-and-gone pioneers of the industry, if they could rise from their graves to resume temporary management of their factories." "Don't imagine, Durand," Puckle would often say, "that any fool is fit for a tea-planter; that is an exploded idea now amongst men of business, who know what tea-planting really is. You want more wits and versatility in our profession than in most. You must not only be Jack of many trades, but master of them. The programme for a successful season is a big order for any one to buckle down to." We are pilfering wilfully from Mr. Compton's volume, as the

best way of showing its excellence, and, indeed, it would be easy to fill a column or two with the apt things he says of that famous expert Pekoe Puckle.

Puckle, we are told, was a capital tea-taster, with a fine vocabulary of technical epithets and adjectives. Thus the samples on which he pronounced came to be described as "handsome, curly, glazed, bright, black, wiry, glossy, even, regular, tippy, and curious in appearance; whilst their drinking qualities were reported on as strong, flavoury, full, rich, ripe, brisk, fruity, thick, fine, creamy, pungent, mally, sweet, good, high-fired, brisk, burnt, rasping, desirable, clean, and superfine. But others would occasionally disgrace themselves and sink into the turpitude of being dull, broken, dusty, flat, choppy, chaffy, uneven, crapey, mixed, round, shottv, stalky, grey, red, brown, greenish, dull, black, and tipliss in leaf; whilst in liquor they were branded as soft, weak, burnt, scorched, coarse, thin, extra thin, undesirable, wanting flavour, wanting quality, wanting briskness, bakey, foasy, poor, and bad." In sad contrast to Pekoe Puckle we have Jack Boyce, an Oxford Man and old Etonian:—"He's the kindest-hearted man in Dulgoorie, and the weakest in a way. He has run through a fortune and has one foot in the grave, and yet he passes his life in keeping open house for the district and passing the bottle round. It is the old story, of course, lifting his little finger too often." His bungalow was popularly known as the *Red Lion*, and was open night and day "of man and beast." Durand tried to rescue him from the toadies and barbies who flattered his failings and used his house as an hostelry, and was, as a consequence, sent to Coventry by the planting community as a body. Boyce came, of course, to "the six-by-two freehold in the planters' churchyard;" and with his pathetic death the better men among the Dulgoorie planters began to respect the energy, independence and character displayed by young Durand in his single-handed combat against the evil influences of the district. His warmest supporter was a half-pay lieutenant of the old Indian Navy—Lieutenant Marling, a quaint, carbbed, old salt, who wasted his half-pay in trying to grow tea so bad that even the tobaccoists would no buy it for packing cheroots in. Durand came across the Lieutenant first, as the old man, in a voice broken with sobs, was reading the Burial Service on a grave dug in the middle of a grim, fantastic landscape:—"Do you know," asked the Lieutenant, "can you guess over whom I read the funeral service just now?" "No." "Then I'll tell you, for it's my duty. It was over a native woman. A heathen, if you will, but my wife, Sir—before Heaven my wife—even though she and I were never married. Perhaps"—he went on in a softer tone—"perhaps I have done wrong. Maybe I have led you into an act which is against your religious principles. She had no right, a parson might say, to the services of the Christian Church, even though she prayed to the Christian's God. I say she had. But, then, I loved her. And believe me, Sir, I meant no harm." This strange meeting led to a singularly devoted friendship. Lieutenant Marling is so happily conceived that we feel quite sorry when his eccentricities are, however amusingly, exaggerated; as, for instance, when Durand recognized the familiar voice of the Lieutenant outside his bungalow:—"Starboard you Lubbers!" Then after a few seconds—"Port your helm—hard-a-port!" They had reached the bungalow. "B'lay! B'lay! Easy! Stand by!" And finally—"Le' go!" alluding doubtless to an anchor. "Le' go" they did—a trifle too promptly. "Daru the lubbers!" roared a crushed voice from within, as a movement in the canvas ceiling of the palanquin was suggestive of a head being unexpectedly shot into it from below. "Daru the lubbers! She's gone aground!"

Lieutenant Marling's funeral service, however pathetic, hints at something amiss in the tea-planters' little circle:—"The greatest drawback of all," we read, "in a tea-planting community in those days was the want of woman's presence and influence, and it lowered the whole standard of morality and refinement, and made the school a bad one for a young man to enter, and full of vicious temptations to which many a lad, just out from home and a refined family circle, yielded,

and so went to the bad." The ladies of Dulgoorie in those days were a mixed lot:—"Some were civil without being attractive, and one or two went in for being very superior; whilst others dropped their 'his,' or wore loud colours, or drove niggers, or did divers things which individualised them unpleasantly, so that in their presence Durand had asserted himself, because he felt that to be shy before them was a sort of surrender of his social status. And then they all talked TEA." Durand happily, and almost by accident, stumbled across a most bewitching little lady, Sibyl Adair, as she was giving her brothers, Isaac Newton and Colenso, their morning lesson. Her father, Mr. Lionel Adair, had been a mathematical tutor at Cambridge, and had had a mathematical bee in his bonnet ever since:—"I am engaged," commenced Mr. Adair, "in a work of Considerable Depth, A Treatise on the Higher Mathematics. It is an Absorbing Task." He might have said it was a Screaming Farce, if it were not that this wretched Work that was to be, had ruined the whole family. When Mr. Adair went to look round the factory he would take up the lid of a tea chest, and work out problems on it with a piece of charcoal; and if he went into the Plantation to inspect the coolies, he would sit down on the first convenient bank and sun out something on the back of an envelope:—"No wonder that the men were getting idle and lazy, and that the fat Jemedar, or native overseer, was nothing more or less than the master of the estate instead of its servant." And the tea sold badly, and there was so little of it, and it was stolen right and left. Little Miss Sibyl—she was barely seventeen—had the cares of a large family on her banas, and did a good deal, too, to prevent the tea-garden going to the dogs. Durand sympathized with her struggles offband:—"Oh, Mr. Durand," she exclaimed, "you don't know what you are saying! Papa will never leave this place. He is getting deeper and deeper in his Work every year, and has not the slightest inclination for change. When Mamma was alive she made him come out of his shell, but since she died he has had it all his own way with those—those—those *beastly* mathematics!" Of course, these two inexperienced young people fell in love with one another at once, and their chequered love-story is told tenderly and very prettily. It is in its way a delightfully oashful and idyllic incident. The subsidiary characters are as good and true to life as those we have picked out. Captain Good a bully and a coward, who swaggers on his title, talks of the "Service," and avoids mentioning the regiment in which he was broke, must have been a familiar type in the old planting days. Mr. Louch, of the firm of Cumming, Jones & Co., Tea Agents, and inventor of the Big Tea Amalgamation Scheme, is probably still remembered in Calcutta. Even at this geographical distance some of the details of his career seem familiar, though we do not suppose that, before bolting from Calcutta (or Jutepore), he ever sold his famous carriage and pair ten times over, or that he ever actually bought Durand's tea estate for a lakh of rupees worth of forged shares, and then branded Durand as the forger. For the plot of the story our readers must go to the "Tea Planters' Romance" itself, and see there how "The Dead Man's Gift" put Lieutenant Marling's twenty-acre estate in the middle of that Golgotha of stone and desolation, the Landslip, into Durand's hands, and how mysteriously Durand was directed to the discovery in the Landslip of some odd hundred-weights of rough, but enormous, sapphires. These wonderful stones set everything right. It is a real pleasure to congratulate Mr. Compton on a book that, coming from any recognized English novelist at home, would have won success as a remarkable effort of imagination. As Mr. Compton knows what he writes about, he must, we suppose, be content to think that he has told his own experiences in his own way and an admirable way it is. If his tea is only half as good as his book, Mr. Compton should, however, have no reason to grumble. He was b'ye-ted at Mincing Lane, if we remember rightly, for selling his teas in an original way. His old enemies will find it difficult to boycott his book. It is a right good "chop."—*Times of India*,

FIBROUS PLANTS AND THEIR TREATMENT.

A factory has been established in High Street, Lambeth, under the supervision of Mr. Taylor Burrows, late of Lisle, for the treatment of various fibrous plants. Samples of these plants of every species can now be submitted for carefully-supervised trial, and if the present machines or processes prove unsuitable in some little detail or other, the defect will be discovered and remedied. In like manner advice will be given as to the best machines and methods of treating fibrous plants, and the opportunity will be afforded of studying the various processes of production, and of acquiring a knowledge of the most scientific methods of preparing fibres. In fact the present enterprise promises to develop into an important public technical school, for it is proposed to establish branches in textile manufacturing and cognate centres. From a still wider point of view the fibre factory may be regarded as an exhibition and a permanent institution for perfecting machinery and processes relating to the treatment of fibre-bearing plants of every description.

The various processes to be carried at the model fibre factory comprise the rapid retting and ungumming of fibrous plants; automatic breaking, snatching, combing, and backling; spinning into simple or mixed yarns; cottonising and woollenising fibres to imitate fine cotton or wool, suitable for the manufacture of various mixed and cheap fabrics as well as for fine and costly goods; bleaching and dyeing the same, and the rapid drying of fibres by means of cold air. The factory consists of a spacious warehouse and store room for machines and samples, with offices annexed; and a large machinery and operating room, with a laboratory and an engine and boiler house. The chief feature in the operating room is a new machine for dealing more particularly with leaf plants, such as phormium tenax, aloes, agavas, palms, and the like.

We saw, says a writer in *The Times*, who describes the factory, some phormium tenax put through this machine with great success, and with rapidity and simplicity. Another machine is a scutcher for hemp, flax, rhea, and, in fact, all stem fibres. In this we saw some rhea stems from France easily decorticated without previous soaking or steaming. The wood was well taken out and the fibre left ready for ungumming and subsequent treatment. In the plants thus treated the fibre is got out mechanically, and is then treated according to requirement, by ungumming, bleaching, and preparing for spinning. There is also a spinning machine in order to test the various fibres in this respect, and to see how they are likely to meet the requirements of a commercial article. Another important improvement is also being introduced at this factory, and that is the rapid retting of flax. The usual method of retting is to soak the flax in water for about three weeks. By the new process this will be effected in about a couple of hours. This quick action is brought about by submitting the flax to the intermittent influence of heat and moisture, which is stated to be very effective, and in no way to act prejudicially upon the fibre.—*H. and C. Mail.*

THE BLACKMAN TEA WITHERING SYSTEM.

Data, based upon actual working experience in India, more than endorse the good opinion we formed of the Blackman system of tea withering when we commented upon it in 1885. The fact of its being a *truly natural process*, or more exactly speaking, a reduction of the *natural process* to complete control, in the simplest manner possible, at once invited sympathetic attention to it, in that all attempts to "wither" artificially as distinguished from "natural wither" had so far proved failures. It was recognised that the extreme simplicity of the Blackman system, by requiring no manipulation of the leaf, no boxing in of space, no trolleys, and in

fact nothing but the simple fans erected judiciously to snit existing tea houses, left it unapproached for efficiency, simplicity, and economy. That this estimate was justified has since been amply demonstrated by the unanimous testimony of those who have tried it according to the plans provided by the Blackman Ventilating Company's exports. As we have said before, the fan is only the tool employed, and though its record of success is without rival, this success in a large measure depends upon the amount of skill shown in erecting the tool to snit local conditions and requirements. From time to time reports have come home from India which have been most encouraging, but it was not till last cold weather that planters seem to have been irresistibly tempted by the results they witnessed on those gardens supplied with the system. Orders then came in freely from those districts where the success of installations erected upon the plans sent out from home had carried conviction to the sceptical. Some of the reports received by the managers of tea companies, from the garden managers, upon the working of the Blackman system this season, speak for themselves. The manager of Teckulpar (Cachar), writing to the manager of the Land Mortgage Bank, Limited, under date June 27th, 1890, says: "The highly favourable characters the brokers give our latest teas, are due to something more than the natural improvement of the leaf, and I think this may fairly be attributed to the excellent work the Blackman propellers do. . . . Experience shows that the temperature is not very high. . . . The morning's leaf is weighed into the tea-house about midday, and the rolling commences some time that afternoon; the evening's leaf is either rolled the same night or very early the following morning. One very great advantage of this plan is the excellent colour we are able to get in the course of fermentation. . . . The fans have been put to a very special test during the past fortnight, the rain, day and night, having been almost incessant, so much so, indeed, that some of our neighbours (without fans) have had to stop plucking as they cannot wither their leaf, but our manufacturing of tea has gone on as usual, and the quality of the tea is as good as if the weather were fine. . . . I am happy to be able to report that the use of the Blackman air propellers in our tea-house has been a very decided success, and that the general adoption of these useful machines should work a revolution in the system of manufacturing tea." The same manager, in a subsequent letter dated July 10th last, confirms his first report as follows:—"The propellers are doing our work admirably, and we are having no difficulty in withering the whole of our leaf with them, and this during a succession of weeks of the worst weather one could imagine for manufacturing."

The manager of Latakoojan Tea Estate (Assam), writing to the manager of the Land Mortgage Bank, Limited, under date June 13th last, says:—"The time occupied in withering, of course, depends in a great measure on the number of dryers in full operation on the ground floor, but in *no case* as yet has it exceeded five hours, the least time being only three hours. *It matters not whether the leaf comes in dry or wet if there is sufficient heat on the ground floor a perfect 'wither,' as good as any natural 'wither,' will be obtained in the time specified. . . . As the new withering loft can accommodate 90 maunds of leaf at a time and wither it at the latest in five hours, I need hardly say that we are now quite independent of all the old withering houses.*

"Then, the manager of Boro Jalingha Tea Estate (Silchar) writing to the manager of Land Mortgage Bank, reports that 'It has been working since April 27th and runs smoothly and well, withering leaf brought in at 12 o'clock in the forenoon, the same leaf being ready for rolling by 4-30 p.m. This I should not consider much of a test of the machine, as the chamber was only completed *in part.*'"

These extracts show that experience is bearing out most satisfactorily the forecast we ventured upon in 1885. It is necessary to reiterate the desirability of the system being erected upon plans sent out from home, based upon the experience already there col-

lected, and with due regard for the expert opinion which the Blackman Ventilating Company possess, to a unique extent, upon all that relates to the laws governing the movement of large volumes of air in motion, and the vagaries to be provided against.—*H. and C. Mail.*

BONES.

The Government of India last October invited the attention of Local Governments to the increasing exportation of bones from India, and asked the Department of Land Records and Agriculture in Bengal to embody remarks on the use of, and trade in bones, in its annual reports. From information gathered on the subject in Bengal it appears that within the last few years the collection of bones from village wastes for export to Calcutta has become the regular profession of a low caste of Hindus—Chamars—and is gradually extending to the outer parts of Bengal, in proportion to the increasing demand of the Calcutta mills, and the extension of railway communication. Heaps of raw bones collected for transport to Calcutta may now be seen along the railway and principal river routes of Bengal. Bones are also collected by the indigo planters of Behar for use on their indigo land. Many of them have erected mills for grinding them to dust. The bones brought into Calcutta are bought up for manufacture into bone-meal. With the exception of a comparatively small quantity of bone-meal sent out to tea-gardens, the report says the whole of the output of the bone-grinding mills in Calcutta is destined for export. The price of bone-meal is said to range from R2 to R2.8 per maund, according to the degree of its fineness and purity.

Numerous experiments to test the efficiency of bone-meal as a manure for paddy have been made in Burdwan and Hooghly. It could not, however, be ascertained how much of the increased yield on any plot manured with bone meal was due to this manure alone, for in most of the experiments bone-meal was mixed with saltpetre, hide-salt, etc., and the experiments made by the ryots were devoid of precision. The best guide to the value of this manure would seem to be the evidence of the ryots who have tried it. The testimony of the ryots and farmers was nearly uniform to the effect that bone-meal is quite as good a manure as oilcake for paddy, potatoes, and sugarcane, but that its effect does not last for more than a year, and that better results were obtained in sandy than in clayey soils. Although bone-meal is acknowledged to be a good manure, oilcake is believed to be superior to it in many respects. It is also much cheaper than bone meal, and is open to no objection on the ground of caste feeling. Until, therefore, bone-meal can be offered at cheaper rates than oilcake, there seems to be no hope of its general adoption in native agriculture.—*Madras Times*, Aug. 19th.

FALSIFICATION OF TEA IN CHINA.

A French chemical journal just to hand gives the analyses of some teas recently seized at Dunkirk and Paris, where they had been sent from China. M. Riche found in his examination of several samples, that they did not differ decidedly from genuine tea in their ash and in the proportion of tannin. But in searching for the alkaloid, the samples were found to give no crystalline theine at all, but in its stead a greenish, viscid substance. It is remarked that the highest percentage of tannin found in the investigation was 16.80. A paper by M. Collin follows, treating

the subject from a morphological point of view. The author gives cuts showing the structural peculiarities of true and spurious tea, both as seen with the naked eye and the microscope. He remarks, that this fraud is more readily detected by means of the lens than by chemical analysis. Every true leaf, of whatever variety, has serrated edges. Mr. Hooper, the Government quinologist, who, has analysed a large number of teas, informs us that the adulteration is, no doubt, due to an admixture of leaves from a tree belonging to the same or an allied natural order of the genuine tea bush. The *Gordonia obtusa* belonging to the tea-order, for instance, has leaves with the same aroma and containing tannin and ash in very similar proportions, but the amount of alkaloid forms a very small percentage of the leaf. The *Gordonia* is a tree very plentifully distributed in the Nilgiris, but the leaves are different to those of tea, both in their margins and apex. A few years ago, Indian planters were looking upon their Chinese brethren with dreaded rivalry, and this was increased when the medical faculty at home were recommending the finely flavoured leaf of the celestials in preference to the so-called harsher tea of India. But we need not fear competition much longer, for when adulteration and falsification are resorted to by men of business, the trade somewhere is radically bad, and China will have to look elsewhere for a market for this time honoured commodity.—*South of India Observer*.

COCONUT BUTTER.

Mr. B. C. Basu of the Agricultural Department of Bengal, writes to the Agri-Horticultural Society, Calcutta:—

"I took four nuts of average size, neither very big nor very small, and had the kernel reduced to a coarse pulp with a native instrument called *karni*. The nuts were not fully ripe; the kernel was fully formed, but was yet a little soft. After the kernel had been made into pulp, the latter was squeezed in a thick piece of cloth to express the 'milk.' A little water had to be added to the pulp to make the milk run out freely. The whole of the milk could not, however, be expressed, as I had no proper appliance to do the work. The 'milk' was measured and found to be 3 *paos* or roughly 24 oz., of which quantity 1 *paos* may be taken as water added to the pulp in the act of expressing the milk.

"Immediately after the milk had been expressed it was churned in a soda-water bottle. I intended to use the English churn which I have recently procured from England, but the quantity of milk was too small to be put into a churn. I should mention here, that in the experiment with coconut milk which I made in the last cold weather, I had no need to add any ice or cold water, but in the present experiment, which was made sometime about the end of last April, the weather was hot, the consequence being that the butter refused to 'come'. I then added a little iced water to the milk in the soda-water bottle, and the butter grains immediately appeared. The whole operation did not take more than 15 minutes and could be finished in half the time if cold water was added in the beginning. All that I had now to do was to wash the butter in cold water and gather it into a lump. The butter weighed just a little over 1½ chittacks or 3 oz., that is, 12½ per cent. on the milk. This I considered encouraging; but my surprise and disappointment were great when on opening the vessel in which I had put in the butter, I found that it had all melted and was floating on the top of the water. In the cold weather the butter kept pretty firm day and night; but in the hot weather it would be impossible to keep it solid, unless it was put in iced water. Under the circumstances, I believe it is useless trying

to make coconut butter in a hot climate like ours."

In a subsequent letter Mr. Basu conjectured that the butter fats of the coconut might be of two or more kinds, with different melting points, and in that case those that melt at a low temperature might be removed and the balance would remain solid.

In connection with the subject, the following from the journal of the Society of Chemical Industry is of interest:—

The following is an extract from the last report of the United States Consul at Mannheim on the subject of the manufacture of coconut butter in Germany:—

"German chemists discovered in the coconut a fatty substitute for butter.* This discovery was made by a Dr. Schlunk, practical chemist at Ludwigshafen-on-the-Rhine. Shortly after the discovery was made a firm was established in this city under the name 'P. Muller and Shone,' which sunk a large amount of capital in an enterprise, having for its object the production of the new article, to which they gave the name of coconut Butter. The results achieved have more than justified their expectations. The firm is not able to meet the constant demands made upon it. Although in existence only one year, it employs 25 workmen, who get from 25 to 75 cents a day, has a 40-horse-power engine, and produces daily 3,000 kilos of butter, which retails at from 55 to 65 pfennings, or from 13 to 15½ cents per pound, or 25 to 30 cents per kilogramme.

"The nuts are obtained from almost all lands lying in the tropics especially from the South Sea and Coral Islands, Arabia, the Coast countries of Africa, and South America. Natives in countries where the nuts grow have for a long time used the milk of these nuts instead of food oils. It contains 60 to 70 per cent of fat, and 23 to 25 per cent of organic substances of which 9 to 10 per cent is of albumen. Liebig and Fresenius had already discovered the value of the coconut oil, or fat, but did not succeed in its production as a substitute for butter. The new butter is of a clear, whitish colour, melts at from 26 degrees to 28 degrees C., and contains 0.0008 per cent water, 0.066 per cent mineral stuffs, and 99.9932 per cent fat.

"It hardens at 190 C. It is better adapted, however, for the kitchen than for the dining-room, that is for cooking purposes than for the uses to which butter is put on our tables. It is neither disagreeable to the taste nor smell. In a country where real butter runs all the way from 25 to 35 cents. per lb., and coconut butter costs but 15 cents, a great future must open up before the latter. At present it is chiefly used in hospitals and other State institutions, but is also rapidly finding its way into houses or homes where people are too poor to buy butter. The working classes are rapidly taking to it instead of the oleomargarines, against which so much had been said in the papers during the last two or three years.

"The new butter is said to be singularly free from acids and other disturbing elements so often found in butter, especially that made from milk taken from cows diseased with tuberculosis. Here it is estimated that fully 10 per cent of the milk-giving cows are so troubled. This absence of acids and other matter renders its digestion much easier, hence the preference already shown for the new article by hospitals and such institutions. There are those who do not hesitate to declare this new substitute as healthier and infinitely preferable to the too often bad butter brought on the market, and not to be named in the same breath with oleomargarines made too often from the diseased fat of horse and sheep flesh.

"When it is remembered that Germany has already some 50 factories making oleomargarines and other artificial butters, and that some 180,000 *centners* are procured annually, it will be readily seen that regular butter will have hard work to hold its own in a hundred uses against its new rivals, and especially so since the oleomargarines and artificial butters of all kinds are placed under severe, careful, and watchful state inspectors."—*Indian Agriculturist*.

* The young kernels scraped to the consistency of cream give special zest to Sinhalese curries.—Ed. T. A.

BANANAS AND MELONS IN ASSYRIA.—In the July number of the *Babylonian and Assyrian Record*, Dr. Bonavia attempts to show that the Assyrians partook of Bananas and Melons at their dessert. So far as the Melons are concerned, this does not seem at all unlikely; but as to the Banana, the case seems rather more doubtful. It may have been so, but the illustrations given from *Botia's Monuments de Ninive*, seem as much like bundles of Asparagus as Bananas. Surely the Assyrians did not make use of a Covent Garden bundling machine?—*Gardeners' Chronicle*.

THE INTERNATIONAL CONGRESS OF AGRICULTURE AND FORESTRY, at which Great Britain, among other States, is represented, was opened at Vienna on Sept. 2nd under the presidency of the Marshal of the Province. The members of the Congress number nearly 900, delegates being present from Great Britain, Belgium, Denmark, France, Germany, Italy, the Netherlands, Norway, Roumania, Russia, Servia, Sweden, Switzerland, South Australia, India, Brazil, and Japan. The representative of England is Mr. Ernest Lark, the secretary of the Royal Agricultural Society of England. Upon the president of the committee, Baron Hohenbruck, Councillor of the Ministry of Agriculture, and the secretary, Chevalier Max von Proskowitz, F. R. G. S., a gentleman well known in England by his exploration in Central Asia and Eastern Russia has fallen the brunt of the labour of organising the congress.—*O. Mail*, Sept. 5th.

MINOR AILMENTS AND THEIR CURES.

II.

BALDNESS, OR LOSS OF HAIR.—This generally results from worry and overwork, or impairment of the general health. Many preparations of cantharides are recommended, but many of these undoubtedly prove beneficial. At the same time, it must be remembered that it is not purely a local complaint, and much may be done by improving the general condition of the health. A bland, unirritating application for the scalp is Lanoline, which is readily absorbed by the skin. Lanoline contains cholesterine (a fatty substance), and it is this which maintains the hair lustrous and soft without greasiness. Lanoline, in the form of Lanoline Pomade, should be rubbed in freely night and morning, preferably in front of a fire. Hazeline applied freely by means of a piece of Lawton's Absorbent Cotton will speedily relieve any inflammation or irritation of the scalp.

ASTHMA.—Asthma is a paroxysmal ailment to which many persons are subject. The attacks usually come on suddenly, vary greatly in intensity, and may last from ten minutes to three or four hours. It is sometimes no easy matter to cut short an attack, but benefit will often be experienced from the use of Nitre Papers, Stramonium Cigarettes, and the use of the Chloride of Ammonium Inhaler (Vereker's). In the intervals, the administration of ten drops of Pure Terebene every three hours, with its occasional inhalation, has been found beneficial. Pinol has also been used for this purpose, and is now largely employed. It is very important that the bowels should be carefully regulated, and for this purpose, Laxative Tablets may be used, one or more being taken every morning according to the requirements of the patient.

BLACK EYE.—One of the best applications for a black eye, resulting from a blow or contusion, is Hazeline, applied freely on lint or absorbent cotton. Very hot water, applied frequently, is one of the best remedies. As a rule the condition runs its course, and it is difficult for the sufferer to prevent an unsightly appearance for some days.—"*Health*," London,

SOME OBSERVATIONS ON TEA DRYING MACHINERY.

(By C. B.)

* * *

In deciding upon the best class of machine, the first question to be considered is *power*; if the factory is supplied with unlimited water power the decision should at once be made in favour of one of the *fan* machines, because the fuel consumed by such is about 10 per cent. less for weight of tea dried than by machines which do not require power. If there is abundance of steam power available the same consideration holds good, but to a limited extent, because the extra fuel used in the boiler will nearly balance the difference of fuel used in the drying machines, and the fact is to be taken into account that the engine will have to be kept going for hours after the rolling work is finished. When power in the factory is limited, it is obvious that the decision should be in favour of such machines as the *Up-draft Sirocco*, because it is independent of the engine, and can be placed in any part of the factory, irrespective of the position of the other machinery.

Several machines to do the required work are better than one only of large capacity, because any little accident deranging the latter would bring the whole of the drying to a standstill, whereas in the former case a difficulty with one machine could be overcome by extra pressure upon the others; and, besides, if the extra heat from drying is utilized for withering floors overhead, it is evidently better to have such heat-producing apparatus distributed than to have it concentrated on one spot, unless indeed withering fans are employed to distribute the heat. Another consideration is that it does not pay to work a large machine for drying a small quantity of tea in the slack season, for it stands to reason that an immense body of iron, and perhaps brick, as well as *floor*, takes a great deal of fuel to bring it up to a temperature of 240 deg.; and this is an expenditure which is greater even for a short day's work than for a long one, because there is a longer interval of cooling down between working hours. Besides all this it is well to have one or two machines doing the finishing off only, as no machine yet invented will, under ordinary circumstances, dry the tea *pucca* at one go. Viewed from every point, therefore, it is better to have, say, not less than four machines for a moderate sized factory than to have one large machine capable of drying the whole.

In choosing a type of machine it is well to look to *substantiality*; of course it goes without saying that a machine which will unfailingly produce tea of even $\frac{1}{2}$ d. per lb. better than others is to be got at all cost; but no such superiority has yet been established for any one, and the fact remains that the most substantial will prove the best in the long run; provided always that the price is not *very* serious (though they are all more expensive than they should be), since it is quite possible that during the next five years some genius may place in the market an article which will meet most of the requirements still left untouched.

A machine with an excessively powerful fan is to be avoided by all, for many reasons. Such a machine is useless for final firing, because it will blow away the finest of the tea; it dries rapidly by passing through the tea a much larger quantity of air than in the more moderate processes, and the fierce strong blast must destroy a great deal of the aroma of delicately flavoured teas; the *power* required to work such a fan is enormously more than people are apt to think when they twirl the thing round by one hand when the bolt is off; and the consequent consumption of fuel in the boiler and the wear and tear of connecting machinery are no small items: the heat in the air after passing through such a machine will be found to be out of all proportion to the amount of moisture carried away, and is therefore a direct waste and in many cases must be a positive nuisance. It is a mistake to think that such heat can be utilized for withering because drying is supposed to be going on when the withering is finished, or nearly so.

It is an undoubted fact that machinery is a saving of labour, and some of the drying machines save a great deal in that way; in most cases this saving is to be reckoned at much more than the actual wages, because it sets free the labour for other work in the most busy season, when increased cultivation may be of vast importance to quality as well as quantity of tea.—*Indian Planters' Gazette*, Aug. 26th.

THE RAMIE FIBRE.

PROGRESS OF ITS MANUFACTURE IN THIS COUNTRY.

Editor, "*Manufacturers' Record*."

Now that fabrics made of ramie fibre, and of American manufacture, are on sale and can be had regularly of the trade, one more staple hitherto unknown to the American agriculturist may be established on a scale that will produce an annual revenue to the farmers aggregating an immense sum. All experiments in the cultivation of the ramie plant in this country have been on a small scale, not ever sufficient in their proportions to demonstrate an efficient and practical method of decorticating the stems.

A serious obstacle to the progress of ramie cultivation in this country has been the element of doubt regarding the demand for the fibre. Enthusiastic writers upon the subject of ramie culture have greatly exaggerated the demand for China grass (ramie) said to exist in Europe. In recent years the price of China grass has been so high, compared with other fibres, as to prohibit its use in Europe except in moderate quantities. Large sums of money have been expended in Europe experimenting in the fabrication of what is universally acknowledged to be the finest and most valuable vegetable fibre known to the commercial world. Costly experiments were conducted to properly unguem the fibre of imported China grass. Generally these experiments have been unsatisfactory, while the appearance of the resulting fibre seemed perfect, being fine, glossy and white. Yet when spun and put into cloth the fabric would crack, and many other difficulties were met with in this fabrication which were known only to the art.

Moreover, the fibre obtained was always costly, which made it necessary to introduce it only into high-priced goods. This involved another class of experiments, such as machinery for spinning and to complete the fabrication of a kind of goods that would command a sufficient price to make the enterprise remunerative. Some of the European experimenters seem to have been partially successful, but they have not created a large demand for the fibre.

From an American standpoint, there is not a large establishment in Europe running on ramie. It has remained for Mr. Charles Toppen to thoroughly and perfectly unguem the fibre, so that it can be spun and carded by ordinary cotton and woollen machinery, giving a result that permits the fibre to be used in the manufacture of cheap fabrics. This has not been accomplished in any other country, and its value can hardly be overestimated, for inasmuch as the fibre is produced cheap enough to be used in low grade goods, now the demand for the raw material will be large. The evidence of this is in the fact that the first six months of 1890 will show a consumption of China grass in the United States greater than was consumed in all Europe in the year of 1889.

The manufacture of goods from ramie is now established, and the fibre will soon find its way into the highest grade of fabrics. Men's suitings and fine underwear are already being made here from it.

A commercial journal, recently commenting on the varieties of ramie, states that there is an annual variety valuable only for cordage. This is probably an error as to its being a variety of ramie. China and Japan produce the well-known commodity we know as China grass or ramie, and while there are several varieties, the plant is a perennial. The annual referred to is probably in no way allied to the China

grass of commerce, but it may be a fibre used to adulterate. The adulteration of China grass for shipment is not new, and has frequently attracted the attention of shippers.

The mechanical decortication of ramie in the field has not made such progress as has been made in the degumming of the ribbons. The reasons are plain. In solving the degumming problem, many tons of China grass were at once imported and the product turned out, not by the pound, but by the ton. Yarn is now being made by the ton, and the products are being sold by the bolt. Machines that effectually and rapidly produce the ribbons from the green stems in the field will put the United States in the lead as a ramie producing and manufacturing country. But the ramie must be grown to be decorticated. The ribbons must be produced by the ton and continued until many tons are produced before results are obtained. Possibly the recent offer of the use of a machine free to those who will grow 25 acres of ramie within the next two years will stimulate its cultivation.

T. ALBEE SMITH.

JAMAICA AND ITS FORTHCOMING EXHIBITION,

BY C. WASHINGTON EVES, C.M.G.
PLANTING PROGRESS IN JAMAICA.

Jamaica is singularly varied in its climate and natural features. Its general botanical resources are of a wonderful extent and richness; its useful or economic plants have been thoroughly investigated, although as yet a small number have entered largely into commerce. These latter have, however, received much attention from Mr. D. Morris, the present Assistant Director of the Royal Gardens at Kew, when he was in charge of the public gardens and plantations of the island, and one of the important features of the exhibition will be the proof of the value in arts, manufactures, and food, of the economic plants of Jamaica. The island is 144 miles long, its greatest width is 49 miles, and its least width—going straight across from Kingston to Annotto Bay—is 21½ miles. It contains 4,193 square miles. It is diversified by mountains and their attendant streams, and the climate ranges from 75° to 80° on the coast and flat lands adjoining, to 60° and 65° on the high mountains, such as the Blue mountain range. The dryness of the atmosphere upon elevated portions, such as the Santa Oruz mountains, has attracted much attention for its health-giving qualities, and its influence upon consumption and bronchial affections generally.

This diversified elevation is naturally conducive to variety of cultivation. Sugar is grown (though to a much less extent than formerly) in those parts of the island specially adapted to its cultivation, whilst the Blue Mountain coffee is the finest in the world. Fruit especially the banana, is grown extensively. Cinchona bark does not, at present, appear to be increasing as an article of export, chiefly owing to the low prices at present ruling. If a febrifuge could be produced on the spot cheaper than quinine, there would be a better prospect of success for this industry. In the cultivation of tea the labour difficulty may possibly be felt. The director of public gardens, Mr. Fawcett, reports:—"From the Blue Mountain ridge down almost to the sea coast on the north side the conditions are favourable for the growth of tea. The plant has become naturalised, springing spontaneously from self-sown seed;" and the manufactured leaf, when shown at exhibitions, has been much approved. Jamaica oranges, says Mr. Fawcett, "ought to be able to hold their own anywhere against those from Florida; they are finer fruit, and produced at much less expense. Land in Jamaica is abundant and cheap, and the soil is fertile." A great drawback is that the fruit is either shipped in an improper condition, or is not packed with care. An object lesson in packing oranges will be one of the most useful features of the Exhibition. While upon this point, I might refer to some remarks

made by Mr. D. Morris, in the paper read by him before the Royal Colonial Institute in February, 1887. Fruit equal to a value of £3,000,000 sterling is yearly imported into the United Kingdom. The import into the United States must also be very large, nearly the whole of the fruit grown in Jamaica going to that country. Mr. Morris says, and I quite agree with him, that "when fruit is produced in large quantities, and it possesses a distinct value in foreign markets, it is a matter which concerns the Government, no less than the people generally, to take every step that is practicable and suitable to place that fruit in such a market in the best possible condition. Great care is taken generally in the preparation of crops of sugar, coffee, cacao, pimento, tobacco, ginger, and other produce; but the careful and scientific treatment of fruit, although capable of yielding returns proportionately quite as large as any of these, is practically overlooked, and consequently the loss entailed upon both growers and shippers is enormous." We may hope that the Exhibition will produce such examples as will remove this reproach so justly made by Mr. Morris. Indeed, his remarks have had already considerable effect.

A select committee of the Jamaica Legislative Council recently reported as follows upon this question:—"Your Committee believe that one chief danger to the fruit trade lies in the fact that the parties engaged in packing fruit are ignorant of the best methods in force in countries where the trade has reached far larger dimensions than is likely to result in Jamaica, at least for some years to come; and they are of opinion that great benefit would accrue if experienced fruit packers could be introduced from the Mediterranean, or the Western or Canary Islands. If the trade accepts this suggestion, and should ask the Government to assist in introducing this class of skilled labour, your Committee recommend that the Government should render all the aid it can in its introduction."

It cannot be too plainly stated that the future of the fruit trade of this island depends mainly on the proper selection and packing of all kinds of fruit exported; and the trade will not only be injured directly but the island must also suffer, if those who are engaged in the business do not combine to do all that can be done to prevent the shipment of fruit of poor quality, or defectively put up.

The total acreage in Jamaica under cultivation and care, in 1879 and 1888, was as follows:—

	1879.	1888.
	Acres.	Acres.
Canes	44,948	33,616
Coffee	22,853	20,075
Ginger	130	218
Arrowroot	33	10
Corn	649	822
Tobacco	341	167
Cacao	37	935
Vegetables	44	51
Ground provisions	58,444	79,382
Guinea grass	122,369	122,197
Common pasture	272,431	313,137
Common pasture and pimento	42,010	44,539
Pimento	1,155	1,455

Total number of acres under cultivation and care ... 565,448 ... 616,594

Note.—Fruits are not included in the above statement, as they grow indifferently among other products.

It cannot be held that the above figures show any sensible advance in ten years. The most satisfactory items are the ground provisions, grown by the peasantry occupying small holdings; and the cacao cultivation. There are a number of small settlers in Jamaica, growing patches of cane, and possessing sugar mills made of the hard woods of the country. The appliances are no doubt very crude, but if they could be improved, and the extraction made more economically, such as industry might increase.

Of the actual resources of the island available for export, the Table of Exports for the years 1888 and

1889 respectively		may be taken—		Value	
		1888.		£ s. d.

The new struggling industries in the above list will be noticed. Tobacco makes no way at present. The difference in the export of yams between the two years suggests an unfavourable season for roots and ground provision. Upon the whole, the above table presents a state of things which is certainly capable of great improvement. The valuable and historic industry of sugar, for instance—an expensive product requiring large capital for expenditure, principally in wages enjoyed by the industrial classes—should not be allowed to die out while Englishmen eat every year nearly a million tons of beet root sugar, produced by foreign labour, and aided by foreign State bounties. A careful consideration of the above figures will show that there is much to be done, not only in maintaining existing industries but in planting new ones, a number of which have been suggested, and will be referred to later on; and it is for the purpose of calling attention to the undeveloped agricultural wealth of the island that an exposition of its capabilities is so much desired.

As the exhibition is primarily a display of Jamaica products, it was opportune on the part of the Governor to issue a "Message to the people," recommending local effort in every part of the island. His Excellency mentions that prizes will be offered for samples of the following, among many other things, grown or made by the people:—Sugar-cane, cacao, kola, bananas, oranges, ground provision, coconut, Sisal hemp, Manila hemp, tobacco, cigars, cinchona, coffee, peppers, ginger, pimento, rum, logwood, fustic, annatto, castor oil, coconut-oil, cattle and horses, sheep, pigs, poultry, birds, fishes, turtle, bees, carpentry, cabinet-making, basket-work, nets, mats, goldsmiths' and silver work, models of cottage homes, boats, fancy work, &c. Greater researches for minerals are recommended. Gold, silver, and copper have been discovered in the Charing Cross mine, and ten tons of ore have been recently shipped to London. Special arrangements are also suggested for collecting large samples of the various rubber substances to be obtained from a number of trees. From the mineral, vegetable, and animal kingdom, a great variety of raw material could be obtained, some that might locally be manufactured or prepared for consumption, and others useful to the manufacturer abroad. In the different parishes are found limestones, sandstones, flagstones, marbles, road materials, sands, ochres, clays, ornamental and precious stones, gypsum, copper ores, lead, iron, zinc, cobalt, manganese, antimony, gold, and silver. Few countries are better supplied with building-stone, which varies in degree from the finest marbles to coarse but enduring sandstones. Fine marbles of different patterns and colours are found in many parts. There is a great extent of granite rocks.

Jamaica is rich in fibres, and a serious attempt is to be made to utilise them for several purposes. Bamboo and megass (or the sugar-cane after crushing) might become important for paper making. In the even of the Esparto grass failing, as was at one time feared, a substitute becomes very important. I have some excellent specimens of paper stock and writing paper, made some years ago by Mr. Routledge from bamboo and megass. There are many other uses for the fibres found in Jamaica. What is wanted is a good and inexpensive machine for their extraction. The Institute of Jamaica has offered a prize of £50 for the best set of machines which may be shown at the Exhibition. I have communicated with the principal English and foreign manufacturers upon the basis of information forwarded by Mr. Morris, of Kew. It might be interesting to quote some extracts:—

"The set of machinery might include a banana machine, as well as others. The banana machine should be portable and simple, adapted for the expression of water from the stem of the banana, to be constructed especially for the use of small plantations, and at a cost so as to be placed within reach of small cultivators.

"The following native and other fibre plants are already found in Jamaica, and machines are desired to clean the leaves or stems of any of them.

1. *Aloe Family*.—1. American aloe (*Agave americana*).
2. Keratto (*Agave Morrisii*).
3. Sisal hemp or heuc

quen (*Agave rigida*). 4. Fœtid aloe or Mauritius hemp (*Furcraea gyntea*). 5. Silk grass (*Furcraea cubensis*). 6. Digger plant (*Yucca aloifolia*). 7. Bowstring hemp *Sansevieria zeylanica*. 8. Bowstring hemp (*Sansevieria guineensis*).

II. *Ananas* or *Pineapple Family*.—1. Pineapple (*Ananassa sativa*). 2. Pinguin (*Bromelia pinguin*). 3. Silk grass (*Karatas Plumieri*).

III. *Banana and Plantain Family*.—1. Banana (*Musa sapientum*). 2. Plantain (*Musa sapientum*). 3. Manila plantain (*Musa textilis*). 4. Abyssinian plantain (*Musa ensete*).

IV. *Nettle Family*.—Ramie or rhea (*Boehmeria nivea*).

“As regards the fibre of the plantain and banana, it is estimated that about two million stems of these plants, after bearing fruit, are cut down every year in Jamaica. In the absence of a suitable machine to prepare the fibre, these stems are allowed to rot on the ground, or are converted into manure. A full-grown plantain or banana stem weighs about one hundredweight, and contains only about two pounds of fibre. The bulk of the stem is made up of watery juices and soft pulp. A simple and effective machine of the nature of a wringing or mangling machine is required, through which portions of the banana or plantain might be passed to free them from water. The machine must be portable, and the rollers should be made of hard wood. Iron would soon rust, and also be too heavy. When the stems have been passed through the machine, they could then be easily carried to a more elaborated fibre machine, or taken to the nearest stream and washed and beaten.

“It is well known that banana fibre is not of high value, and probably would not be worth more than one penny or penny half-penny per pound. On the other hand, its production, under present circumstances in Jamaica, would entail very little expenditure, and, with a suitable machine, would bring in a considerable revenue to the cultivators. Even at one penny per pound, Jamaica could produce banana fibre worth about £20,000 per annum.”

We also want information as to the latest processes of sugar-making—that is the means of extracting the greatest quantity of juice from the cane, and the greatest quantity of sugar of good quality from the juice. We should like to obtain, for instance, a model of a diffusion plant, now so largely used in Europe in the beet factories. It is possible that the fibres of the cane may prevent the rapid and easy slicing by knives, which is found adapted to the beet-root, and that the process may not be found a good substitute for the old-fashioned system I believe that enterprising planters, both in Demerara and St. Lucia, are making practical experiments, and we hope to be able to obtain for the information of sugar makers in Jamaica a model of the apparatus employed. Rum distillation, too, is important for Jamaica. Rum is a natural product of the sugar-cane, and is an article for which Jamaica has long been famous, the flavour and quality depending not so much upon manufacture as upon soil. The Chancellor of the Exchequer recently asked: “Who drinks rum?” It is evident that a considerable quantity is drunk, and some is no doubt employed in the manufacture of European brandies and whiskies. So long as there is a demand for rum, Jamaica is justified in producing it, and no other country has such natural advantage for its production. A knowledge of the latest improvements in distillation might supersede the somewhat crude and rule-of-thumb method too frequently adopted.

It would be also interesting to obtain models or specimens of machines for preparing the coffee berry for consumption, and others showing the different forms into which cocoa and chocolate are made such attractive articles of food. The preparation of turtle for food, castor-oil for medicine, and the different gum and rubber manufactures, would likewise be desirable for the exhibition.

DISCUSSION.

Mr. Morris said Mr. Eves had stated that the cost of producing cinchona was too great for it to be

successfully cultivated in Jamaica, but he thought that was not quite the case. After the cultivation had been carried on for some time, the price fell so low that it was really not worth exporting, and no doubt it would be better for the people to keep their trees for the present, and let the bark become more matured, so that when the price rose they would get a better return. The cinchona trees were more healthy in Jamaica than in many parts of the East Indies, so that he had little doubt about the ultimate success of the industry. As to tea, he thought that in face of the enormous shipments from Ceylon and India, that it would not be wise for the people of Jamaica to take up this matter. The fruit industry was one which had grown very considerably within the last fifteen years, for whereas in 1876 the total value of the fruit exported was only about £10,000, it was now between £300,000 and £400,000. That trade had done a great deal of good to the island generally, though there was no doubt better picking and preparation of the fruit would still further increase its value. The oranges grown in the island were very fine. With regard to fibre industries, he had urged the people to take up this branch, and as the price rose 50 per cent. during the last four years, they might have reaped the full value of the increase. However, it was not yet too late to take up the matter. The Jamaica Institute had offered a prize—£50 for a set of machines to produce fibre in different stages, and he had great hopes of such a machine being brought out. They also wanted a machine for preparing Liberian coffee. Lately the price of this coffee had increased to such an extent, that in Java it fetched a price equal to that of the best estates coffee, and it could be grown upon the old sugar plantations. With regard to the rum industry, attempts were now being made for the first time to carefully examine the yeast, and trace the real cause of the different qualities of rum produced. There were numerous industries in Jamaica which might be taken up, but the people were so comfortable, and so satisfied with their beautiful climate, that it was very difficult to stir them, and get them to take sufficient trouble to develop fully the resources of the country. He had no doubt that the Exhibition would be a very great success, and that it would be a benefit not merely to Jamaica, but to the whole group of our possessions in the West Indies.

Rev. D. J. East, who had resided for thirty years in Jamaica, said:—The great want of the island with regard to minor products had already been dealt with by Mr. Morris. What was wanted was a better class of machinery, both with reference to fruit and fibre. The people needed instruction as to the gathering of the fruit. He had seen oranges pulled from the trees, thrown into carts, and brought into Kingston in a condition which gave very little promise of their realising a return. He had also seen them hand-picked and properly packed, first in paper, and then in suitable barrels for their conveyance, and the difference in the result had been perfectly amazing—the one method as contrasted with the other. Another great want in connection with the fruit industry was better roads in order to bring the produce to the wharves for shipment, and he was glad to know that Sir Henry Blake was giving special attention to this subject. He thought Jamaica might supply the world with fibres. Some of the most valuable fibrous roots would grow on land which was hardly suitable for any other production; but the great want with reference to fibre was suitable machinery. They had not yet had a machine of so simple and effective construction as to be of much use, especially to the peasantry of the country.

Mr. H. Stern said:—Reference had been made by Mr. Morris to the advantages which might have been reaped by cultivating fibre plants, but it was no use doing so unless they had a machine to extract the fibres. Some years ago the Government offered a prize of £50 for any machine which would extract the fibre from the Sisal hemp, and a machine was invented by Mr. Kennedy, but it was found that that would not extract the fibre with sufficient economy to make it marketable. He was very glad to see that another prize had

offered, and he hoped that some good would result therefrom.

Mr. Morris remarked that fibre machines had been at work for eleven years in Yucatan and six years in Mauritius. There was no great difficulty about cleaning Sisal hemp, or the pineapple family; the great difficulty had been with regard to the banana and ramie. He had examined some machines at Paris for dealing with china grass, and it was hoped that M. Favier would send one of his machines to the Exhibition. These machines would prepare one ton per day of the ribbons. The cost of such machines was about £20, while the machines in use at Mauritius cost £25. Full particulars of these machines are given in the *Kew Bulletin* for November, 1889, and May of this year.

Mr. O'Halloran asked what success had attended the efforts of Mr. Morris to cultivate Manila hemp, which was always marketable, and in very great demand.

Mr. Morris said the Manila hemp, which was yielded by a kind of banana, was introduced into Ceylon and Jamaica a good many years ago, but unfortunately, they had not been able to get it to flourish; in fact, they had the utmost difficulty even in keeping the plants alive at Kew. He did not believe that the Manila hemp could be a success in the West Indies. It had been under cultivation in Trinidad, Demerara, Dominica, and at St. Vincent, but they had found that at no spot outside the Philippine Islands would the plant flourish. It would be possible to send the Manila hemp to any part of the West India Islands, where the conditions were likely to be favourable, but up to the present the results had been most disappointing.

Mr. Scott regretted that more attention had not been devoted in the discussion to the sugar and cocoa industries. He thought, also, great advantages might be derived from the Exhibition in connection with the United States and Canada.

Mr. Morris replied that the cultivation of cocoa in Jamaica was well understood, as was also the preparation of the bean. It was understood they had really been talking that evening of industries which had hitherto lacked success on account of the absence of machinery, or from want of special knowledge. They could not expect to cover the whole of the ground at that meeting, though he was very glad that Mr. Scott had mentioned the subject. They were now dealing with the special difficulties which had hitherto arisen in Jamaica. He believed as land was opened up, and the facilities for transport improved, the cultivation of various industries, both new and old, would be undertaken in the West Indies.

The Chairman said:—I do not know how it may be now, but 50 years ago there were great differences between the coast aspect of Jamaica, and of San Domingo and Cuba. These larger islands are equally beautiful in scenery, but in those days Jamaica alone seemed well cultivated, and to show along the coast line the residence of a population in favourable conditions of life.—*Journal of the Society of Arts.*

EXPERIMENTS WITH MANA-GRASS —ECONOMIC PRODUCTS FOR THE ZAMBESI.

A long letter obligingly written me yesterday by Mr. Ibotson is not very encouraging as to anticipation for success with the present set of experiments for testing the suitability of mana-grass as a board-making material. When my last notes on this topic were written you, my letter stated that it was intended to try the effect of subjecting the boiled grass to the action of edge-runners in the pug mill before passing it into the pulping troughs. It will be as well to give you Mr. Ibotson's own words on this subject, though even his trained opinion must not be accepted as conclusively proving that mana-grass cannot be utilized for the purpose desired, because so much might follow as the result of chemical admixture during the boiling process

which is antecedent to those undertaken at the Poyle Mills. Opportunity has not yet occurred for me to learn what the chemical experts may think on this special point, and speculation by myself as to possible remedial treatment had better therefore be omitted, though I can see no insuperable obstacle to its success in anything that Mr. Ibotson has written me. The following are the terms of that gentleman's letter to me:—
"Poyle Mills, Colnbrook, Bucks, September 2nd, 1890.—My dear sir,—The treatment of the mana-grass with edge runners certainly improved it a great deal; for whereas we could not at the first trial without edge runners get the stuff to mix with the water at all, on our subsequent trial after being put through the edge runners the fibres mixed with the pulp and worked very well on the cylinder.

"But there was no alteration in the making of the board on the winding cylinder. The fibres or stalks appear to be too hard, and will not felt together into a board. We made two long trials on two separate days—one was of the grass alone, and the other of the grass with boiled starch added, but in neither form could we get a single board that would hang together so as to be taken off the roll. We obtained a few pieces, but that was all; there was no consistency in it to make the board hang together.

"Mr. Stanley and Dr. Evans came down and saw the stuff on the machine. We shall send up to the Syndicate the boards—such as they are—with all pieces that seem likely to throw any light on the subject. But our own opinion is that the grass is a very troublesome material to treat, and that any process that would render it suitable for making into boards would be found a very expensive one to work.—Yours very truly,
(Signed) H. P. IBOTSON."

Mr. Thomas Christy, F.L.S., who has on so many occasions obliged me with his valuable opinion as to the nature and properties of Ceylon products, has just shipped this week from the London Docks to a Portuguese trading colony on the Zambesi the largest consignment of economic plants which has even left this country to a single order. The plants shipped included coffees, teas, cocoas, peppers, and vanilla, all plants in fact which have formed leading products among yourselves. Mr. Christy selected and packed all the specimens, and he views it as a singular fact that the Portuguese should be compelled to turn thus to the English to assist them in developing the resources of their African territories. What a change this is significant of that has arisen since the Portuguese were the chief colonizing power of the world!—*London Cor.*

LAWES' CHEMICAL MANURE.

The ordinary meeting of this company was held this afternoon at the New Corn Exchange Hotel, Mark-lane.—Mr. W. Colchester, who presided, moved the adoption of the report stating that the net profit for the past year amounted to £25,877, added to which was the balance brought forward, making a total of £33,692 available for distribution. Out of this sum the directors recommended dividends of 7 per cent. on the preference, and of 10s per share on the ordinary shares, carrying £2,500 to the reserve, and writing £5,000 off the land, plant, and goodwill account, leaving £7,789 to be carried forward. During the past year six of the company's acid chambers at Barking had been renewed, and a proportion of the cost charged to revenue. The remainder, amounting to £3,755, the board proposed to write off in equal amounts during the next two

years. The directors had commenced to erect some additional sheds at the works to enable them to store the raw materials required in the manufacture of manure in such a manner as would prevent the necessity of their removal after once being discharged. By this and other means the board hoped to reduce the increase in cost of production caused by the higher wages conceded to their workmen during the past year.—The report was unanimously adopted.—*Globe*, Aug. 29th.

NATIVE PERUVIAN COTTON.

The United States Consular Agent at Payta says that, after five years of drought, the province and State of Payta are naturally depressed in the way of commerce and all kinds of industry. The valley of Obira forms a favourable exception. The production of the valley consists principally of native Peruvian cotton (*Gossypium herbaceum peruvianum*), an article used very extensively in Europe for the manufacture of woollen goods with which it mixes readily, on account of its rough, strong, and long fibre, is produced abundantly throughout the State after the rainy seasons, which are periodical, and occur generally every seven years, and is cultivated always along the banks of rivers, on lowlands irrigated by the overflow of streams. The plant is arborescent and perennial, and after fully developing continues producing cotton for five or six years in succession, provided there be some moisture in the ground, needing, however, very little of it on account of its deep rooting, thus reaching moisture at great depths. The system of cultivation of this plant is quite primitive, the seeds being planted by making holes in the ground with spades, without tilling or manuring the soil. The plant becomes developed and begins to bear cotton in dry and sandy soil about six months after planting, and about nine months in rich and wet land, continuing to yield at short intervals for five or six more years in succession. The plant may be observed in blossom, with pods, nuts, and cotton all at the same time, and giving a continual yield for the time above stated. In certain seasons of the year, about every seven years, the rains are incessant for about two months, both in the interior and on the coast, and water descends in such abundance as almost to inundate the country. Large torrents stream down the mountain side, the valley of the Obira is deluged, flat lands within it are turned into morasses, and morasses into lakes; in fact, the lowland becomes submerged, and the accumulated mass of waters rush with great force down the central valley which forms their only outlet. The valley, however, is wide, and the descent very gradual. The extent of the valley through which the water flows is from three to four miles wide, and although it is nearly 200 miles in extent, the valley for the whole distance is almost level. The rains generally cease in March, but it requires from thirty-five to fifty days for the water to disappear and leave the land dry. As soon as that is effected there springs up, from the whole surface of the ground which has been thus submerged most luxurious vegetation. The soil is wonderfully rich, and has been under cultivation by the aborigines from time immemorial, and its fertility is kept up unimpaired by the slime which is abundantly deposited during inundation. The cotton is collected, when the pods open, by women and children, who are paid in proportion to the quantity collected, the prevailing rates being about 1s 8d for every 100 pounds. It is taken from the field to the ginning house, where it is cleaned and made up into bales of about 175 pounds each. There are five of such establishments in the province of Payta, one in Querecotillo, on the east side of the river, owned by an Englishman; two in Sullana, a city of about 4,000 inhabitants, on the west side of the river, owned by natives; two at La Huaca, owned by an Englishman and an Italian. A considerable quantity of cotton is annually exported, and seeds are now also exported for oil-making. Europe is the market for both products.—*Manufacturer and Inventor*, Aug. 20th.

RUBBER COLLECTING IN THE AMAZON VALLEY.

A correspondent, signing himself M. C. M., writes to the *Daily News* as follows:—

May I be allowed to speak a word of warning through your columns, to any young men who might be induced by the offer of a high salary to go out to the interior of South America? Last autumn four young men were induced by a wealthy Spaniard, who was visiting Liverpool and Manchester, to go out with him to his estate on one of the tributaries of the Amazon. They found when they arrived there that it was a rubber plantation worked by slave labour, and that two of them were expected to act as overseers. It is not, indeed, slavery in name, for payment is given in the form of a nickel token, with which the labourer buys his rations; but it is compulsory labour, extending to mere infants, and enforced by the cruelties of the lash, and sometimes of the rifle bullet. The English nature of these young men revolted against such a system and they resolved to escape on the first opportunity. Two of them succeeded in doing so, and are now in England, eager to tell their story to save others from being similarly deluded, and if possible to stir up an agitation which may lead to the deliverance of the poor oppressed natives. The third (a near relative of my informant) was drowned by the upsetting of a canoe on his way down the River Madeira. The fourth was unable to accompany his comrades, being ill of fever when they left. I write this in the hope that their fate may deter others from venturing into an unknown region among strangers, unless after searching inquiry they can obtain satisfactory assurance as to the kind of work required, and the character of those who engage them.—*India Rubber Journal*.

SOUTH AFRICAN EXPANSION.

About a month ago Mr. Stanley when referring in laudatory terms to the Anglo-German agreement used these words:—"You have a glorious tableland, and you are in the heart of Africa. So I see now prospects by which British people could breathe in the heart of Africa, whereas before I was very doubtful whether colonists could live there and multiply there as they have multiplied in America; but I see now a possibility, because you will have the whole slopes of Kenia, that magnificent tableland rising to 7,000, 8,000, or 9,000 ft. You have also Mfumbiro, the Mountains of the Moon, and that great escarpment of marl stretching right up to the neighbourhood of the fortress station of Baker. All that territory is fit for colonisation—900 miles in length and 700 miles in breadth." Yet this territory is traversed by the equator. We thus have the great explorer's testimony to the fact that British settlers can be expected to live and multiply under the vertical sun of the line, provided that the country they occupy is at such an altitude above the sea level that the effects of equatorial heat are qualified and neutralised. Heat in a rarefied atmosphere is not only bearable but is compatible with salubrity of climate and vigour of life. This view is corroborated by observation in other equatorial regions—in Peru, in Ceylon, and in the Eastern Archipelago.—*Natal Mercury*, July 30th.

EXPERIMENTS which have lately been made in the Madras Presidency in the treatment of rinderpest with solid cinchona febrifuge, have been encouraging. Out of twenty-two cattle experimented on, fifteen recovered, one was relieved, and only six died. The inspector of cattle diseases says that the drug reduces the temperature very considerably in the first stages, but that in an advanced stage it is of little or no use.—*Indian Agriculturist*.

THE STEEL ROPE MOTOR: A NEW DEPARTURE.

We call special attention to the following account of the completion and success of the first steel rope motor or conductor of power, utilized in Ceylon. Mr. N. M. Adam, who has seen the Rosneath machinery at work, expressed the opinion to us that the principle is capable of being applied for steel ropes travelling very much longer distances than in this case. There is no reason indeed why steel ropes from a huge turbine, or series of turbines, below St. Clair, Devon or other falls should not be carried to Factories in half-a-dozen directions, for distances up to a mile or so?—Wo heartily re-echo the regret felt that the respected designer—that able and good man, Mr. John Walker, did not live to see the successful issue of his Rosneath proposal.

(Communicated.)

Ceylon is not generally behind other tea-growing countries; but it has been so in the matter of conveying power from a distance by means of a wire rope, and utilizing it for driving purposes. We have had wire shoots and tramways, which have done excellent service; but for this higher work, although much has been written and talked about it, the planters somehow have fought shy and been chary of introducing it. At Darjeeling, as well as at home and elsewhere, it is not uncommon to see the steel rope carrying power from a distant point, and this too in a highly successful way. Here however, a good deal of money will rather be expended in excavating a bad site for a factory so as to bring it to the power, than the other way of bringing the power to the factory; and if this can't be done, well an engine is gone in for, which needs constant feeding, and the cheap water motor is sighed over and neglected.

The first introduction to Ceylon of a wire rope arrangement has been made at Rosneath estate, Kandy, and has turned out a complete success. It was during the last visit of the late Mr. John Walker, founder of Messrs. John Walker & Co., that the matter was talked over and arranged for; the details and plans being in the hands of Mr. John Grieve of Messrs. Walker & Grieg. Those who know Mr. John Walker, and have seen how this his last work in Ceylon is as eminently successful as aught else he set his mind to, have considerable regrets that he is not alive today. He would certainly have been satisfied.

Rosneath has no firewood and but a small water supply, so to make the most of what water there is was a necessity. The factory is built on a suitable site at the top of a fall of 70 ft.—the ground, which is very rocky, sloping gradually away from the factory. To utilize this fall the turbine had to be placed a considerable distance from the factory. The turbine is supplied with water from a dam and is regulated at the roller. So that the whole arrangement is well under command and no water need be wasted. The wire rope which transmits the power from the turbine is nearly 100 ft. long, and is carried over a cart road. There was a fear that this might be an objection, as the noise might frighten horses; but so silently does the rope slide along that it can scarcely be heard.

The difficulty of adjusting the rope to suit the change of temperature, and the wear, is got over by means of a very ingenious, efficient, and automatic arrangement. Had this been known to the railway engineers at the time they were struggling with the wire shoot at the Blackwater slip, most of their difficulties would have disappeared.

There was one point which caused some fear and trembling. That was the possibility that the rope itself would absorb much of the power. This however has turned out only nominal: so easily is the rope driven that four times more power can be taken out of the water than was formerly developed by a water-wheel. Messrs. Walker & Greig have the credit of erecting the first steel-rope motor in Ceylon; and, as has already been said, they have done this most successfully. Mr. John Grieve, who has seen to the erecting, and generally supervised the work, is fairly justified in feeling not a little proud of it.

TROUT FROM NUWARA ELIYA.

Mr. Le Mesurier's experiment in trout breeding is producing good results when he is able to give out lively good sized trout to stock other streams. Last week, Mr. Nock of Hakgala got no less than 32 of such trout to carry down and place in the "Sita Ella"—the romantic as well as beautiful stream (a big "burn" in Highland terms) which derives its name from the traditions which fill the neighbourhood with the names of Rama, Ravana and the Queen Sita. Mr. Nock most carefully discharged his duty and was rewarded by seeing all the trout swim away as lively as possible, in the sheltered pool into which he placed them. Anyone who has travelled down the road to Hakgala may have observed that the Sita Ella is, in many respects, the *beau idéal* of a trout stream with its clear pure water, numerous level reaches as well as tumbling cascades. We trust there will be no interference by natives, (there was a rumour of a Sinhalese with dynamite being heard of interfering with streams towards Horton's Plains: should he be caught, severe punishment ought to be awarded); and as the Sita Ella runs along so public a road, travellers should be a check on would-be depredators. We would fain hope that a full measure of success may attend the trout experiment here as well as in all our higher streams. Already trout of several lb. each are spoken of as having been seen in connection with some of the earlier experiments, and a Straits visitor—an eager angler—wrote to us the other day from Singapore that he was never more tempted than by a fine trout he saw in the Nuwara Eliya stream.

COTTON GROWING IN CEYLON.

In answer to Mr. James Robertson's enquiry, the Hon. W. W. Mitchell is good enough to give the following information:—

Mr. Robertson sent us sample pods about a month ago and I reported on them to him. It is just the kidney cotton, that so much has been written about, and I really cannot say more than Mr. Robertson says, that "it is the proper kind for Ceylon." I don't think that seed need be imported, for there are trees in many parts of the country, but they are scattered and no quantity can be got anywhere.

I have been supplying Egyptian and New Orleans kinds free to Government and we have plenty of such, but to their requests for kidney kind I have had to say: "Collect it in the villages through headmen—for I have none."

To that part of Mr. Robertson's letter about oil from seed I cannot reply. It could not compete in Europe and would only do for India.

The S. & W. Co. are selling lots of seed of the other kinds at £2 per cwt. and it seems as if the production of it would all be taken off for cattle feeding.

MR. SCOTT BLACKLAW ON BRAZIL.*

PLANTING AND RAILWAYS—MINERAL WATER SPRINGS AT POSSOS DE CALDAS—THE ARGENTINE REVOLUTION.

We cannot leave Campinas without recording that it was here amongst the wealthy coffee planters that the great agitation for railway extension was commenced, and continued. British engineers, working with British capital, showed how railways could be made and managed. The Sao Paulo Railway was opened in 1862 to São Paulo, and a few years later to Jundiáhy, where they stopped. The wealthy coffee estate proprietors saw the advantage of cheap and expeditious transport for their produce to the seaport, and did not flinch from risking their own spare capital. The Paulista Railway Company was formed, and no guarantee of interest was asked for. The object of this local Company was to continue the line westward on the same gauge. Starting where the British Company left off at Jundiáhy, they had their first section opened to Campinas at the beginning of 1873 (28 miles) and to Rio Claro in 1876—56 miles further. They made a branch towards the north from Cordeiros, a station south of Rio to Claro, and this they extended until they have now 150 miles opened.

To give traffic for their line they removed several obstructions on the Rio Magyquassú—a river at the terminus of the branch—and put on its steamers of small draught to tow barges which ply for some 100 miles towards the west. The Company has paid an average of 9s.

Campinas continued to be the centre of railway agitation, and it was here that the great Company Moggana was floated and a metre gauge adopted. The first section of forty miles on this narrow gauge—the first which was tried here—was opened in 1875. The writer of these notes was present on that occasion. It was considered so important an undertaking that the Emperor and Empress came from Rio to do the opening.

I well remember how surprised I was to see the small American locomotives and the small saloon carriages, long and projecting over the wheels. Little did any one then think, that in a few years the same Company would carry their line far into the north-west of the Province and into Minas and have by the end of 1888—including branches—a length of 500 miles. The Stuaena Railway I have already mentioned, as going in a south-westerly direction from Jundiáhy. It was commenced and continued about the same time as the Moggana, on a metre gauge, and as already noted has with its branches a length of over 100 miles: the actual length is 113 miles—but it has not paid so well. The districts through which it passes are not so suitable for coffee, but cane and cotton grow well. Both cotton and sugar have fallen considerably in price, and were it not that there is a local demand for the fibre, to supply three or four local cotton factories, the cultivation of cotton would be entirely abandoned. Cane—whose juice is oftener turned into rum than into sugar, pays the cultivator fairly well, but depends for its success on the local demand for inferior sugar, and rum. A great deal of Mascava sugar and molasses rum from the northern ports are imported into Santos for consumption in the Province of São Paulo. There are three large central sugar factories which although worked at a loss for few years are now paying fairly well.

The Sorocabana Railway branches off from the town of São Paulo, goes south-west, through cane and cotton districts, and in the meantime stops at Botucatu, a rising coffee district. It has already opened 233 miles, and is extending some 150 miles

southwards towards the river Paranapanema, where in anticipation large blocks of land have been bought up. The river Paranapanema is the division between the province of São Paulo and that of Parana. The county on the sides of this river has not been explored, and consequently there are a good many Indians who may give trouble to first settlers. Notwithstanding this, land-seekers are looking towards it, and Land Company schemes are being organized to buy land from the Government. This soil is said to be good on the high lands for coffee cultivation and there are millions of acres in the plains suitable for pasture. I cannot say that the Sorocabana railway has paid well, there is a sort of mystification between original shares, preference shares, 1st debenture stock, 2nd debenture stock &c., &c., but they always keep on extending, and with the opening up of the "Wild West" of São Paulo and Parana. I feel certain the shareholders and debentureholders will have a secure investment. I have already mentioned the Bragança Railway striking northward from the São Paulo railway 30 miles from São Paulo. It goes northwards to coffee districts and measures about 33 miles.

The Paulista Company, which I have already mentioned, had extended to Rio Claro directly west and to the River Magyquassú to the North of Rio Claro, and although they had the preference to extend west preferred to from the latter place. They give their attention more to the opening of the river navigation I have mentioned than to extending the railway beyond Rio Claro westward. The cry of the planters had to be listened to, and the Rio Claro Railway Company was formed to carry a meter gauge line from Rio Claro westward, and with branches this Company now have a length of 165 miles. The line has paid well, and has only a few months ago (June or July 1889) been bought up by a British Company at a handsome profit to the Brazilian shareholders. This line has a bright future before it, for its zone extends also toward the rich *terra rocha* and pasture plains in the west of São Paulo, and to the Province of Mattagrossa. At present the communication between the last-named province and the Capital of the Empire—or even the Capital of São Paulo—is by sea via the River Plate. The lands in Mattagrossa are said to be good for coffee, cane, cotton and tobacco and cereals. In the forests are mate, rubber, copaiba, and cinchona, with a host of other industrial and medicinal products. An excellent quality of wheat can be grown, and the high elevation of the great plateau, extending from the Serra de Mar to the foot of the Andes, has a climate which European people can work in and live in.

The following is a list of the railways which have been made since 1873 when the present writer arrived in this province for the first time. At that time only 120 miles were opened, the São Paulo Railway from Santos to Jundiáhy 93 miles, Paulista from Jundiáhy to Campinas 27 miles. Now there are Rio de Janeiro and São Paulo Railway from Cachoeira to São Paulo starting from the end of São Paulo branch of D. Pedro 20...141 miles "Sorocabana" from São Paulo passing

Soraciba	233	"
"Bragantina" branching off São Paulo Railway	33	"
"Suana" from Jundiáhy passing by Suana	113	"
"Paulista" from Jundiáhy to Rio Claro and branches	150	"
"Rio Claro" from Rio Claro to Arara-guara and branches	165	"
"Mogyana" from Campinas, passing Mogymerim and branches	500	"

* From notes in September 1889, supplemented in July 1890.

Or in round numbers 1,300 miles of railway since the agitation was begun at Campinas sixteen years ago. We all remember the great rise that, about these times, 1873-5, took place in the price of coffee. The leaf-disease had not taken such hold on coffee trees in Ceylon, there were hopes that a cure might be found, or that it might leave in the same mysterious way that it came. Brazil was then looked on as the great rival of Ceylon. In these times your readers seemed incredulous at the figures I gave in estimating coffee crops to be shipped from Rio and Santos, but we were always at one in calculating the great benefit to this country and to your own of railway extension. And how much have all our estimates and calculations been exceeded as regards Brazil in both of these? But, alas! owing to that leaf-disease calamity, Brazil is no more the rival of Ceylon, and the impetus which railway extension has given to coffee production in São Paulo does not interest you since the cultivation of the valuable bean is not your standby any longer. In any case looking at the subject from an economical point of view, the same arguments showing that railway extension is the most important factor for the increase in production, can be applied to any country. Let us look at the figures for São Paulo as applied to coffee alone. At the same time all of these railways, which I have given you a list of do not depend for traffic on coffee alone. In many cases, in particular districts, where little was expected owing to their being out of the coffee zone, large quantities of other things, such as cotton, cane for central factories, Indian corn, beans farinha, lime timber, stones (flags or slates), and a host of things, that no one formerly thought of being transported, have contributed to make receipts exceed expenditure. The same thing would take place in Ceylon, were your colonial authorities to reverse their stick-in-the-mud policy, and spread a net work of railways over your luxuriant island. Leaving out your mountain zone, there is no reason why railways to Mannar, Jaffna, Trincomalee, Batticaloa, and right through Bintenna, could not be made as cheap as in Brazil—£3,000 per mile. Many things which would contribute to give traffic, we do not dream of at present, both from the interior to the seaports and from the seaports to the interior. Given means of transport, a healthy climate, good soil, an energetic class of men to direct, and there is no end to the resources of a new country; and you have all these factors.

But let us return to São Paulo.

In 1860-61 just before the Santos-São Paulo Railway was opened:—

The export of Coffee from Santos was	82,608 sacks
In 1876-77 just as the first metre lines were being extended	628,898 „
In 1888-1889 with the mileage I have given above	2,641,706 „

Each sack holds 60 kilograms of coffee, and 1,790 to a ton.

Let us give all honour to the coffee planters around Campinas for seeing the great advantage the railway system was to bring them, in a cheap and expeditious means of sending their produce to market, and for their courage in risking their spare capital in these metre gauge railways. What though these projects were to open up parts which were almost geographically unknown, hunters, wandering pedlars and pack-mule men could tell of large blocks of forest at such an elevation above the surrounding grassy plains as to be entirely free from the visitation of frost; and they with beaming eyes would listen to eloquent descriptions of the enormous size of and produce from some few coffee trees, near

some native hut in the interior; and then the *terra rocha* was always richer the farther west one went. Wherever a railway was projected, land seekers would flock, land would be bought, forests felled and burned, coffee planted if not with plants or stumps then with seed, enormous crops of Indian corn would be taken off the land while the coffee plants (put in 12' by 12') would be growing, beans, and rice would be grown largely, houses would be built which would be the nucleus of luxuriant palacettes to be. Villages would spring up, churches, post offices, tax-collector's offices, would follow, and soft, hard and dry goods storerooms would flock to the centres and build huts in which to vend their wares. So that what a short time ago was a waste wild as the dark continent would soon be turned into a flourishing countryside, so that by the time the railway would be opened traffic would be ready for it.

But what about the working population for the development of all this? Well, we shall see as we get further on. Meanwhile we are embarked—as they have it here—on the great metre gauge railway at Campinas. This Mogyana railway, which has given 14 per cent from the commencement to the shareholders and every year added a large sum to its reserve fund, which by its results owing to economical construction, and good traffic management has enamoured the people of this country with metre gauge railways.

In Brazil after this great success no other gauge is thought of, and only the first made line, the Dom Pedro 2o, and the São Paulo, with the continuation the Paulista, are on a wide 5' 3" gauge. The extensions of the great Dom Pedro 2o, are now made on a metre gauge, and at the time the Government took this new departure with its own line, it was only after an agitation by the Club of Engineers of Rio de Janeiro that the authorities were prevented from tearing up about 100 miles of broad, and putting down a narrow, gauge. Although I have all the discussion of the Club in my possession I do not care to revive the subject: how often has a discussion of gauges hampered the promotion and delayed construction of useful railway lines!

But after this long digression, let us continue our journey along the Mogyana railway. Up to Mogymirim, some 45 miles, there is nothing worthy of note; the country is undulating and owing to this the line is very crooked. The exploring engineers seemed loth to lose the side of a small stream when they found one, and unwilling to lead the trace where deep cuttings and heavy embankments would be necessary. As should be in tropical countries the waterways are ample, open culverts being the rule. Bridges were first made of timber, but are now being replaced by iron. In large bridges, which are very few, preference seems to be given to the American truss system. Now and then a ridge higher than the ordinary level of the surrounding country has to be crossed, and there we see coffee fields. The current crop is nearly all picked, (September 1889) and the trees have suffered very much; in fact old coffee trees are left a mass of dry sticks. The late dry season has contributed greatly to this, but the old hand sees it is the result principally of excessive bearing. The dry weather has not prevented the weeds from growing, and although the majority of estates are pretty clean, many are requiring the mamoty. It is astonishing how soon coffee trees planted in *terra rocha* recover vigour after a few showers:

* Better a line on any gauge than none, but the standard gauge will ultimately supersede all others. As we in Ceylon have now over 200 miles of 5' 6" railway made or under construction, our wisdom is not to break gauge.—Ed. T. A.

drought or heavy bearing does not permanently affect it. All the same on all these coffee estates between Campinas and Mogyimirã I prophesy scarcely any crop at all for season 1890-91, that is coming season. Labour seems plentiful enough. The planters hereabout were the first to avail of European colonists—indeed they were in a manner forced to try something, for the exodus of negroes from the cane plantations in the north, or indeed their introduction from any other province was stopped by putting a tax of £100 on every slave entering the province. This was in 1830. Judging by the number of labouring men's houses one sees on all the estates, and the number of European children one sees playing about them, there does not seem to be a scarcity of labour here.

At Jaguary station, 12 miles from Campinas, a branch line of the Mogyana railway goes to Amparo, north-about 20 miles, (31 ks) on the same gauge, to a rich coffee district, and from Mogyimirã another branch goes north by a place called Penha to the boundary of Minas Geraes about 35 miles. I may here mention that from the end of this branch a line is under construction which goes along the other side of the Serra Negra, and continues on the west side of the Serra Montiqueira, coming out at Barra de Pirahy on the D. Pedro 2o Railway. It is thought that this new line has a great future before it. It certainly opens up a large extent of agricultural country and will compete largely with other companies for passenger and goods traffic to Rio de Janeiro, the distance being shortened from here to the last-named place, some 50 or 60 miles. It will also pass by Caximbu mineral water establishments, the resort of many invalids, and the water springs of Lambary, a sort of Brazilian Seltzer, which is bottled and sent to the large towns.

Mogyimirã is a very pretty, clean-looking country town, of some 4,000 inhabitants, and built on rising ground above the level of the railway line. It gave the name to this railway. In these early days of railway construction the Company were doubtful if they could go beyond this district. They soon, however, opened to Casa Branca, making their line 106 miles long from Campinas. On the extension to Casa Branca (*anglice* white house), at 80 miles from Campinas, is the station of Cascavel (*ang.* rattlesnake); from here goes a branch of the same company to Possos de Caldas (wells of Caldas) some 45 miles (77 ks).

Possos de Caldas has been for many years a resort for invalids suffering from various chronic diseases. Sulphurous waters spring out of the ground at a very high temperature. I have for many years had a wish to visit this wells, and you will remember our late lamented friend G. A. C. was to have accompanied me there in 1875, after our shooting excursion to the west, but at this long time I cannot now recall the reasons why we did not go. From where I lived the journey would have taken on mule back four or five days to go; and as long to come back. Now-a-days we have a railway all the way. In the absence of personal observation of this part, I can only give you second-hand information. *Nossa Senhora da saude das aguas de Caldas* (our lady of the health of the waters of Caldas—such is the literal translation) is the name of the village which has of late years sprung up around these thermal springs. The wells have long been known, but being situated in a wild almost inaccessible district, in the south of the Province of Minas Geraes. Few people visited them before the Mogyana Railway was made. Being some 15 miles outside the Province of S. Paulo, it was not within the zone allotted to the Railway Company. That was not the only reason however which delayed the construction of a branch railway to Possos de Caldas. The country is barren, sandy and rocky,

and offers very little prospect of traffic, for goods of any description. The soil is not suitable for coffee, and the pastures are not fit for fattening bullocks. The Company got a guarantee from the Government of 6 per cent per annum. The line has not been open for more than a year, and in that year the receipts were some £2,000 less than the expenditure. The Company were thus justified in being reluctant to make this branch sooner. Here are the figures in Brazilian money. You will see that coffee is nowhere and animals are a small item:—

PassengersR52,398	\$43
Parcels and baggage 4,708	520
Animals 366	340
Carriages 3	900
Merchandise 41,613	440
Telegraphs 1,723	620
Store Rents 19	000
Accessories 354	710
		<hr/>
Expenditure ..	R101,181	960
	.. 120,591	450
		<hr/>
DeficitR19,409	\$499

The merchandise mentioned, there would be general goods, to supply the local stores, hotels, vendas, &c.

The Company after they saw the line was not paying commenced to run the train once in two days, but a paternal Government, anxious about the health of its people, ordered daily trains, and as Government guarantee 6 per cent of course they are bound to run them. The attractions of the place in these wild hills, at an elevation of some 4,000 feet (1,200 metres) above sea-level, ought to draw many passengers bent on pleasure only, but the unfortunate thing here is that the hot season which ought to send people to the hills is in this country always the rainy one, and the uncomfortable-ness of these hilly regions in wet weather is in the inverse ratio of their pleasantness in fine. Still enterprising hotel-keepers offering comfort and luxuries at a fair price, which is rare here, ought to draw many visitors; and I have no doubt when the usefulness of these sulphur baths is better known, tourists and invalids will come from all parts of Brazil and from other countries to test their efficacy. Their history may be summed up as follows:—Some time during the last century when Brazil was a Portuguese colony and very thinly populated, some huntsmen on their chase after tapir, deer and wild boar were led by the accidents of the chase into a small valley surrounded by high hills. At the sides of this valley they discovered some earthslips, and noticed sulphurous warm water oozing through them. It was afterwards found that these springs were almost similar to those at Caldas in Portugal. This gave the name to a town which sprang up some 15 miles to the east, about 1813, and which is now the city of Caldas, and the county town of a large district. The efficacy of these waters in curing rheumatic disorders was known before the year 1815, for in that year a wealthy planter who had been obliged through sickness to experiment on his person their effects, set about purchasing a square Portuguese league of the land (16 square miles Eng.) with the springs in the centre. The Provincial Government laid claim to the land, but the original deed on which they relied, dated 1795, could not be found, only a copy of it. The proprietor found difficulty in retaining quiet possession. In 1865 the rights of the Provincial authorities were again agitated, and to get rid of the annoyance the owner or occupier gave, by deed of gift, some 250 acres (26 $\frac{1}{2}$ alqueires) in which was included the land on which were the wells and the village, and to settle the question once for all the Pro-

vincial Assembly in 1870 authorized the President to disappropriate the land, declaring it of public benefit.

In three years the Government spent some £3,000 in trying to make the waters useful to the public, but with very poor results, as the money was spent uselessly. Then it was thought they could be better developed by private enterprise, and a concession was given to Dr. José Caetano dos Santos, and he raised a company in Rio de Janeiro in 1873 under the name of Don Pedro 2o Thermal springs. Unfortunately the Company did not succeed, it is said they did nothing at all and in 1880 Dr. José Caetano dos Santos was notified by the President of the province that his contract was rescinded. After public competition the right to make baths, build hotels &c., was given to some private individuals, who after bartering and selling parts of their rights, and speculating, the proprietors are now reduced to poor persons. It is said that up till now there has been spent by the syndicate from first to last some £40,000.

The syndicate had a good deal to do, for they found the springs in almost their primitive condition, a series of holes full of boulders and mud, as the tapir and wild boar had left them. These animals made the same use of them as your buffaloes make of a muddy hole or wet paddy field. The first thing to do was to build easiers for enclosing the springs. There was little difficulty in doing this, as the pudding-stone rock, through which the water comes, was reached at from 3 to 4 feet from the surface. The names of the first three so enclosed are *Pedro Botilho*, *Chiquinha*, and *Mariquinha*. There was greater difficulty in the canalization, for the water could not be taken far without losing heat on the way to the baths. This was successfully effected: the water of these three springs was united and conducted in pipes to the bathing establishment by gravitation. This was in 1882. The temperature of these three is from 41° to 45° (Centigrade 112° to 113° Fahr.): at the springs and baths can be taken at the establishment at 37° Cent. (98° Fahr.), which is blood heat. There is another fountain some 600 metres further away named *Macacos*. The baths from it are taken at 35° Cent. (or 95° Fahr.). At the fount this one has a temperature of 42° Cent. (107° Fahr.) It is of this one that water can be drunk if so ordered. The rule seems to be to take a bath at the general baths during the day and in the cool evening take a walk to *Macacos*, to have a drink, the distance from the bath-rooms to *Macacos* being 600 metres—about a third of a mile; but as I said above the water from *Macacos* is also canalized and brought to the bathing establishment losing some of its heat on the way. The two cisterns of *Macacos* water at the bath-house hold 4,500 gallons each.

As to gases 10 cc. 6 were encountered per litre being the same at all the founts. (sulph hydric acid)nitrogen and sulphurated hydrogen in equal portions.

The complaints the waters are said to cure, or to assist medical treatment, are serofula, chronic rheumatism in all its forms, chronic bronchitis, catarrh of the lungs, asthma, diabetes, functional paralysis, female complaints, and effects of mercury in the system.

The visitors to *Caldas* are not confined to those suffering from the above, but it is beginning to be looked on as a sort of resort for people who feel seedy, and for families going to spend a month or six weeks for a change of air. There are nice views from the tops of the hills which surround the little town, and being 4,000 feet above sea level, the climate in the hottest part of the year (barring the rain) is very agreeable.

Visitors from Rio if they go by rail spend one night in S. Paulo and next afternoon they are at the wells. Return tickets are given which extend for a month, these would not exceed £7 for first class: the hotel and bath charges would be about 12 shillings per day.

I have mentioned that the rock through which these waters come is a conglomerate, or pudding-stone, composed of gravel and stones of various sizes with a binding matter of hydrosilicate of lime. The geological formation is no doubt volcanic.

But let us return to our journey and our old friend coffee whom we seem to have last sight of. From *Moygmirim* to *Casabranca* at which place we arrive after a run of some 27 miles from *Cascaes* (where the junction of the *Caldas* branch is); very little coffee is to be seen. The land is what is called *campo*, undulating, and covered with illuk grass. These campos are burned every year whether it be the owner's wish or not, if he do not set fire to them, some mischievous person does. These fires are dangerous things, for often forest land and dwelling-houses get involved in them, and there is no way of finding out who the fire raiser is. Of course one may expect that this keeps the ground in a dry baked state, and not fit to grow any kind of crop. The young herbage which shoots out from the roots of the burnt grass is very sweet and is greedily eaten by cattle, horses and sheep. I should say that nine-tenths of the land one sees along the line from *Mogy* to *Casabranca* is of this class.

At *Casabranca* commences the new districts for coffee which were begun to be cultivated after the railway agitation mentioned above. The great pioneers here were the family of *Prado*. *Antonio Prado* who was for some time Minister of Agriculture and *Martinho Prado*, junior, who was Provincial Deputy, did so much to encourage immigration of Europeans, and was the means of effectually putting an end to buying and selling slaves, being the agitator for levying a heavy tax on all slaves entering from other provinces. These two and their father *Martinho Prado*, senr. were amongst the first to give unconditional liberty to their slaves before the emancipation law was passed, and finally they were the foremost advocates for unconditional liberty being given at once to all which I have already noted. But as this letter has run out to a length which may try your patience I must leave what more I have to say for another occasion. Rio, July 28th, 1890.

P. S.—I intended to have given you some notes on our political situation, but the 'John Elder' has come in, and goes away sooner than I expected. The Republic of Brazil is doing well. I have some notes and translation in pencil on the constitution, which will be revised by the constituent assembly in November next, but I shall write them out for the New Zealand steamer on 31st.

Our Financial Minister, in spite of great opposition from all commercial classes, is adhering to his decree of obliging 20 per cent of import and export duties to be paid in gold at 27d per *milreis*, while paper is valued at 22½d at present. It is calculated that each farthing up or down of exchange counts 1 per cent more or less of duty. This will make up as total tax *ad valorem* on imports of some 50 per cent on most European goods, —unless agricultural machinery, which has to pay 6 per cent emancipation tax.

A fearful revolution has broken out in our neighbouring republic, the Argentine, brought on principally through financial mismanagement and robbery by the governing powers—so says the *Proclamation of the Provisional Government* as the insurgents call themselves. At present the *Telegraph* says they are killing each other in the streets at Buenos Ayres—some 300 having been killed yesterday. At present the fighting is confined to the military, but it is expected the people will take the side of the insurgents, who have some battalions of the army and the part of the navy on their side. The *Proclamation of the provisional Government* accuses the president *de jure* of great irregularities, of robbery, bribery, and interference with the liberty of the subject, and the rights of property. Their paper money is at 310 per cent. That is to say for a 100 gold dollars: one must pay 310 in paper, and duties have to be paid half in gold. The late President is blamed for the depreciation of the currency. President Juarez elman entered into office poor, and is now said now to be a millionaire: the same with other members of his Government. The head of the revolution is General Campos, who has already proved himself a brave officer in the wars, but Leonardo Allem is put forward as President, a respectable citizen and honest.

THE CEYLON HANDBOOK AND DIRECTORY FOR 1890-91.

(From the *Aberdeen Free Press*, Aug. 23rd.)

"The Ceylon Handbook and Directory," compiled and edited by Messrs. A. M. & J. Ferguson, editors of the *Ceylon Observer*, has been mentioned in our columns before now. In a supplementary sheet issued with the overland edition of the *Observer* of 28th July, the preface to the edition of the Handbook and Directory for 1890-91 is printed in full. And in it a very hopeful view of the condition and prospects of our leading Crown colony is given. The knowledge and experience gained in collecting information and making all the needed investigations "justifies us," say the editors, "in repeating the expression of the sanguine hope that, during the term of office—1890-5—of Governor Sir Arthur Havelock, Ceylon will have fully regained (through the great tea enterprise) that planting prosperity which was lost through the dire effects of the coffee-leaf fungus in the time of his predecessors; and we further see the promise in our other new industries, together with the continued extension of palm as well as grain cultivation, of a degree of stable comfort and even wealth for the people such as could not be imagined when Ceylon was at the very height of its ancient glory in the days of the great king Parakrama, the creator of 'the Inland Sea.'"

Of the social and intellectual condition of the "Spicy Isle," the editors say:—"We cannot regard with satisfaction the fact that twice as much is annually spent on 'intoxicating drink' in Ceylon as on 'education and the teaching of Christianity'; the proportion being, according to our estimate, between four and five millions of rupees, say £450,000, on the former, and not quite £230,000 on the latter, or less than twopence per head of the population!"

"Nevertheless, as compared with India, in public instruction, Ceylon is far in advance, having 1 out of 26 of her population in school, against 1 in every 150 in India; while in England the proportion is now, we suppose, 1 in every 4 or 5. Education is very cheap in Ceylon, and in respect of teaching in the vernaculars especially, a small amount goes a long way; but it is an 'English' education that the natives—both Sinhalese and Tamil—crave after, and it is evident that, *volens volens*, our educators, whether missionary or Government schoolmasters, cannot help themselves until in a comparatively short time, perhaps before another century dawns, from Dordra Head to Point Pedro, English will practically be found to be the language chiefly used by the people of Ceylon."

THE PROSPERITY OF CEYLON.

Says the London correspondent of the *Glasgow Herald*—a copy of which has been sent to us by a Ceylon colonist:—

One of the most striking economical incidents in recent British colonial history is the prosperity of Ceylon. Fifteen years ago "coffee was king," as the saying ran in that island; Ceylon depended on coffee as absolutely as Guatemala does now; coffee built railways and made roads, paid the taxes and kept up many an establishment at home. Then came the failure, caused largely by the growth of the South American produce and the fall in prices, and for several years Ceylon was on the verge of bankruptcy, and many of the principal planters went down never to rise again. After a short time, tea was tried, with the now well-known result, I have lately seen a return from Ceylon which shows that tea plantations now cover a larger area than those of coffee did in the palmiest days. Tea flourishes where coffee failed. In whole provinces where coffee was tried over and over again with no result, tea plantations now flourish. Tea, again, grows luxuriantly where coffee languished, for it is hardier, and will grow at higher altitudes. "As a general rule, wherever coffee has succeeded best, there also tea has yielded good results. Hence it follows that tea dominates over all the old coffee region, and a vast territory besides where coffee failed." The consequence is that Ceylon has for several years past enjoyed even more than its old abounding prosperity; its revenue shows a good surplus, public works are being steadily continued, and planting is once more profitable. But this time it is under the reign of King Tea.

AN EXCHANGE DIFFICULTY.

TO THE EDITOR OF THE "PIONEER."

Sir,—Now that exchange has taken an upward course which it is likely to maintain, I, in common with others of your readers, am somewhat at a loss to know why it has not already gone higher. For two or three weeks past the American Government have been buying silver at 119½ to 119¾ cents the ounce, which unless the American dollar has gone down in European exchanges, is within a small fraction of a penny of the rate at which silver sold in the years before 1873, when the bimetallic ratio of the Latin Union was in force and the rupee was at or about two shillings: yet the rupee is at present worth only 1s. 8½d. Can you explain the discrepancy or rather can you explain how the rupee ever came to be worth two shillings? An ounce of fine gold, I understand, exchanges at the English mint for £3 17s. 6d., and that the old bimetallic ratio of 15½ to 1 makes the price of fine silver 60s., which was practically the rate at which that metal sold for many years prior to 1873. Now a rupee weighs 180 grains and contains about 165 grains of fine silver, which at the above price makes its intrinsic value (neglecting alloy) 1s. 8½d. How did it ever come to be worth two shillings?

TYRO.

[Our correspondent has overlooked certain factors in the value of the rupee. The silver in the coin was never worth two shillings sterling: for its value is enhanced over that of bullion by the seignorage of 2-25 per cent which is charged by the Government of India for coinage. One has to add also the cost of transport to India, freightage and insurance, and the loss of interest on the money while it is passing through the mint, a process which generally occupies about 14 days. These expenses are generally taken to add about 3½ per cent to the intrinsic value of the Indian standard coinage. At this rate we get the following table of equivalents, which may be useful to our readers:—

Price of silver per ounce.		Value of the rupee.		Price of silver per ounce.		Value of the rupee.	
d.	s.	d.	s.	d.	s.	d.	s.
45	1	5.27		50½	1	7.40	
45½	1	5.47		51	1	7.59	
46	1	5.66		51½	1	7.79	
46½	1	5.84		52	1	7.98	
47	1	6.04		52½	1	8.18	
47½	1	6.24		53	1	8.37	
48	1	6.43		53½	1	8.56	
48½	1	6.62		54	1	8.75	
49	1	6.81		4½	1	8.95	
49½	1	7.01		50	1	9.14	
50	1	7.20		65	1	11.7	

Pioneer, Sept. 10th.

NUTMEGS AND WEATHER.

North of Kandy, Sept. 26th.

Some of the nutmegs we have put out show already a growth which has surprised me, knowing as I do the deliberate nature of the nutmegs' advance. On the whole I was more than satisfied with the clearing.

The weather for tea has of late been of a very rough nature. Cold winds taking the tea bush by the throat and demanding that it should deliver. No good got that way. It has been an abominable bad quarter this, but the weather is now turned genial; so we trust to make up later for the backwardness of the past.

THE MADRAS REPORT ON CINCHONAS.

A copy of Mr. Lawson's report has now reached us from the Madras Government. We have already quoted the report from the *Madras Times*, but we now give Mr. Hooper's analyses of the soils:—

From the Government Quinologist, to the Government Botanist and Director of Government Cinchona Plantations, Nilgiris, dated Ootacamund, 8th April 1890.

I have made an analysis of four samples of sub-soil taken from different parts of the Wynnaad and representative of that in which the cinchona plants are grown.

The four samples were labelled, respectively—

- | | |
|--------------|-----------------|
| 1 Pallacoon. | 3 Carpenicilli. |
| 2 Glenmary. | 4 Alexandra. |

Separated from the few stones present, powdered and sifted, the samples had the following appearance:—

- | | |
|-------------------------|------------------|
| 1 Bright reddish brown. | 3 Reddish brown. |
| 2 Dull reddish brown. | 4 Brown. |

The soils were very similar in mechanical composition. They were ferruginous earths with variable amounts of quartz sand. Nos. 2 and 4 contained micaceous schist. They might be catalogued as light sandy soils, except No. 3, which contained an appreciable quantity of clay, and was, therefore, a sandy loam.

A chemical analysis revealed the presence and amount of the following constituents:—

	1	2	3	4
Molsture	3.64	2.92	2.58	3.24
Organic matter and combined water	11.61	9.24	4.69	6.85
Soluble salts11	.13	.10	.02
Alkaline chlorides26	.46	.14	.27
Iron oxides and alumina	15.77	11.03	7.90	14.11
Lime26	.21	.14	.17
Phosphoric acid23	.16	.11	.21
Silicates and quartz sand	71.63	77.62	85.29	72.87

In comparing these figures with those obtained by the analysis of Nilgiri soils, it is observed that, with regard to the mineral matter, there is a full proportion and there is a fair amount of lime, phosphoric acid and alkalies (potash and soda). The soluble salts are small and they consisted of chlorides and sulphates of the alkalies and alkaline earths. The chief feature in the chemical composition of the soils is the small amount of organic material and the consequently small quantity of nitrogen present. In soils, which I have analysed from the Nilgiris, Gudalur and other places acknowledged to be good for the cultivation of cinchonas, more than double the amount of organic matter and combined water is usually met with. As the greater part of the samples was made up of rocks in a state of incipient decomposition, this will account for the absence of much nitrogenous and carbonaceous substances and the high proportion of silicates and sandy matter.

The results obtained by Mr. Hooper clearly indicate the application of stable manure, or of rotted straw, grass or weeds with some form of ammonia. But at present we fear manuring cinchonas will not pay.

CHIEF INDUSTRIES OF THE MADRAS PRESIDENCY DURING THE YEAR 1889.

[The following summary affords hints of importance as to industries that might be established in Ceylon.—Ed. T. A.]

Of the important industries carried on in the Madras Presidency during the year 1889, there were six bone-crushing factories, two in the Coimbatore district, one in South Canara, and three in Malabar. Of these four were not worked, viz. Messrs. Pierce, Leslie & Co's in Coimbatore, Messrs Volkart Brothers' and Ochterlony & Co's at Calicut, and Alston, Low & Co's at Kottayam. Messrs. Stanes & Co's factory in Coimbatore crushed 63 tons of bones valued at R3,162 and the Boloor Works in South Canara, 97 tons valued at R4,075. The Cement Manufactory of Messrs Arbuthnot & Co. at Madras turned out 60,000 cwt of cement, valued at R1,20,000. This factory also makes tiles and carries on the industry of lime-burning. 60,000 tiles, valued at R3,600, were made during the year, and 1,600,000 measures of lime, valued at R11,040. Of Coffee curing works twenty-three are returned viz., two in Coimbatore, five in South Canara, ten in Malabar and six in Madras. The most important is Messrs. Volkart Brothers' Works at Kottayam which turned out 4,724,720 lb. valued at R20,82,294, followed by Messrs. Pierce Leslie & Co's works at Calicut, which produced about R12,97,949 and Messrs. Arbuthnot & Co's Plantation House Works showing an out-turn of R9,00,000 for Coffee and R1,07,711 for Cinchona. The three works in Coimbatore—Messrs. Stanes & Co's, Messrs. Pierce, Leslie & Co's and the Jeppu Coffee Works—are worked by steam power. The works of Hinde & Co. and Pierce, Leslie & Co. at Kottayam show a falling off in the out-turn as compared with last year owing to the fact that coffee-producing districts (Coorg) on which T. L. chery mainly depends for its supply of coffee suffered much from the leaf-disease, which seriously affected the produce. Of cotton presses and cotton weaving establishments other than mills there were forty-three viz. three in the Kistna District, two in Cuddapah, three in Anantapur, seven in Bellary, one in Trichinopoly, ten in Tinnevely, eight in Coimbatore, four in Malabar, and five in South Canara. The most important works were those of Milligan & Co. in Tinnevely, with an outturn of 1029,7,000 lb. of Cotton, valued at R27,60,190, besides 329,700 lb. of cinchona, valued at R61,819, and 151,400 lb. of senna, valued at R7,550; the Fort Press, Taticorin, with an out-turn of 7,874,000 lb. of cotton valued at R21,57,476, besides 546,800 lb. of senna valued at R43,744; the Taticorin Cotton Press Company, Limited, out-turn 5,929,500 lb. valued at R15,17,952; Dymes & Co's. Press at Adoni, out-turn 6,008,606 lb. valued at R13,96,532; and the New Berar Company (Limited) in Tinnevely, out-turn

4,760,000 lb. valued at R13,18,400. Messrs. Groves & Co. had a flour mill and bakery on the Nilgiris, the annual out-turn of which was R15,000. There were only two Ice Factories, those in operation in the Presidency town. The Madras Ice Manufacturing Company turned out 606 tons valued at R33,855 and the South Indian Ice Company, 268 tons valued at R12,504. As regards the manufacture of Indigo there were 44 factories in Salem and six in Ganjam. Forty-nine vats in Vizagapatam, 40 in Godavari, 1,408 in Kistna, 1,465 in Nellore, 1,021 in Cuddapah, 208 in Anantapur, 23 in Bellary, 794 in Kurnool, 272 in Chinglopt, 569 in North Arcot, 465 in South Arcot and 40 in Trichinopoly. There were six iron and brass foundries, viz. one on the Nilgiris, two in Madras, one in South Canara, one in Trichinopoly and one in Godavari. The number of mineral and Aerated Water Manufactories are returned at 32. One Indian Condiment factory alone is returned for Madras, that of Messrs. P. Venkatachellum & Co. Messrs. Stanes & Co., have an Oil-cake press at Coimbatore and Messrs. Alston & Co., in Malabar. There are sixteen lamp-oil manufactories in the Godavari district with an aggregate out-turn of 9,903,037 lb. valued at R10,06,398. Only one Rice-Mill is returned, belonging to the Ooriuga Rice Mill Company (Limited). There were 5 Coir Works, four in Malabar and one in South Canara. The Mylitta Silk Mills Company (Limited) carries on work in Madras and Coimbatore; the out-turn was 1,920 lb. of tassar silk thread, valued at R21,120. Five Sugar Factories are returned, one at Aska and four in South Arcot. The Aska Factory turned out 26,896 cwt. of sugar, valued at R3,58,620. Of tanneries conducted on the European system thirty were at work, viz., three in Madras, one in Bellary, 14 in Madura, three in Coimbatore and two in Trichinopoly. There were 11 Tile Manufactories in South Canara, two in Malabar and one in Madras. Messrs. Groves & Co., possess timber mills on the Nilgiris, and the Basel Mission has carpentering works in Malabar. Thirty-two Cigar Manufactories are returned, viz., 18 in Trichinopoly, four in Madura, nine in Godavari and one in Malabar. Of these the most important are John Heimpel's Cigar Factory, Dinigul, with an out-turn of 5,000,000 valued at R75,000 Spencer & Co's., T. B. Arumuga Mudaliar's and Ibrahim Khan's of Trichinopoly, the out-turn of each firm being returned at R75,000.—*Madras Times*.

BOOK NOTICES.

GEMS AND PRECIOUS STONES OF NORTH AMERICA. By Geo. F. Kunz; illustrated, 336 pages, size $7\frac{1}{2} \times 11$ inches. Ornamental cloth cover. The Scientific Publishing Co. Price, \$10.

Two years ago popular interest was awakened in the subject of the precious stones of this country by an illustrated article in *Harper's Magazine*, by Geo. F. Kunz, gem expert, with Tiffany & Co. Last year Mr. Kunz was in charge of the exhibit of precious and semi-precious stones sent by Tiffany & Co. to the Paris Exposition, part of which is now in the Museum of Natural History in this city. The exhibition attracted world-wide attention and won for Mr. Kunz a gold medal and high honors. An indefatigable student, he stands foremost in his line; Special Agent of the United States Geological Survey, member of the Mineralogical Society of Great Britain and Ireland, the Imperial Mineralogical Society of St. Petersburg, the Société Française de Mineralogie and other scientific bodies.

The Harper article and the exhibit paved the way for the appearance of a sumptuous volume, an *édition de luxe*, illustrated with eight colored plates, each one of them a revelation of the wonderful skill of the printers in color, and attesting the great advance made in that art since the days when the count-y went wild over the now much despised chromo. The work is a popular description of the gems and precious stones of North America, of their occurrence, value, history and archeology. It also contains a history of the collections in which they exist, a chapter on pearls and remarkable foreign gems found

in the United States. We recall no work in which the subject of precious stones, mineralogy and archeology have been so closely associated.

Thus far, searching for gems has not figured, in American industries, save in two States—Maine and North Carolina; and yet, Mr. Kunz tells us, nearly all the known varieties of precious stones are found in the United States. The eight plates in colour furnish fac-similes of many of the gems found in this country. One lingers in admiration over the illustrations which have a depth and brilliancy and fidelity to the originals that is remarkable. Plate 7 is a reproduction of drawings—A., Rutile in quartz cut heart shape (Venus hair stone, Fleche d'Amour, Sagenite) found in Alexander County, North Carolina. B. Smoky quartz, from the same locality. C. Rutile in quartz, West Hartford, Conn. This latter is a superb bit of work, the smoky, almost clove-brown color being closely copied, while the crystals of varying size, from the fineness of a hair up to one-quarter inch in diameter, and which cross and intersect each other in all directions, and of a reddish brown lustrous color, are reproduced with surprising fidelity.

Plate 6 is a study in color that will charm the most critical. It represents a cut amethyst from Maine and a group of amethyst crystals from Pennsylvania. The gradations of color in this plate, and the prismatic effects and the play of light on the cut gems give them an approach to the brilliancy of the stones themselves, which is a revelation of the printer's skill.

Plate 5: This is a double-page illustration showing five gems. A large crystal of emerald found in North Carolina; an Amazon stone (Microine) from Colorado; a cut Aquamarine from Maine; Azurite and Malachite in concentric bands from Arizona, all evidence of rare skill and fidelity in color illustration.

In plate 4 attention will be arrested by illustrations showing different varieties of tourmaline and a section of a crystal of tourmaline from Maine, showing dark blue and pink centre with white exterior. A close approach to the original is found on plate 3 in a representation of chlorastrolite from Lake Superior and an almandite garnet crystal from Alaska.

Plate 2 shows the holy toad of the Zuni Indians, a clam shell incrustated with turquoise and shell. Also a specimen of cyanite from North Carolina and a bit of turquoise in rock from New Mexico, all three rare bits of coloring.

While the volume is artistically of great value its practical worth is immeasurable. The identification of specimens can readily be made from the plates, thus giving the miner and prospector the advantages that hitherto have been enjoyed by the expert, collector, mineralogist and geologist. It is a guide for the dealer and the jeweller. The volume should find its way into every school library, for here we have the history of gems and precious stones. The chapter on pearls is of intense interest. The most important pearl fishery on the American coast is that of lower California where the true pearl oysters are found. This and other fisheries on the west coast extending for 3,500 miles have been confirmed to the Pearl Shell Co., of San Francisco, by special franchise from the Mexican Government.

In 1857 a pearl of fine lustre, weighing 93 grains, was found at Notch Brook, near Peterson, N. J. It became known as the "Queen Pearl," and was sold by Tiffany & Co. to the empress Eugenie, of France, for 62,500; it is to-day worth four times that amount. In the same locality was found a large round pearl weighing 400 grains, which would doubtless have been the finest pearl of modern times if it had not been ruined by boiling open the shell. Within one year pearls were sent to the New York market from nearly every State. Kentucky, Tennessee and Texas are the principal pearl-producing States.

We have in this work an account of seventy-four different collections of precious stones, including those of the United States National Museum, New York State Museum, Metropolitan Museum of Art, those in different colleges and in the hands of private

collectors. The finest known collection of precious stones, and the finest collection of those found in the United States, is the one presented by Mr. J. Pierpont Morgan to the American Museum of Natural History, Central Park, New York. It contains over 1,000 specimens.

We recommend this magnificent volume to all our readers, particularly those who reside in New Mexico, Arizona, California, Oregon, Washington and the Southern States. Each important gem is described and a series of analyses given, indicating the composition of each precious stone. There are many illustrations other than the colored plates, the work of Messrs. L. Prang & Co., of Boston. Orders can be filled at the subscription price direct from this office.—*American Grocer*.

THE NEEDLE-AND-THREAD TREE.

Imagine the luxury of such a tree, and the delight of going out to your needle-and-thread orchard and picking a needle threaded and already for business. Odd as it may seem to us, there is, on the Mexican plains, just such a forest growth. The tree partakes of the nature of a gigantic asparagus, and has large, thick, fleshy leaves, reminding one of the cactus, the one popularly known as the "prickly pear." The "needles" of the needle and-thread tree are set along the edges of these thick leaves. In order to get one equipped for sewing, it is only necessary to push the thorn or "needle" gently backward into its fleshy sheath, this to loosen it from the tough outside covering of the leaf and then pull it from the socket. A hundred fine fibres adhere to the thornlike spider webs.

By twisting the "needle" during the drawing operation this fibre can be drawn out to an almost indefinite length. The action of the atmosphere toughens these minute threads amazingly, to such a degree as to make a thread twisted from it, not larger than common No. 40, capable of sustaining a weight of five pounds, about three times the tensile strength of common six-cord thread. The scientific name of this forest wonder is *Tensyana mucudina*.—*St. Louis Republic*.

AN ENTERPRISING GROCER at Petersburg, Virginia, has hit upon a somewhat novel plan for taking orders from his customers. He sends to different residences each morning tame carrier pigeons. Small order slips with a loop on the end of them are furnished the customers, and on one of these is written the order. The loop is thrown over the bird's neck and it sails back to its owner. After all the birds have returned the orders are at once filled by delivery wagons. The scheme works admirably.—*Farm Journal*.

AFRICAN FEVER AND THE BLUE GUM TREE.—Dr. J. Crombie Brown, with his customary zeal, has compiled some particulars relating to the culture of the Eucalyptus in Italy, and its effects in ameliorating the climate. The results obtained are such as to warrant the culture on a large scale of the Eucalyptus in the malarious parts of tropical Africa. From experiments made and calculations based on them it is shown that the leaves of these plants evaporate double or treble their weight of water, and even a much larger quantity. The trappist monks who formerly could not sleep without risk of life in their monastery in the Pontine Marshes, but betook themselves every evening to a convent in Rome, can now remain at their monastery of Tre Fontanes, with little risk, and the peasantry who were formerly obliged to migrate to the mountains in summer now reside on the Campagna all the year round. This improvement has followed upon the extensive plantation by the monks of various species of Eucalyptus.—*Gardeners' Chronicle*, Sept. 6th.

TROPICAL PRODUCTS IN BRITISH NORTH BORNEO.—The information given by Mr. W. D. Gibbon in his letter elsewhere regarding the cost of and profit from a Liberian coffee estate in British North Borneo is interesting, but we fear of no practical value to Ceylon planters.—Liberian coffee being now little more than a name in our island. The pamphlet which accompanies the letter consists largely of extracts from letters and reports that have appeared in the *B. N. B. Herald*, and which we have extracted from time to time; to which are added land regulations and rainfall and other tables.

HOP TEA: A NEW INDUSTRY IN KENT.—There is at last some hope for the unfortunate hop growers who for so many years past have been carrying on their business with the figures on the wrong side of the ledger. Hitherto they have only had one outlet for their produce, but in future they will have a choice between the brewers' mash tun and the British housewife's teapot. A company has been floated for the manufacture of the hop tea, to be blended with some of the stronger qualities of the Assam and kindred sorts. In view of the approaching hop-picking season, the company have acquired the large riverside premises belonging to Mr. E. S. Tapply, near Maidstone Bridge, where the work of drying and preparing the hops for conversion into tea will be carried on. Already 700 casks of the mixture have been disposed of in the tea trade, and the "brew" is highly spoken of by those who have tried it. A Maidstone grocer has, it is stated, given an order for a ton of the hop tea, and it is expected that the commodity will command a ready sale on the market. The premises are, we are informed, being fitted with the necessary machinery by a local firm of engineers, and in the course of a few weeks it is hoped that the new industry will be in full operation, and thus add another important branch to the commerce of the county town.—*Sussex Express*, Aug. 26th.

OPIMUM-DRINKING IN ENGLAND.—The use of opium is alluded to after a rather too trifling fashion in the story (fictitious of course) reproduced in our *Household Register* today. Our readers are aware how serious an evil the addiction to opium in the shape of laudanum drinking, has become in the Fen districts of England, and about Gravesend and other low-lying parts. We have shown how great a boon quinine ought to be in these cases: that is for example, if every clergyman and philanthropist in the Fen districts got the people suffering from ague, to try quinine in place of laudanum. The opium practice we refer to is of long standing and it may be worth reproducing the paragraph in which (in Charles Kingsley's "Alton Locke") "Varmer Porter" enlightens Alton, during their drive to Cambridge, on the meaning of "a penn'orth of elevation":—

Varmer Porter:—"Love ye then! they as dinnot tak' spirits down thor, take their pennord o' elevation, then—women-folk especial."

'What's elevation?'

'Oh! ho! ho!—You goo into druggist's shop o' market-day, into Cambridge, and you'll see the little boxes, dozens and dozens, a'ready on the counter; and never a ven'man's wife goo by, but what calls in f'r her pennord o' elevation, to lust her out the week. Oh! ho! ho! Well, it keeps women-folk quiet, it do and it's mortal good agin ago pains!

'But what is it?'

'Opium, bor alive, opium!'

'But doesn't it ruin their health? I should think it the very worst sort of drunkenness.'

'Ow, well, yow moy say that—mak'th 'em cruel thin hen, it do; but what can bodies do i'th' ago? Bot it's a bad thing, it is.'

CEYLON TAMIL COOLY MISSION.

Many who have supported this Mission seem to be growing weary of doing so, and many more wholly decline to help at all, giving as a reason that we are doing no good. I am far from endorsing this statement; but I am as far from satisfaction concerning results as any real friend of the Mission who desires to see souls converted to Christ and His Kingdom extended. I realise more and more that the best efforts of man will accomplish nothing apart from the immediate presence of the Lord Jesus and the power of the Holy Spirit. But I think with many others that the time has come for making some new plans to bring the Gospel message to the coolies. For this purpose I am about to start an associated band of Evangelists, whose aim will be to carry the good news to as many as can possibly be reached. They will visit estates, preaching and teaching in the lines, and holding meetings wherever they are invited or permitted to go. They will also conduct prayer and revival meetings amongst the Tamil Christians. The great object of these meetings will be to show to the nominal Christians as well as to the Heathen that Jesus is a Saviour who is able to save, and that when He saves, righteousness, truth, love and purity are the result. We believe that Jesus does this, and that He will do it. Therefore we confidently appeal for help. I have two or three men into whose hearts God has put a loving strong desire to preach a full Gospel to their fellow-countrymen and women. I need special funds for supporting them. I need also help to build a commodious house for the associated workers to come to for rest as a centre. This must be near to myself at Lochiel, so that I may meet them as often as possible. We have a good school at Wootton where they may work whilst resting. I purpose building their house on to the School room which also needs rebuilding. A few musical instruments are a great help in itinerant preaching—these must be bought. I am not without hope that God will give me one or two young Englishmen whose hearts He has kindled with love to the Saviour, who will lead and work with these Native brethren under my general direction. I myself am too old to be the leader in the field, but as far as duties and strength allow, I hope not only to say to them go, but also to say come. God is enabling me to believe that He will do greater things than we have seen of late years. We will put no confidence in an arm of flesh, our trust is in the Lord; He is the God of Salvation. We believe we shall yet join in singing the 98th Psalm. Any help for this new effort, independent of that given to the General Funds of the Mission, will be thankfully received.

J. D. SIMMONS.

Lochiel, 15th September 1890.

DANGER IN WATER FILTERS.—The old charcoal and gravel filters, which once had the entire confidence of families and physicians as entirely efficacious in purifying drinking water, have been recently found to be not only of dubious character, but even in cases to aggravate the danger which they were expected to allay. The investigation of the Rhode Island Medical Society seems to show conclusively that the meshes and interstices of the filtering matter become clogged with the deleterious organisms of the water, and that these increase in number when the filter is not in use, standing in the warm air of the kitchen. In one examination by this Society unfiltered water containing thirty-six colonies of organic growth increased to 10,000 after filtration. The danger of the filter seems to lie in the impossibility of cleansing it. A simple way of purifying the water is to boil it freely for ten minutes. Then pour it into a broad earthen dish, in the open air, where it can cool away from any chance of contamination. The water thus prepared may be kept in a stone jar in a cool cellar for four or five hours at a time, and when cooled with pure ice is a good substitute for spring water where spring water cannot be obtained, and it is probably as harmless as this gift of bounteous nature can be rendered in the restrictive environments of a large city.—*New York Tribune.*

CINNAMON AND COENUTS.—Kadirana, Oct. 3rd.—There is a change in the weather, and light showers have fallen during the last few days, yesterday's fall being 0.53 of an inch; till more comes this will at least cause the grass to grow and give food to the half-starved cattle.

TEAMEN will be interested in the following telegram:—"Chicago, 29th July.—Ernest Theodore, a prominent tea exporter from Hankow, China, is in this city. In speaking of the tea commerce Theodore said: 'The recent passage of the Silver Bill raised the price of tea 10 per cent. We make all our payments in silver out there, little gold being used. The purchase of 4,500,000 ounces of silver a month by our Government is equivalent to taking out of the market just so much that was hitherto available. The eastern markets have felt this influence, and silver in London has risen in price. The tea crop in China is heavy this year and of prime quality.'"—*N.-C. Herald*, Sept. 5th.

CULTIVATION OF TOMATOES IN ENGLAND.—At a conference of the British Fruit Growers' Association, held at Brighton yesterday, it was stated by one of the members that from the two stations of Worthing and Laucing, during the three summer months, 35 tons of fruit were despatched by rail weekly, and for the remainder of the year six tons per week, making 663 tons of fruit during the year. Of this amount, 350 tons were tomatoes, the remainder being grapes, cucumbers, apples, &c. The value of the tomatoes at 5d. per pound was estimated at £20,000, and the other fruit at £14,000, making a grand total of £34,000 from the Worthing district alone. Other speakers maintained that the industry was not fully developed, and that for a long time to come the supply of English tomatoes would not exceed the demand.—*Globe.*

DARJEE CLING.—Tea is, of course, going on in the even tenor of its way, and it appears as if, although the nights are getting markedly colder plucking would be kept on until about the middle of November—on a small scale of course. Taking into consideration the long drought at the beginning of the year tea gardens in the hills do not seem to have done so badly after all in the hills, and the rise in prices has been decidedly encouraging to planters generally. What effect the improved exchange will have on Calcutta prices of course remains to be seen. I have always been given to understand that a low rate of exchange always meant good prices for Indian productions of all kinds. Here is another problem which will need solving later on. What effect will the gold finds in the centre of India have on tea prices in the future? This is a question which I leave others to solve, as it is quite beyond me.—*Indian Planter's Gazette*, Sept. 16th.

WHOLESALE DESTRUCTION OF FISH.—Colonel Campbell Walker, Conservator of Forests, Southern Circle, Madras, recently brought to the notice of his Government the wholesale destruction of fish in rivers. In the Bhavani river the main and subsidiary streams are dammed up and the fish destroyed by dynamite, or the water baled out and fish, both large and small, taken and sent into Mettupalayam in bullock and cart loads; and as a similar practice is followed in almost all rivers, it would ultimately tend to the extermination of fish in the rivers of southern India, as by the above system both fish and fry are destroyed. It is under contemplation to alter the rule in the Madras Forest Act which permits "the catching of fish by the damming or baling of water" by a proviso that "the Collector may attach such conditions to the issue of the permit as he may consider necessary." This would only affect fishes in rivers running through reserved forests, and it is incumbent on Government to adopt some legal measures to regulate the wanton destruction of fish and fry, such as their capture only by the net and rod, the meshes of the former being regulated to such a size that fry may not be taken.—*Pioneer*, Sept. 18th.

CINNAMON, CINCHONA BARK AND CITRONELLA OIL AT THE LONDON DRUG STORES.

In the *Chemist and Druggist* of 26th July is an interesting paper entitled "Through the Drug Show-rooms," in which a description is given of the new drug show-room at the Crutched Friars warehouses, where the sales are now held. We extract the following portions, which relate to Ceylon productions:—

CINNAMON AND SPICES.

At the London and St. Katharine Docks huge supplies of drugs and gums are stored amid still larger quantities of wool, coffee, wheat, wine, and other commodities. The first warehouse which appeals particularly to druggists is "No. 6," situated immediately to the right of one of the principal entrances. Two floors of this huge building are devoted to the storage of spices—one contains cinnamon, and at the top floor immense quantities of cinchona bark may be seen. There are very rarely any "shows" of drugs or spices at these warehouses. They are situated too far to the east of Aldgate Pump—that Ultima Thule of London City—to be easily accessible to the busy City man, and when, some time before the closing of Fenchurch Street warehouse, it was suggested in an unofficial sort of way that the drugs might in future be shown at the Docks, the opposition threatened to this project on the part of the druggists was strong enough to cause the Dock Company to relinquish the idea—if they had ever entertained it seriously—pretty promptly. The cinnamon floor of "No. 6" warehouse is a much less interesting place now than it was before the cinnamon trade entered upon its present period of decline. Cinnamon is imported from Ceylon in canvas-covered bales about four feet in height, and packed with considerable care. Exceedingly thin quills of the spice are placed one within the other until they form a long and compact, though brittle reed or stick. A large number of these sticks are packed together in a roll, or bale, and upon their arrival in the warehouse they are sorted, re-packed, and classified in four different grades, according to thickness, the thinnest bark being the best. Besides these four varieties of whole sticks, the broken sticks are sold separately—mostly to druggists. Cinnamon "chips"—which, are, or were, exported separately from Ceylon in large quantities—are the small shoots removed from the long quill bark when it has been stripped of its leaves. They are very largely used for the distillation of essential oil, but the recent combination of cinnamon growers in Ceylon has placed a veto upon their export, on the ground that their extensive sale spoils the European market for the more valuable product. In the spice floor's Zanzibar cloves take up an immense amount of room, the stock of that article being at present very large. The Zanzibar cloves are imported in fibre-plaited mats or bales known sometimes as "conjes," of about 140 lb. weight. They are much darker and smaller than the cloves imported from Perang and Amboyna, but so far as commercial importance goes, the latter are now-a-days very insignificant. Nutmegs, mace, cassia, and cassia buds are also stored in considerable quantities in this warehouse, and on certain days the air is heavy with the odour of the spices which are being repacked, sorted, and sifted to render them suitable for the European market.

CINCHONA.

The bark floor is now mainly occupied by Ceylon and East Indian barks, which are usually packed in oblong canvas bales, weighing from 200 lb. to 300 lb. into which the small chips or shavings—in which the bark is now almost always sent over—are tightly packed by hydraulic pressure. The bales usually bear on the outside the name of the plantation and some mark indicating the species of the bark and the character of the contents, whether in shavings or chips, original or renewed. The barks intended for "pharmaceutical use," as distinguished from those more particularly adapted for use by the quinine manufacturers, are sent over in cases of varying weights, that mode of packing

being resorted to the better to shield the quills against breakage, and to prevent the moss with which they are frequently overgrown, and which adds to the value in the eyes of many purchasers, from being crushed or torn off. The South American "seron" of bark is not so often seen now as formerly, but it is the most characteristic form of package. The hide serons are usually light—from 1 to 1½ cwt. being the general range—and consist of undressed cowhide. The serons are usually provided with handles made of small strips of hide, by which the packages are slung across the backs of the mules, which are the chief if not the only means of transport across the rough paths of the Andes. Some of the South American quill barks frequently flavoured strongly of the smoke of the fire over which in their rude way the "cascarrillos" were wont to dry them. Other quills again possessed an earthy flavour which they acquired from the soil upon which they were roughly thrown to be dried by the heat of the sun. The original fluted bark from the South American forests, the "Cortex China Regia," is now very seldom met with in commerce. It was mostly bought by French firms, and is generally thought to have been employed principally as an ingredient in a remedy against drunkenness, and in tooth-powders. There is still in the warehouses a large supply of the Cupira, Pitayo, and soft Columbia barks, which were imported in huge quantities some ten or twelve years ago, and in making his way out of the building the visitor passes through alleys between immense piles of packages of cinchona of all varieties.

ESSENTIAL OILS.

East Indian sandal-wood oil arrives here in huge copper pots, protected by a strong netting of rope-work. A pot usually contains about twenty gallons of very turbid oil. The oil is therefore emptied from the pot into large copper "jacks," or vats, about 5 feet high and quite 3 feet in diameter, and left to settle. The "jack" is provided with two taps—one, about 12 inches from the bottom, being used to draw off the clarified oil, while the lower tap allows the thick dregs to run out. The latter are sold separately. Indian rose-oil is treated in the same manner, and so, in fact, are many other essential oils stored at this warehouse. Rose-oil is imported in metal drums provided with a handle and a bung-hole at the top. These tins—usually old kerosene tins—are used for packing quite a large number of East Indian drugs which come into the market. In close proximity to the oils is found East Indian eungeo-paste, in tins weighing about ½ cwt. each, four or six of which make up an original case. Cinnamon sawdust is often used for stuffing between the bottles or other breakable packages in the cases of essential oils. Citronella and lemongrass oils were formerly imported almost exclusively in bottles of about 21 oz. each, 24 or 36 in a case. Under this mode of packing they were liable to considerable damage, and recently an innovation has been introduced by the importation of these important articles in 5-lb. tins. Quite lately the oils have been shipped in so-called "tanks"—heavy iron casks protected and kept from rolling about by a strong wooden crate. The tanks have evidently been sent to Ceylon as containers for a different liquid, and are returned to us filled with oils.

COFFEE GALORE!

Who says coffee is dead in Ceylon? Up and down in Uva this year, there is an experience of blossom and a promise of crop sufficient to prove the contrary. The way in which native coffee is bearing and blossoming in the Principality astonished Dr. Trimen we learn, and we ourselves saw most satisfactory evidence of good crops to come all along our route, more especially in Haputale where we were just too late to see a whole countryside white with blossom. But there is also crop on the trees nearly ready for picking, and we have brought back from New Galway, a couple of primaries as a specimen of crop on Mr. Kellow's fine little Albion property, which ought to be a cure for the "sore eyes" of the V. A., whose sight got

damaged trying to see and estimate any coffee berries for his employers! On one of these branches no less than 954 coffee berries have today been counted. Mr. Kellow and some of his neighbours are believers in the old Uva system of cultivation *without pruning*, and certainly the result in the case of Albion seems satisfactory. Of course there is liberal cultivation otherwise; and indeed if coffee planters anywhere in Ceylon expect crops in these days, there must be a liberal reliance on manure as well as on Providence.

UVA AND HAKGALA GARDENS, &c.

The Director of Botanic Gardens (Dr. Trimen) accompanied by Mr. Nock of Hakgala, has been on a visit of inspection to the Badulla Garden, which we can testify to be a very pleasing addition to the amenities of the capital of Uva, and in itself—considering the soil and situation—a wonderful success reflecting credit on the Department. Dr. Trimen returned via Haputale and Horton Plains where the successful growth of plants put out there was noted—and others are to be sent. Some new or rare plants were collected by Dr. Trimen and Mr. Nock during the Horton Plains expedition; and the former has been much pleased with the progress made in the various experiments at Hakgala Gardens, where the new vegetables, fruit bushes and trees are giving satisfaction. Apples and pears have been produced with a flavour far superior to that of any yet grown in Ceylon. All the fruit trees are for the present, “resting.” As for potatoes, we have some specimens of the “fourth generation” from the seed brought by Mr. Nock from England, and they weigh up to over 1 lb. each, and are perfectly healthy. To other features of the Gardens we must refer later on. Dr. Trimen returned to Peradeniya on the 19th instant. It would be well if every province, and indeed revenue district, had its Experimental Garden, subject to the oversight and inspection of the Director and his Assistants.

THE LATE EXPERIMENTS WITH MANA GRASS FAILURES.

During the week it has been possible for me to read over the reports made by Messrs. Ibotson and Dr. Evans relative to the late trials made of mana grass, respecting the progress of which you have been kept fully informed by me. That by Messrs. Ibotson is certainly very discouraging, all the attempts made by them having been failures. There are, however, very curious facts relative to the trials made which lead us to the conclusion that very probably a mistake has been made somewhere or other which would sufficiently account for the disappointing results as yet reported. Dr. Evans, after personally witnessing the later trials made by Messrs. Ibotson, took away with him some of the grass which had formed the basis of those trials. This he tested in his own laboratory, and found that the product of his endeavours differed wholly and entirely in its character from that he obtained when testing the first lot of mana grass. You will recollect that the sample sent you by me of the result to that first testing—and as to which Dr. Evans reported most enthusiastically—was an eminently strong and fibrous paper. The outcome of the trial made by that gentleman with the second lot of grass received was identical in character with what was obtained by Messrs. Ibotson, namely a dusty weak paper which would scarcely bear handling in pieces of only a few inches square. Indeed the specimens produced of

this broke with their own weight and were absolutely worthless. Now the question consequently arises, What can account for the vast difference between the results to the two trials?

Dr. Evans inclines evidently to the view that the two lots of the grass obtained, differed altogether in character. Whether this difference be due to the different localities in which the grass was grown, or whether it may be owing to the different conditions of age or ripeness at which it was plucked, the expert professes himself unable to say; but he suggests both explanations of the very striking contrast between the results obtained. To my own mind it occurs as possible that the second lot of grass received was not mana grass at all, but citronella grass. To a great extent, this possibility is based upon a fact mentioned by Dr. Evans in his report that, during the boiling operation, the grass gave out a very powerful odour of citronella. Whether that oil may be to some extent contained in mana grass is not known to any of us. At all events, that the reputed mana should give out such a scent is a circumstance worthy of every consideration in estimating the gravity of the conclusions to which we have been forced by the ill-success which has attended the working of the shipment of grass specially sent home for these trials. The first lot of the grass dealt with was but a small parcel, and was obtained from Mr. J. L. Shand. The second—in quantity some fourteen hundredweights—was obtained by Mr. Kelly in Dikoya, but I am as yet uninformed whence Mr. Shand obtained his supply. Anyway, there is a radical difference between the two lots of the raw material which have hitherto been tested. Of the first Dr. Evans spoke in terms even more highly commendatory than he permitted himself to use in his written report, and no one is more astonished and disappointed than himself at the result to the larger scale trials lately undertaken. As yet there has not been sufficient time for the Stanley-Wrightson Syndicate to determine what the next steps to be undertaken by it shall be. Probably the endeavour will be made to obtain the judgment of expert botanists upon the character of the two lots of grass. That such great diversity should be found as the result of the treatment of these is most perplexing, and certainly lends colour to the idea that they must have been radically different in character. If the examination by competent botanical knowledge should decide that such difference is marked, it will be vital to future success that a larger quantity of grass, plucked at different stages of growth and from different soils, should be obtained from Ceylon. I hope when writing next to have learned more conclusively what has been done, or is in contemplation, with respect to this matter.—*London Cor.*

NOTES ON PRODUCE AND FINANCE.

ARE THE CHINESE LIKELY TO ADOPT NEWER METHODS IN TEA CULTIVATION.—As the Chinese will have to take rigorous action of some kind if they are to retain a tea trade of any importance, the question arises, will they cultivate with more care and adopt newer methods of manipulation in manufacture? The British Consul at Canton hints at this in a recent report when he says: “From observation of the tea plantations in the immediate neighbourhood, the quality of the teas might be considerably improved if a little more care was devoted to the cultivation of the bushes, and if foreign appliances for drying the leaf immediately it is plucked were introduced, for the plantations seem utterly neglected, and much leaf is ruined while on its way to Canton to be fired when it chances to be rainy weather.” But he also says, and this adds to the hopelessness of the outlook for the Chinese,

"The weight of taxation to which they are exposed, and which there seems little possibility of hope of reduction, renders it impossible for them to compete with Indian and Ceylon teas in their chief recommendation—cheapness."

COTTON CULTIVATION IN CENTRAL ASIA.—In order to develop the cultivation of cotton in Central Asia, the Russian Minister of Finance has ratified the project of leasing 60,000 decistines of land (about 162,000 acres) in Turkestan to the Commercial and Industrial Company of Central Asia in order that it may form plantations of cotton there. The *Journal de la Chambre de Commerce de Constantinople* states that the lease is for ninety years. The company has the privilege of growing, besides cotton, all other plants; it is exempt from any rent during the first fifteen years of working. After that period it will have to pay a rent which will be equal to the land tax collected on Turkestan territory.

A NEW COFFEE SIZE.—The Americans are using a mixture for sizing coffee which may be effective but it is not nice. According to the *Grocer*, its active ingredients consist of common or condensed milk, ground or powdered glue, glycerine, refined lard, and in some cases, bicarbonate of soda, fine table salt and vinegar. The latter only affects the gloss or polish of the roasted coffee in keeping down too high a polish. The action of the bicarbonate of soda is said to keep all these heterogeneous ingredients "sweet." In preparing the coffee for the "size" it is first roasted dry, and allowed to cool somewhat; the mixture is then added in such proportion and in such a manner that each berry gets a thin coating of varnish. It is claimed that by this process the berry is hermetically sealed and the pores completely closed up, thus preventing the aroma from escaping, and so preserving the full strength of the coffee. No moisture can penetrate through the varnish. Further, when the coffee is being made in the pot the "size," it is claimed, acts in such a way that the "grounds" are caused to settle rapidly, so nothing is needed to be added to the liquor to "clear" it. The natural flavour is not modified, and it is stated that the caffeine or active principle of the coffee is reserved to the fullest extent.

THE TEA DUTY IN AMERICA.—We learn by cable from New York that the majority of leading American tea dealers have forwarded to Washington a protest against the section in the McKinley Tariff Bill which provides for a ten per cent. *ad valorem* duty on teas, the produce or growth of countries east of the Cape of Good Hope, when imported to America from places west of the Cape of Good Hope. The protest declares that the section is avowedly intended to retaliate against Canada, but is in reality aimed at the London markets, on which the United States depend for Indian and Ceylon teas, England being the only convenient halting place between the East and the States. It is further stated that the section is really the scheme of a few big dealers to monopolise the United States market.

THE PRODUCE CLEARING HOUSE AND INDIAN TEA.—As mentioned by our Special Commissioner last week, it was resolved, at a recent meeting of the Produce Clearing House Tea Committee to definitely commence business in Indian teas on January 1st, 1891, and, as soon as the experts have been appointed, the types of quality will be chosen and circulated amongst the trade.

ALCOHOL AND TEA.—The following interesting paragraph is going the rounds of the papers. It is not a new form of conundrum, although it reads very much like it:—"A series of physiological experiments is being made by Dr. Kraepelin as to the respective effects upon the mental powers ("psychical reaction") of alcohol and tea. By this finding alcohol diminishes ideas and strengthens the verbal association of words and the association of auditory impressions. But as to tea, he finds that it favours the association of ideas and intellectual work, while embarrassing the association of words."

PLANTING IN JAVA.—The financial statement for Java will shortly be submitted to the Dutch Chamber. It is expected to show a large deficit, the amount being

named as twenty millions of guilders. Last year the crops in Java were very poor. Most of them suffered from blight, and the yield was much below an average amount. Many planters came out owing to the comparatively high prices of sugar and coffee. Others suffered severely, however, and the rice crop was not more than "middling." The native population in Java is undoubtedly very poor, and it is burdened with heavy taxation. This is the real trouble in Java, and nothing but very good crops can make the people at all prosperous.—*H. and C. Mail.*

SIR CHARLES BRUCE ON INDIAN LABOUR EMIGRATION.

Sir Charles Bruce (in the *New Review*) gives an able and interesting history of the emigration of labour from India, specially to the West Indian colonies and Demerara, since the period when the abolition of slavery rendered necessary supplies of men able and willing to work regularly. Sir Bartle Frere is quoted as stating in 1873 that

"The Bengal labourer with wages at 1½d or 2d a day, and no roads or canals to bring him food, is always terribly near the brink of starvation"; and again, "Though I believe the existing population of India is, as a mass, better fed than it was forty years ago, still there are large masses, especially in Bengal, living on the limits of starvation."

The testimony of Mr. Grierson, an officer deputed by the Government of India to inquire into the system prior to the passing of the Indian Emigration Act of 1883, is as follows:—

"The Colonies importing Indian labour are in the belt of the Tropics. The only exception is Natal, which is sub-tropical. The conditions of life in these Colonies are much the same, viz., an equable climate, free from sudden or extreme variations, and an amazing fertility. The original natives of these countries, living for generations where life without labour was easy and pleasant, have developed into a type of human beings peculiarly unfitted for the higher forms of cultivation of the soil. When, therefore, European enterprise attacked these countries with the hope of carrying off the richer products of the earth, the indigenous natives were found unsuited for aiding them in the work. Coolie labour had accordingly to be introduced; and the only places where suitable labour was found to be available were India and China. Both these countries are subtropical, the greater portion being outside the tropical belt. Here the conditions of life are very different. The climate is anything but equable, and is subject to sudden and extreme variations. At one time the country is deluged by rain, at another parched for months together. Here life is impossible without labour. The most elaborate precautions have to be taken to obtain even a probable chance of raising a moderate crop; and the result is that the inhabitants of India and China have, in the course of generations, developed into human beings possessing considerable agricultural skill and a wonderful capacity for continuous hard work. The Indian's whole life is one long labour—he never has a moment's rest. . . . When an Indian coolie is transported to a tropical Colony, he finds himself in a place quite beyond his experience. He finds a soil capable of yielding good crops with hardly any cultivation, and he naturally applies to it all the labour and all the skill and industry inherent in him. The result is an out-turn such as would be impossible in India, and such as he had never even dreamed of before. Subsequent experience confirms his first impressions, and he rightly considers that he has found a place free from cholera and famine of a warm equable climate, where his natural industry, if rightly applied, makes its possessor in a few years the owner of a large fortune."

This is the sensible view of the case; and what remained for the Indian Government to do was to secure the well-being of their subjects en route to and while employed in the scenes

where they sold their labour for wages, but did not sell themselves into slavery, as some of the former slaveholders, especially those in the French Colonies, were too apt to think they had done. Sir Charles Bruce states:—

It was only after long experience and many years of tentative experiments in the passing of regulations that the Home and Indian Governments were satisfied that the introduction of Indian labourers into our Colonies conduces as much to the welfare of the emigrants as to the general prosperity and commercial wealth of the Colonies. Many of our readers will recollect the Commission of Inquiry which was sent to the very Colony from which Sir Charles Bruce now writes, of the results of which Mr. Jenkins, the author of "Ginx's Baby," gave so fair an account. Emigration to British Colonies was not only continued but encouraged, while the persistent cruelty and injustice of the planters in French Colonies deprived them of the benefits of this form of labour. After showing that the conditions of emigration to the Straits and Ceylon are essentially different to those applying to the more distant Colonies, the writer proceeds to give a summary of the conditions which apply to the latter. We quote a passage which shows that the cooly who earns wealth in one of those *eldorados* is not permitted its free enjoyment in his own country:—

The wealth of the returned emigrant often excites the cupidity of his neighbours, and unless he can soon find a good investment, the attempts to get money from him under various pretexts, such as caste dinners, &c., and even by theft, become burdensome, and so many re-migrate, after a few months, fairly disillusioned with Hindustan.

The conditions under which Indian emigrants are generally employed are thus summarized:—

Generally the period of indenture is five years. In some Colonies coolies are allowed to re-indenture, in others their industrial residence, as it is termed, terminates at the end of the original period of indenture. Everywhere the coolie is entitled to a free dwelling and garden ground, and it is the constant care of the Government that all needful requirements of accommodation, ventilation, and sanitation shall be observed in the construction and maintenance of his dwelling at the cost of the employer. The rate of wages varies according to the nature of the work, which includes the cultivation of the soil and the manufactures of the mill. The minimum daily wage for able-bodied adult males is generally about one shilling. There are many kinds of work at which larger wages can be easily earned when the immigrant has had practice and experience. In some Colonies wages are partly paid in rations, and in all arrangements are made for the rationing of coolies in certain circumstances. The hours of work vary generally from five to ten hours, according as the work is in the field or in the factory buildings. Where task work is set, an able-bodied adult can earn the minimum wage well under eight hours. The indentured coolie is always entitled to medical care and maintenance during sickness. The hospitals provided in the Colonies for the accommodation of the coolies place them in times of sickness in a position of singular advantage as compared with agricultural or urban labourers in Europe. Return passages, when claimable, are given generally after a continuous residence of ten years, five years having been passed under indenture. Such passages are claimable in the case of all the more distant Colonies, but a comparatively small proportion are claimed. As the Indian population in a Colony grows, as children are born and families become bound to the Colony by new ties, each succeeding generation becomes more and more firmly rooted in the soil. Of those who do return to India, a large number bring back their friends and relations to the land of their adoption.

Sir Charles Bruce proceeds:—

The Imperial interests concerned in the system were

broadly stated by Lord Salisbury in a despatch to the Government of India of the 24th of March, 1875, in which he said: "Having regard to the greatness of our Indian population, and to the probability that under the protection which the British Government affords from depopulation by war, and, as far as possible from famine and other evils, that population must continue very greatly to increase—especially in the healthier and more densely populated parts of the country, where the numbers already press on the means of subsistence, and the lowest classes are at all times little removed from want—it appears to me that, from an Indian point of view, it is desirable to afford an outlet from these redundant regions into the tropical and sub-tropical dominions of her Majesty, where people who hardly earn a decent subsistence in their own country may obtain more lucrative employment and better homes. While, therefore, from an Indian point of view, emigration properly regulated and accompanied by sufficient assurance of profitable employment and fair treatment seems a thing to be encouraged on grounds of humanity, with a view to promote the well-being of the poorer classes, we may also consider from an Imperial point of view the great advantage which must result from peopling the warmer British possessions, which are rich in natural resources and only want population, by an intelligent and industrious race to whom the climate of these countries is well suited, and to whom the culture of the staples suited to the soil and the modes of settlement and labour are adapted. In this view also it seems proper to encourage emigration from India to Colonies well fitted for an Indian population. Under extraordinary circumstances—such as famine, flood, or other great calamities, when large numbers of the poorer classes are deprived of the means of subsistence, or are left without house and home—the Government officers might themselves engage emigrants for those Colonies which have agreed to receive people recruited under such circumstances."

Lord Salisbury deserves all credit for his large and statesmanlike views of what is best for the Indian Empire, for the British Colonies and for the Indian labouring classes, who are in their own country multiplying beyond the means of existence. As Mr. Grierson wrote:—

"Surely emigration may be looked upon as an engine of immense power for good to India. The more safety valves there are for a pent-up population in time of famine the greater chance there will be of saving life; and, if I may venture to offer an opinion on such a point, I maintain strongly that it is Government's imperative duty to actively encourage emigration by every legitimate means in its power, and to let it be known far and wide that the Emigration Department is a Government one."

Sir Charles Bruce adds:—

It may be said that up to the time of the passing of the Emigration Act of 1883 the Government of India tolerated the system as a favour to the Colonies, while from that date it has actively encouraged it as a power for good to India.

And now comes the portion of Sir Charles Bruce's paper which will be read with most local interest, from the frank testimony he bears to the courage and enterprise of the Ceylon planters. We are also grateful for the terms in which he recognizes our own efforts to help forward the enterprise on which the prosperity and progress of the Colony depend and which has rendered it famous wherever "the cups that cheer but not inebriate" are prized.

As a homely but none the less important illustration of the Imperial interests concerned in the successful conduct and expansion of emigration from India, may be pointed out its effect upon the cheapness and abundance of the commodities of the breakfast table. So far as the production of these commodities in British possessions is concerned, it may be said that the possibility of their remunerative cultivation depends upon immigrant labour. In the year 1878, when I became officially connected with the Island of Ceylon, the export of tea amounted to some 400 lb.; the export of the present

year is estimated at 40,000,000 lb. The growth of the tea industry in Ceylon has been justly described as one of the wonders of the modern world, and to the courage and enterprise of its planters, supported by the intelligent force of the Ceylon *Observer*, infinite credit is due for results which nevertheless could not have been accomplished but for the cheap and efficient labour of emigrants from India. In the far distant province of the Empire with which I am at present connected—in British Guiana—the fortunes of the sugar industry have been no less dependent on emigration from India. Without this resource no capital would have been attracted to the Colony, no estates would have been maintained, and no sugar made. The Indian labourers return not only with wealth but with expanded ideas and independent self-respect. Sir Charles Bruce adds:—

In a recent return furnished by the Emigration Agent-General in Calcutta for British Guiana, it is shown that since the year 1854 the number of emigrants who have returned from that Colony to India has been 30,433 (inclusive of a large number of children) who have taken with them remittances to the amount of £157,243. They have also taken with them jewellery of the estimated value of £55,000 since the year 1875, prior to which no returns of jewellery were collected. The amount standing to the credit of the Indian emigrants in the savings banks of the Colony exceeds £100,000. This represents but a small proportion of their savings, for the coolie is an astute money-lender, and his ideas of a fair rate of interest are based on the principle that a bag of rice borrowed at seed-time should be repaid by two at the time of harvest. I regret that I am unable to give an estimate of the value of property held in the Colony by coolies, but in 1871 the value of their cattle alone was shown by the Report of the Commissioners to exceed £130,000. They are rapidly acquiring substantial territorial interests. In British Guiana, and I believe also in Trinidad, there are among them prominent owners of racehorses.

We have quoted very largely, but we must add the conclusion of this able and interesting paper, in which it will be seen that Sir Charles Bruce contemplates not only the beneficial continuance of Indian emigration to such Colonies as that in the administration of which he holds so high a position, but also its extension to the vast new empire which Britain has acquired in Africa:—

In dealing with the subject of Indian coolie emigration in its bearing on the interests of the Government and people of India, and on the development of the territorial and commercial resources of the Empire, it must not be thought that I overlook the question of the influence of emigration from India on the resident labouring population of the Colonies. With this question it is impossible for me to deal within the limits of the present paper. I desire, therefore, that what I have said may be understood as referring to the emigration of Indian coolies to British possessions in which the population is admittedly inadequate to the development of their resources. For instance, the area of British Guiana considerably exceeds 100,000 square miles, and, when its limits are determined, will probably be found to be about equal to the area of the British Isles. Of this area only about 150 square miles, the area of the Isle of Wight, is beneficially occupied. The population is under 300,000. In countries thus or similarly circumstanced, it would be a waste of time to argue that the development of their natural resources, which, without immigration, is impossible, is for the interest of all. The late Sir Philip Wodehouse, when Governor of British Guiana, said that "Since he had come to the Colony he had endeavoured to continue immigration on such a footing as would do more good to all. His reason for so doing was simply because he believed that there was not a single class of the population of the Colony that was not vitally concerned in the continuance of immigration. It might be that every class did not derive equal benefit from the introduction of immigrants into the Colony, but it was clear that all derived benefit. He believed that the estates could not be maintained if immigration ceased.

The mercantile community, if the estates were abandoned, would find a cessation of trade; the public funds of the Colony would be distressed, and public officers would lose their salaries and their occupation in life; the mass of the population of the Colony would also suffer, inasmuch as the necessary consequence would be the loss of all those social, political, and civil institutions which, in point of fact, constitute civilisation."

Apart from all consideration of the direct advantages which coolie immigration has brought to British Guiana, an ethnic and historic interest attaches to the transfer of the population of Asia to the continent of South America. The adjustment of the balance of area and population is a question worthy of the statesmen of the greatest Colonial Empire the world has ever seen; and now that the Government has accepted the policy of an active encouragement of emigration, and that experience has indicated the principles on which emigration can be conducted consistently with an equal regard for the interests of capital and labour, it may be conceded that the time has come for the Government of India, together with the promoters of the great commercial enterprises recently undertaken, to consider whether a field for the organisation of Asiatic emigration on a scale of magnitude is not open in the sphere of British influence in tropical Africa.

OUR STAPLE EXPORTS AND THE CLOSE OF THE COMMERCIAL SEASON.

Although the Chamber of Commerce no longer lay themselves out for making up the export returns for our staples to 30th September—their season having been altered to suit the calendar year;—yet it is of interest to see how the actual shipments in the twelve months expiring today and the estimates framed a year ago compare. We cannot pretend to give exact results; for the latest Chamber of Commerce return is only made up to the 25th and the last statement for 1889 very probably overlaps a little with the fresh one begun from 1st January. But supposing that these two elements of error about balance each other we should get figures somewhat like the following for the total exports in Season 1889 90:—

From 1st Oct. 1889 to say 30th Sept.

TEA	43,067,101 lb.
COFFEE	90,263 cwt.
CINCHONA BARK	8,694,452 lb.
COCOA	16,842 cwt.
CARDAMOMS	320,994 lb.

If this result prove to be fairly correct as regards tea, Messrs. Rutherford and Scovell will deserve credit for coming so near the mark as 43 million lb. a year ago. But there may be one qualification to that remark in the fact that but for the temporary stoppage of immigration and the derangement of labour in mid-season, the tea exports would probably have been larger. But there is always some unforeseen contingency to take into account, and we think the tea result may be fairly compared with the following estimates:—

TEA EXPORTS FOR SEASON 1889 90:		Estimates:
Mr. Rutherford and Mr. Scovell	...	43,000,000 lb.
Messrs. Somerville & Co.	...	42,650,000 lb.
<i>Ceylon Observer</i>	...	42,000,000 lb.
Messrs. Forbes & Walker	...	40,000,000 lb.

Then in respect of the minor staples, we are gratified to see how nearly our own estimates published on October 9th, 1889, have worked out. Here are the comparisons:—

<i>"Observer" Estimate, Actual Shipment as above</i>			
Coffee	...	90,000 cwt.	90,263 cwt.
Cocoa	...	16,000 cwt.	16,842 cwt.
Cardamoms	...	300,000 lb.	320,994 lb.
Cinchona Bark	...	7,500,000 lb.	8,694,452 lb.

A difference of 1,194,000 lb in bark may be considered very large; but we have the satisfaction of believing that our estimate was nearest the mark—in fact the highest framed so far we know—our contemporary of the "Times" for instance keeping to 6½ million lb., while he was also below us in coffee and cocoa.

As regards the leading native export staples we may mention the following—:

"Observer" Actual Ship-
Estimate. ments about.

Coconut Oil	...	350,000 cwt.	307,349 cwt.
Plumbago	...	350,000 "	405,429 "
Cinnamon (Quills & Chips)	...	2,000,000 lb.	2,266,837 lb

We do not pretend that the figures for shipments are quite correct; but they are near as can be worked out from the Chamber's returns at present and must be fair approximations.

Above, we give an approximate reckoning of the total amount of our Staple Exports to the end of the season—which is now abandoned in favour of the calendar year,—as compared with the estimates put forth a year ago. The result is singularly close in the case of tea to the estimates framed by Messrs. H. K. Rutherford and A. E. Scovell, quite independently the one of the other. Our own estimates were not far behind, while in the case of coffee, cocoa, &c., they were as near as could be desired.

In regard to the season we are now entering on, although we reserve our more careful investigation and estimates for the calendar year, yet it may be of some interest to indicate roughly, to what extent we anticipate shipments between Oct. 1st, 1890, and 30th Sept. 1891. Here then are the figures for,—

"Ceylon Observer" Estimates:

TEA	...	51,000,000 lb.
COFFEE	...	80,000 cwt.
COCOA	...	17,500 "
CARDAMOMS	...	320,000 lb.
CINCHONA BARK	...	6,500,000 "
CINNAMON	...	2,200,000 "
COCONUT OIL	...	320,000 cwt.
PLUMBAGO	...	400,000 "

The way in which Tea exports have increased may be seen from the following return going back only 5 years:—

Season 1885 6	...	7,170,329 lb.
" 1886-7	...	12,013,686 "
" 1887-8	...	20,755,779 "
" 1888-9	...	32,516,682 "
" 1889 90 (about)	...	43,067,101 "
" 1890-91 (Est.)	...	51,000,000 "

It will be observed that we have diminished the estimated annual increase this time, but this is in correspondence with a falling off in the extent planted after 1886.

In regard to Coffee the figures run very sadly the other way:—

1885-6	...	223,693 cwt.
1886-7	...	180,429 "
1887 8	...	136,295 "
1888-9	...	86,440 "
1889 90 (about)...	...	90,563 "
1890-91 (Est.)	...	80,000 "

Last year our estimate proved exactly correct. This season Haputale and some other parts of Uva are to have good crops, but we fear this will be counterbalanced by a falling-off on this side of Nuwara Eliya, and we doubt if our declining staple will even reach 80,000 cwt.

For Cocoa, the return is:—

1885-6	cwt.
1886-7	13,347

1886-7	16,638
1887 8	12,611
1888-9	14,461
1889-90 (about)	16,842
1890-91 (Est.)	17,500

The cocoa crop is a very difficult one to estimate although our last year's prognostication was exactly fulfilled, and we trust the moderate increase we specify will be realized.

Of Cardamoms, the shipments have been:

1885 6	236,056 lb.
1886-7	321,560 "
1887-8	310,685 "
1888-9	361,706 "
1889 90 (about)	320,994 "
1890-91 (Est.)	320,000 "

Then as regards Cinchona Bark, although our estimate a year ago for season 1889-90, was the highest published, yet we were found fault with in several quarters for venturing so high; but the actual shipments give nearly 1,200,000 lb. in excess of our estimate! Our reckoning for the current season is based on the annual fall already experienced, more than on a vain attempt to judge of what bark is available for shipment, such depending almost entirely on the prices that may be offered. Here are the figures for shipments and estimate:—

			lb.
1885-6	15,364,912
1886 7	14,389,184
1887-8	11,704,932
1888-9	10,498,487
1889-90 (about)	8,694,452
1890-91 (Est.)	6,500,000

The low prices prevailing give no encouragement to cultivate cinchona, and unfortunately as Ceylon decreases her exports, those from Java are on the rise, so preventing the natural result of a lessened supply from this island.

In respect of Cinnamon, it was hoped that a great difference in the shipment of "chips" would be witnessed by this time, but such is scarcely the case, although for some years there has been a gradual decline; we trust the falling-off may be much more apparent by and by. Here is the return:—

	lb.	lb.
1885-6	...	1,629,548 bales; ... 548,037 chips.
1886-7	...	1,793,893 " ... 505,951 "
1887-8	...	1,657,424 " ... 496,887 "
1888-89	...	1,857,865 " ... 466,401 "
1889-90 (about)	...	1,830,422 " ... 434,415 "
1890-91 (Est.)	...	1,850,000 " ... 300,000 "

In Coconut Oil, we have a varying and yet on the whole wonderfully steady export:—

		cwt.
1885-6	...	234,308
1886-7	...	304,478
1887-8	...	385,758
1888-9	...	327,430
1889-90 (about)	...	307,349
1890-91 (Est.)	...	320,000

Finally in regard to Ceylon's one mineral of commercial importance that appears among our staple returns—Plumbago—(although it is no secret how large and valuable is the quantity of precious stones dug out every year and quietly disposed of)—the export figures for Plumbago indicate a wonderful development of mining:—

		cwt.
1885-6	...	190,153
1886-7	...	234,473
1887-8	...	254,046
1888-9	...	370,290

1889 90 (about) ...	405,429
1890-91 (Est.) ...	400,000

We trust then that the season just entered on may be a busy and prosperous one for both European planters and native agriculturists and miners.

STAPLE EXPORTS FOR THE OLD COMMERCIAL SEASON.

We have now had our monthly export tables corrected at the Customs up to the end of September as follows:—

1889.	Coffee Plan- tation, cwt.	Coffee Native, cwt.	Coffee Libe- rian cwt.
Months ...			
January ...	10,941	1,863	19
February ...	12,263	1,861	72
March ...	4,567	799	65
April ...	1,313	1,582	97
May ...	1,215	852	70
June ...	4,139	867	113
July ...	7,533	25	51
August ...	11,608	181	90
September ...	2,917	131	85
October ...	2,415	121	8
November ...	5,666	263	13
December ...	12,610	142	21
1890	77,207	8,697	707

Although there has always been a discrepancy between the Customs and Chamber's reckonings, it is of interest to see how the additions work out from Oct. 1889 to Sept. 1890 in the above tables. Here are the Results:—

Exports by Customs monthly report.

TEA .. 1st Oct. '89 to 30th Sept. '90=	43,864,233 lb.
Cocoa .. " " "	18,268 cwt.
CINCHONA BARK .. " " "	8,686,243 lb.
COFFEE:	
Plantation ..	90,104
Native ..	5,436
Liberian ..	2,757
	98,297 cwt.

In all these cases save Cinchona Bark, the Customs returns show higher figures than the Chamber's returns, for the exports.

LIGHT PLOUGHS FOR CEYLON

Trials of various kinds of bullock ploughs for use in India and Ceylon have taken place with more or less success, and at the present moment further reports on their use are looked for. The obstacles to their use are well known, and some, if not all, of these have been overcome; there is one, however, encountered

in the prejudice of the native cultivators, which will require a long course of practical demonstration to overcome. The price has been brought down to almost the lowest possible limit, the means of repairing the simple implements manufactured by Messrs. J. & F. Howard are provided, and the amount of work done is excellent.

The Sailapet Plough is a very good and useful implement, but when tried against Messrs. Howard's Simbaleso Plough is found wanting, as testified by Mr. G. S. Williams, the then Government Agent, Kurunegala, who prefers the latter by reason of its extreme lightness and its capacity for cutting a better furrow. In South India a lighter plough has been introduced by Messrs. Massey & Co., of Calicut, and tried in a variety of districts with partial success. The Collector of South Arcot in reporting on the same says he considers that their price is the great objection to the introduction of improved ploughs, and suggests that either Government should manufacture ploughs and sell them at cost price, or train local artisans in technical schools to manufacture efficient and at the same time cheap ploughs. He alludes also to the fact that the ryot does not as yet appreciate the value of time, which is a great factor in estimating the value of improved ploughs; it is cheapness that attracts them.

Practically the same difficulties have cropped up in all places; the cultivator fears, or pretends to fear, that the improved ploughs are too heavy for his cattle; the prices asked, though perhaps low enough in themselves for the articles offered, appear high to a villager who ordinarily spends but little cash on the purchase of a plough; the novelty of the implement renders the local smiths doubtful of their power to repair the ploughs; these men also discourage their introduction from fear of losing their customary payments for repairs; and finally, too often, much is both expected or exacted from the ploughs, and disappointment follows.

The Director of Public Instruction in Ceylon is doing much good work in endeavours to popularise improved light ploughs amongst the natives, and now that the cultivation of cotton and tobacco is being taken in hand by European planters, more attention may be given to the ploughs manufactured by Messrs. Howards.

As regards the native's objection to English ploughs, and his ignoring the great gain in the saving of time by their use, it would be well to point out to him in what way the value of time saved becomes an important factor in the calculation as against cost. The cultivator knows well enough how often scarcity of ploughing cattle from murrain or sickness amongst the village herds, hinders work in the field, losing half the time required for ploughing, and so causing the sowing to be too late, to the loss of many a field of un-sown faddy; whereas had the work been put through quickly, the whole extent of tillage might have been accomplished within the time of the rainfall. It too often happens that cattle cannot be hired for any sum, so great is the demand at ploughing time. Then it is that an improved implement doing the work in half the usual time, would be of infinite value, and amply repay the cost. We feel confident that if this advantage of the improved English plough over the ordinary village implement were impressed on the cultivators' attention, it would be more generally adopted than is now the case. In South India many hundreds of light English pattern plough are being worked with advantage, yet at one time in no part of the East was the prejudice against them stronger than in the Indian Peninsula.—Ceylon Advertiser.

TOBACCO COMPANIES AND TOBACCO

SOIL.

THE eagerness with which capitalists and planters are taking up the cultivation and preparation of tobacco in Ceylon and elsewhere, is almost equal to that with which others are investing in auriferous

land in South Africa. Perhaps a few words of caution on this subject may not be out of place in the columns of a periodical devoted to the interests of Ceylon industries.

As regards climate, there is such a variety in the island, from the very humid to the extremely parched, to be found in western and south-western localities on the one hand to the northern and eastern on the other, that there should be little difficulty in meeting with what is required. As for soil, however, the matter is not so easily settled, for there can be no doubt that none but fairly rich land is likely to produce good tobacco for a series of years. In Ceylon there is very little coming under this denomination in the majority of districts, and there is the probability that even where the land is well suited to the cultivation of the plant, that it must, after a short time, be assisted by artificial means. Those means are, according to experts, a supply of lime, phosphates and animal and vegetable manures.

The present range of prices for fine "wrapper leaf," from 1s. 6l. to 2s. 10d., will doubtless enable a good deal to be done in the way of manures, but we would advise intending planters not to reckon on a continuance of such figures. The planting of new land with tobacco in Sumatra, Borneo, Ceylon and Jamaica must, as in the case of tea, lead to the over supply of fine tobacco, one leaf of which suffices for wrappers for several cigars.

It is more than probable that the conviction of this in the minds of some of the largest proprietors of tobacco estates in Sumatra is the true explanation of so many of them disposing of their properties to Limited Companies. We have heard of another reason for this change of proprietorship in the decreasing fertility of the soil, caused by the exhausting nature of the cultivation.

That in the future, near or remote, there will be any falling off in the demand for tobacco of ordinary quality we do not apprehend; the habit of smoking is too deeply implanted in the rising generation to allow of any such foreboding, beyond which there is the additional reason for a continued expansion of the trade in the growing fashion of cigarette smoking amongst ladies. At the same time we are bound to confess that of late years there has been a marked deterioration in the quality of cigars sold in this country, far more so than in the quality of cut tobacco used for cigarettes, so much so is this the case that unless a very high price is paid it is almost impossible to obtain a pleasantly smoking cigar.

The reason of this falling off in the favour of ordinary cigars is that the employment of a fine quality of "wrapper leaf" for the outside of cigars enables the manufacturers in this country to palm off the veriest rubbish of leaf in the inner portion, the inferior quality of which is only apparent when it is being smoked. The Ceylon Tobacco and Cigar Company will do well to avoid this palming off inside rubbish by means of a fine looking wrapper, and adhere to a good selection of well-cured leaf throughout.

The inferiority of cigars generally, and the very high price demanded for anything like quality in the article, have led to an enormous increase in the demand for cigarettes, for which a medium description of cut leaf is required, and this must sensibly restrict the use of wrapper leaf. It is worth while for Ceylon tobacco planters to take note of remarks made by the British Consul at Amsterdam on the trade in Sumatra tobacco at that port, which he describes as very unsatisfactory to importers. The quality of the crop was not so good as in previous years, the plant not having fully developed. There was, in consequence, a much larger quantity of dark-coloured and second-class tobaccos among the importations, and the light-coloured kinds, which command high prices, were comparatively scarce. There was a large crop, and the few lots of fine quality fetched high prices, but the rest had for the most part to be sold at rates which were exceedingly discouraging to importers. The more favourably-situated plantations still gave good results, the dividends for 1888 being excellent, but so serious a drop in the prices of tobacco affected many undertakings still struggling with difficulties, and some of them have already gone into

liquidation. It has been stated that this falling-off in quality is due to a great extent to exhaustion of soil, just as in the Western States of America, wheat crops are decreasing.

In another place will be found an interesting account of the cultivation, curing, and manufacture of Mexican tobacco in the State of Vera Cruz, from which it will be seen how much pains are being taken in the development of the industry in that country. The remarks in question point to the fact that those planters who combine the manufacture of cigars with that of tobacco-growing and curing, realize very large profits.—*Ceylon Advertiser*.

THE COCOA BEETLE.—Agriculturists of this island, says the *Chronicle* of St. George's, Grenada, continue to be considerably exercised over the cocoa beetle, and well they may, for the pest is extending its ravages in all parts of the island at an alarming rate. Acres upon acres of trees, chiefly of young growth, have already fallen victims to the destructive insect, and many more are threatened. The Commission appointed by the Governor to inquire to what extent the beetle is destructive to the trees, and to determine upon measures for its destruction, has commenced its inquiry, but when that will terminate it is hard for us to say. One or two planters have set an excellent example to their brethren by employing boys and girls to go through the fields and destroy the larvæ and the beetles wherever they are detected.

KALUTARA, Sept. 27th.—A case of some magnitude, in which Mr. Simon de Fonseka as plaintiff claimed damages, R1,312.50, from the lessees of his cinnamon estate, Pitaguelly, for breach of covenants of lease, was heard on the 25th instant, the claim being resisted for the lessees by the Hon. Mr. A. de A. Senviratne, Advocate, assisted by Mr. Proctor Wij ratne. The plaintiff was represented by Mr. Walter Pereira, Advocate, assisted by Mr. Proctor de Silva. After a lengthened investigation, during which the evidence of the headmen, who had assessed the alleged damages at plaintiff's request, was led for plaintiff's side, judgment was reserved, and was pronounced yesterday in favour of plaintiff for R1,200 and costs. The breaches complained of were that drains were not well opened out and kept clear, so that cinnamon bushes were detrimentally affected by water being allowed to remain stagnant; that tender shoots were cut; and that weeding was done in a very unhusbandmanlike manner. Mr. Jardyne, a cinnamon planter from the Negombo District, having inspected the land at the plaintiff's request, gave evidence for the plaintiff. The judgment is likely to be appealed against.

TRAVANCORE TEAS SOLD IN COLOMBO.—At yesterday's (Oct. 2nd) public sales of tea a small invoice of Travancore tea brought down by B. I. steamer, was catalogued, and, though not sold in sale, afterwards realized high prices privately. The tea was catalogued by Messrs. Forbes & Walker, and the following particulars are gathered from their catalogued:—

PENSURST.		
14 hf.-chs. Bro. Pekoe	...	910 lb...76 c. bid
6 " Pekoe	...	300 lb...53 "
17 " P.-k. Sou.	...	765 lb...41 "
6 " Unassorted	...	300 lb...45 "
43 hf.-chs.		2,275 lb.

The tea is described to us as very well made, and altogether an attractive parcel, as the prices bid in the room testify. Higher prices were paid privately after the sale, and the proprietor of the estate ought to be well satisfied with the result of his experiment in sending his teas to Colombo for sale, where they meet with ready competition from buyers shipping to all parts of the world. We hope that we shall not only see Penshurst teas continue to be sold on our market, but also that other Travancore proprietors will follow this excellent example and send their teas to Colombo for sale, where full value can always be obtained for them.

WYNAAD COMMERCIAL PRODUCTS.

At the meeting of the South Wynaad Estates Company on the 29th ultimo, at the Office of the Company in London, Mr. A. R. Hinde spoke as follows:—

When first asked by Mr. Spain to assist in the re-constitution of this company, I did it with a view to planting tea, but my views were overridden by the advisers of the company in India, who preferred to go in extensively for planting ledgers, which, I think, was a mistake. At the same time, it is but just to them to say that at that time there was scarcely a man in the Wynaad who would have endorsed the views I held with regard to the cultivation of tea. But now you find that one of the principal shareholders in one of the Wynaad manes has been out to India and has come back strongly urging that his company should plant the whole of its estates in this way. On the Ouchterloy estate, almost adjacent to your property, they have gone to the extent of planting 1,200 acres with tea, and the manager of the two companies that have already written with regard to having joint works, Mr. Peterson, is so satisfied as to the result of tea cultivation that I believe, or at least I think, he has written both to his companies urging them to cultivate their spare lands with tea. Mr. Harolin, who is now the manager of the Oriental Bank Estates in Ceylon, and who has had, therefore, exceptional advantages of knowing what tea will do, and who has had a still longer experience of the Wynaad, tells me he calculates there is nothing in Ceylon that can beat Wynaad as a tea-producing country, and that the one fear Ceylon has is that Wynaad will embark extensively in tea cultivation. I may safely say that there is only one estate in Ceylon that yields anything like the results obtained in the Wynaad. On the Ouchterloy Estate there was produced 600 lb. made tea per acre, and on an estate abandoned for coffee they are getting an average of 800 lb., and upon the Periasola Mr. Minchin has $\frac{2}{3}$ of an acre of this tea, and tells me that he got 800 lb. of made tea from even that quantity of land. It is upon the yield of tea that everything depends, and I calculate, and think I have allowed a liberal margin for everything, that you can put your tea on the market here and sell it at 6d. per lb. and if carefully prepared, it should realise fully 1s. per lb., which will give you on the 150 acres it is proposed to plant, an income of £1,000 a year.

THE PLANTING OF PEPPER.—I also advocated. It has been adopted on a good many estates, where it is planned in conjunction with coffee. There is a drawback, because you have to coppice your standards once a year, and that is injurious to the coffee, but I have seen vines growing upon Mr. Walker's estate at Perungodda, the yields of which was sometimes extraordinary. The question that arose was whether our pepper would be equal to Malabar pepper grown below the Ghats. The first pepper brought a higher price than any on the market, and the natives are turning their attention to its cultivation in the Wynaad. If you grow the pepper amongst the tea, you have to coppice the tea, and therefore you do not injure the tea one atom. You would get the whole of the profits of the vine as no case, because the cost of cultivation is borne by the tea, so that all you have to pay is the outlay in harvesting. I propose that the precaution be taken of planting through the cinchona trees standards also, so that if by possible chance you did get clobber then you would have the pepper vine standing, and by the time your ledger has given out you would have a pepper estate in its place, which would subsequently be planted with tea. I think I have given fair and reasonable grounds for saying that the prospects of the company are good, because you can calculate something like £60 an acre profit from your land when it has come to maturity. You will get tea (so well has it come on) within nine months from its being planted in the open.

On the cinchona I have placed apparently a high value, but the figures are based upon actual returns obtained, and figures as given to me by the leading planters in the Wynaad. I have calculated simply 4 lb. of dry bark to the fully matured tree, and that

it will yield you only $\frac{1}{4}$ per cent. of quinine, though I have had an analysis of 11 per cent., and I have taken the inside value of that at 2*l.* per lb., so that I do not think I have been guilty of over-valuation, especially as 7 per cent. would be about the actual produce. The market for cinchona is perhaps lower now than it has ever been, and I have the assurance of Mr. Humlin (and there is nobody more qualified to speak than he) that the visible stocks of cinchona are simply kept up by the destruction of the plantations—a fact that the consumer does not know—and it is only the question of a year or two when of necessity you must have a rise in the value of your bark, which I have not discounted in the slightest degree. In the Wynaad the same process is going on. I should think there is a material reduction in the actual acreage under cultivation, and practically not a single acre has been put in to supply what has been destroyed, because the low prices do not induce plantation. Moreover, the actual area from which bark can be successfully grown is exceedingly small. In Ceylon it will not grow except in a few favoured districts, and when I tell you that 40 or 50 acres of ledger embrace the whole of it, you may fancy how limited is the area upon which it can be produced. The result will be that probably we shall have Cinchona at as many shillings per pound as it now is in peace. With regard to coffee I can support all that Mr. Gramshaw has said. When you took over the estate the coffee had been so neglected that they actually had to take axes and cut down the trees to the destruction of much that was valuable. I do not know any other place in the Wynaad that would have stood such treatment, because at the present time, with the exception of the Ouchterloy, that is the best; and that estate is notoriously good. What the chairman has told you as to the cost and trouble of bringing this estate round is perfectly correct. With regard to tea it had been so abandoned, and was actually burnt to the ground. The jungle has now been cleared away, and Mr. Punnett has written to say that as regards tea there has scarcely been the failure of a single tree. All the mining operations took place above what is now the cultivated ground and the debris was thrown upon it. I think it is a healthy tea and when we will no longer require the plant for seed purposes it can be cut down and commence to yield probably 800 lb. of tea per acre. (Hear, hear.)—*Madras Mail*, Sept. 25th.

FROM THE MEDITERRANEAN TO
LAKE TCHAD.

The *Nouvelle Revue* has an article on the Trans-Saharan railway scheme. The writer warmly espouses the views expressed the other day by Mr. Stanley. France must construct a railway, and construct it soon. The moment for action has arrived. The economic future of France is, more or less, entirely involved, and her political importance is no less concerned. Financially, scientifically, diplomatically, the way has been cleared. The great objection to the scheme lies in its name. The Soufan causes everyone to think of Tonquin, of Dahomey, of distant and fruitless expeditions. But there is no true parallel. The base of the project must be Algeria—the goal, Lake Tchad. The topographical conditions are shown to indicate this unmistakably. Lake Tchad is the “enviable port” of French African enterprise. “In order to enter it it is enough to reach the plateau of Ahir in the centre of the zone of influence which Her Britannic Majesty is good enough to recognize as ours. Masters of this point, we hold the African continent strategically from the Equator to the Mediterranean. We cover the Niger and Timbuctoo. Our Senegal will not have to wait long before we join hands with it.” The tide of Eastern and Western Islamism, which at present

flows undisturbed across North Africa, will also, it is urged, be broken by the establishment of French influence in a Northern and Southern line, and the new force of the Senoussiya has thus prevented from communicating itself to the Mahometans of Morocco. The commercial advantages of the railway are of course made the most of. But possible alternatives for the direction of the line seem numerous enough to be likely to keep the construction yet a long time from the range of practical enterprise.—*Review of Reviews.*

COFFEE MIXTURE LABELS.

The thirty-third Report of the Commissioners of H. M. Inland Revenue, for the year ended March 31st, 1890, has just been published, and contains statistical and other information of interest to the trade. As regards coffee mixture labels, we note that the following table gives the number of coffee labels issued up to March 31st, 1890, and the amount of revenue received:—

	Labels		Net amount received	
	½ lb. Labels	1 lb. labels	£	s. d.
	No.	No.	£	s. d.
England... ..	518,917	289,084	2,264	15 2
Scotland... ..	12,782	6,286	52	16 5
Ireland.....	45,864	4,820	115	12 8
	677,563	280,190	£2,443	4 3½
Year 1888-89	670,050	309,828	2,686	17 9
Decrease...	62,487	29,638	£283	13 5½

The following table gives the receipts since 1882-83 in which year the duty was first imposed:—

Year	Labels		Net amount received	
	½ lb. Labels	1 lb. labels	£	s. d.
1882-83.....	1,440,305	802,434	6,314	2 2½
1883-84.....	1,432,203	645,429	5,973	0 10½
1884-85.....	1,106,664	539,893	4,563	8 9
1885-86.....	1,021,868	446,525	3,939	8 3
1886-87.....	799,914	370,971	3,212	4 0
1887-88.....	704,862	332,921	2,855	12 8
1888-89.....	670,050	309,828	2,686	17 9
18-90.....	607,563	280,190	2,433	4 3½

The Inland Revenue Commissioners add to these tables the following significant note:—"The continued reduction in the revenue arising from these tables still, in our opinion, results from the unpopularity of coffee mixtures and substitutes for coffee."—*Grocer*, Sept. 6th.

THE FOOCHOW TEA TRADE: GREAT COLLAPSE.

If one half of the stories reaching us about the trouble and distress amongst the Teamen are true, they reveal a very sad state of affairs. Men, hitherto well to do, are ruined. Homes have been broken up by the score. Wives and children have been sold, and many suicides committed. One of the most painful cases brought to our notice is that of a whole family of eight, reduced to a state of utter destitution, taking their own lives by eating opium. But indeed all the stories are more or less heart-rending. These men have our sympathy. They have never come into contact with foreigners and therefore had no opportunity of hearing what was going on in the outside world. They knew nothing of the great depreciation of values in the foreign markets, any more than they did of the great American Silver bill which was to affect their interests so disastrously. All they had to guide them was the course of prices in this market last season. They could not foresee that they would have to take 30 to 40 per cent under those prices on the average, as they have had to do. If we are rightly informed, there are few, if any, of these men who can escape ruin. Capital has been sunk, and what remains is now in few hands; and

credit will be very charily given after late experiences. There will be changes and probably very important changes in the working of this part of the industry. It goes without saying that the ruin of the teamen has not come about without very considerable loss to the hongmen. Several of the Hongms indeed will have to close their doors. The consequence will be, that we shall have the small supply of this season still smaller next; and if the annual falling off is to continue on its present scale, the future of Foochow is gloomy in the extreme. But we will not despair. We have before given it as our opinion that, with these high exchanges, we can lay down tea cheaper in London than the India and Ceylon producers, and if we can only fight those countries with their own weapons, and pauder to the popular taste by sending them machine made teas, we should have better times to look forward to. The foregoing consideration of getting the natives to make tea by machinery suggested itself after hearing of a telegram from London advising that 'Foochow Congous were not wanted.' It is evident that something in the shape of novelty is necessary to catch the popular taste, and this form of novelty or reform would appear more easy of attainment than the previous suggestion of the government employing Indian planters to instruct the natives in their special mode of cultivation and manufacture which has proved so successful. The proposal is to make a trial. It would not apply to our Specialities, namely Sonchong and Flowery Pekoes; and probably some other district teas should continue to be made as they are at present.—*Foochow Echo*, Sept. 18th.

BARK AND DRUG REPORT.

(From the *Chemist and Druggist*.)

LONDON, Sept. 11th.

CINCHONA.—At Tuesday's auctions a moderate quantity of bark was offered, the total being as follows:—

	Package	Package
Ceylon cinchona	1,160 of which	877 were sold
East Indian cinchona	282 do	199 do
Java cinchona	55 do	55 do
S. American cinchona	1,202 do	81 do

Total 2,699 do 1,212 do

Among the bark offered were a good many second-hand parcels of Eastern growths, and nearly 700 bales Cuprea, which were once more placed on sale in the hope that the improved value for the article would enable holders to obtain their limits. Such was not invariably the case, however, and several parcels were bought in at more or less nominal rates, though a small concession on the part of the holders would in several instances have led to business. The Cuprea bark appears to be held at prices considerably in excess of the present market value, and none of it was sold. A very satisfactory amount of competition was manifested during the auctions, although only one firm bought very largely; and the general opinion is that prices, though slightly irregular, were on the whole fully up to the previous auction rates, the average unit being placed at 1½d to 2d per lb.

The following are the approximate quantities purchased by the principal buyers:—

	Lb.
Agents for the Mannheim and Amsterdam works	100,346
Agents for the Auerbach factory	35,047
Agents for the Brunswick factory	33,209
Messrs. Howards & Sons	30,757
Agents for the Frankfurt o/M and Stuttgart works	25,943
Agents for the Pelletier factory	21,488
Agents for the American and Italian works	16,961
Mr. Thomas Whiffen	5,650
Sundry druggists	19,105

Total quantity of bark sold	238,506
Bought in or withdrawn	19,728

Total weight of bark offered ... 430,229
 SOUTH AMERICAN CINCHONA.—Of cultivated Bolivian Calisaya 499 packages were offered, of which 81 (13,230 lb.) were disposed of at 7½d to 9½d for bold quilly chips and somewhat irregular grey quill. A large quantity of old Cuprea bark (699 packages) was bought in, the price asked 3½d per lb., being unobtainable. Four cases low lced bark, dull colorless quill, were also bought in only 3d per lb. being offered for it.

ESSENTIAL OILS.—In Citronella there has been a very good business, and the demand keeps up well, the spot price is \$1 to \$1.4 per oz.; and business has been done at 12d per lb. c. i. f. The price cabled from Ceylon is higher, viz. 13d per lb. c. i. f.; while for Lemougrass 1d 9-16ths c. i. f. is required.

COCONUT OIL has advanced in price since last week, and closes very firm indeed. Fine Ceylon oil on the spot is held for 32s 9d, while for shipment near at hand 31s c. i. f., and for distant delivery 30s 6d c. i. f. is required.

QUININE.—Market stagnant. The only business reported this week is a sale of 5,000 oz. second-hand German bulk, at 1s 13d oz. There was some faint expectation that the American Senate might decide to re-establish the duty on quinine during the debate on the McKinley Tariff Bill. In that case our market would probably have been temporarily influenced, but, as it is, the amendment to subject quinine to a customs duty was defeated.

HILLCOUNTRY PLANTING REPORT.

THE VALUE OF JARRAH TIMBER—THE "KEW BULLETIN"—THE ECONOMIC PLANTS OF MADAGASCAR.

After I had written at such length on Australian fuel trees,* I opened the latest number of the *Kew Bulletin* and found a notice of the celebrated Jarrah tree of Western Australia (*E. marginata*), in which Baron Von Mueller is quoted to the effect that this is one of the least inflammable trees for building structures and at the same time the very best of the West Australian trees for charcoal. We have some splendid specimens here of this famous eucalypt, the wood of which compares not unfavourably with mahogany, but neither we nor any others who have grown Jarrah trees are likely to convert them into charcoal. The immediate reason for the tree being noticed in the *Kew Bulletin* was that blocks of the timber were being used for paving streets in London. A similar use of the timber in Melbourne is mentioned, but when I was there in 1890-81 I saw blocks of red gum (*E. rostrata*) being laid in Collins Street; and while Victoria is rich in this excellent timber and Jarrah is found only in Western Australia, it is not at all likely that the imported and more expensive wood (probably not better for the purpose) would be resorted to. In the London *Times* I find a condensed form of the information in the *Kew Bulletin* ready to my hand, which I quote:—

JARRAH WOOD.—The new *Kew Bulletin* contains an interesting section on the properties and uses of the jarrah wood, a species of eucalyptus, native to Western Australia. The main difficulties in connexion with its use in this country are the cost of freight for such heavy timber from Australia and its intense hardness, which makes it difficult for ordinary English carpenters' tools to work it. The tree which produces it grows generally to a height of 100 ft., and sometimes 150 ft. It is found only in Western Australia, extending over the greater portion of the country from the Moore River to King George's Sound, forming mainly the forests of these tracts. According to Baron Mueller, when selected from hilly localities, cut while the sap is least active, and subsequently carefully dried, it proves impervious to the borings of insects. Vessels constructed solely of it have, after 25 years' constant service, remained perfectly sound, although not coppered. It has been tried at three places in the Suez Canal, and, after having been down seven years, the trial samples were taken up in order that a report on their condition might be sent to Paris. From certain correspondence between Kew and some London vestries, it appears that jarrah has lately been used by the Chelsea Vestry

for paving the King's-road, and by the Lambeth Vestry in the Westminster Bridge-road.

There are few trees about which such contradictory accounts have been given, especially as to its ability to resist submersion in sea water and the attacks of *Teredo navalis*. Conspicuous in the Western Australian Court in the Melbourne Exhibition of 1880 was a fine slab of Jarrah said to have been for 40 years part of a pier at Fremantle and which certainly was uninjured. The result of other trials, however, was stated to be its liability to be bored equally with other trees; but the evidence in favour of the timber largely preponderates. The non-inflammability of the timber renders it specially valuable for chingles. It can be used for the purposes to which *säl* (*Shorea robusta*) and teak are put, and also where those woods are inadmissible, while it is said to be cheaper. Mr. Allen Ransome reported: "It is beautifully marked, and somewhat resembles mahogany in colour. Railway sleepers, joinery, casks, spokes and hammer handles were made from it. The planed and moulded specimens left the machines with a very fine surface." Like teak its breaking strength is not to be compared to that of the Australian iron and stringy barks. The figure 1,982 for average specific strength, however, is not bad. It attains a great size, exceptional planks having a diameter of 10 or 11 feet. This, like other eucalypts, is liable to the existence on its stem and branches of enormous protuberances, most beautiful slabs of which were exhibited at Melbourne in 1880. Those from the Jarrah are described as rivalling in beauty the finest specimens of walnut or pollard oak. The protuberances occur 6 to 10 feet in diameter.

There is other matter of interest in the September number of the *Kew Bulletin*. Mr. W. F. H. Blandford identified an insect which injured barrel staves as a small beetle called *Trypodendron signatum*, Fabr., "Prickly pear" has spread so in South Africa that legislative measures have become necessary for dealing with. This reminds us that a member of the Madras Civil Service once reported that he found this plant useful as a protection for tree seeds which he sowed in spaces cleared amongst it. We have also seen it stated that if the thorns are burnt off the sliced leaves make good fodder for cattle.—There is an article on the treatment of mildew in vines. The remedy is "Bonillie Bordelaise," a mixture of sulphate of copper, slaked lime and water, a mixture likely to be useful not only as a fungicide but as an insecticide.—There is an interesting account of cultural industries in West Africa. But of chief interest in Ceylon, which is supposed to have been once joined to Madagascar, is an elaborate paper on the economic plants of the great African island, by the Rev. Richard Baron, F.L.S. In the prefatory matter it is stated that,

In a valuable paper by the Rev. Richard Baron, F.L.S., on the Flora of Madagascar (*Journ. Linn. Soc.* vol. xxv., pp. 246-294), it is stated that the vegetable productions of Madagascar have been very extensively "explored, and that the majority of the plants inhabiting the island are known to science." The flora of the low lands of the southern part of the island is still, however, the least known. Our knowledge of the flora of Madagascar is due to the labours of numerous botanists from Flacourt, Dupetit Thouars, and Commerson to Grevé, Bojer, Granddier, and Ellis. Within the last few years this knowledge has been greatly increased through the very successful labours of Mr. Baron himself, and his collections, received at Kew, have been determined and described by Mr. J. G. Baker, F.R.S. It is estimated that whereas until recently less than 2,000 species of plants were known from Madagascar, there are now named and described about 4,100 species,

* See page 352.—Ed. T. A.

Mr. Barou has been good enough to supplement his paper on the Flora of Madagascar by preparing for the *Kew Bulletin* some brief but interesting notes on the economic plants of the island. These plants are of considerable interest and importance. One of the earliest notices of Madagascar economic plants is contained in Rochou's *Voyage to Madagascar and the East Indies* (English translation, 1793, pp. 230-297). In this work plants from the north of Madagascar, "now transplanted in the Royal Botanical Garden at the Isle de France" (Mauritius), are given under their native names. The Ravensara (*Ravensara aromatica*), the Tanguem or Tangena (*Tanghinia venenifera*) and the Filao (a species of *Casuarina*) and many others are noticed. The later tree is quaintly and not unappropriately described as "Equisetum arborescens."

Dr. G. W. Parker, a medical missionary sent out to Madagascar, has recently prepared a Malagasy Materia Medica, with special reference to the use of native plants. This, with determinations made at Kew, was communicated to the *Pharmaceutical Journal*, 1881 vol. xi, pp., 853-855. There are numerous scattered notes respecting the economic plants of Madagascar to be found in other works, but the above appear to include the more systematic attempts to describe them. It may not be inappropriate to mention here that there are still some very valuable plants of Madagascar about which at present we know very little. As shown in the *Kew Bulletin* for May 1888, p. 135, we are not acquainted with the source of Madagascar Ebony nor of Madagascar Sandal wood. There is also the plant which yields Madagascar Piassava. This is doubtless a palm, but not a species of *Raphia* as is generally supposed.

While much of the flora of Madagascar is identical with that of Ceylon, the great island has far the advantage, and to it we owe, amongst other productions, "the flambeau tree" (*Poinciana regia*) and "the traveller's tree." Mr. Barou recognizes three separate zones, regarding which he states:—

"That the flora of the central region should differ widely from the flora of the eastern and western regions is accounted for by the great elevation above the sea of the central part of the island. But how are we to explain the existence of so great a difference between the floras of the eastern and western regions, occupying, as they do, the same latitudinal and altitudinal positions, for of the 2,206 plants found in the eastern and western regions only 128 (not reckoning the 100 occurring in all the three regions) are common to both. I believe the explanation to be simple. The central elevated plateau of the island, which runs from north to south, is undoubtedly of very great antiquity, having existed not improbably from Palæozoic times, and has therefore always formed a barrier between the floras of the eastern and western regions. The floras therefore, even if they were formerly similar, which is doubtful, have had abundance of time to become differentiated in character; and if they were originally different, they have been kept, by the existence of the mountain barrier, distinct to the present day."

TEA CULTURE TO BE ABANDONED IN CHINA?

The following is from the *Foochow Echo*:—

On account of the distressed condition of numerous tea garden owners in the tea districts, the authorities are advising them to do away with the tea plant and replace it with either rice or potatoes, as these two articles of necessity will not in any way so fatally injure them. We learn that many owners of land at the foot of the mountain, where water is to be had, have readily taken the advice. Opium, we are told, will also be extensively planted. Something must be done no doubt, as tea will never again be able to offer thousands of men the liberal support they derived from the trade years ago.

THE NEW CUSTOMS ORDER.

The announcement by the Board of Customs that tea is to be weighed and tared to the half pound is strongly resented by the tea trade. The *Grocer* says:—The intended change will entail a serious loss upon grocers, who can ill afford it in the present time of extreme competition, and particularly of opposition from civil servants themselves, and we cannot too strongly impress upon our readers the necessity of taking immediate steps of petitioning the Board of Customs and the Treasury against the proposed change. One thing is certain if the trade are to be harassed by the paltry charge of two-pence upon half-pounds of tea, the sooner the duty is abolished the better, and the Customs Department merged with the Inland Revenue, as this will save expenses and loss all round. The large wholesale dealers are stirring in the matter, but the weight of evidence to be brought before the authorities rests with the grocers, who distribute the tea, and they must individually and collectively take an immediate interest in the matter to prevent the change taking effect. Such an alteration should not have been contemplated when Parliament was not sitting, and no opportunity can be taken of bringing the subject before the members of the House of Commons, who passed the Act which imposes the duty of 4d per lb., and does not mention or contemplate the payment upon any fraction thereof.

The *Produce Markets' Review* says:—With reference to the second portion of the boards' order, the system of selling India teas on average weight has been tried and has been found to be altogether unsatisfactory. It is evidently quite useless for Her Majesty's Commissioner to waste the public time, or order systems to be kept up or altered, which the trade has absolutely refused to buy upon. What is the use of weighing tea by net weights to nominally oblige the importers, when no one will buy it after it is weighed? Here, again, the board acts without consulting those who are interested, and who understand the subject.—*H. and C. Mail.*

FISH-CURING IN THE MADRAS PRESIDENCY.

The fish-curing operations during the official year 1889-90 show the usual upward tendency of the industry from the period it was taken under Government management. The following figures for the past five official years show the increase from year to year of the fish brought to the fish-curing yards to be salted:—

	Tons.
1885-86	27,396
1886-87	30,373
1887-88	37,495
1888-89	41,611
1889-90	43,496

At the beginning of the year there were 149 yards under operation, a new one was sanctioned but not opened during the year, and seven yards which did not turn out enough work were closed, leaving 142 yards open at the close of the year. 11,84,058 maunds or 43,496 tons of fish were taken to the yards to be cured, against 11,32,756 maunds or 41,611 tons in the previous year, showing an increase of 51,302 maunds or 1,885 tons, being 4.5 per cent, which is highly satisfactory. The quantity of salt used in the operations was 1,75,111 maunds, valued at R1,16,278, being at the rate of 12-16 lb. of salt per maund of fish. The quantity used in the previous year being 12-55 lb. per maund of fish. There have been great variations in the quantity of salt used in the various yards, and as no satisfactory explanation can be obtained, an intelligent Sub-Inspector has been ordered to be placed for a time in charge of each yard, to watch the operations carefully. The results of this step will probably elucidate the reason of the variation in the various yards. The total expenditure by Government under all heads in connection with fish-curing operations during the year, was R1,08,149-4-9, while the receipts amounted to R1,16,278-4-2, exhibiting a gain to Government of R8,128-15-5. Since these operations were taken

Under the management of the Salt Department, the State Exchequer has benefitted to the extent of Rs3,079-0-7, while the general public have been able to obtain a healthy article of diet instead of the rotten and putrid fish cured with salt earth, etc., hitherto sold in the bazaars. The great opposition shown by the cures to resort to the yards has gradually given way, and applications are now being constantly made to open new yards. Most of the fish cured passes into general consumption, only about 2,750 tons having been registered as exported by sea.—*Madras Times.*

THE QUARTERLY SALES OF CINNAMON.

These sales were held on Monday last, when only 1,300 bales Ceylon were offered, which at the opening, met little demand, and previous rates were with difficulty obtained, but the competition afterwards improved, as it was seen that several shipping orders had to be executed, and, excepting the portion "unworked," which was mostly retired, the whole of the above quantity was taken off, prices towards the finish showing an advance of 3d to 1d per lb. on the May rates, especially for the finer qualities, viz.:—Ordinary to fine first at 7d to 1s 2d, superior plantation at 1s 3d to 1s 7d; seconds from 6½d to 1s 1d, finest at 1s 2d to 1s 4d; third at 5½d to 1s; best at 1s 1d to 2d; fourths at 5½d to 8d, with extra fine at 10d to 11d; and broken, in twenty packages, at 5½d to 7d per lb.

The details of the marks and prices are as under:—

Marks	Superior and First Quality 410 bales	Second Quality 340 bales	Third Quality 290 bales	Fourth Quality 290 bales

CINNAMON CHIPS are in request, and 357 bales and bags Ceylon put forward were chiefly sold at full prices—common at 2½d, cuttings, quilings, and clippings at 6½d to 7d.

The next series of auctions are arranged for Monday, November 24th.—*London Grocer.*

COMMERCIAL NOTES ON INDIAN DRUGS

The word tamarind is derived from the Arabic "Tam r-Hindi," or Indian date, the fruit being introduced into Europe from that country by the Arabs. At present the most esteemed variety of East Indian tamarind are the red ones from Guzerat, and which are worth as much as 50 rs. per kandy, or about 10s per

cwt. The pulp is prepared for the market by removing the seeds and epicarp by hand, then mixing the pulpy portion with about 10 per cent of salt, and treating it into a mass with the naked feet. The best qualities are free from fibre and husk, the commonest contain both as well as seed. The seeds, after the outer shell is removed, are eaten by the natives boiled or fried.

Goa-powder was, until 1861, known as a remedy only, to the native Christians of the Portuguese possession of Goa. In that year Mr. D. S. Keap, of Bombay, first called attention to its medicinal value, but not until 1875 was the fact finally established that Goa-powder was identical with the araroba of the Brazilians. Now Goa-powder is known as a rim worm remedy all over India, and one wholesale drug house in Bombay alone imports over a ton of it every year. It is sold under the names of ararobine, chrysarobine and Goa-powder.

The sappan-tree is cultivated in the Madras presidency; and it is stated that it is the practice among the Thean families, whenever a girl is born, to plant a certain number of sappan-trees which are given to her as a dowry upon her marriage. Sappan-wood is largely used as a dye. The natives do not seem to employ it medicinally but at the Bombay Medical Depot it is now used in the place of logwood. Three qualities are known in the market, Singapur, Dhunsari, and Ceylon, the last named being the most inferior.—*Indian Agriculturist.*

PLANTING IN PERAK; STRAITS SETTLEMENTS.

(By Mr. J. F. M. Cock.)

GENERAL REPORT ON PLANTING BY THE SUPERINTENDENT GOVERNMENT PLANTATIONS.—On viewing figures presented along with this report, the question naturally arises what benefit has been derived from the expenditure? That there was no adequate return in revenue has always been apparent, and the collapse of the coffee crop in 1888 was met by a reduction in expenditure. At one time it was proposed to manure the whole of The Hermitage, but when the actual cost and dubious result were duly weighed the proposal was dropped. Similarly, we could have continued tea manufacture at Cicely, but the tea would all have had to be drained and manured, and the purchase of a new rolling machine was demanded by the report on the twist of the leaf.

Everyone interested knows that coffee has grown of the finest quality in this State, and can see it growing on Waterloo now. The tea made at Cicely was recognised by the whole commercial world as a good and useful tea, but no one well advised would put money into tea in Perak. Till the results named above—viz., the production of a first class coffee and a well-priced tea had been attained—the expenditure incurred was justified by what had been already spent on the plantations. Nothing has been spent this year except on necessary buildings, grass fields, roads and drains, on the curing and dispatch of the coffee crop, and dispatch of the tea crop of last year. Next month I shall pack up the balance of the tea to be ready to be shipped off wherever it shall be determined to send it.

In the end of June Mr. Li Chin Ho took over the tea on Cicely and The Hermitage on behalf of the lessees, Mr. Li Poh (his father) and Mr. Ah Kai. He is working monthly labour at present. If the lessees hold out till others are encouraged to join them on the tribute system this experiment will be a success. At present money is all going out, nothing coming in.—*Perak Government Gazette.*

A CEYLON COFFEE PLANTER tries to eclipse the gaiety of nations by alleging that the failure in the Ceylon coffee crop is due to permanent causes, which operate in South America as well, and that coffee will soon be an unknown beverage. Are the stars in their courses fighting against the great cause of temperance? *Brooklyn Times*, Sept. 12th. Refers to interview with Mr. Grinlinton published in the *New York Tribune*.—*Cor.*

GIRDLING FRUIT-BEARING TREES.

According to the American journal *Science*, some highly interesting results have been obtained at the Agricultural College in Massachusetts from the girdling of fruit trees. A row of crab-apple trees was selected. Three were girdled by cutting out a ring of bark one-eighth, a quarter, and a half-inch wide at the ground; three more were girdled to the same widths just below the main branches, and others on one or more of the main branches. All the girdles made near the ground healed readily and completely; those on the main trunk healed less completely, but sufficiently to ensure a good growth of tree; those on the branches healed less completely still, and in two instances the new growth failed to meet and the branch died in the spring. All showed a marked increase in fruitfulness over those not girdled, and little difference was observed in the effect of the various widths. But no definite conclusion can be drawn yet as to the consequence of this treatment on the permanent health of the tree; observations for many years can alone determine this point. A series of experiments made at the same place ten years ago showed that by removing a ring of bark early in July from fruit trees the ripening was hastened one or two weeks, and that the increased size and early maturity were not obtained at the expense of the quality.—*Oeylon Advertiser*.

BOYCOTTED BANANAS.—Considerable amusement, not unmixed with alarm, has been created in Queensland by reported political pressure brought to bear upon the Victorian Government with a view to the virtual exclusion of bananas from the Melbourne market. Southern fruit-growers complain that the apples and pears grown in their orchards cannot compete against the toothsome banana under present conditions. First rate bananas are sold from hand-carts in the streets of Melbourne at 3d and 4d a dozen, or relatively cheaper than Victorian fruits, and the tropical luxury has been established as a primè dessert favourite. This state of things led to an agitation for the imposition of a prohibitive duty on bananas, and at a recent conference of Victorian fruit-growers it was decided to ask for a duty of 1s a bunch. Mr. Cowley promptly communicated with the Melbourne authorities, with the satisfactory result that it if now understood there is no intention of acceding to the demands of the jealous pomologists. The importance of the matter to Queensland may be guessed from the fact that our exports of green fruit—principally bananas—last year amounted to a money value of £36,778, of which sum the shipments from Cairns represented £16,666, while Brisbane was credited with £12,074. The incipient trade indicated by these figures would have been well nigh crushed if the Victorian fruit-growers had succeeded in their object, but the danger is now past. It was, to say the least of it, a curious conspiracy to prevent people eating that of which they had become fond, and forcing them to return to the more insipid products of a temperate climate. In some respects the project reminds us of the plan advocated recently in an American State for the purchase by the Government of all the whisky made in the country and the issue of legal tender certificates to the value of the purchase money. The whisky would improve with age, it was urged, and the Government would thus be the gainer. But the distilling industry failed to gain the desired protection, and so have the apple and pear men. Where people prefer beer or tea, or develop a taste for bananas, it is certainly better to leave them free to gratify their inclinations.—*Queenslander*, Aug. 23rd.

DOORAS, DAM DIM, Sept. 19th.—During the past week the weather has been about the finest we have had for tea, since the season commenced. Outturns are in consequence looking brighter, but it is now too late in the day for estimated yields to be expected. A heavy thunderstorm last night, with a perfect deluge of rain looks as if we were at the last "kick" of the rains. Very heavy thunderstorm on Thursday night twelve inches of rain fell in as many hours; green fly, mosquito red spider all flourishing; weather cool except two or three days.—*Indian Planters' Gazette*.

TEA NOTES—**Debra Dun, Sept. 9th.**—Rain is badly wanted. We have not had half an inch of rain since the 20th August. We shall only make about a half tea crop this year. The rice and other crops are suffering from want of rain. **Mangaldai, Sept. 9th.**—At last there is a fair flush, but it has come too late for many to make up their decrease. Road to steamer ghât quite impassable; this generally seems to be the case with roads directly under the P. W. D. **Sileng, Sept. 7th.**—Only '84 rain in week, making to date 54 in. against 96 in. last year. So this promises to be the shortest on record as last year was highest. Leaf plentiful. Good outturn for month expected. Rumours that a short crop is expected. Something of the kind wanted to raise the prices. **Burragong, Sept. 7th.**—We have just enjoyed a week's weather that has given no cause for complaint, and leaf is making a decided effort to again struggle through mosquito blight and green fly. Although many of the concerns will never be able to make up the tremendous decreases, prospects are less hopeless than they were ten days ago.—*Indian Planters' Gazette*, Sept. 16th.

SCHOOL OF FORESTRY.—A deputation from the Associated Chambers of Commerce waited upon Mr. Chaplin (with whom was Sir James Caird) at the offices of the Board of Agriculture, in St. James's Square, for the purpose of urging upon him the desirability of establishing a National School of Forestry. Colonel Hill, addressing Mr. Chaplin, said those who were with him desired to point out that the growing of timber as an industry might be most usefully extended in this country, especially in view of the timber supply from abroad becoming more and more diminished. They recommended, therefore, that Her Majesty's Government should establish a National School of Forestry which would be an encouragement not only to the planting of Crown lands with trees, but would also induce private landowners to utilise ground which was at present of little or no service in the same direction.—Mr. G. Harper next spoke, and said he had received letters approving of the objects of the deputation from Lord Basing, official venderer of the New Forest, Sir Edward Lechmere, and other gentlemen. He further pointed out that, with the exception of Spain, this was the only country of any position that did not have National Schools of Forestry. England was the greatest timber-buying nation in the world, and at present imported annually something like £13,000,000 worth of that commodity. There was a vast acreage of land now lying waste in this country which might be the proper instruction forthcoming, he used for timber growing, and partially enable it to produce all the timber it required.—Mr. Chaplin said there could be no doubt of the growing interest and importance of the question under discussion. The purport of the remarks he had heard seemed to be that his department should establish a National School of Forestry. He desired, however, to point out that the Act under which that department was instituted provided only for its inspecting and reporting upon schools which provided education either upon agriculture or upon forestry. So far as he could see, his department had no power to institute a school, but he would consider the matter very carefully, with a view to seeing if he could recommend such a course to the Government. Before he did this, however, he should like to obtain some further information upon the climate and soil of the waste land which Mr. Harper had said it would be possible to turn into profitable forest land.—*Gardeners' Chronicle*,

THE VELLUM PAPER manufactured by the Insatsuyoku deserves to rank among the curiosities of Japan. It is made from a tree called Mitsumata. The tree is easily cultivated and grows quickly. At three years of age, the pruning can be used for paper making. In appearance the vellum paper is rich and glossy, its colour cream-like and its texture fine. It is as pliable and thin as the best writing paper, but so enormous in its strength that four people can grasp the corners of a sheet and raise a man standing on it.—*Madagascar News*.

THE DOUBLE COCO-NUT.—There are several Nuts of this extraordinary Palm, *Lodoicea Seychellarum*, in an advanced stage of germination at Kew. One of them has already produced a leaf, and has a mass of healthy roots, whilst two others are bursting into leaf. There is now, therefore, a prospect of our seeing this Palm among the many species which are the most striking features in the great Palm house. The process of germination in the *Lodoicea* is exceptionally slow. In its native habitat the Nut is said to be about two years, after falling on to the ground, before it produces its first leaf. The leaf on the Kew seedling is 2½ ft. long by 2 ft. broad, and it is folded double laterally, so that if spread out it would measure 4 feet. It is divided along the top into about forty segments the texture is unusually stiff and leathery even for a Palm.—*Gardeners' Chronicle*, Sept. 13th.

INDIA THE HOME OF THE SUGARCANE.—In the great German work of Dr. Lippmann, according to the *Sugar Cane*.—

He quotes Decandolle and Miquel to the effect that it is undoubtedly a fact that the whole of the wild kinds of the genus *Saccharum*, perhaps with one single exception, belong to India. The whole of the varieties of the true sugar cane (*Saccharum officinarum*) even those which by many botanists are regarded as independent varieties, as, for instance, the Chinese sugar cane (*Saccharum sinense*) point to the same origin. Botanical reasons also require us to look for the home of the sugar cane in India, and the occurrence of almost every wild variety of *saccharum* in Bengal, the oldest name of which—Gaura or Gauda—is derived from guda—is derived from guda or raw sugar (modern, *goor*?) and whose inhabitants call themselves “the men of the red sugar cane,” points in the same direction.

The original stock of the sugar cane is, we are told, no longer known, nor is it believed to exist in a wild state. This deduction is based on the united testimony of all who have written on the subject. Dr. von Lippmann alludes to the idea formerly prevalent that the sugar cane was *apogamous*, and to the experiments and discoveries of Soltwedel and Harrison, but does not consider that any of these shake the theory of an Indian origin.

The mention of sugar in the earlier Indian writings, the Institutes of Manu, and the great epics of the *Mahabharata* and the *Ramayana* is alluded to, and the probable age of these discussed, and the name applied to the sugar cane and its juice are given. As regards the time when solid sugar was first manufactured only two data can be given, viz., the reception of sugar cane as tribute in China in the 4th century, and a remark of Hiuen-Tsang, who travelled in India in the first half of the 7th century, distinctly mentioning both syrup and solid sugar, as also the fact that solid sugar was obtained in Northern India from the sugar cane. From these Dr. von Lippmann deduces the opinion that the discovery of solid sugar must have taken place between the 4th and 7th centuries, nearer the latter than the former.

In connection with the above we would refer to the interesting discussion of the subject by Col. Yule in his *Hobson-Jobson* s. v. “Sugar.” The Sakya tribe, to which Buddha belonged, claimed descent from the first king of Ayodhya named Ikshvaku (in Pali Okkaka, Sinhalese Okka), which means ‘sugarcane.’ The Sinhalese kings claimed the same honour.

FUGAR.—In respect to the sugar crop of Guiana, we learn this week that competent authorities estimate that this year's crop of sugar will fall 30,000 tons below that of last year. This falling off is ascribed to the same cause as at Trinidad, namely, the very heavy rains.—*London Grocer*.

CEYLON ENTERPRISE is thus noticed by “Peripatetic Planter” in the *Indian Planter's Gazette* :—

It is good for reflection to note how much Ceylon enterprise is ahead of Indian enterprise in the Tea matters. Almost every day one meets with instances. In the smallest suburban Grocers' shops, and in all sorts of shops of country villages, one can always find Ceylon tea in original, estate-picked tancy packages. It would be a rare thing to find an Indian *estate-packed* packet. Yet by this means the Ceylon men are sure their Teas are not being spoiled by an admixture of China Tea, and that full justice is being done them, and that their reputation is in their own hands, and not in that of all the intermediaries between the Indian planters and the consumer. The way in which Ceylon estate-packed packets have become procurable in the smallest villages within the last year or two is really remarkable, and is greatly to the credit of those who have achieved this big task. The way, too, in which the very much awake Ceylon Association protects the Ceylon planters by prosecuting people making fraudulent attempts to pass off blends as pure Ceylon tea, and others using misleading names on packets, is an example to the I. T. D. A.

Then the famous “Lipton,” who from selling hams, sausages, &c., by the million, has of late become also one of the largest retail vendors of tea in the U. K. has been “got at” by Ceylon enterprise, and he is off out to buy estates in Ceylon. His agency alone will be a stupendous advertisement for Ceylon teas.

SCIENCE AND PRACTICE.—From the proceedings of the American Association of Nurserymen, as reported in “Garden and Forest” we quote an opinion on pruning and pollarding, which seems interesting in its bearing on tea culture and horticulture generally :—

Mr. Thomas Meehan said that it had been fifty years since he wrote his first article for a horticultural paper, and it seemed to him, although horticulture had made rapid advances in all of those years, that it had not progressed as far on the scientific side as it ought to have done. As a practical example of some scientific truths, upon which good practice is based he instanced the fact that fibrous roots live only a year. They do their work and then die. Where there are a hundred small roots now about a young tree there will be in a few years only a few large ones radiating from it, like rail-roads on a map. These big roots alone have the strength to send out fibres, and the root is of no value to the tree until new white fibres are growing. Therefore, it may be that a mass of fibrous roots in a tree for transplanting is injurious. They are weak, they have no vital power to put out rootlets, and they may keep the soil from contact with the big roots, which, therefore, do not find the proper medium in which to throw out feeding roots. Another fact which observation teaches is that roots die in exact proportion to the amount of tops that are cut off. If a tree is pollarded nine-tenths of the roots may die and then invite a fungus which spreads to the living roots. It is said that the branches which sprout from these pollards grow strongly because the roots are stronger below them, but in fact they grow from the food stored up in the trunk, just as shoots three or four feet long often grow out of logs which lie by the wayside. Generally pollarded trees die after this operation has been frequently performed. Look, for example, at an Osage Orange hedge. If one of the trees at the end is allowed to grow it will make a trunk as big as a man's body in twenty years, while the hedge plants of the same age, their vital power being weakened by constant cutting, are no larger than a man's wrist. Of course all pruning is not to be condemned, although it does weaken the vital power of the plant. We prune for other purposes than to make long lived trees.

TRINIDAD HAS ITS "AGRICULTURAL BOARD"—not giving special attention to any one industry or branch of agriculture, but to all. At a meeting of the Colonial Institute Mr. Morris, the Assistant Director at Kew, spoke of the Agricultural Board in the following flattering terms:—"At Trinidad Mr. Fowler has very ably assisted Sir William Robinson in developing industries in that island, and more especially in regard to the work of the Central Board of Agriculture. This Board and its local branches will undoubtedly do much good, not only by directly encouraging industries, but by bringing persons engaged in them into contact with the best markets for the produce in this country and in the United States.

THE NETHERLANDS-INDIA Agricultural Company held its annual meeting on the 8th inst., when the report for 1889-90 was presented, which shows that a good profit has been made. The disease in the leaves of the coffee trees was only observed to a small extent. The crop of the four undertakings amounted to 6,290 piculs of coffee, being about 300 piculs above the estimate, which figure would have been more if a fearful inundation had not destroyed a large quantity on the Sonosehar Estate. The quality of the coffee was very superior, and the prices fetched were high—viz., from c. 55½ to c. 57½. According to the profit and loss account there is a net profit of f. 84,704, and a dividend will be paid to shareholders of 15 per cent. or f. 45 per share.—*L. and C. Express.*

TENDER FOR THE MYSORE RUBY MINES.—The Dewan of Mysore has, says a Bangalore paper, informed Messrs. Streeter & Co., the great gem merchants of New Bond Street, London, that the Mysore Government cannot entertain any proposal having for its object a monopoly of any particular industry, nor can it grant an exclusive right to prospect for gems for five years in so large an area as a whole taluq. A tender for a square mile or so will be entertained. The Mysore ruby mines are said to be even superior to those of Burma, and Dr. Clarke speaks of specimens shown him from the limestone rocks of Banawar as being "oriental of the purest water and not spinelles."—*Indian Engineer.*

RAILWAY SLEEPERS FOR THE HINDUPUR RAILWAY.—It is stated that the Mysore Government have decided to utilise the forests of Mysore for the supply of teak sleepers for the Hindupur Railway. About 80 miles of this line will be in Mysore territory and the requirements being about 2,000 sleepers per mile, 1,60,000 sleepers will be required. The sleepers are 6 ft. long 8 inches wide and 4 inches deep, or one and a third cubic feet each, and will cost about R2.4-0. Mr. Lee, son of Mr. Standish Lee, Sanitary Engineer of Mysore, has, it is believed, obtained the contract for preparing the sleepers from the rough logs as delivered by the Mysore Forest Department.—*Indian Engineer.*

ARTIFICIAL TEA.—The Germans are endeavouring to establish a new industry in the production of an article which they call artificial tea. They take the leaves of the wild strawberry plant and add to them the young leaves of bramble and woodruff, and the beverage brewed from the mixture is said to be of nearly the same taste as the tea of India and China. There is nothing artificial about this German tea, but it is a mistake to suppose that it can be produced inexpensively. It will cost quite as much as the imported tea, especially if it should be required in such quantity as would render it necessary to cultivate the herbs required in its fabrication. The cultivation and preparation of tea are not more expensive than the gathering and drying of substituted leaves would be.—"Science Gossip" in Melbourne *Leader.*

THE KOLA NUT, of which a good deal has been said lately, is rapidly increasing in favour as an indispensable adjunct to a traveller's kit. The French Alpine Club has just adopted it as a stimulant and nutrient in their mountain-climbing expeditions. The nut has, it is stated, been found to act most usefully in strengthening a person's "breathing powers" and keeping off muscular fatigue. The German military authorities have, it is said, determined to employ it in the German army. The acting principle of the nut is caffeine.—*Indian Agriculturist.*

THE "AWETO": A VEGETABLE CATERPILLAR.—The *Graphic* of 30th Aug. has the following:—The oddest insect in existence—so odd, that unless it were vouched for and explained scientifically would be considered a hoax—is the Aweto. It is not easy to decide whether it ought to be classed under the fauna or flora of New Zealand, for it is as much vegetable as animal; and, in final stage, it is a vegetable, and nothing else. This is the Vegetable Caterpillar, called by naturalists *Hipialis virescens*. It is a perfect caterpillar; and a fine one also, growing to three and a half inches. Until it is fully grown it conducts itself very much like any other insect, except that it is never found anywhere but in the neighbourhood of the Rata tree, a large scarlet-flowered myrtle, and that it habitually buries itself a few inches under ground. Then, when the Aweto is fully grown, it undergoes a wonderful change. For some inexplicable reason, the spore of a vegetable fungus, the *Sphæria Robertsii*, fixes itself directly on its neck, takes root, and grows, like a diminutive bulrush, from six to ten inches high, without leaves, and with a dark-brown head. This stem penetrates the earth over the caterpillar, and stands up a few inches above the ground. The root grows simultaneously to the body of the caterpillar, which it exactly fills in every part, without altering its form in the slightest degree, but simply substituting a vegetable substance for an animal substance. As soon as this process is completed, both the caterpillar and fungus die, and become dry and hard, but without shrivelling at all. The thing is then a wooden caterpillar, so to say, with a wooden bulrush standing up from its neck. *Papier mâché*, perhaps, would better describe it than wood. It can be taken out of the ground entire, and preserved for any time. Where the Aweto is found, many specimens can be obtained. It is a light green when alive, and the Maoris eat it in its soft state, when it resembles marrow. When dry, they powder it for use as a flesh-dye in tattooing. It is certain that the caterpillar and fungus were made for each other, as the *Hipialis virescens* is never found without *Sphæria Robertsii* growing out of it, and *Sphæria Robertsii* is never found without this caterpillar attached to it.—Our engraving is from a sketch by Major-General Robley, and the specimen is in the possession of Comte L. de Jouffroy d'Abbans, French Consul at Zurich.

Major-General Robley has gained fame lately as a *badineur*; but in this case we do not think that he is "pulling the leg" of the public. A similar fungoid growth is not uncommon in the case of the white grub in Ceylon. In fact, as our entomological referee states:—

This fungoid disease is not confined to the larva of one species of moth alone. I have noticed it occasionally on mole crickets from several localities, and on other insects that reside underground, and which have succumbed to its attack. It must not be supposed from the statement that "the *Hipialis virescens* is never found without *Sphæria Robertsii* coming out of it," that every individual of the species is fated never to reach the perfect state from that cause, for how could reproduction be effected? I send herewith a book in which you will find a description and figure of the fungus.

The figure given in the book sent is of *Torrubia militaris* on the pupa in moth, and is very similar to the one drawn by Major-General Robley,

HILLCOUNTRY PLANTING REPORT.

"THE BATTLE OF THE WATTLES."
THE BEST TREES TO GROW FOR FUEL.

I come up here to find the battle of the "wattles" revived and raging, promising almost to rival "the battle of the gauges." When about three years ago I had the pleasure of visiting Mr. Kellow's fine and fertile estate of Albion, adjoining the reef of lime-stone so rich in spinel sapphires, below Hakgala, I remember we could scarcely get along the paths which had been cut on the patana from the abundance of the up-springing suckers from the roots of a wattle, which I suppose was *Acacia dealbata*? Now Mr. Kellow cultivates in preference a plant raised from seed he obtained from Australia as that of *A. decurrens*, which grows rapidly into a good-sized tree, but which does not send up suckers from its roots. I am sorry I have not Mr. Kellow's memorandum of a tree of this kind which Mr. Nock has at Hakgala, and which at the age of seven years has attained large dimensions,—60 feet in height and 7 in girth near the root, I believe. † *Acacia decurrens*, especially the variety known as *mollissima*, yields about the finest tanning bark in the world; and although it might not pay us in Ceylon to grow this tree for its bark, yet, in cutting trees down for timber or fuel, the bark might be stripped and saved. The local tanners of hides or those who have made tanning hides a great industry at Madras might give a remunerative price for the bark. I am glad to see the specimen Mr. Kellow has sent, because it enables me to class as identical with it one of two magnificent Australian acacias which we have grown without knowing their names, but merely distinguishing them as the "golden flush" and the "silver flush" wattles. As far as foliage goes the former is the same as Mr. Kellow's, and the other is probably *A. dealbata*, if, as seems to be the case, there is a variety of *A. dealbata* which grows into a large timber tree and does not send up suckers? Our two gigantic wattles have never shown the slightest tendency to this latter habit. Here as in Australia several of the numerous acacias which bear golden-coloured flowers have been indiscriminately called "golden wattles." In Nuwara Eliya this name has been applied to a species which sends up suckers and which has formed such a dense and shady grove near the Church. I am told that Dr. Trimen has identified this tree as a *decurrens*, var. *mollissima* †. The true golden wattle, *A. pycnantha*, however, is now grown in the forest nurseries in Nuwara Eliya,

* The name is an old English one, and signifies the interlacing of boughs together to form a kind of wicker-work. The aborigines used them in the construction of their abodes, and the early colonists used to spit the stems of slender species into laths for "wattleing" the walls of their rude habitations.—*Maiden's Native Plants of Australia*.

† Mr. Nock was good enough to measure his three giant trees in Hakgala Gardens in our presence the other day, with the following result:—

A. decurrens—8½ years old—50 feet high, 7 feet 2 inches in circumference a foot above the ground, and 5 feet 3 inches circum. 5 feet above ground.

Pinus longifolia—14 years old—6 feet 8 inches and 6 feet 4 inches in circumference respectively at 1 and 5 feet above ground.

Cypripedium (species)—40 feet high—9 feet and 7½ ft. in circumference at 1 and 5 feet above ground respectively—age not certain.—Ed. T. A.

‡ On reference, Dr. Trimen is good enough to report as follows:—"So far as my memory goes the acacia in question (near Nuwara Eliya church) is the silver

and has an undivided leaf, instead of the feathery foliage of the "golden wattle" we have been referring to. The true *A. dealbata* is, I suppose, the tree with silvery foliage, to be seen at and beyond Kellow's cottages, and which is specially remarkable for sending up groves of suckers from its roots. We have two "golden wattles" here at Abbotsford, neither of which is *A. pycnantha*. One species we are propagating from seed which the trees have yielded. The foliage and the blossom are equally beautiful, and some of the trees which were cut down yielded excellent firewood, as I believe all the wattles do. Of another species we have only one specimen, and it is remarkable from its horizontal and contorted habit of growth. Its leaf is exactly that of *A. pycnantha*, but the blossoms, instead of a series of little mimosa heads along a stalk, are regular catkins, closely resembling those of the willow. This wide-spreading tree burst into full blossom recently, and "magnificent" is the only term which can describe the spectacle it presented. There are probably from 200 to 300 acacias in Australia, and a large proportion of them have golden hued and sweet-scented blossoms. I can never forget the banks of the Mitchell river in Gippsland, both sides lined as it were with gold. The Australians when they go "a-maying" (in the month of January) carry home branches of golden-blossomed wattles, instead of the hawthorn of "home," which however flourishes exceedingly on the banks of the Derwent, in Tasmania. It may be well to give a notice of the species of acacias, native to Australia, of which we know most in Ceylon.

A. pycnantha, the typical "golden wattle," has been only recently introduced, and except as an ornamental plant it does not seem likely

wattle, *A. dealbata*. I do not think that *A. decurrens* or its variety *mollis* (= *A. mollissima*) sends up suckers from the roots. The three sorts can be readily recognized by the young twigs of unopened foliage. In *A. dealbata* ("silver wattle") these are white and silvery; in *A. mollissima* ("black wattle" or "green wattle" in Australia, but often "golden wattle" in Ceylon) they are golden yellow; and in *A. decurrens* (also black or green wattle) they have but little silkiness and are merely pale green. *A. dealbata* rarely opens its flowers here and seems to be always in bud. *A. mollissima* has pale sulphur yellow blossoms succeeded by pods constricted between the seeds. Of true *A. decurrens* there does not seem to be much in Nuwara Eliya and its neighbourhood. There is no doubt, we believe, that Mr. A. J. Kellow has now on Upper Albion a fine grove of the true *A. decurrens* (the same tree as Mr. Nock's giant in the Hakgala Gardeus) cultivated on patana land; and the growth made in three years is so great that already Mr. Kellow has been able to cut down trees for the posts and rafters of some lines he is building. His chief object in planting this acacia was a windbelt, for which the tree has proved itself admirably adapted. The grove runs straight up hill, and it has become so conspicuous as to be a landmark seen from the side of Numamaknaksanda or the neighbourhood of Badulla, as Mr. Nock was able to tell us. We must mention one other fact: we received at Naseby some seed from Messrs. J. P. Wilham & Bros. of Henaratgoda, and one packet marked *A. decurrens* was identical with seed received the same day from the manager of Abbotsford (given as a wattle that did not throw up suckers), and both packets were, we believe, recognized by Messrs. Nock and Kellow as of the right acacia (*decurrens*). Still, it may not be safe to trust to seed, and now that Dr. Trimen has given a ready means of recognizing the three wattles so apt to be confounded, there ought to be less doubt as to their identity in the future. It is just possible that Mr. Kellow's trees, the Abbotsford and Henaratgoda seed may belong to *A. decurrens* var. *mollissima*, as it again throws up no shoots?—Ed. T. A.

to be of much value to us. According to Baron Von Mueller, it is next to *A. decurrens* for tanning bark, but the tree does not seem to grow more than 30 feet high. In our climate, however, this and other Australian trees are likely to grow more luxuriantly than in their native habitat. The wood of this tree, though small, is well adapted for staves, handles of implements, articles of turnery, especially bobbins. [N. B.—The Colombo Spinning and Weaving Company.] Maiden describes it as the golden, green or broad-leaved wattle, the bark rich in tannin and gum and the flowers in perfume. Osborne described the wood as tough and close grained.

A. decurrens Von Mueller describes as a small or middle-sized tree. Its wood is used for staves, turner's work, axe and pick handles and many other purposes. The Baron adds what is of special importance to our planting community, that it is an excellent firewood. He also states that it is a good first shelter for treeless localities [our patanas] for raising forest. [Officers of the Forest Department to note.] "The typical *A. decurrens* with large leaflets [?], occurs particularly in New South Wales and is seldom above 30 feet high." But he adds a mention of trees 60 feet high, so that there must be distinct varieties, or, as is probable, the soil and climate of different localities give very different results, the tree is easily propagated and grows rapidly. It is content with the poorest soil, though it makes better growth in better soil. Cultivation easy, broadcast or in rows. Seeds can be obtained in Melbourne at about 5s per lb., each pound consisting of 30 000 to 50 000 grains. The seed ought to be soaked in warm water before being sown. Von Mueller adds: "Hardier than *E. globulus*, although, unlike *A. dealbata*, it hardly extends to sub-alpine elevations." He means, of course, in Australia, where 2,000 feet, except in tropical Queensland and South Australia, may be the equivalent of 5,000 or 6,000 in Ceylon, Maiden gives the names, "black wattle," from the colour of the bark; "green" and "feathery" wattle.* The timber is light tough and strong but he adds that it is generally much bored by the larvæ of coleopterous insects. [We have not seen or heard of this occurring in Ceylon.] But the next quality attributed to this tree shows that it is just what is wanted to be cultivated in factory fuel groves. "EVEN IN A GREEN STATE IT FURNISHES EXCELLENT FUEL. Yields over 26 per cent charcoal. Wood easy to work. The sap wood is white, while the heart is of a pinkish colour. Slabs in the Technical Museum at Sydney were 12 to 18 inches diameter. But it is not timber we want so much on tea estates,—while the supply of tea boxes comes to us from Japan and other sources, as fuel, and especially fuel which will burn as this wood does when green.

And now of *A. decurrens*, var. *molissima*, which we hope is really the golden-blossomed species near the church and in other places in Nuwara Eliya, Von Mueller states that all he wrote about *A. decurrens* applied to this variety; while Maiden says that the timber is light, tough and strong; used for staves for beef and water casks in Tasmania. It is subject to attacks by insects. [Not here, so far as we know.] A tree 2 feet diameter of this species was tested in Victoria and gave an average specific breaking strength of 2 063 lb. Not a word is said by Von Mueller or Maiden about *A. decurrens* sending up suckers; and Mr. Kellow's trees and ours do not; but we suspect that in both cases we have a departure from type? The golden-blos-

* The broad-leaved, typical species can scarcely be feathery?

somed wattle in Nuwara Eliya certainly sends up suckers as readily as does the so-called silver wattle, *A. dealbata*; and we do not think it advisable to grow any of the wattles amongst the tea, but only in ground devoted to them and to other trees. A large proportion of the Australian trees have a tendency to throw up suckers, and this tendency has been strongly developed with us by a favourite species of casuarina, which grows tall and straight and generally one-stemmed, the very reverse of the habit of our prevalent casuarina, which grows comparatively short, with dense foliage and numerous crooked branches. Many trees of this kind are inclined to die off at 7 to 10 years of age, but we have arrested this tendency by pruning; and even the trees which go off yield good firewood, as do all the casuarinas, their ashes retaining heat for a prolonged period. No more valuable trees can be cultivated or planted; but, as in the case of the acacias, not amongst the tea. The bushy casuarina seldom throws up suckers, but the enormous quantity of spines it drops is very adverse to other vegetation. The beautiful tall casuarina is objectionable amongst tea, though not equally harmful, by reason of its wonderfully profuse subsidiary plants in the shape of suckers. One tree near our bungalow has extended its roots full thirty yards around its stem, and all along they can be traced by fine young plants springing up from them, which, like those of *A. melanocylon*, we are transplanting into pieces of ground where they can "increase and multiply" at their will. If as I think, our graceful, tall and slim casuarina, which shows no tendency to "insidious defunction," is *C. torulosa* (syn. *C. tenuissima*), it is "one of the best woods for oven fuel," while of *C. stricta* the record is, "As fuel it can hardly be excelled." Your readers are aware that on the sandy sea-shore near Madras large plantations were formed for fuel supply to the railways of *C. equisetifolia*, the large and beautiful tree so common in Colombo, and of which a remarkable avenue, planted by the late Mr. W. Ferguson, runs for a long distance from the new Lunatic Asylum. My apology for thus digressing to a notice of the casuarina (she-oaks and beef-wood trees of Australia) is that no better, at any rate few better, trees can be grown by planters and others for firewood than those trees and the "wattles." Of these I have now to notice the much despised and in Ootacamund execrated

A. dealbata, which, according to Von Mueller is a still better tree for the purpose we have mentioned than even *A. decurrens*. It is known to colonists as "silver wattle," "Prefers humid river bank, where it sometimes attains 150 feet, yielding tough timber, used by coopers and other artisans, but principally serving as

SELECT FUEL OF GREAT HEATING POWER.

This tree is distinguished from the black wattle, by the silvery or rather ashy hue of its young foliage." Maiden states that *A. dealbata* is called silver wattle, from the whiteness of the trunk as well as the silvery or ashy hue of the young foliage. It is evident that this is the terrible spreader by suckers which has been denounced as a nuisance at Ootacamund, because it was allowed to grow everywhere unchecked until it monopolized the ground and afforded cover which was abused with invidious results. There is an extract from the *Madras Mail* about the desperate war with the plant which had invaded garden and grassland alike. "The myriads of suckers which spring from the extensive and encroaching wattles come up with renewed vigour and amazing rapidity as fast as they are cut down, and form an inexhaustible fuel reserve." Surely that is what

planters want, even if, as Col Beddome writes, the tree can be depended on only for small firewood. He means from the suckers, no doubt, as the tree grows large and probably the larger, original trees and those derived from them can be successfully coppiced. Even small firewood of good caloric properties will be useful for tea furnaces. Besides the two wattles I have noticed,—*A. decurrens* and *A. dealbata*, to wit—

A. melanoxyton has been well established in Ceylon, and fine, large pyramidal trees of this wattle are amongst the ornaments of Nuwara Eliya. Many of them are infested by the loranthus parasite,* but a cooly with a sickle or knife at the end of a long pole could easily free these grand trees of their enemies. In cultivated ground, these trees while growing well themselves, send up numerous suckers which speedily rival them in growth. This, which is reckoned their best wood in Australia, (equivalent to walnut or ebony, is not so favourably spoken of on the Nilgiris, where it is said to be slow of growth, which it certainly is not here. Even if the timber should, in this forcing tropical climate, not be equal to what the tree yields in Australia, what we mainly want are quick-growing trees, to supply fuel for factory and railway engine furnaces and like purposes.

There are others of the Australian acacias which might well be grown in Ceylon, such as *A. acuminata*, the best of the West Australian woods for charcoal,—good fence posts—fine ornamental timber,—dark reddish brown, close-grained hard wood; *A. cunninghami*, like red cedar but heavier; *A. excelsa*—beautiful cabinet wood with odour of violets.

A. stenophylla, called ironwood on account of its hard heavy timber: close grained, dark, beautifully marked and takes a fine polish. It planes excellently, showing a smooth surface. Diameter 15 to 24 inches, height 40 to 60 feet.

Of the Eucalypts the blue gum yields a fairly good fuel and it coppices splendidly. Where the original trees looked thin and scraggy, the numerous coppice shoots look exceedingly fresh and flourishing. Mr J. L. Anstruther some time ago communicated to the *Observer* a very interesting account of his successful coppicing experiment with blue gums. "Mr. Gaze found in the Newman plantation, then 5 to 6 years old, an amount of material equal to 152 tons per acre, and Col. Beddome is of opinion that the best treatment of Eucalyptus plantations, so as to get the greatest profit, will be to cut for coppice every five or six years, obtaining at the cuttings at least 100 tons per acre." GAMBLE, *Manual of Indian Timbers*.

The red gum would yield excellent fuel, were it not too good for such a purpose. So with jarrah and others of the family. The eucalypts we find specially mentioned as good for fuel are:—*E. gonicalyx*, "when not used for better purposes it is sought for fuel;" *E. sideroxyton*: "It is one of the best fuel wood of New South Wales for domestic uses and steam engines;" *E. longifolia*, "This wood is in request for fuel;" *E. macrorrhyncha*, "furnishes a fair fuel;" *E. pauciflora*, "excellent for fuel;" *E. punctata*, "affords a superior fuel;" *E. siberiana*, "burns well even when fresh." "It is generally considered a first-rate firewood, by some even the very best; in fact the choice lies here between it and *A. stellulata*." It will thus be seen that amongst the acacias, casuarinas and eucalypts of Australia, most of which flourish as well, in some cases better, in Ceylon than in the country to which they are native, are many good fuel-yielders, such are now wanted for cultivation on or in connection with tea estates.

* Our Ceylon substitute for the mistletoe.

[It may be of interest to add the summary of the different "Wattles," given in the "Treasury of Botany":—

Wattle. An Australian colonial name applied to various species of *Acacia*.—, Black, *Acacia decurrens*; also *A. mollissima*.—, Green, *Acacia decurrens*.—, Raspberry-Jam, *Acacia acuminata*.—, Savannah, *Citharexylon quadrangulare* and *C. cinereum*.—, Scrub, *Acacia stipulgera*.—, Silver, *Acacia mollissima*.—, —, of Tasmania, *Acacia dealbata*.

The following paragraph from a Brisbane paper is worth reproducing: the questions were put at the instance of Mr. Kellow. They show among other things that his *A. decurrens* grew 12 feet within the first year:—

"THE WATTLE—H. W. K. (Cooktown, Q.): Would you kindly give me through the medium of your valuable journal the following particulars relative to wattle culture: 1, age of tree before cutting; 2, average of bark per tree; 3, mode of harvesting; 4, whether shipped to England or used locally; 5, average rate per ton; 6, would 12 feet in height for *Acacia decurrens*, under 12 months, be considered good growth for trees raised from seed? Any other information regarding this valuable product would be thankfully received.—Answers:—1, from 5 to 10 years; 2, about 1 cwt, though from gigantic trees as much as $\frac{1}{2}$ a ton has been collected; 3, stripping in the ordinary way; 4, both; 5 in the Colonies about £5 per ton, in England it ranges from £8 to £11 per ton; 6, yes. Wattle seed can be sown broadcast, and the tree flourishes on the poorest of soils. The bark contains about 50 per cent of tannin. A ton of bark is said to be sufficient to tan twenty-five hides."—ED. T. A.]

FOR CEYLON TEA PLANTERS—CROAKING PROPHECIES
FALSIFIED—INSECT ENEMIES—THE
NORTH-EAST MONSOON AT HAND—DELAY IN THE
RAILWAY EXTENSION WORK.

NANUOYA, Oct. 7th.

Respecting a second plant, brilliant with white blossoms and abounding in the forests of this region, up to the mountain sides above Nuwara Eliya, in association with the one previously noticed,—Dr. Trimen has been good enough to give the following account:—

"Your plant is another *Hedyotis*—there are a great many of them—*H. Lessertiana*. It has but little of the beauty of its congener, though a stately plant when well grown in damp forests. There is a very large form of it in the highest elevations which might almost be called a tree.

"My memory of the *Acacia* by the church at Nuwara Eliya does not quite serve me, but I think it is rather *A. dealbata*. Neither *A. decurrens* nor *A. mollissima* I think send up a crop of suckers. I have sent a line as you suggested to the *Observer* Office."

I suspected erroneous information respecting "the golden wattle" so prevalent and so beautiful in Nuwara Eliya. I was struck by the silence of Baron Von Mueller and Professor Maiden, as to any tendency in *A. decurrens* to send up suckers. But if the two trees in Nuwara Eliya which send up suckers so freely are both *A. dealbata*, then its varieties are very distinct. The one which forms the remarkable grove near the church is clean-stemmed, with very handsome, warm-tinted foliage. The other with silvery or ashen-coloured foliage is by no means so handsome a tree. The comparative value of the timbers for fuel purposes is another question.

NANUOYA, Oct. 8th.

I have been considerably disappointed to find so little information available respecting the beautiful

foliated *Pinus sinensis* which I mentioned as having been obtained from Hakgala and as growing luxuriantly near the Bund of the Nuwara Eliya Lake. Fortune, in his book on the tea districts of India, notices its occurrence without describing it. Gamble does not mention it in his Manual, so that it does not seem to be amongst the foreign plants established in India. Still more strange is it, that neither in Lindley's Vegetable Kingdom nor in the Treasury of Botany is it mentioned. By the name which indicates the tree as specially indigenous to China, I have failed also to find it in that valuable and comprehensive book, Baron von Mueller's "Select Extra Tropical Plants." But I suppose it really is the tree there given as *Pinus massoniana* (Lambert), which is referred to China and of which it is said that it is "a good sized pine, with widely spreading ramifications. The wood is durable, and when well seasoned, is much employed as material for tea boxes." The Baron adds:—"Professor C. Koch regards *P. sinensis* (Lambert) as a distinct species." Whether identical with *P. massoniana* or not, *P. sinensis* must certainly be a valuable tree, for it is of this species that Mr. Ford, the Botanist and Forester of Hongkong, has planted out hundreds of thousands in the process of afforesting the British-owned island on the borders of China. Perhaps Dr. Trimen may possess and be ready to impart more definite information regarding *P. sinensis* and its utility as a timber tree to be cultivated on the mountains of Ceylon. Of the exceeding beauty of its foliage there can be no possible question: provided the specimens I obtained from Hakgala were, as I suppose they must have been, correctly identified as the Chinese fir.

From a tree which is associated with the tea plant in China and which yields timber suitable for tea chests, the transition to tea is easy. In the large and well appointed factory here, this morning, I witnessed every process connected with the manufacture of the fragrant leaf, including sizing of the green leaves, withering, rolling, breaking the roll, re-rolling, "fermenting," roasting and binning,—with the bulking and final firing and packing into lead-lined and hermetically closed boxes of tea accumulated in the bins, while still hot from the final firing. For roasting or drying the tea, we have a Davidson's Sirocco, a Jackson's original Drier and a Jackson's Venetian. When we require an additional tea drier, as it seems probable we soon will, we are strongly advised by those whose judgment is worthy of respect to supply the factory with a Brown's Desiccator. What was new to me this morning was the process of breaking up "the roll" by means of a noisy but effective machine manufactured by Walker & Greig. With the attendance of one man it does the work which formerly required the manual labour of four coolies. It has also removed so much necessity for handling the moist leaf, of which no doubt the less the better. For the benefit of the uninitiated I may say that the green leaf, after undergoing a withering process, prolonged or shortened according to the prevalent weather, is rolled by a machine which beautifully imitates while it has happily superseded the motion of multitudinous human hands. In this process the juice expressed in the squeezing and twisting of the leaves causes masses of them to adhere,—masses which, previously to the introduction of the roll-breaker, had to be separated by the human hand, preparatory to being fermented, or, as is now the practice, to a second rolling before the leaf is finally broken up and left to be fermented or rather oxygenized, for true fermentation would mean destruction of the leaf or at any rate of all the properties which make the leaf pleasant and profitable. The second process which specially in-

terested me was that of "bulking" the tea. This is still done here by human agency; and although the handling by the coolies of the dried leaves, which are subsequently submitted to the effects of a final firing, may not be objectionable, yet I can quite conceive of a bulking machine which, while mixing the leaves effectually, would be appreciably labour-saving. The "bulking" of the leaf means such a mixing together of teas made day by day and stored in metal-lined and closely shutting bins, for a week, a fortnight, or a month as the case may be, as will secure a uniform quality throughout, so that, if a sample of one chest is tasted, that sample will fairly represent the contents of the whole of the boxes of the particular description of tea,—broken or orange pekoe, pekoe, or pekoe souchong, our three staple grades in Ceylon. I saw a pyramidal heap of the latter quality operated on this morning. It rested on cloth spread on the floor considerably beyond the base of the heap of tea. At a signal, the dozen of coolies who surrounded the heap drew the tea with their hands onwards on the cloth until a vacant space was left in the centre. Into and over this space the tea was then thrown back, until the pyramid was restored. Then the pulling down and the building up processes were repeated, so that the whole of the daily makings of tea were thoroughly amalgamated. If this process is always as carefully carried on as it was this morning, I cannot understand why our invoices are not invariably accepted as "factory bulked," instead of an exception being occasionally made, as recently, "all except the pekoe souchong," which 'of course' had to be subjected to the damaging effects of being turned out of the boxes on the perhaps damp floor of a London warehouse and repacked into packages the lead of which was probably torn and some of the wood broken. We are inclined to think that London objections to the bulking here are often capricious, but, of course, the varied moods of coolies differ from the uniform action of material machinery; and it seems to me that a really good bulking machine would be a useful addition to our factory appliances. I have never seen such a machine, but I have been told of one which somewhat resembles an hour-glass, the leaf being inserted in an orifice at the top and being spread out as it descends. Perhaps a correspondent of the *Observer* will describe a bulking machine in use and its action,—whether quite effective while appreciably labour-saving. There is one operation of which I have omitted to mention, although I witnessed it this morning, and which unreasoning machinery can never effect. That is the picking out of "red leaf," stalks, bits of coir and other foreign substances from the roasted tea, in which necessary although slow and expensive work women are chiefly employed. By the recommendation of a competent authority the tea cutter has recently been superseded by a process of breaking in which also hand labour is employed. The whole of the processes of tea manufacture, much of which consists of chemical action, are complicated and exceedingly nice in their nature, and require intelligent and constant, and I may add unremitting, attention from year's end to year's end, forming a complete contrast to the pulping, washing and partial drying of coffee, crowded into a few months of the year and leaving room for a holiday or comparatively easy work during the remaining months. We in Ceylon have not even the winter during which tea is inert and planter active in hunting, visiting or holiday-making in India and Assam. It is curious, now that Ceylon tea has obtained so high a place in the world's esteem, to recall the prognostications of Assam

planters that tea could never be a success in an island so near the equator, without a winter and with the rainfall distributed over so large a proportion of the year. There never was a case perhaps ever preconceived ideas and the traditions of an enterprise were so falsified by actual results. The immunity of our tea from insect and fungus pests is also remarkable. The grubs, brown and white, which were so fatal to coffee in its young and mature stages, find nothing attractive in tea bushes. We could wish they were equally indifferent to nurseries of timber trees and greensward. For small patches of the latter which have been attempted here, the white grubs have a most annoying predilection: what is one day emerald green becoming brown tomorrow, as if sun-withered, although copious rain continues to fall. The number of cockchafer beetles we ever see, seem in entirely inadequate proportion to the prevalence of white grubs. But the latter spend three years underground eating the feeding rootlets of such plants as are acceptable to them before they develop into the winged stage. Even the moths which have been pretty abundant lately are innocuous as far as tea is concerned. For several years now the species which lays its eggs in young flush, the young leaves curling up and withering, has been absent, or if present has altered its habit. There is neither *helopeltis* nor green fly, red rust nor scale insect to meddle with flush which is so plentiful that work in the factory had to be carried on until $\frac{1}{2}$ past 2 this morning. I speak, of course, of estates within my purview, while I have heard of one estate and one only where the prevalence of scale insect necessitated the cutting down of some acres of tea. Free planting ought to be carried out, however, not merely for a supply of fuel, but to interrupt that continuity of one product in widespread expanses, which seems to invite the visitations, such as have proved so injurious to potatoes, and in Ceylon so fatal to coffee. At high elevations, too, the shelter of trees seems beneficial to tea, while their shade does not seem injurious. In Japan, as we have lately read, they shade tea to increase the proportion of theine in the leaf.

NANUOYA, Oct. 7th.

After the morning mists had cleared away, yesterday was, here and at Nuwara Eliya, a glorious sunny day. Indeed the sun during noon and forenoon allowed of no mistake as to our being in the tropics, even when standing on one of the knolls in the Sanatorium at an elevation of 6,400 feet. At the meeting in "The Town Hall" between 3 and 4 p.m., the temperature was oppressive, due I suppose to the heating of the iron roof. In passing through the Inverness forest, *en route*, we were struck by the beautiful white inflorescence, contrasted with the large, deep green glabrous leaves of a tree, which turned out to be the *symlocos* so fatal in tea plantations from a fungus which forms on its decaying roots. But still more remarkable was the profuse and beautiful flowering of fine *Cinchona robusta* trees, of which there are still so many on Inverness estate. Apart from the value of this hardy hybrid, few plants can be more ornamental, the prevailing tint of the flowers being a rich orange-red. If the cultivation of cinchona is to be continued in Ceylon, this is certainly the

kind to plant; and if seed is, as it is likely to be, in proportion to flower, Messrs. Cross and Ballardie will be able to supply a very large demand. Meantime I have to report Iodgerianas as flourishing at 5,700 feet elevation, where at the commencement of the enterprise they had to be coaxed into growing. Is this valuable species adapting itself to our higher elevations? Inverness, like Mariawatte, shows what a plentiful application of manure can do for tea. In these high altitudes, as might be expected, the young tea plants are longer in "coming away," and the older plants require two or three more years in coming to maturity than in the medium elevations or in "the lowcountry"; but the tea which runs up the side of "One Tree Hill" to the verge of 7,000 feet, shows that the plant with this qualification is at home at nearly our highest as well as our lowest elevations above sea-level—responding fully everywhere to high cultivation and fertilizers. At Nuwara Eliya we met Mr. Nock of the Hakgala Gardens and we were sorry we could not go down to enjoy the spectacle which he described to us: 5,000 blooms on his collection of rose bushes, of which 675 were counted on one bush of "Lamarck." We had our day's work cut out for us in examining the progress of the *Cedrela toona* and other trees on a ten-acre lot of land near "the Bund," where the waters of "the Mahaweliganga," as the river which forms the lake is called in the Nuwara Eliya titledeeds, are thrown back to form a lake. But the *Agraoya* which rises on Kirigalpotta is really the main source of the great sand river. We found the toons, with their red-coloured heads of foliage, looking really grand in their luxuriant growth and in their complete and striking contrast to the other vegetation around, native jungle or introduced plants. The toons and the cryptomerias (*C. japonica*) which are interspersed amongst them were planted out in Sept. 1886, so that they are now just four years old. We measured a toon, one amongst the tallest, which turned out to be 40 feet high and 16 inches in girth a foot above the ground. The rate of growth, therefore, was 10 feet per annum upwards and 4 inches in girth at the lower portion. Considering the rapid skyward growth the girth is satisfactory, and a few years hence, judging by our 11 years old trees, the Bund toons will devote their energies to the thickening of their branchless trunks. The average growth of the toons in the four years may probably be taken at 34 feet. The cryptomerias have made as nearly as possible half the vertical growth, but a lateral growth more in proportion than the toons, besides covering their trunks with a series of branches from the very roots. One of the tallest cryptomerias which we measured was 19½ feet high with 10½ inches girth. Some Australian eucalypts planted in our grove only lately will soon overtop even the toons. Amongst ornamental trees obtained from Hakgala, prominent for beautiful and luxuriant growth is *Pinus sinensis*. For ornamental purposes it cannot be surpassed even by *Pinus longifolia*. The only question is, as regards economic use, whether its tendency to go off into numerous stems cannot be corrected. Some of the wattles in Nuwara Eliya were in beautiful blossom, but for rich, deep golden bloom the furze or gorse or whins, near Bellwood,—truly a sight of glory,—far excelled the acacias. Pity it is "the lang yellow broom" is not equally successful. New species of Australian acacias have been planted out on the Plain, and the time seems to have arrived when all should be identified and described for the benefit of planters in search of the best firewood plants. The grevillea, which grows so well at

elevations below Nuwara Eliya, is more a timber than a firewood tree, and so, perhaps, is *Acacia melanoxylon*, respecting which observation during yesterday's visit has puzzled us. The old typical, dark-foliaged pyramidal trees have never, to our knowledge, flowered or seeded. But yesterday we saw a tree at the Post Office, with *melanoxylon* foliage but of umbrageous habit in full flower. Not only so, but quite young trees which looked like *A. melanoxylon* had flowers on them, and we were told that a gentleman in Maturata was selling seeds of *A. melanoxylon*. We want "more light" about these curious acacias. We have measured the girth of one of the grand blue gums at the Grand Hotel, and found it to be, at $\frac{1}{2}$ foot above the ground, 9 feet 6 inches. Its height we did not ascertain, but it probably ranged above 100 feet. There are other fine gums in Nuwara Eliya. The sunny weather had brought out the north-east monsoon butterflies as well as the flowers, and every feature of the Pidurutalagala ranges, as well as the three peaks of the grand isolated mass of Hakgala, was revealed in the clear sunlight, in which mountains, plains, lake and river were bathed. The balsams, osbeckias (purple and pink), St. John's wort, pink orchids and the white flowers recently noticed, with many others, were in beautiful bloom. The Forest Department have planted part of the vacant space below Nuwara Eliya with cryptomerias, frenalas, &c. When all is planted and grown, a new attraction will be added to the grand drive from the Nuwara terminus to the mountain sanatorium. But "tappal time" warns me to stop.

NANUOYA, Oct. 8th.

When writing this morning about one of our most beautiful wild flowers, the pure white of which contrasts so strikingly with the bright red of adjacent osbeckias, I forgot to mention what I heard with interest from Nuwara Eliya. A lady resident there, distinguished for literary talent and good taste, has commenced the aggregation of all our wild flowers in a garden specially devoted to the purpose. It may convey to some a new idea of the wealth of our upland regions—especially our grassy prairies—in indigenous flowers, when I add that already the collection has reached 150 different specimens. Mr. Nock is giving his valuable and cordial aid to the design, and he will, of course, see that foreign plants long naturalized and recent escapes from gardens and estates are either not included or distinguished by being planted separately or otherwise indicated. When one enters on the investigation, it is startling to find how few plants—economic products especially—are native to India and Ceylon: how much both owe to other countries, especially to the western world. We suppose the plantain is indigenous, and so, perhaps, is the coconut palm,* but is it patent to the bulk of your readers that the pineapple and some varieties, at least, of the custard-apple came to us from America, with the tobacco plant and the red peppers we call chillies, as well as the sensitive plant, passion-flowers, &c. The orange, Bonavia seems to think, came from the Eastern Archipelago and China, although it appears to have existed in Mesopotamia in far back antiquity.

THE AGRICULTURAL SHOW IN NUWARA ELIYA.
And this mention of plants and flowers reminds

* The original home of the coconut palm is supposed to be in the Eastern Archipelago—the nuts floating to the Mataru coast of Ceylon? [and so eventually giving rise to the tradition of the Kusta Rajah?] Cinnamon has perhaps a greater claim to be considered indigenous than our leading palm?—Ed. T. A.

me of a circular which has been issued by the Assistant Government Agent of Nuwara Eliya summoning a meeting at 3 p. m. on Monday next to consider a proposal which has been made for an Agri-Horticultural and General Show at the Sanatorium at the Easter season, similar to the one held in 1888. If there is fair evidence available that such a Show is likely to be well supported, especially by native exhibitors, whose interests it is desired above all others to further by such exhibitions, I suppose the decision will be in the affirmative. On such occasions the various classes of our population are brought together to exchange amenities as well as to compare notes, and the results cannot but be beneficial. I hope it may be possible to conjoin with the Show a Bazaar in favour of the funds of the Tamil Cooily Mission. No doubt our new ruler will patronize the show if held, giving it élat by the presence of himself and family. [The resolution to hold a Show has since been announced.—Ed. T. A.]

October 9th.

The temperature yesterday morning, with a mist-laden breeze from the south-west which tasted of the north-east, was lower than we have had it since the 25th of last month. But as the day advanced there was a clearing up, and the day continued fine with short showers occasionally. But it rained copiously during the night, and we have rain and some wind this morning, though not accompanied by the cold of yesterday morning. Those who have planting to do will rejoice in the rain, which is, after all, seasonable, as a prelude of the more copious deposits which the now near at hand north-east monsoon will bring. The weather will, however, if it continues wet, hinder progress on the railway; and this remind me that the process of laying down the permanent way on the lower portion of the line may be somewhat delayed until the short-length rails, required for the numerous curves, are separated from those of standard size for the straight portions. To persons who do not recognize the necessity of "super-elevation," in the rounding of curves by trains, the difference of level between the two ends of small culverts across the surface of the line on curves seems very strange.—The rainfall for the 24 hours has been 1.30 inch.

EXTRACT OF EUCALYPTUS LEAVES FOR SCALE
IN BOILERS—FINE WEATHER AGAIN.

NANUOYA, Oct. 11th.

While discussing trees which are beyond question not indigenous in Ceylon, although they have made themselves quite at home in our hill and mountain regions, it is interesting generally, and ought to be especially so to the officers of our railway department, the owners of engineering works and all who use steam boilers, that in India a liquor from the leaves of the Australian *Eucalypts* has been found very useful in removing scale. Any quantity of the leaves can be had in most of the planting districts of Ceylon for the asking. In a report on the Lucknow Horticultural Garden, it is stated that

With regard to the use of the extract obtained from eucalyptus leaves for cleaning locomotive boilers, Mr. A. E. Ryles, the Locomotive and Carriage Superintendent of the Bengal and North-Western Railway, after a year's trial, pronounced it to be a ready first-rate disincrustator. He obtains 1,000 gallons of strong fluid from a maund of leaves, and finds that from 8 to 12 gallons of it enable a locomotive to run 1,000 miles without it being necessary to wash the boiler out.

To experimenters it may be useful to know that when first used on a dirty boiler, the incrustation does not

begin to movet ill from three to six weeks, and it takes about six months to remove all the scale. Though slow, it appears to be certain, and should be perserved with. In a communication from the railway officer indicated we find it stated that

The leaves are at present purchas'd from the Horticultural Gardens, Lucknow, though at most two years hence we will have our own supply from young plants bought from the above gardens or raised in Gorakhpur from seed.

The advertised patent fluid, called the extract of "Eucalyptus Globulus" is sold at R3-8 per gallon in Bombay. We got plants of the Eucalyptus globulus, rostrata and resinifera. The whole of the first died but the other two are growing vigorously, and I do not find that there is any more strength in the liquid from the globulus than from the others, so our supply is certain.

We extract 1,000 gallons of strong liquor from one maund of leaves, which cost us in Gorakhpur R2-8 with R5 for fuel, and cost of labour nil;—total one and a half pie per gallon.

We put into a dirty boiler 12 gallons of liquor and repeat it after each trip of from 300 to 450 miles. The action begins after the first trip, and takes the scales clean off the copper box in a month, and is during this time acting more slowly in softening and loosening scale from the iron shell, and still more slowly from the brass tubes.

From my present knowledge of this fluid, I think it will take no less than six months to remove all the objectionable scale from a boiler at a cost of R5 and R3 per half-year per boiler afterwards.

The saving in coal should be many times the above, not to mention the saving we expect in repairs to boilers, as also in washing out water, as I find we can run from 1,000 to 1,200 miles without a wash-out, and without priming. Our old system was to wash-out after every 300 to 400 miles, and then often have to blow off half a glass of water on account of priming before the run was complete.

The scale comes off both softened and in large pieces, and in great quantities, as you have seen. When first it is put into dirty boilers, great care is needed to see the water space does not become solid, as the scale will block them if allowed to remain too long without a wash-out.

Altogether, the results so far are very satisfactory, and I will duly report the internal appearance of the first boiler I have occasion to examine as to whether pitting has ceased or not.

The maund mentioned is, we presume, the maund of 80 lb., and from this quantity of leaves, it will be seen, no less than 1,000 gallons of strong liquor (strongly acidulous, we presume?) can be obtained. This seems a most important use to which the gum tree leaves, rich in an essential oil, valuable for many other purposes,—including the treatment of diphtheria,—can be put, and we cannot doubt that local experiments after the Indian example will be instituted. The uses of the Australian trees are many and varied. For instance the pine-like foliage of the casuarinas is not only a good fodder for animals, but, as we have learned recently from Madras, a substitute for mulberry leaves in the feeding of silkworms.

Oct. 12th.

After a pretty strong blow of wind from the north-west last evening, there is a lull this morning; and it looks as if we were to have another interval of fine weather before the north-east monsoon puts itself in evidence. The rainfall for the 24 hours has been 30 cents, so that in four days we have had nearly 2 inches, actual quantity measured being 2.95 inches.

THE SAP OF TREES.

79, Mark Lane, London, E.C., Sept 26th, 1890.

Gentlemen,—I send you a short review of an interesting new work which is attracting considerable notice in scientific circles. The author certainly seems

to have made out a strong case in favour of the Sap descending instead of rising—and it follows that if the leaves perform such important functions in obtaining plant food, it can scarcely be wise or economical to prune heavily as is the custom now on certain Tea plantations in Ceylon.

Yours faithfully;

JOHN HUGHES.

A keen observer and ingenious experimentalist, has been writing a book on "Sap: Does it Rise from the Roots?" a question which he proceeds to answer with a decided negative. To those who merely "run and read," the whole question and answer may appear as a very slight matter indeed. In reality, however, the right answer to the question is of great moment to us all. In the first place, a negative reply simply means the ruthless upsetting of all our preconceived ideas, the reversal of what has been taught in schools for ages.

It is true that, if we examine into the theory of plant growth as set down by botanical and biological authorities, we find that they disagree among each other to an astonishing degree. They all, however, join in declaring that trees and plants derive sap from their roots, and breathe its gases by their leaves. How the sap rises, whether by capillary attraction, endosmose, root-pressure, suction, or evaporation, or a combination of all (described by Professor Huxley as pulling, pushing, and pumping), the greatest biologists, including Herbert Spencer, Sachs, Huxley Darwin, and others, have by no means been able to decide or prove. They all, nevertheless endorse the theory of rising sap, and agree moreover that it rises in spring and descends in summer. Now, if all this the rising is proved to be wrong, we shall not only have to alter our school teaching, but largely modify our agricultural practice. Clearly if the roots suck up the soil will quickly become exhausted and require constant feeding, while the leafy parts of the plants must be cut and pruned down. This is the present practice. And it is certainly worthy of remark that our best cultivated—according to the theories of the day—orchards and gardens are those that suffer most readily from blight and disease generally. Our new botanical revolutionist, Mr. J. A. Reeves, with his book on "Sap," tries to prove that we are altogether on the wrong road; that sap does not ascend, but descends; and that gas does not descend but ascends in all trees and other plants. To the unprejudiced physicist and mechanician this theory of Mr. Reeves seems by far the most credible and intelligible. It is, for one thing, strictly in accord with the proved and universally acknowledged laws of gravitation. We all know that water naturally falls, and can only be made to rise under great pressure; absorption and capillary attraction can only raise it some thirty feet in wet wood, practically not at all in dry wood. On the other hand, gases naturally rise, and to reverse the process great force, exceptionally applied, must be brought into play.

These facts brought home must be a fearful stumbling-block to Professor Huxley, though, doubtless, less so to Mr. Herbert Spencer. But we are told off-hand that sap descends in autumn and rises in spring. Seeing the impossibility of getting liquids absorbed upwards by dry wood, how can we account for the alleged phenomena of rising sap in the dry trees in spring? In this connection it is remarkable that trees cut down early in the year before they are in leaf will often sprout out some months after they have been severed from the roots and stacked away. Another curious fact is that a tree which has been "ripped" near the ground dies at the root first while the upper part flourishes. Nobody has yet observed the rising of sap. Mr. Reeves has actually witnessed its descent. To do this our experimentalist tested his theory by removing a ring of bark from a growing tree. Soon the sap was seen to accumulate on the upper edge of the bark, while the lower remained dry; the sap gradually descended and hardened in the air. A branch cut close to the tree bled profusely in the upper part.

Testing theories is always the safest plan. We find roots the driest parts of plants, the leaves the wet-

test. If we carefully exclude the leaves from moisture the plants die, however much water may be applied to the roots. The roots are particularly dense in texture; the leaves offer a large surface, covered with innumerable little hairs for the retention of moisture, and mouths (or stomata) for its absorption. A great variety of trees and plants flourish in the most arid, sandy, and stony soil. If we examine sap, we find that in the leaves and upper twigs and branches it is almost perfectly limpid; it grows dense as it reaches the roots. The maple trees give a plentiful supply of water in the upper part, but the thick syrupy fluid from which sugar is obtained can only be tapped near the roots. All this goes far to show that the water, the principal constituent of sap, is taken in by the leaves and sent down to the roots; it grows thick as it descends by being exposed to the chemical influence of the rising gases. But it is not only water that is taken in by the leaves. The mineral constituents of the tree-blood also seems to be derived from the air and not from the soil*. Independent experiments on a wide scale have clearly demonstrated that our atmosphere is heavily charged with organic matter, dead and living, in organic atoms—the beams which we see in the sunlight-rays of a darkened room. Mr. J. H. Aikin found that the dust particles in the atmosphere of Cannes fluctuated between 1,500 and 140,000 per cubic centimetre. At the top of the Eiffel Tower 104,000 particles were found to the cubic centimetre; but this fell to less than 23,000 after heavy rain, so that clearly the rain had washed the atmosphere, and taken the organic and inorganic atoms to the vegetation below. At all events the air contains abundance of mineral and other solid food for plants; and when we find the leaves containing more mineral matter and greater colour than the roots, it seems hard to believe that our teachers have been over accurate in instilling into us the theory of rising sap.

Now, as to the gases. We must acknowledge that gases are plentiful enough in the air, but it is beyond dispute that those found necessary for the life and growth of plants are most richly elaborated in the soil. Plants with very deep roots are rarely fruitful. We know that soil dug up from great depths is practically dead, and will not afford a habitation for plants. Earth for successful plant growing must be impregnated with organic matter capable of decay, and consequently of evolving gas. This is an important point from the economic as well as the biological point of view. Fruit trees are found to prosper best and give the largest crops when their roots are near the surface of the soil. Indeed, some of the grandest orchards are partially paved at a depth of a few feet from the surface with large stones or hard pressed debris, which forces the fruit trees to spread their roots near the surface of the soil, where the decomposition of natural vegetable refuse and artificially applied manures are in the most active state of decomposition, and consequently in soil richly impregnated with gases. Roots, while ill-suited for absorbing water, can easily take up gases. We find the roots comparatively free from colouring matter and dry, the sap being thick. The gases in rising act chemically upon the sap, the water and its organic and inorganic constituents, and finally escape through the leaves, and even the bark. That a very large amount of gas is given off by leaves, flowers, etc., is an undeniable fact. We crush a leaf or twig between our fingers and obtain a more or less pleasant odour, and that this is due to gases can be easily proved, for many aromatic plants will soon charge the atmosphere of a closed room uncomfortable, sometimes even dangerously, with compounds of oxygen, hydrogen and nitrogen, some of which are probably alkaloidal in character. Indeed, to such a large extent is this the case with certain plants that the natural escape of gas from the rue plant on hot, still nights can be actually set on fire.

All this, it may be said, is very interesting, but what practical lesson does it teach us? The great

practical lesson is this—the leaf is the most important part of the tree. If the plant procures its liquid and solid material for life and growth from the leaf, then clearly it is a mistake to be continually lopping and pruning, for by following this practice we reduce the assimilating powers of the plants. This seems to be proved by the fact that heavily pruned trees are constantly throwing out suckers and shoots—in reality endeavouring to exceed their foliage in order to compensate for their mutilation. Cultivated trees that are pruned and deprived of their life-giving foliage decrease in strength, and fall easier victims to disease than the heavily-folaged trees in their natural state. If, therefore, we are to accept the descending sap theory, we shall have to spare the upper branches and cherish the leaves. Again if the sap, the water with its organic and inorganic matter, comes from the air, and the gases from the soil, then the recognition of such facts would have an undoubted influence upon our present methods of agriculture, depending upon arbitrary theories of soil exhaustion and rotation of crops. Agriculture will be as much a science as ever, but a more remunerative one, and our economic of the soil will have to undergo some modification.—*Globe*.

PADDY, which forms the principal monsoon crop in the Madras Presidency, has this year been planted over an area of 1,272,100 acres, which is a little under the normal area. Gingelly, which comes next in importance, shows a slight decrease as compared with last year, but the most marked falling off is in indigo which has decreased from 191,900, to 114,200 acres. The cause of this is said to be the fall in the price of indigo, and also the late and insufficient rains. The reports from various districts show that the rains have, on the whole, been favourable. Cotton is cultivated over about 70,000 acres, but reports on the condition of this crop have not yet been received.—*Indian Agriculturist*.

NUTMEG CULTURE IN CEYLON.—We call attention to the letter of "W. D. G." further on on this subject. We do not expect that Ceylon will ever be the scene of any great extent of nutmeg, any more than of cacao cultivation, and for the same reason, the absence of good deep rich soil save in exceptional "pockets." But wherever the soil and climate are suitable and the nutmeg is found to grow, we certainly think that special attention should be given to it, even though the planter may feel that his children or posterity, rather than himself, are to reap the benefit. The lowest of "W. D. G.'s" estimates or returns—or R200 per acre—is so good as to encourage not a few to run after nutmeg cultivation.

FORESTRY IN BENGAL.—The Bengal Forest Department is a flourishing branch of the administration to judge from the financial results, which show a net profit for the last official year amounting to over 3½ lakhs of rupees. The profit is very great in the Sunderbuns Division, from which Calcutta is supplied with fuel, as are also the important sugar and other works scattered through Khulna and Jessore. The Lieutenant-Governor is in favour of strengthening establishments as much as possible in this division, and of making free use of steam launches for inspection, it being generally believed that the revenue here is capable of much greater expansion. It is also desirable (His Honor considers) to free more officers for making working plans—a duty too generally neglected, and this can only be accomplished by reducing establishments where they do not pay, namely, in Chota Nagpore and Orissa. In the latter province work will probably be considerably reduced when the forest boundaries have been re-aligned by the exclusion of village grazing and fuel grounds—a measure to which the Lieutenant Governor attaches great importance in the interests of the cultivators.—*Pioneer*, Oct. 7th.

* This is very doubtful, as the mineral portion comes from the soil more likely.—J. H.

CEYLON CACAO AND THE DUTCH:

WHEN WAS CACAO FIRST INTRODUCED
HERE?

The following note appears in the *Trinidad Agricultural Record* for August:—

Extract of Letter from Assistant Director Royal Gardens, Kew, to Superintendent Botanical Department, Trinidad, June 23rd, 1890. "With regard to Ceylon Cacao it is well to bear in mind that a good deal of this is produced by 'Criollo' Cacao introduced into Ceylon by the Dutch. This, I believe, will account for the fine colour developed by fermentation."

We should like to know where Mr. Morris got this idea: the explanation can scarcely account for the larger proportion of the superior Ceylon cacao.

Dr. Trimen, to whom we referred for information, kindly writes:—

"I have met with no records leading me to think that we are indebted to the Dutch for the cacao tree. I am rather inclined to think that Mr. Moon introduced it early in this century. The first record I have of it is in 1819, when it was advertised for sale in the old Botanic Gardens at Kalutara; and Moon includes it in his 'Catalogue' published in 1824. Cordiner, whose records refer to 1799-1805, does not allude to it as being then in Ceylon. We may, therefore, conclude on the evidence we have, that we got the plant between 1805 and 1819, and probably between 1816 (when Moon was appointed) and the later date. It is not possible to speak with certainty on the point, but it is probable that this was of the 'Caracas' variety, and that many of the trees in Peradeniya and elsewhere are lineal descendants. I find it was still being advertised by the Gardens as for sale in 1833.

"It was in 1834-5 that Sir R. W. Horton obtained a stock of seedling plants from Trinidad. These were cultivated at Peradeniya and at the Pavilion garden and elsewhere in Kandy, and one of them planted in the Army Surgeon's garden there was the source of the cacao on Pallekelle estate, first planted I believe about 1855. There is no doubt whatever that this consignment was of the 'Caracas' variety, and most of this kind of cacao now grown in Ceylon traces its origin to Sir R. W. Horton's importation.

"I am not aware of the date when the cultivation of this fine sort of cacao went out in Trinidad, but it appears evident that it must have been later than 1834, when we obtained it."

We are aware that Bennett ("Ceylon and its Capabilities") is often not a reliable authority, and probably Dr. Trimen has noted and discounted his statement quoted in our "Agricultural Review" (in "Handbook and Directory"). Bennett wrote:—

Theobroma Cacao.—I have had very fine specimens of the fruit in my own garden from trees planted by the late Jacobus Burnand, Esq., a Dutch gentleman whose name is deservedly remembered in Ceylon with respect and regard, for he was distinguished both by his zeal for the welfare of the island, through the introduction of the culture of valuable exotics from the Malay peninsula, and the Dutch islands of Java, Banda and Amboyna, and by his botanical acquirements. The nuts were equal to the finest I had seen at Penang and Malacca, or in the West Indies, and in no degree inferior, either in size or nutritious properties, to the best productions of South America.

All this is, however, quite compatible with Dr. Trimen's belief that the plant was not known in Ceylon before the beginning of the present century.

BARK AND DRUG REPORT.

(From the *Chemist and Druggist*.)

London, Sept. 18th.

ANNATTO.—Damp but fair seeds sold at 2½d, and one barrel ordinary St. Vincent at 1½d per lb.

CINCORONA.—Among the South American barks shown at today's auctions were 13 serous Huanoco, one of which attracted attention on account of its unusually fine quality. It consisted of fine medium to stout silvery quill,

and sold at 1s 7d per lb. Such fine Huanoco bark has not been seen on our markets for a long time. Good stout brown quill sold at 1s 1d to 1s 3d, thin and broken mixed quill at 10d to 12d per lb. Of 32 bales Carthagea in very large prices part sold at 5½d to 5½d for stout flat. For 3 serous good strong quilly Loxa, partly very stout mixed, 1s 10d per lb was paid. The parcel of 134 bales Guayaquil bark, which were announced as coming up for sale, was offered today and mostly disposed of: fine thin even grey mossy quill, 1s 6d; partly silvery, woolly 1s 1d to 1s 3d; long, thin brown, more or less broken, from 7d down to 5½d. Of flat Calisaya bark several parcels were offered, and some sales were made at 1s 8d to 1s 9d for good stout rather dark, 1s 5d for damage; these prices were rather cheap.

COTTON SEED.—The market is quiet. The price ranges from 12s up to 18s 3d, according to quality. At the auctions 12 bags fairly bright seeds were bought in at 20s per cwt. nominally.

ESSENTIAL OIL.—In Citronella rather considerable sales are said to have been made privately at firm prices. At auction a few drums were bought in. The quotation remains ½d to ¾d per oz. on the spot.

CEYLON TEA IN AUSTRALIA—MORE
ABOUT MANA GRASS.

Meeting a gentleman this week who but recently returned from a visit to Australia, the question was put to him by me as to how Ceylon tea was getting on there. In reply he told me that he believed a good start had been made and that there was a fair prospect of very considerable success. But he said that he thought it a pity, from all that had been mentioned to him in the course of his inquiry in the several colonies he visited, that no agencies which were directly authorized by your Planters' Association had been established. He believed that if a choice of firms in the leading cities could be made to whom the imprimatur of the Association could be safely entrusted, the use of Ceylon tea would spread far more rapidly than it has any chance of doing under the present system of gratuitous distribution of teas. On my remarking that I had always heard that the difficulty as to this was in the status of your Association,—that I did not pretend to be a business body,—it was replied that the distinction set up was scarcely an appreciable one. "Surely," my friend remarked, "if the Association goes the length of purchasing and sending your teas, even although it expects to get no direct money return of it, it has adopted a business element, and I for one cannot see why it should not extend that adoption, for I am very certain that teas advertised for sale under the guarantee of the Association would find a far readier sale than the unguarded public are now disposed to accord to them." My answering observation was that I had always recommended some such course as he had suggested when endeavor was first being made to introduce Ceylon tea into England; but that without it the tea had become more popularly drunk than any other. "That's perfectly true," was replied, "but the conditions here and the condition in the Australian Colonies are wide apart in their characteristics, and if you don't take these into account you will probably find the progress made in Australia to fall greatly behind what has been achieved at home. Throughout Australia I find a guarantee to be required to induce its people to make a change in their ordinary course of tea drinking. You will find the education to a refined taste much more difficult to accomplish with the coarser palates of the Australian Colonists than you found with the more highly sensitive ones of the upper and middle classes in England."

You will doubtless have hoped to hear from me by this mail more as to the future of the mana grass experiments respecting which my letters have lately given you so much detail. Since last writing it has been told me that the first lot of the grass

which was obtained from Mr. J. L. Shand, and which gave such good results, was grown in districts closely neighbouring on Dikoya, whence the second lot was derived, so that it would seem as if mere locality of growth could not have materially contributed to the differences in result which have been experienced to the several trials made. But "a fresh hare has been started," and by myself, though I am unable to tell you yet whether there is a justification for hunting in a new direction. At all events there was this week shown to me a letter from Dr. Evans with which he forwarded a specimen of the grass (the second lot) as it left the boilers. "Why," I immediately said, "this is no more like what they received at the Poyle Mills and experimented with than chalk is like cheese." Nor more it was. What Dr. Evans sent was pure grass blade, quite unaltered in form from the green (or rather dried) grass. What was taken by me from the sacks at Poyle Mills (as you will recognize from the specimen sent you by me) was just like the heaps of fibre and dust resulting from rotten coir beating. A specimen of this has just been posted by me to the Syndicate in order that they may judge of the difference and make further inquiry, for really it seems to me certain that either some mistake has been made by Dr. Evans or else that the stuff which was sent to Poyle Mills and which proved such a failure in the working was not mana grass at all, but some other product which the firm who did the boiling had under treatment about the same time. Of course it is impossible for me to let you know by this mail whether or not my suspicion on this point can be justified. Personally, I feel very hopeful that some stupid mistake has been made which may account for the discrepancies that have become apparent as the result of the two sets of experiments and which have been so disappointing. But the Syndicate is by no means discouraged. It rightly says that one case of failure cannot negative others in which success has been attained, and its members are determined to pursue the subject fully out, feeling what great results may follow if they are ultimately successful. There is some probability, we now hear, that they may arrange to take over from Messrs. Curtis & Harvey the ton of the grass which, as you were informed by my last letter, that firm has ordered from Ceylon, and may be willing to defer themselves experimenting upon until a subsequent shipment can be obtained.—*London Cor.*

CINCHONA CULTIVATION IN BOLIVIA, SOUTH AMERICA.

The production of cinchona bark, or cascarilla as it is called, from which the alkaloid quinine is extracted, was for many years Bolivia's most important industry in the agricultural line; but during the last four years it has proved unprofitable, owing to competition in Java and the British provinces in southern Asia. That class of individuals known at home as "smart Alecks" are found even in this out-of-the-way corner of creation. One of these is a certain Señor Shucroft, who was a heavy planter of cascarilla a few years ago, prosperous and presumably happy. One unlucky day the idea struck him of sending a quantity of quina seed to his home government—that of Holland—thereby getting himself into the papers and winning the gratitude of posterity. In uncalculated generosity he sent a very large amount of seed, with minute directions for its treatment derived from his own experience, and the suggestion that experiments be made in Java. The remarkable success of cinchona in that island led the British government to encourage its planting in Ceylon, and already the business is ruined everywhere by over-production. Mr. Shucroft received a little gold medal from the Dutch king in acknowledgment of his enterprise, but at the

same time he lost all his fortune by having made valueless his own extensive cascarilla plantation.

DIFFICULTIES OF TRANSPORTATION.

Bolivia can never compete with those countries that now take the lead in cinchona production, because of her immense disadvantage in the matter of transportation. All her products must cross the successive cordilleras of the Andes on their way to the sea, mostly on mule back, at a cost of transportation not less eleven than Bolivians per hundred weight, an expense five times greater than that of carrying it from the coast around Cape Horn to Europe.

On the other hand, the bark produced in Ceylon and Java yields only two-thirds as much sulphate of quinine as that grown in this part of the world. Fully nine-tenths of Bolivia's cascarilla is of the red variety, known as quina morada. As an example of the rapid depreciation in the price of bark may be mentioned the Erickson plantation, which was valued at 1,500,000 Bolivians five years ago and is now offered for sale at less than a quarter of that amount, but cannot find a purchaser.

The number of quina trees now under cultivation in Bolivia is said to exceed 15,000,000, about two-thirds of them being in the province of Mapiiri, near the northern border, whose business centre is Sorrate. The department of Yungas cultivates half a million trees and a great many are grown in the Beni province, farther to the east. It is impossible to get any reliable statistics regarding Beni's productions, because they all go to the eastern coast of the continent via the Amazon and its tributaries. Indeed, there are no printed statistics of any kind concerning Bolivia's exports or imports, and no history of the country was ever written except one small and very incomplete edition in Spanish published forty years ago.

TREATMENT OF CINCHONA.

As to the treatment of cinchona—at this distance from the equator it will not grow at a greater elevation than 5,000 feet, nor lower than 3,000. The seeds, which are sown in beds, are so very small, lighter than the lightest thistle down, that the least breeze will blow them away, necessitating great care in the handling. When the plants are about one foot high they are transplanted five or six feet apart to the sunny side of a mountain. It is asserted that virgin soil is absolutely necessary and that the addition of any kind of fertilizer would be ruinous. Twice every year the earth between the tree is slightly disturbed by the primitive plows of the country, and that is all the "cultivation" they require. At the age of eight years the trees are ready to strip, or if the owner is hard up, as is usually the case, a part of them may be utilized sooner and young plants put in their places. In some sections it is customary to remove from each tree about a quarter of its bark every year, but here the tree is cut down to the ground, its trunk and large limbs peeled and the smallest branches carefully scraped clear to the leaves. An eight-year-old tree yields from twelve to fifteen pounds of bark, which in the present depressed state of trade is worthy only about seventy-five cents.

THE QUININE TREE.

If the peeled-off bark happens to get wet, it loses much of its alkaloid quinine; hence every planter has to build ample sheds in which to dry it. The trunk of the tree, after having been peeled, is entirely valueless, not even good for firewood in a country where fuel is scarce. The cost of cutting, drying and packing the bark is about \$1.90 per hundredweight. The process of packing is as follows:—A box is lined with coarse sacking and then a layer of banana leaves. The bark is put in and pressed down with machinery until the box will hold no more and the scale indicates exactly one hundred pounds. It is then removed from the box, banana leaves and all; a second sack is added and the whole bound tight with raw-hide thongs. There are no fewer than twenty-one varieties of the quina tree, some worthless, others ranging in the amount of quinine contained in the bark from one-half per cent to seven per cent. The buyer must know his business, for if not an expert he is likely to be badly sold. This "gold brick" swindle has not been so often perpetrated in the United States as that of selling for cascarilla the worth-

less bark of some other tree. A well known dealer of La Paz, who ought to have known what he was about after years of experience, recently lost \$160,000 at one fell swoop on a ship load of bark supposed to be cascarilla, but which, when arrived at the English market, turned out to be a species of oak, good for nothing at all. The only way to test the bark is by tasting it. That which gives out a bitter taste immediately on being taken into the mouth will yield a comparatively small amount of quinine, while the best must be chewed before the quinine taste is apparent.—*Exchange.*

NATIONAL WOOD SUPPLIES.

Bulletin No. 4, just issued by the Division of Forestry, is a sequel to some previous publications of the division which discuss the relations of railroads to the wood supplies of the country, with reference to the conservation of our forest areas. It contains a brief discussion by the chief of the division, setting forth upon the basis of a recent canvass among the railroad companies the enormous consumption of wood material for railroad construction, and especially showing how future supplies are being endangered by the use of the most valuable timber and of the young growth. To satisfy this demand requires the annual culling of the best timber from probably more than 1,000,000 acres of our natural forest lands. The chief value of this part of the bulletin consists in the directions which are given for increasing the durability of wooden ties. These are found to last on the average less than seven years, so that for replacement alone an annual cut of 80,000,000 ties is required. By lengthening the life of the tie a single year it is evident that a considerable saving would be effected, tending to reduce transportation charges and also to husband our forest supplies. For lengthening the durability of ties various means are suggested, among which are the selection of lasting timber, proper care in the seasoning of material, attention to the drainage and ballast of the road-bed, precautions against fungi, improved methods in fastening rails, and various preserving processes, some of which are new. The information here furnished is likely to be of value to any consumer of wood material.

The bulk of the bulletin is taken up by a report of R. E. Tratman, c. e., collating the experience of the world in regard to the substitution of metal for railroad ties. It had been stated hitherto that metal ties were used experimentally, but that the time for their introduction was still far distant. This report shows that not only are there something like 30,000 miles of railroad track of the world laid on metal ties, but that where these ties have been used most extensively, namely, in Germany, India, and the Argentine Republic, they have shown themselves superior to wooden ties in producing a safer, more permanent, and in the end more economical track.

The report is exhaustive, full of the detail which alone can make it valuable to the engineer, and promises to be an important aid to the metal tie question, which in this country has received little consideration, from the belief that it is either impracticable, or with our seemingly inexhaustible timber supplies premature. The use of the metal tie is expected to economize wood supplies and by its cheaper maintenance and other favourable features to reduce transportation charges and increase rapidity and safety of travel.—*American Grocer.*

TEA NOTES: DARJEELING, Sept. 20th.—Some very good sun commencement of week, which has brought on fair growth. Foggy though latter end, with rather too cold rain to make heavy flush. Rainfall to date 121 inches.

CEYLON TEA IN RUSSIA.

To the Editor of the *Tropical Agriculturist*, Colombo. Kandy, Oct. 11th.

SIR,—I beg to enclose letter received from Mr. M. Rogivue on the subject of making known and pushing the sale of Ceylon tea in Russia.—I am, sir, yours faithfully, A. PHILIP, Secretary.

Moscow, 30th Aug./11th Sept. 1890. A. Philip, Esq., Secretary, Ceylon Planters' Association, Kandy.

TEA FUND.

Dear Sir,—I wrote you last from St. Petersburg on the 23rd July/14th Aug. I have since been in correspondence with Mr. Wm. Martin Leake of London, to whom I have asked to communicate to you the contents of my letters.

ST. PETERSBURG.—As I have already informed you I visited there all the principal tea merchants, most of them were in Nijni at the time, but everyone I have seen has tasted my samples of Ceylon teas, and before leaving that place, I have left to Mr. D. Haverlandt, who will act as my agent there, all the necessary instructions by samples to continue the work, see the people and push the business. I hope that orders will soon follow, when the parties interested return from Nijni.—I have also distributed more than 150 lb. of tea, in 1s 8d and 1s 4d lb. packets, all over the town, to restaurants, tea houses, public bars and friends.—The general report is that the tea is good. More was impossible for me to do, I had to leave for Moscow, having been in St. Petersburg quite enough time, a little over than one month.

Moscow.—I arrived here on the 13th/25th August and lost no time in visiting the firms interested in tea, such as

Alexis Gombzin's successors (Héritiers) A. Kousietzoff & Co., the first and best wholesale tea house in Russia.

Vve. Rostergueff & Successeurs }
 „ Catairo & Fils } Second best
 Wogan & Co. }

Behrend and Stern & Co. &c.
 and Popoff Bros. & Co., first retail tea house in Russia having over 30 warehouses and shops in every large town, such as St. Petersburg, Moscow, Odessa, Riga, Varsovia and other places all over Russia.

Most of their principals being in Nijni, I thought best of going there to see them. I did so last week. They have all taken great care and trouble in tasting my samples, compared them with Chinese kinds, Caravan and others—and, I am glad to say, reported very favourably upon their quality which they say, is on the whole far superior to that of the equivalent grades of Chinese kinds, against which the present general complaint is, that they are getting every year more and more inferior. They find our teas well made, of fine flavour and good liquor, but would prefer them of somewhat darker infusion than the ones I had to show them, viz:—

“Aberdeen” }
 “Mahousa” }
 “Patiagama” }
 “Ferndale” } Pekoes.
 “Glengariffe” }
 “Labukelle” }
 “Rahatungoda” }
 “Labukelle” }
 “Kuruwitte” } Pekoe Souchongs.

The “Labukelle” and “Rahatungoda” pekoes have been found the finest of all these teas, but rather too pale of infusion, and, as pointed out above, teas of a darker colour in cup, which would keep about the same for the second and even the third infusion,—the same as Chinese teas do—would be preferred.

I remarked in my previous letters the way of making tea in Russia, viz:—To pour in the tea pot—sometimes up to four times—boiling water on the same tea; the first infusion is of course darker than the second and so on, but the last must still have enough colour for appearance's sake, although there is no

more, or very little taste remaining in it, and this is the reason why the Russian market required dark liquored teas, just the contrary than what I had been told in London, where very little indeed is known about Russian tea business.

This, of course, applies chiefly to teas sold to the general public in Russia—the common people—which are the largest consumers. Better classes drink better tea and some of them make it better with one infusion only—broken pekoe of any "Labukelle" sample or equal to it—would do for them very well, but, as a rule, fine and finest teas are sold in much smaller quantities than common and medium to good ordinary qualities.

Now, as to the question: "Whether Ceylon teas will suit the Russian taste," and "whether they can be introduced in the country, to be drunk as pure Ceylon teas and supplant or replace Chinese kinds," there are two ways of answering it:—The large and wholesale Merchants will say, no, but I have no hesitation in saying yes! The wholesale merchants—importers—much more conservative, in their way of trading, than the consumers, in a matter of taste, pretend that Ceylon teas cannot be drunk by themselves—pure—and appreciated by the public for their merit, because they are not known well enough and do not suit the Russian taste. This is their old and only song, and they say, that they can only be used for blending purposes, mixed with Chinese teas, and it is easy to understand that these importers who, finding their profit in selling to retailers, mixture of any kinds of all sorts of teas, which they have introduced, and have made known, will not take the trouble now to introduce any new kind, against which they have at first, a sort of antipathy and which they think could perhaps stand the risk to remain for some time unsold in their stores. The Retailers think exactly the same, and the Public—the consumers—who up to the present time, have never had the opportunity of seeing, buying or drinking anything else but what was offered and sold to them in retail shops, are therefore cut out entirely of "Pure Ceylon Tea," and cannot get at it! In St. Petersburg and here, I repeat it, everyone, friends and others, who have tasted my samples, have found them excellent, cheap, even in the good qualities, and economical, and have asked me where the tea could be bought in retail; this of course I was unable to answer just at present for the simple reason that nobody sells it pure, but I told them that it would be the case before long.

In Nijni-Novgorod, installed in the shop of a friend, a watchmaker, visited by a large number of people of all classes, Russians, Siberians, Tartars, Armenians, etc., etc. I had some of my samples made in cup and offered, to every visitor, some of it. The voices were unanimous to declare the tea very good and cheap, and who 10 lb., who 20 lb., etc. everyone, wanted to buy some; and asked me where to get it, but I could not sell my samples—having no license for retail. The fine in Russia is a heavy one, for the sale of any article without a license.

This is to show what the general public think of these teas and that they would buy them if they were to be got anywhere in Russia, in retail. And I can say, that to only friends and acquaintances, here and St. Petersburg, I could, at once, sell over 1,000 lb. of tea at a good and very profitable price, if I had a stock and a license.

Mr. Hadimiroff (in Nijni) had partner in the large firm of A. Dousentzoff & Co. has taken special trouble with my samples and pronounced himself very pleased with their quality; he is of opinion that Ceylon teas will have, before long, their time in Russia and be drunk extensively all over the country, will sell well and replace advantageously the Chinese kinds, which are getting now so bad and inferior in quality. He promised me to give a trial order of some importance, on his return to Moscow—in about a week's time—but says, that it would not do for his firm to advertise and make a Reclame for the tea:—Large and wellknown firms (wholesale) in Russia it appears, do never advertise.—This I do not understand and I am afraid that, here again,—even with a large order from this firm—

we shall miss our object in bringing the article, as "Pure Ceylon Tea," within the direct reach of the consumer.

I have already written extensively on the question. I consider that I have also done a great deal of good for the object of my missions, although it is nothing when considering what remains to be done,—and I come now to the conclusion that, the only way of introducing "Pure Ceylon Tea" in the country, quickly and surely, is to give the public the opportunity of buying it as such, and this is only feasible by opening here. Moscow is the centre of Russian business and the largest market for tea. And for other places, depôts of Ceylon tea and retail warehouses for its sale. The first enterprising man to do it will make his fortune in no time. It will be objected, I am sure, that the very fact of his doing a retail business might influence the wholesale trade in combining to shut him out of the market altogether; this may be correct but, I repeat it, the importers, although perhaps willing to give a few orders will only use Ceylon tea for blending purposes and will never introduce it to the reach of retailers and consumers—for its own merit, whatever it may be, good or bad,—to prejudice another article they have already introduced, and are selling easily and advantageously and, supposing even that some of these importers give some orders of a few hundred chests during the year, just as they did, through London houses, before my coming here, mix the tea with some other kind and take perhaps one year to sell that quantity and order a fresh lot, here ends the business and the aim your Association proposed, in sending me here, is not attained.

In accordance with the foregoing remarks, what I would like to do, is:—

1st. To have here, in Odessa, Riga, St. Petersburg and even Varsovie, stocks of Ceylon tea in low medium and fine qualities of pekoe and pekoe souchong, very little broken pekoe,—say about 2,000 lb. of sorted in each place to begin with, of well made teas, not too black, of good aroma, mild, mellow and soft flavor and liquor, not too pungent, but of somewhat dark-reddish coloured liquor.

2nd. To open a small office in Moscow, and

3rd. A few retail warehouses at above-mentioned places, in order to sell tea by packets of $\frac{1}{2}$, $\frac{3}{4}$ and 1 lb. or more voluminous packets, by chests and otherwise, and

4th. To start a well conducted Reclame by means of Government analysis—published in newspapers, advertisements, circulars, placards, pamphlets, etc., circulated and distributed all over Russia.

In my opinion, this would be the only possible way of obtaining success and, I am sure, would prove, before long, a very good and most remunerative business, which could also be extended to other products of Ceylon and export of Russian produce.

Duty paid Chinese teas, mixtures or others, are sold in the country from Roubles 3-50 kop. downwards to Rbl. 1-25 kop. per Russian Pound, as per quality, and taking a Ceylon pekoe or pekoe souchong, superior in quality to the lowest Chinese or mixture tea, sold here at Rbl. 1-25 kop. Something for instance equal to my sample "Kurnwitta" pekoe souchong, bought in London, first cost at 9d per Eng. lb. charges to Odessa—Riga or St.

Petersburg	1½d	"	"
about ½ penny per lb. to be added			
for railway freight to Moscow	10½d	"	"
and say Rbl. 8-30 per £ str. average rate of exchange, equal to 37 kop.		"	"
plus	89	"	"

for duty, customs and other charges would cost Rbl. 1-26 per English pound or (1/10th less for Russian pound) Rbl. 1-15 at any of the above sea ports or Rbl. 1-17 in Moscow, which tea selling at only Rbl. 1-25 here would leave a gross profit of 8 copecks per pound. This calculation is based on the clearing at St. Petersburg of my 671 lb. samples, but duty, customs and other charges could be considerably reduced on a larger quantity imported at a time and of course duty alone being the same on ordinary and fine teas, the profit would be much larger on the latter qualities.

Shipments to Odessa direct from Colombo, would again be more advantageous and when shipped by the steamers of the Russian Volunteer Fleet could be stored free of rent for any length of time, in the Company's bonded warehouses; this has been offered to me by Mr. Vachtine, Director-Inspector of the Company.

As to quantities to be sold the future will show it as soon as Ceylon teas begin to be known in the country. I do not like to anticipate with figures, but it may interest you to hear that it is calculated that the firm Popoff & Co., the largest retail tea house in Russia, is selling alone over 50,000 pounds of tea daily in their various stores all over Russia, and supposing that I would sell only 10,000 lb. per month for the first and even the second year, or 120,000 pounds a year,—and this quantity I have, no doubt, will be easily reached—at an average profit of 15 kopecks a pound only, this would leave a gross profit of 18,000 roubles to cover expenses which I estimate about as follows:—

Réclame, advertisements, circulars placards, cards, printing, etc.	Rbl. 5,000
For one Year.			
Rent of office in Moscow	500	
Furniture for same	250	
Wages to men	500	
My own expenses	2,000	
		3,250	
Rent of 5 warehouses and furniture...	6,000	
Five Licenses at Rbl. 200	1,000	
Wages to 5 warehousekeepers	3,000	
Interest, insurance and travelling expenses	1,750	

Say, Rbl. 20,000

Thus clearing in the first year all the expenditure and stock-in-trade as I do not admit that the profit is to be only 15 kopecks per pound of tea—this can easily be doubled. The article is then introduced with all probabilities of a splendid and increasing business in the following years.

For this, a capital of about Roubles 25,000 would be necessary to cover the first advances and start the business on a sure footing viz. Duty and charges are 10,000 pounds of tea say a

	rouble 1 per lb.	Rbls. 10,000
First urgent réclame to be made in starting	..	2,000
½ year rent in advance for office and five Warehouses	..	2,000
Furniture for office and Warehouses	..	3,000
Five licenses	..	1,000
¼ year Wages, Salaries, Insurance in advance	..	1,500
Travelling expenses and sundries	..	500

Roubles .. 20,000
plus about £st600 or say .. 5,000

To cover the value of about 10,000 pounds of tea Cost, freight and Insurance at one Russian Port. Or say about £st3,000 to float on a good scale. the whole concern which could be, of course, extended later on proportionally as for the yearly results of the business.

Now for the enterprising man to advance this money, I have no hesitation in guaranteeing him the success. This would be a good thing for a Colombo firm interested in tea business. Remember that all the tea retailers in Russia have made their fortune and are wealthy people, and that as Mr. Vladimiroff told me Chinese Teas decreasing considerably in qualities as well as in quantities, it is now the very favorable time for introducing Ceylon Teas in Russia.

Moscow will have next year about June 1891 a large exhibition, and I think that Ceylon ought to be well represented with a large kiosk for tea and a good collection of other Ceylon produce.

Please give the foregoing your very earliest consideration and place these remarks before the Committee of your Planters' Association "Tea Fund" who, I hope, will understand that to do such a difficult work like the one I did undertake to do, I must be well supported by means of more liberality.

As regards Funds: It is useless for me to repeat

that the £st100 granted to me by your "Tea Fund" Committee was quite inadequate and insufficient to do what I have done up to this day travelling from Switzerland to London, where I had to stay over a fortnight, to St. Petersburg, via Berlin and Königsberg two days in each place, and over one month's stay in St. Petersburg, to Moscow and Nijni Novgorod and stay of already three weeks between both places! When you add to this, all sorts of expenses such as duty and charges on Tea samples over £st80! Printing matters, carriages, hire, packing of tea, rent of godown, interpreter, tips, postages, &c., &c., you may easily believe that I have already spent over than double that amount of which more than £st100 are out of my own pocket, considering moreover that I only received £st86 out of the £st100 granted, Mr. Leake having kept the balance of about £st14 to cover the surplus of Messrs. Malcolm Kearton & Co.'s invoice for Tea Samples, which I had to increase over the £st30. granted by the "Tea Fund" Committee for their purchase in order to complete my assortment in every desirable grade and qualities suitable for the Russian market. I may just as well inform you that I am now left here without money, in the most difficult position and not knowing what I have to do: "Abandon the field and return home" or "Hang on a little longer with the hope of getting a further allowance from your Committee to enable and to continue my work"?

But as winter is drawing now very near, I should like very much to know, before long what is to be decided.

I do fear to remain during the winter, idle and without means, in a country like Russia, where the life is so expensive, and I would be very thankful to your Committee to take a decision without further delay.

It is quite true that it was my own proposition to come to Russia and that the amount I have been granted for my expenditures, was the figure stipulated by me. When I estimated at a £st100, the approximative amount of my expenses, I did it in perfect good faith not knowing what a country Russia was. That the duty on Tea was so high, and with the hope that the "Tea Fund" would be liberal to me after a first start here as expressed in the resolution of its Committee. It was only in London that I heard more positive information and I remember having heard Mr. J. Capper saying:— That it was ridiculous to expect anyone to do this work with so little money quite inadequate to it. My previous reports from St. Petersburg have proved it superabundantly, but I left London for this country encouraged by many that the Ceylon Tea Fund Committee would understand my position and reconsider their former decision.

I acknowledge having made a mistake in my estimate of expenditure, but is it a reason why the scheme should now be abandoned, when I am so near and so hopeful of obtaining success, and should the first money spent, be left behind without return at all? With my work not even half done. This would be a very sad conclusion to my mission! I do not pretend having shown yet any satisfactory results, but, I consider having done already good work, and I am sure that I could obtain a complete success if more money was to be spent and if I was well supported in my above proposals. Why could not a Company be floated for this purpose in the same way as Mr. Pisco did it for America. This is well worth considering by your Ceylon merchants and capitalists. The capital required is not a large one and I think shares could be easily placed.

Duty on every article or produce—except tea—imported in Russia has, since a week, been augmented of 20 per cent.

The Nijni fair was a very interesting sight, it closed last Saturday, the 25th August 16th September. Confirming my card from thence, I beg to remain, dear sir, yours faithfully,

M. ROQUIE.

I. 13 h Sept.

I have written to Mr. Leake regarding the packing of Ceylon Tea, he must have communicated my

remarks to you and I hope that something will be done in Ceylon to improve the packages, at any rate for shipments to Russia.—My present address is care of Madame Mathey, Maison meublée, Grande Nikitsky, Moscow, and in case a telegram should be addressed to me, Rogivne, Mathey Nikitsky Moscow, would do. Again yours faithfully,
M. R.

A FUEL SUPPLY FROM WASTE GRASSES.

The rapidly narrowing field from which our needed supply of fuel can be drawn, and the widening demand due to the consumption necessary for the curing of tea, justify us in considering every possible suggestion that can be made for averting a difficulty already felt and promising soon to increase in seriousness. With many suggestions emanating either from correspondents or started by ourselves we have dealt on previous occasions, and we do not propose in this article again to discuss them. But few of these have been put to a practical test, and it is impossible, therefore, to say whether any of them will fulfil the hope entertained of them or not. But just now very much interest is felt at home in what have hitherto been the waste products of the island, and the more the utilisation of these can be promoted, the greater the gain, both present and prospect, to the Colony.

As an instance of such utilization, we can well recollect the time when the accumulation of coffee husk or chaff in the Colombo mills of that day was found to be a positive nuisance. Trials made, however, proved it to be an admirable fuel for steam boilers, and while the supply could be kept up we believe every steam factory in Colombo fired with this material. At the Government Factory its use gradually superseded that both of wood and coal, with the result that a very large saving was effected. That was a single case in point, and it emboldens us to write further on a subject with the technicalities of which we do not profess to be acquainted, but which, under the circumstances, may be found to be deserving of some thought by those whose interests are becoming greatly affected by the scarcity of fuel within our planting districts. We have but lately been informed by our London Correspondent, that Messrs. Curtis & Harvey, the well-known manufacturers of fine gunpowder, believe that it may be found to pay them to import from Ceylon a quantity of mana grass for the purpose of making charcoal. Now in the production of that article a very great amount of heat is evolved and lost. The question is, whether from the many varieties of grass which cover waste lands in this island charcoal could not be made in a special apparatus, the wasted heat from which could be availed of to do us valuable service while leaving the residue as a marketable commodity? If this could be accomplished a distinct step in advance would be made towards solving the difficulty apprehended as to our future fuel supplies.

Of course we know that dried grasses of this kind burnt in an ordinary furnace would be simply flashed away uselessly by the strong draught, and would leave an ash certain to choke the bars and flues so as to completely check after-combustion. But, assuming that they were fed into some kind of incinerator which would utilize the heat of the gases evolved for general purposes, leaving behind a pure charcoal, it is possible, we think, that if the latter were possessed of sufficient value for export or home use, this question of fuel supply might in a great degree be satisfactorily solved. As to this last point, we can only say that if Messrs. Curtis & Harvey believe that it would pay them to import the grass and burn it into charcoal at home, there is good ground for us to

believe that it would pay our planters to transform it on the spot, using the wasted heat we have written of for their own purposes and exporting the charcoal produced. We must leave it to those better acquainted with the character of such processes, to determine whether or not the idea that occurs to us is in any way feasible. As we have on previous occasions said, we do not offer our suggestions on this and kindred matters with any conviction of their full practicability. But there is often a shade of truth and a grain of practicability even in the most crude ideas; and in the face of anticipated difficulties we do not hesitate to propound any scheme which might from bare theory be advanced by experts to practical usefulness.

NOTES ON POPULAR SCIENCE.

BY DR. J. E. TAYLOR, F.L.S., F.G.S., &c., EDITOR OF "SCIENCE GOSSIP."

Some months ago I drew attention to Mr. D. Morris's paper, read before the Linnæan Society, on the fruit of the sugarcane. The practical result of that paper is that seedling sugarcanes are now being grown in Kew Gardens. The Government of Barbadoes took up the question in great earnest, and they have just published a valuable report on the seedling sugarcanes, in which are fully recorded the interesting results obtained on the experimental fields at Dodd's Reformatory in that island.

I observe that the Italian navy has recently been trying a new fuel—a mixture of kerosene and coal-dust. The men-of-war thus fired are said to have increased their speed by its use two knots an hour. This will be very convenient in war time for a battle ship to get away. However, one drawback is recorded—the increased heat seriously affects the boiler-plates. Then who is going to sit on the safety-valves?

You have in Australia nearly all kinds of climate and physical conditions for the growth of plants. It is no good drawing anything that the world does not want. Therefore, the following facts may not be without interest. Perhaps we should never have heard of India or the Malayan Archipelago, nor would Europe have been embroiled in a host of wars, if it had not been for the spices those lands produced. With the increased growth of the world's population the amount required is of course increased. Take cloves for example. Not only are these rice fruit-capsules the most pungent of spices, but an important oil is now extracted from them for microscopical and other purposes. One cannot wonder, therefore, that the cultivation of cloves has become a speciality. Sixty years ago the plant was introduced into the Island of Zanzibar, so that it may have influenced the Arab slave trade, just as the introduced cotton-plant is historical associated with the importation of niggers into the Southern States of America. However that may be, the chief supply of cloves now-a-days is not from India but from Zanzibar, where it has been cultivated to a high state of perfection. In that island a ten-year-old plantation of clove trees produces an average rate of twenty pounds of cloves per tree, while trees twenty years old frequently produce fully one hundred pounds. It is stated that the yield of cloves from Zanzibar alone for this year will amount to thirteen millions of pounds, the average market price being 5d. per pound. Surely, in many of the tropical regions of Australia there must be opportunities even for planting clove trees.—*Australasian*

RICE GROWING.

The accompanying figures and information may prove useful as shewing the value of Rice planting. The land planted was the bottom of ordinary drains in portions of laud laid out as Banana and Cocoa plantations. It is not general in Trinidad to take advantage of the drains to raise a crop, but the experiment shown here proves that it can be done without

damage to the drains or detriment to the land. In fact to a cocoa planter growing Rice in the drains, especially on flat land is a perquisite, and now that indentured labour is being employed on such estates there is everything in its favour, for sufficient Rice might be grown to furnish the labourers with their staple food for the year, and this might be done year by year, as the decomposed vegetable matter on the higher ground washes into the drains and remains there to a great extent would thus supply manure to yearly raise a crop of splendid Rice. Shade does not appear to interfere with the growth or ripening of the grain, this has been fairly tested for three seasons on land fully shaded by the large growing gros michel banana. The general result compares favourably with Rice growing on open ground.

No. 1.—SOWING IN JUNE.

Collected area of drains 9,220 square feet or little less than one acre,

			£	s.	d.	
Rice for seed	... 38 lb @	1d. ½ lb	...	0	3	2
Sowing	... 3 days @	1/0 ½ d. ½ day	...	0	3	1 ½
Reaping	... 21, " @	" "	...	1	1	10 ½
Threshing & winnowing	... 12, " @	" "	...	0	12	6
Cost of Labour, &c.	...		£2	0	8	

Reaped 1,250 lb Rice, weighed after threshing @ 1d. per lb=£5 4 2.					
Value of Crop	...	£5	4	2	
Labour, &c.	...	2	0	8	
Profit	...	£3	3	6	

No. 2.—SOWING IN JUNE.

Collected area of drains, 12,800 square feet, or rather more than 1 acre.

Rice for Seed	... 21 lb @	1d. ½ lb	...	£0	1	8
Sowing	... 5 days @	1/0 ½ d. ½ day	...	0	5	2 ½
Reaping	... 3 ½ " "	" "	...	1	15	5
Threshing & winnowing	... 12 " "	" "	...	0	12	6
			£2	14	9 ½	

Reaped 1,350 lb Rice, clean in husk @ 1d. ½ lb	...	£5	12	6
Value of Crop	...	£5	12	6
Labour, &c.	...	2	14	9 ½
Profit	...	£2	17	9 ½

No. 2 shows a larger area planted with not such good results as No. 1. This is accounted for by roots not being so well cleared out of the drains of this portion.

From experiments I find that by cleaning the Rice from the husk in the primitive way the Coolies clean theirs, a loss of ¼ lb. takes place. This would bring the weight of crop to 1,950 lb. Two coolies can clean 60 lb per day. The total result would be as follows:—
2,600 lb less ¼ lb = 1,950 lb @ 1d. ½ lb. = £8 2 6
Deduct 2 men, 30 days, @ 1/0 ½ d. per day = 3 5 0

Profit on 2 acres ...£4 17 6

The sowing was done by Coolies in their own style, simply passing up the drains and at every few inches making a scratch with the hoe, dropping in the grain and at the same time covering in the ground with the foot. Nothing further was done until harvesting. Of course, the rest that follows is well known, as the Coolies may be seen going through the operation any day of the year at their doors. With machinery for winnowing and making white rice, much more favourable results could be obtained. But the experiment is worth trying, it could be done on shares with the labourers or contractors, or the proprietor might take the whole risk which I feel satisfied would not be great on favourable land.—*Agricultural Record*.

THE FUNCTIONS OF THE BOTANIST

were thus indicated in a lecture delivered by Mr. J. H. Hart, F. L. S., Superintendent of the Royal Botanic Gardens, Trinidad:—

The study of Botany is too wide for any one man, but yet the teaching of the first principles of the science is essentially necessary to a purely agricultural community, and should form one of the first considerations of our educational system. That teaching also which gives a knowledge of what are known as the lower forms of vegetable life is coming daily more necessary to all sections of every community, for how few are there who are aware that as the vegetable kingdom provides for the sustenance of the human being, so also does it produce agents which are destructive to the human body. The many germs of disease which are present among us have been found of late years to belong almost entirely to the field of botany. The ferments without which even our bread cannot be made, our wine, or tobacco, prepared, are known to be caused or set up by infinitesimal organisms which belong to the vegetable kingdom. The fungi which causes dry rot in houses—spoils the taste of our wines, and turns sweetened liquor into vinegar—the bacteria of fevers, and other diseases of man and animals—and also the germs which cause and propagate disease among so many plants, are now referred almost entirely to the vegetable kingdom. There are of course the harmless, as well as the destructive and baneful species, and it is a part of the work of botanists to find out their life history to enable those whose special work it is to counteract the influence of those which have mischievous effects upon either plants or animals. So much has this become the work of Botanists that in stating the qualifications for a recent botanical vacancy it was especially laid down by the Legislative Council of that Island that the incoming officer should be a competent Bacteriologist. Travelling into a secluded part of Jamaica shortly afterwards I was entertained by the District Medical Officer, and the subject of Bacteriology was introduced into the conversation through it having lately appeared in the newspapers in relation to the before mentioned appointment, but I was completely stumped when the venerable doctor asked me the meaning of the word Bacteriology. It was evident, therefore, that the old gentleman was not able, or only able by "rule of thumb," to crush an enemy of whose form and habits he was entirely ignorant, and I ask you to whom would you sooner trust your lives—to the hands of a man who keeps up with the progress of medical science, or to one of the old school practitioners who prefers to fight the enemies of human life without a knowledge of the character, form, magnitude or life history of the organisms which cause disease in its various forms? Thus the first class Botanist, instead of being merely a walking dictionary of long names, has to become a microscopist, and to be a microscopist, has to possess a primary knowledge at least of the elements of Chemistry. Botany is therefore elevated among the list of important modern sciences of late years, for no medical student can become competent unless he knows the series of facts which the science of Bacteriology teaches. Only a few years ago it was, I believe, almost impossible to diagnose with any degree of certainty the state of the human lung known as Tuberculosis. While now with the aid of scientific facts recently brought to light, that disease, Leprosy, and many others (daily increasing in number) are each to be readily determined by the presence of the special Bacterium which is peculiar to each disease.—*Royal Botanic Gardens Bulletin*.

MANA GRASS EXPERIMENTS.

It has not been possible for me since last writing to have the mystery about the Mana Grass last experimented upon cleared up. There is such a strongly marked difference, however, between the specimens of the boiled outturn, that my confidence that some careless error has been made must remain until it

can be indisputably upset. During the week opportunity has been afforded me to test specimens of the grass which have been long subjected to steeping in water *n.7*. It was possible to draw from the stalks so treated two very distinct characteristics of fibre. Those stalks which were well matured gave a long and comparatively tough fibres; those of a more immature growth yielded a very short fibre on being separated by the fingers, and this broke readily. It, therefore, seems very feasible that Dr. Evans's suggestion that the two lots of grass experimented upon had been gathered at different stages of growth, and that the fact might account for the variance in result obtained during the experiments made, may have been a correct one. But at present this point remains undecided. It has been told me that a proposal has been made to the Stanley-Wrightson Syndicate that it should take steps to obtain from Ceylon a complete collection of samples of wild growing grasses, each sample to be distinctly labelled with all possible information regarding stage of growth, locality of production, &c., and that these should be submitted to careful laboratory testing. This proposal bears a close analogy to what a previous letter by me recommended; and if it be acted upon information might be obtained which would be likely to prove extremely useful in determining what grasses that your island affords would prove most economically useful for the purposes the Syndicate has in view.

Only this week a conversation was had by me with a gentleman well versed in tramway engineering relative to the best methods for working any system of tramways which may eventually be adopted in your larger cities and towns. On my mentioning electricity as offering to my mind the best method, he remarked:—"Perhaps you may not be aware of a very serious difficulty which has lately been discovered as to this course. It is found that unless a very heavy expense is gone to for the insulation of tramway lines, probably £1,000 a mile—the earth in the neighbourhood of such electrically-worked lines becomes polarized over a large area, and no telephone wires or any other telegraphic system using the earth for return currents can be worked. Experiments have shown that this polarization of the ground in the vicinity of strong currents such as those used for electric propulsion extends to almost an unknown distance, and in America there has been a complete stoppage resulting to the working of some of the ocean cables. This is a matter which is likely to disincline Governments to sanction electric tramways, especially in cases when the telegraph or telephone is their property." As we hope Colombo is not to be left much longer without its local tramway system, one which would prove of great service to the residents in a place covering so large an area as your capital city does, it will be as well that this recently discovered objection to the use of electricity upon them should be known and be well-considered when the question of the means of working them is being discussed.—*London Cor.*

COFFEE IN JAVA.—The opening statement by the Minister of the Colonies to the States-General in Holland is not so cheerful about Netherlands India as could be hoped. The serious failure in the yield of coffee is at the root of all trouble, and will cause a serious deficit in the Government accounts, reckoned at twenty millions of guilders. Nor is the loss only confined to the Government, for the commercial community and the natives feel the situation. It is satisfactory to note that the Government will not have to borrow, however, and that irrigation works and the extension of railways will not be thrown back. They are both to be proceeded with.—*L. and C. Express.*

WET AND DRY.—The Style district of Cumberland is the rainiest in the kingdom, and the Dingwall district of Ross shire the driest. 175 inches a year is the mean fall in the one place; 14.57 is the mean in the other.—*Rod and Gun.* [This statement surprises us; for we had seen it stated that the records of over half-a-century showed that the highest average annual fall of rain was 117 inches on the Cumberland range and that the lowest fall was in Durham, not more than 20 miles due East of the scene of the maximum, and was about 17 inches—*Ed. T. A.*]

DISCOLORATION AND OTHER AFFECTIONS OF TEA LEAVES.—It is natural after their experience of coffee that Ceylon planters should be particularly sensitive about any evil appearance in their tea leaves especially when such may recur after an interval and perhaps in the same locality. We hear of nothing of the kind generally, but every now and then we have an inquiry about discolored or punctured leaves which are puzzling to account for and which may look like the beginning of a minor pest. It is, therefore, satisfactory to be able to publish the following letter from the Director of the Royal Botanic Gardens in answer to one such inquiry by a planter living at a medium elevation. Dr. Trimen writes to our friend:—

Peradeniya, Oct. 2nd.

Dear Sir,—In reply to your letter of yesterday, I may say at once that I do not think there is anything seriously the matter with your tea. Such little patches, spots or pimples of unhealthy or dead tissue are very common on nearly all leaves of an evergreen character especially when of some age, and are quite compatible with the good general health of the plant, as they do not materially interfere with the functions of the leaves as a whole.

I notice that the younger leaves you send are scarcely at all affected.

What may be the actual cause of the local affection of the leaves I am not able to say, probably some irritation from the presence of minute insects, the scorching of sun after rain, &c.

The condition is, I think, scarcely of sufficient importance to warrant the name of "disease," though such a term is technically justifiable.—Yours faithfully,

HENRY TRIMEN.

THE CHARACTERISTIC INTEMPERANCE OF THE INDIAN CLIMATE—says the *Pioneer* of the 16th ult.—has been carried so far during the present rainy season that the weather reports land us in the region of paradox. It is the standing objection to India that for eight and a half months in the year it is far too dry, and for the remainder far too wet; but during the present season an unusually large rainfall has been compressed into little more than two months, and complaints of droughts are abroad before the monsoon in the ordinary course should be nearly over. Districts showing far more than the whole of their average annual allowance of rain are already crying out that unless more comes there will be no autumn crops. Districts that were mostly under water in the middle of August are by the middle of September complaining that it will be impossible to sow. Within a month the tone of the Provincial Summary has changed from "a break urgently needed" to "rain urgently needed," and that through every district. The next few days will show how far this urgency has been met by the showers which have come in the nick of time to the Allahabad Division. But Lower Bengal, still more unfortunate, is suffering simultaneously from the effect of both extremes. Through the Burdwan and Chota Nagpur Divisions the winter rice crop is said to be suffering badly from drought, while in other parts of the Province both autumn and winter rice have been apparently destroyed by floods. In Murshidabad, Jessore and Nuddea the damage from this cause is so severe that relief has already become necessary.

PLANTAIN GROWTH AND PLANTAIN FOOD IN AFRICA

are noticed by a writer of reminiscences in the *Pioneer*. Writing of Uganda, he states:—It is a marvellous country in many respects, full of rivulets, banana groves, clustering hamlets and wild fig trees. Whether one approaches it by way of the Nile or from the East Coast route, it is like stepping into a new world to set foot in Uganda, so totally different is it to anything one has met with before. Perhaps the most striking feature to a new-comer is the immense number and size of the plantain trees, which grow in such profusion that he may walk for miles with nothing but the shade of their broad leaves above his head, and nothing to be seen on either side but long vistas of their stems. In one sense this luxuriant growth of plantains may be said to be the curse of the country, for since the Waganda find their food so easily (literally bending down for their acceptance), they never take the trouble to cultivate the soil or to sow cereals, but live in lazy idleness upon the provisionse bountifully supplied by Nature. The plantain trees grow to a large size in that humid climate, compared to which those met with in India seem a most degenerate species, the bunch of ripe fruit being as much as a strong man can lift. There were four or five distinct kinds: the ordinary eating banana; a second kind with a very thick pink stem and long three cornered fruit called "gonja," which they always cooked in hot ashes, when it resembled a roasted apple in flavour; a third species which bore very small fruit, in taste not unlike jargonelle pears, from which the national drink mwengi was made, and another kind which is never allowed to ripen but invariably cooked in its green stage. This last was the "staff of life" to the Waganda, and as long experience had made them connoisseurs in the art of cooking it, it may prove interesting to describe the operation briefly.

A bunch of fruit is selected whose colour is just commencing to change from green to a tinge of yellow, and the tree from which it hangs is cut down at the root. All the larger and more perfect leaves are then cut off and passed rapidly through the flame of some burning straw or other dry combustible, the centre rib of the leaf being first split up with a knife along its whole length to serve as string afterwards. The action of this flame renders the leaf soft and pliable without injuring its strength and a number of the plantains, carefully peeled and cleaned are then tied up in some of the best and most perfect leaves, the bundle being placed in a large open-mouthed earthenware pot with several pieces of the thick leaf stalk underneath to prevent the bundle touching the bottom of the vessel. About a pint of water is then poured in and a quick fire started underneath, the bundle of plantains being carefully covered over with layer upon layer of the flexible leaves neatly folded up, which both prevent the escape of steam during the process of cooking and serve the purpose of a table-cloth afterwards. If they have meat it is wrapped up in a similar manner, great care being taken that the leaf wrapper has no crack through which the gravy can escape, and deposited in the very centre of the plantain bundle: a rude and perfect imitation (or original?) of Captain Warren's cooking-pot. When the women judge that the steaming has continued for a sufficient length of time, the top layers of folded leaves are removed from the pot and spread out upon the rush floor: and a most aromatic appetising odour dees that smoking table-cloth emit, as I can testify from experience. Then the great bundle of plantains is extracted

and kneaded by the women while still wrapped in leaves, until the mass is of the consistency of mashed potatoes, when the leaf coverings are untied and portions handed round to every guest. The smaller bundle of meat is placed in the centre of the cloth, and each one helps himself to gravy by pressing his thumb into a small ball of plantain mash so as to make a kind of cup, which he dips into the liquid.

A more appetising way of cooking plantains could hardly have been devised, and it is small wonder that the Waganda thought no food could compare with it. In fact they openly asserted that the reason why white men visited their country was because no such trees grew in their own. To them the plantain tree means so much that they entertain an undisguised pity for those whose lot is cast in a country where it does not flourish. It not only supplies them with their daily bread, but gives them ropes to fasten up their fences, napkins to wash and wipe their hands with, dried provisions to take with them on their journeys, and a delicious beverage to drink which is fully equal to cider. The only purpose for which they grow cereals is to start fermentation in this mwengi or country beer, and when the ambassadors were returning from Khartoum they were constantly longing for plantain food, although liberally supplied with wheat, rice, meat and vegetables. Of the merit or demerits of this natural food supply it is difficult to judge. It evidently suited the Waganda, for they were physically well formed and surprisingly intelligent; but we noticed that they required to eat an enormous quantity of the food to extract the due amount of nourishment, and one result of this was that most of the children (between the ages of four and twelve) were mere or less pearshaped about the abdomen. It is very doubtful whether Europeans could subsist for any length of time on such a diet, as the power of assimilating it could probably only be acquired when young: but it only needs the demand for cereals to be created for the supply to be forthcoming, as the soil is rich enough for anything.

THE NORTH BORNEO PEARL FISHERIES.

Several letters having been received lately at Sandakan on the subject of Pearl Fishing on the Borneo coast, the Government have forwarded to the *West Australian* a copy of a letter sent to Messrs. Erickson and Wood, in June, 1888. Information was asked for on their behalf by Capt. Gray, of the "Australiad." The following are the chief parts of the letter, and the Government offers to give any further information desired, adding, however, that a permit would not be allowed to interfere with a bank known to and worked by natives.

PEARL SHELLS.—Mother-o'-pearl are found around the coast and island of North Borneo, particularly in the Sulu Seas, where they are fished for by natives in the most primitive way. The shells form one of the most important exports in the Sulu Islands. From time to time pearl banks have been found round Balambangan, Banguey and Malliwalle, and round the Islands of Calibabang Paya and Omadal on the East coast, all included in the territory called British North Borneo, but as yet nothing has been done to discover or develop them, the attention of the Government having been given to opening up the country. The natives of the coast, however, are beginning to give more attention to pearl-shell fishing, and within the past two years pearl-shells have been exported from Darvel Bay. A bank is also known to exist in Marnda Bay. The reason why pearl-fishing in North Borneo has not received more attention, is on account of the reports about pirates; up to within a few years ago the coast was infested with them. The Batanians, Illamins, and Bajows were at one time very successful in keep-

ing the coast to themselves. Since the advent of the British North Borneo Company, however, these marauders have had to retire or become peaceful subjects, or suffer the penalty of their misdeeds. At the present moment there is not a pirate in our coast, trade is entirely free, and the Company is entirely free to open up and develop industries on land or by sea. Regarding pearling (I refer to mother o'pearl). Government are prepared to give encouragement and special advantages to pioneers in those industries.

PERMITS AND LICENSES.—A permit or license would be required from the Government, the fee for which would be nominal: a monopoly for a certain time would be granted to the discoverer of new pearl banks.

RULES AND REGULATIONS.—We have no rules or regulations in force, but in the event of the pearl fishing becoming important, rules and regulations such as are in force in Australia would probably be adopted, with the modification necessary to such circumstances.

TARIFF OF IMPORTS AND EXPORTS.—With this letter I am sending you a copy of the *Herald*, official gazette for March, which contains these, together with Harbour, Custom and Quarantine Regulations. It will be observed that the export duty on mother-o'-pearl-shell is 10 per cent. ad valorem. The ad valorem duty is calculated on the local value.—*Singapore Free Press*

CEYLON UPCOUNTRY PLANTING REPORT.

Practical Information on "Nutmegs."

NUTMEG CULTURE—MANURING NUTMEGS—NUTMEGS vs. CACAO—MODE OF CULTIVATION IN THE LOWCOUNTRY AND ON THE HILLS—YIELD OF HALF-AN-ACRE—INCOME FROM A SINGLE NUTMEG TREE—PRICES IN LONDON FOR NUTMEGS AND MACE.

Oct. 6th.

Periodically, with longer or shorter distances of time between, there is a rage for nutmeg culture in Ceylon. The last "boom" was some six or seven years ago, and there is another "boom" on again.

People can get very enthusiastic about the nutmeg, especially during the initial stages; and, having no certain data to go on as to what might be expected in the way of returns, hazard wild enough guesses, touching in some cases, as it did the other day, the magnificent figure of R50 a tree! But the man who would grow the nutmeg must be a man with a good stock of patience; and as Europeans in Ceylon are, as a rule, impatient for returns, they are not all suited for the cultivation of this spice. Hence it is that the regularly recurring nutmeg excitement burns itself out long before the tree has had any chance of showing what it really can do; and the plants which had been put out amid great expectations are, after a longer or shorter time thought nothing of and perish from neglect. I can remember of one man who even forestalled this: so disgusted was he with the slow growth of the young plants that he put an end to their existence and his own hopes by pulling—what he called—"the wretched things" up, and closed his experiment in that violent way. Those who know the nutmeg are too well aware that it is not likely to overgrow itself, or hurry into bearing, and the pauses between each recurring pair of new leaves are trying even to a patient spirit. The grower in the old days was afraid to stimulate the plant in any way:—"Manure it, and it dies," was the scientific dictum, believed in and acted up to; and the young nutmeg was left to pick up what nourishment it could from an already worn-out soil. The failure of the nutmegs in the Straits—brought about we were told by high manuring—was what paralysed anything like culture here.

We are getting over this, and the successful experiment in the lowcountry—which is the result of an intelligent patience, and manure applied from

the first year of the nutmeg's life—is likely to inaugurate a new era in the production of this valuable spice in Ceylon, and add to the tropical products which the planter may successfully grow, and on which he may depend. We have learnt that the dying out in the Straits was much more likely to have been the effect of the cutting down of the shade and forcing the trees to overbear than the fact that they were well-manured. Even although no special cause can with certainty be assigned for the catastrophe, it must always be remembered that a wave of blight is liable to pass over any product which is extensively cultivated and artificially forced, and that the nutmeg has not been an exception to this rule. It is the waiting for returns which staggers most people, but if one considers how long a cacao plant takes before it is in full bearing—the supplies got up, and everything else in order—the extension of time which the nutmeg demands dwindles into very little. One cacao planter whose place is a credit and has been for a long time in the front rank, told me that it was nearly ten years before his estate had been what he called complete, and the vacancies regularly filled up.

The culture of the nutmeg in the lowcountry differs somewhat from those on the hills, in this way: that in the warm, sweaty, low elevations, shade is demanded. One who has now a good show of nutmegs in a low place, and has given much thought and attention to the growing of the spice, gives me (for the benefit of others who may yet try) the following as the outcome of his experience:—"The plants should be raised from selected seed in nursery beds, and planted out when about one foot high, with a 15-inch 'Scowen's Transplanter,' into holes cut 2 feet deep, and at distances of 25 to 30 feet. They must be at once carefully shaded with cadjans or other suitable shade, and this must be renewed, whenever necessary, until the young nutmegs are about three years old, and the permanent shade trees (*Albizia molluccana*) sufficiently well grown to shade the ground. The young nutmegs must be kept free from moss and any parasites. Manuring should be commenced when the plants are one year old—the manure spread on the surface and lightly worked in without injuring the under rootlets. When the trees are five or six years old they will blossom, but they will not set fruit until the seventh year and will afterwards yearly increase in production." On the hills the nutmeg wants shade at first but not afterwards; and if the seed is germinated it can be put out after having been duly protected, with a fair prospect of success. To have any kind of decent show of nutmegs one must keep pegging at it, and not count the losses of seed and plants as anything very serious. As to the nutmeg paying, I am in a position to give some figures which may be relied on and which are a rough average of something like fifteen years' returns. The nutmeg grove is a small one, about half-an-acre in extent, contains 58 trees of which 36 are bearers and 22 are males. The trees are planted about 18 ft. apart and are crowding and crushing each other, and the shade below is so dense that no weeds whatever can grow. The trees, I fancy, must be from 35 to 40 years old. The produce from this grove was sold locally, and for the time I refer to, the nutmegs fetched in their shell at the rate of 37½ to 50 cents a lb., and the mace R1 a lb. on the spot. The price today is very much better, R1 a hundred for the nuts and R1.25 per lb. for mace, while selected nuts for seed are R2 a 100. It takes from 50 to 80 nutmegs with their shell, on—I don't mean the husk—to make up a pound. The produce of the above half-acre has averaged for these fifteen years about R100, that

is to say, R200 an acre. The cost of cultivation, except keeping down parasites, had been nothing: the crop only had to be gathered. The proportion of male trees is, of course, very excessive; and in a regularly planted place the excess of males would have been wiped out and fresh plants put in. I regret I am not able to get the proportions received from nutmegs and from mace separately, otherwise it would have been a simple matter to have calculated the average yield of each. But the information given above, so far as it goes, is thoroughly reliable.

Here there is nothing so handsome as R5) which has been mentioned to be the income that may be derived from a single nutmeg tree, but, nevertheless, the prospects ahead of the successful nutmeg cultivator are such as to class it among the most profitable tropical cultivations in which one can engage.

The price in the London market for nutmegs and mace is very much higher than obtains here. I have, however, no late circular at hand to quote the figures. Perhaps Mr. Editor, you will kindly supply them.

[We quote from Messrs. Lewis & Peat's fortnightly Circular, Sept. 11th:—

	QUALITY.	QUOTATIONS.
		1890.
NUTMEGS, large	...57's a 80's, garbled...	2s 10d to 4s
medium	...83's a 95's	2s 8d to 2s 9d
small	...100's a 160's	1s 6d to 2s 7½d

—Ed. T. A.]

A LONDON TEA WAREHOUSE.

(From *Chambers's Journal*.)

It is 8 o'clock of the morning and a numerous body of workmen are passing into the doorway of a huge barrack-like building some half-dozen stories high, occupying the site of a considerable village of London houses which have been swept away to build it. In quiet orderly fashion the morning muster-roll of labour is accomplished, and the gangs of men are told off for work. Steady and well-mannered fellows mostly, but not much resembling ordinary labourers, as currently understood, are these warehouse hands. A most varied lot certainly, with a very general appearance, for the greater part, of artisans out of work, or "down on their luck," as they would say. Indeed, many of them look like anything that could be named in a wide range of choice, not excluding the liberal professions and the gentleman "born."

HOW TEA IS LANDED.

The great ocean steamers are berthed at the various docks as soon as they arrive in the Thames. Their cargoes are discharged at the principal docks, and immediately dispersed over the port of London in vans by land and barges by water, all of which conveyances are jealously crown-locked by the sleepless Customs officials, who watch this fruitful source of revenue from the first "hail" at Gravesend until it is finally deposited, duly paid, in the hands of the consumer. But, primarily, its destination, on being sent from the ship's is the bonded warehouse in town or by river-side, where the warehouse-keeper gives ample security for its safe keeping, alike to the owners thereof and to the Crown as having a lieu on the goods at first hand.

SORTING.

On arrival at the warehouse the tea is pounced upon by gangs of the handy and civil labourers; and, anon, the chests are whirling in mid-air on their way to loopholes of distant floors near the sky-line, or are being transported thither on men's shoulders in endless streams like human ants, up bewildering flights of stairs to similar far-off stowage. Other gangs, *ad infinitum*, there receive them. Squads of coopers hammer them, prune and heap them, and otherwise

ameud them. Drawers of samples pierce and tap them. Expert hands carefully assort the multifarious packages into "chop" and "bed," with nice regard to size, quality marks, garden marks—delightfully suggestive these of orient tea-fields—and uniform weight and description. The tea-chests are then ready for the weighing scales, at which Oustoms officers and warehouse clerks busily ply their pens, entering into account-books the gross and net weights of the goods by each ship, in successive importations, as the packages, are past in swift review before them. Odd things come to light sometimes when the chests are emptied to be weighed for tare and refilled. "Unconsidered trifles" from far-off homes in Assam are occasionally revealed. White rats, dead and flat, have been seen, and bogus chests are not unknown. A frequent importation by the China tea-ships is the delicious fruit lychees in a dried condition.

A CHECK ON ADULTERATION.

But to return to tea. In the history of its progress up to the weighing-point the rigid scrutiny of the revenue officers has been exercised mainly with a view to fiscal and statistical returns; but at this stage of the proceedings the various teas—Kaisons, Capers, Congous, Pekoes, Souchongs, Oolongs, Assams, Hysons, &c.—are inspected by an officer acting as an official analyst under "The Sale of Food and Drugs Act 1875," who selects samples and subjects them to a searching examination, with at times, the wholesome result that spurious or adulterated teas are prevented from entering the British market; and even to the extent of causing such vitiated goods to enter the destruction furnace instead. Large quantities of damaged tea are disposed of in that manner.

A DELECTABLE MIXTURE.

Tea is frequently spoilt on the voyage by salt water or other causes, and, being thus rendered unfit for human food, it becomes "prohibited." It is, however, allowed to be delivered duty-free from the warehouse on condition of its being denaturalised by the effective process of mixing with it a proportion of asafetida and lime. This delectable compound is used in the manufacture of the alkaloid caffeine.

"BULKING."

For home use the tea from China is generally cleared out of bond in the same condition as on arrival in this country. But Indian tea appears to be so much varied in quality and "make," even when produced in the same tea province, or district that it is found necessary very frequently to throw it together in quantities, taking care not to blend different marks and importations. This arrangement is termed "bulking," and the effect of it is to make the whole bulk of the tea operated on more uniform in appearance and quality. In a large tea warehouse capable of holding perhaps a quarter of a million packages, amounting, it might be, to twenty-five million pounds of tea, the bulkiog of Indian produce assumed stupendous proportions. Floor after floor will at a busy time be crowded with enormous heaps of the emptied contents of many hundreds of chests. These fragrant mounds are thoroughly "roused" by gangs of men, deft-hand varlets with wooden shovels. A faint and balmy odour fills the rooms, and the atmosphere is heavily charged with a very palpable dust of tea, of dull red hue, which settles upon the clothes like down. The bulked tea is refilled into the original chests and again weighed in the presence of the Crown officers, each empty chest having been previously weighed for tare; the merchant paying duty on the exactly ascertained net weight of the tea.

TEA EXPORTED FROM LONDON.

Immense quantities of tea are annually exported from London, noticeably to Germany and the Baltic Provinces. It is also largely sent to the colonies and to South America. The latter trade is peculiar, the tea being prepared in bond expressly to meet certain native demand. Packets as small as four, or even two, ounces are greatly in vogue. Those goods are frequently also weighed in French kilograms (2lb 3oz 5dr.)

Great attention is paid to careful packing for the voyage, and subsequent inland transit; and to elegance of design and pictorial display as to the wrappings and labels embellishing the packets and setting forth the attractive charms of the various judicious blends and mixings. In this particular branch of the trade much latitude is given under the revenue regulations, in bond, as to blending and mixing—practices not allowed to the home trade.

COMPRESSED TEA.

Compressed tea is also occasionally exported from a bonded warehouse. This is tea pressed into brick or cake shape—indubitably tea-cakes! The operation is performed by powerful machinery moving a massive metal disc, which is pierced at regular intervals with oblong holes. Into these moulds the loose tea is poured; and as the iron table slowly revolves, each small parcel is treated in turn to enormous dry pressure from a steel mallet, which infallibly meets the mould with accurate and terrific accord, and squeezes the tea into a solid and shapely lump. In these latter arrangements female labour is greatly employed; the various packing and other arts connected with the system requiring much quick handling of goods and delicate manual skill.

Tea is sold in bond to the dealers by samples which are daily on show; and it is needless to say that the moment the chests leave the warehouse the price paid is enhanced by the fourpence per pound which goes to swell the annual Budget of Her Majesty's Chancellor of the Exchequer. Subsequently, the value is not easily determined. Indeed, it might be said, ethically at least, that it is priceless.

MR. MAXWELL ON COCONUT BEETLES.

The Resident of Selangor issues the following notification about what he calls cocoa-nut trees; but probably he means coco-nut trees:—

No. 185.—THE COCONUT-TREE BORER (BEETLE)—District Officers are instructed to use their influence with the native owners of coconut plantations in order to induce them to clean their trees periodically and rid them of beetles. The palms should be ascended once every month or six weeks. The lowest leaves, if shewing signs of drying up, should be chopped off and the trunk cleared of any old leaf-stumps and of ants'-nests, etc., which the latter may have harboured. At the same time the top shoot should be carefully examined. If they are of a yellowish, sickly colour the beetle is probably the cause. There is no difficulty in finding the hole, as an accumulation of short loose fibre marks the spot. This fibre should be removed and a wooden or metal probe pushed into the hole (one of the side-ribs separated from a frond will answer the purpose.) The beetle is soon transfixed and pulled out. A little sand should be thrown into the hole.

The above is the system employed on the Malabar Coast where the removal of beetle is one of the ordinary routine operations of the coconut-growers. A single toddy-drawer will there clear from fifty to one hundred full-grown trees in a day.

The insertion of a little kerosene oil into the hole may be usefully tried. Kerosene oil if mixed with an equal proportion of milk forms an emulsion which can then be diluted with water to any desired extent.—*Straits Times*.

CEYLON TEA IN AMERICA:

MR. GRINLINTON'S MISSION AND THE NEW COMPANY.

We have been favoured with the use for publication of the following letter from Mr. Grinlinton to his colleague, Mr. Mitchell:—

S. S. "City of New York," on passage from New York to Liverpool, 491 miles from Queenstown, 22nd September (noon) 1890.

My dear Mitchell,—I last wrote to you on 12th instant from New York, I had at that time accomplished 2,160 miles by rail and had visited Baltimore, Cumberland, Chicago, Bloomington (in the West), and paid flying visits to Philadelphia, Detroit, Buffalo, Niagara, Southampton, 90 miles from New York) and some other places, having made tea, written on tea and on Ceylon products, given private lectures, been interviewed by newspaper correspondents and editors till I was fairly worn out; and some of my relatives who travelled with me (I was always accompanied by some one or more of them) feared I would break down, but I did not, and I am on my way to the mother country as fresh as ever I was, only a little tired, as if I required sleep.

I found the American people most kind and courteous and ever ready to help me, and having been well introduced in every place I could not have been better received. Members of my family, first and second cousins as well as others nearer akin came from all parts (hundreds of miles) to meet me, and I was simply delighted with the country and its people which I saw under the most favourable circumstances. I heard the English language spoken by everyone, and on Sundays I heard our English services in the churches and I felt that I was not in a strange land, but as a visitor to a distant part of our own country. I heard our beloved Queen, our constitution and system of Government spoken of in the highest terms, and the good feeling entertained for the mother country made me feel almost ashamed of the opinions I had at one time entertained of our American consins.

Now to business. It took some 8 to 10 days to draw up the needful deeds and papers with a prospectus of the New American Company. After we had settled on all the points, and while the formal clerical work was being attended by the lawyers, I travelled and made our Ceylon products known in many places, so much so that I have been urged to press on our friends in Ceylon to have our little island well represented at the Chicago Exhibition of 1892 and we shall get a good position in the Exhibition I feel sure. Men of business and many others to whom I spoke took a lively interest in our interesting and beautiful island and promised me every help.

On my return to New York on the 11th instant, I had a paper put into my hand which caused me considerable anxiety, as it contained statements which I felt bound to investigate thoroughly, before I could ratify officially what I had agreed to on my arrival. It took me two days to call upon men of business to whom I had taken introductions from Ceylon and from London to obtain their aid in making my enquiries. I left no stone unturned that I could think of, and having consulted some of the best men of the city, I was more than satisfied that the fears entertained by well-intentioned friends who were so good as to place me on my guard were perfectly groundless. One gentleman, to whom special allusion was made by name, came out of the enquiry with flying colours, and what promised to be an ugly blot has proved of service to us in more ways than one. To Messrs. Wattson & Farr I owe a debt of gratitude for having placed everything at my disposal. To all my proposals which were discussed with the new Board and with the Company's solicitor, they gave due weight, and I had the satisfaction of seeing all the important points carried,—more particularly that in respect to the purchase and sale of pure Ceylon tea; the payment out of the funds, before transferring the balance, of interest at 9 per cent from the date of their payments to 30th September (instant) to the old Company's shareholders who continue in the new Company; the continuation of our Ceylon Directors as a Board of Management in Ceylon; the appointment of our Agents and Brokers for the purchase of teas both in Ceylon and in London.

The old shareholders receive two shares for every one held now.

The legal documents have gone to our agents in London to be handed to me there and I take duplicates with me.

The share scrip has been engraved and is being printed.

The prospectus is being printed and will be advertised probably by this time.

Nothing had been done except the formal registration (which I read with care and approved of) until I arrived at New York, and had the Company not gone on, those signing the memorandum would simply have lost the Registration fees. I think I have now mentioned the principal matters. There are many minor points which I shall reserve for another time. It is no easy matter for a landsman to write in a ship going 20 miles an hour and rolling.

I wired you from New York on 15th inst. to the following purport:—"Letter derogatory New York parties sent Ceylon. There is no foundation for the report. We have made careful enquiry and the result satisfactory. Sailing 17th. Everything settled and papers signed." My remarks above are in explanation of this telegram.

It is with great pleasure I mention the name of Mr. Pinco, whose exertions are beyond all I expected. He has been unremitting in his endeavours to place Ceylon tea. Everyone speaks of him as the right man to be placed at New York, and many people have mentioned him to me as most obliging and attentive to everyone seeking information. Consequent on the new start given to matters in America and to Mr. Pinco's exertions, large orders with credits to enable you to draw in cash for the shipments have been sent you. Mr. Pinco has been of the greatest assistance to me, and I feel assured that no one could have shown more zeal in pushing our largest Ceylon industry in the new world. It is only common justice to say this of Mr. Pinco.

We have no idea in Ceylon of the efforts needed in such a vast country as America to push an industry like our Ceylon tea. Our little paid-up capital (some £30,000) would have disappeared within the next 12 months. The movement now on foot is to obtain shareholders everywhere—in every city, town and large village; and to do this Messrs. Wattson & Farr will have to distribute a vast number of shares by giving such shareholders as will work for the Company, in placing Ceylon tea in the several towns and villages, an additional share for every share they take and pay for. Very large sums will also have to be paid for advertisements, &c. Not a cent is to go into the pocket of any man out of the capital raised in cash, nor for any purpose until the whole of the cash capital (200,000 dollars) has been raised and placed in the Treasury. A bond has been executed between the New York Directors to this effect.

You will be glad to hear that I have met Mr. Lipton first at Chicago and secondly at New York, and I am greatly indebted to him for kindness and attention and for the valuable hints and information given me. I cannot write too highly of all he did for me. He took a personal interest in everything. It is quite wonderful what he is doing in Chicago. I saw a property which he had just purchased for 200,000 dollars and had paid for it in hard cash. He is a very well-known man in New York and Chicago, and his command of capital enables him to make good purchases. I went over his cattle yard and packing warehouses.

We expect to arrive at Queenstown at 1 p.m. tomorrow, and at Liverpool at 7 on the morning of the 24th. We are having a race with the Star Liner "Teutonic" which left New York half-an-hour after us. The two vessels kept in sight for 2 days and were then lost in a fog. We think we see the smoke from her funnels now, but we are not sure. It is most exciting. The "City of New York" beat the "Teutonic" on her last voyage home by 2½ hours—but the "Teutonic" was first in on the last outward voyage to New York by 3 hours. This present voyage will pull the thing off, and whoever wins will carry the American Mails next time. The "City of New York" is a splendid ship of 10,500 tons gross. Her accommodation is simply magnificent, with a flush deck throughout. She is just a floating palace.

I must now close; and with all good wishes from yours sincerely,

J. J. GRUNLINTON.

P. S.—I hope to leave London about the 16th Oct. via France and Italy for Naples and to embark there on 25th October on the "Khedive" for Ceylon. I can hardly write, the vessel is rolling heavily. I have backed our opinion (*i.e.* yours and mine) by taking £200 sterling worth of new shares for each of us in the New American Tea Company. You will recollect that you authorized me to do for you whatever I was prepared to do for myself. I hope some of our Company's Directors in Ceylon will take some new shares; also many of our old shareholders. I omitted to mention that when at New York Mr. Wattson (who was at Philadelphia) spoke to me direct through the telephone to Messrs. Wattson & Farr's office, a distance of 100 miles, so distinctly that his voice was clear and he heard my reply equally distinctly.—J. J. G.

TOBACCO IN DELI (SUMATRA), AND CEYLON.

The S. S. "Peshawur" has brought us a visitor in Mr. Chas. Kitchin, Tobacco planter of Deli, who has come across to see what prospect there may be of taking up or extending the cultivation in Ceylon. Naturally, Mr. Kitchin wished to know about the land in the Eastern Province, but he considers a country liable to protracted drought as useless for his purpose; nor does he believe in irrigation for a European's plantation. The expense over a considerable area would be prohibitory, and yet the margin for expenditure is very great. For, in answer to our mention of the lucky hit made in Dumbara when £800 an acre return from 50 acres was got in one year, Mr. Kitchin remarked that two or three times that amount is not uncommonly got in Sumatra. Of course, there are good and bad estates there—some wonderfully profitable up to 150 per cent per annum and some barely paying their way. This year has been a very profitable one through the high prices paid in Amsterdam, and also for Deli tobacco to go to America where its fine quality is greatly appreciated. Manila has been, in this respect, quite superseded by Sumatra.—Mr. Kitchin considers it very important that fine tobacco should be guarded from deterioration. He thinks that a great drawback to Europeans opening plantations in India is the great inferiority and yet abundance of the native tobacco. But the cheapness of labour here and in India is an immense advantage over Sumatra where sometimes £20,000 are spent in trying to secure 100 labourers. Mr. Kitchin is to run up country; he will probably visit Matale and Dumbara and we bespeak for him planting attention during his visit to the districts.

COLONIAL-GROWN TOBACCO COMPETITION.

The following is the report of the Judges in the Tobacco Prize Competition:—

In making their award the judges have had a due regard to the conditions under which the prize was originally offered by the Section, the principal of which were (1) that specimens submitted for competition should amount to not less than 400 lb. in weight, grown on a commercial scale; (2) that each sample should consist of an average of the growth; (3) that the name of the grower, the locality, and total quantity of the growth should be stated; (4) and that the care bestowed on the handling, sorting, and packing of the tobacco for commercial purposes, should be taken into consideration. With the consent of the Section the competition was kept open more than two months beyond December 1, 1883—the date originally appointed for determining the same—in the hope that additional specimens would be forthcoming from the Colonies and India. The judges regret, however, that their anticipations were not

realised, and, consequently, they have only had to report on the three specimens from North Borneo, the West Indies, and the East Indies, which had been entered prior to the extension of time being granted.

These three entries were duly inspected by the judges on February 18th, 1889, at the Fenchurch Street warehouse, and their award was agreed upon; at a subsequent meeting after they had had an opportunity of comparing the merits of the North Borneo and West Indian tobacco—from which samples were drawn for manufacture into cigars. The East Indian tobacco, as stated below, was only suitable for cutting purposes, and hardly entered into competition with the others.

The judges much regret that through inadvertence a sample of East Indian tobacco, marked L B X and T F 782, was not brought under their notice; but they have added (Appendix B) a report by Messrs. Grant, Chambers and Co., of 37, Fenchurch Street, on its commercial qualities, which was drawn up some time subsequent to their inspection of the three exhibits mentioned in the foregoing paragraph.

Some difficulty was experienced by the judges in arriving at a decision, owing to the varying characteristics of the tobaccos submitted to them, and opinions being nearly equally balanced in favour of the West Indian and North Borneo specimens—which were comparable as cigar tobaccos—they decided to recommend to the Section that the prize of fifty guineas should be divided between the growers of the two specimens.

The judges are much indebted to Dr. Bell, of Somerset House, for his analysis of the specimens submitted to competition, which they append to this report.

Subjoined are particulars as to the cultivation and preparation furnished by the growers, and our remarks on the tobacco sent in for competition:

1. WEST INDIAN TOBACCO (445 lb.). Grown by Señor Nicaor Moreno, box 80, Kingston, Jamaica. This parcel, in two cases, was grown from Havana seed, on an estate at Airy Castle, St. Andrew, the total quantity of the crop being 2,500 lb., and the approximate yield per acre about 600 lb. The cost of production for the whole is stated at from 60s. to 80s. per 100 lb., and the grower explains that 'on account of dry weather the produce was not half of what it should have been.' The entry was made by Messrs. B. and J. B. Machado, of Kingston, Jamaica, who point out, with reference to the two cases, that the first contained about 200 lb. ratoon tobacco or second cut, viz., first and second fillers mixed, and that the second included about 245 lb. of first cut, mostly first and second wrappers. At the top of the latter, however, there were also about 50 lb. of fillers as a fair sample of the first cut. The method of assorting adopted, it was explained, was due to the fact that the tobacco was not intended for exportation, but only for use in Messrs. Machado's factory. These points were duly brought under the notice of the judges.

Remarks of the Judges.—In some important respects, this tobacco most fully complied with the conditions of the competition. Its general appearance was good, and it was of a uniformly dark brown colour. The leaves were fine and clear, there were some white veins, and about 18 per cent. of stalk. Viewed commercially, the tobacco was more suitable for fillers than for covers, the leaves being comparatively small, and consequently not very productive for wrapping purposes. The flavour was good, but too strong for the English market, and more suited for Continental consumption. The tobacco burned well, though slowly, and did not hold the fire as satisfactorily as the Borneo; but if matured it would improve in burning. For blending with Cuba, Brazilian and Havana, it was specially suitable. The samples submitted apparently embraced all the classifications in the crop, thereby satisfying the conditions of the competition. They possessed some resemblance to some sorts of Havana, and for certain qualities justified the opinion that parts of Jamaica are well adapted for raising the finer kinds of tobacco. In the Island of Cuba only some

limited districts produce the more valuable descriptions, and similar selected places probably exist in other islands of the same group.

2. BRITISH NORTH BORNEO TOBACCO (533 lb.).—Grown by Mr. P. Peryn, Panow Estate of the Borneo Tabac Maatschappij Kudat, British North Borneo. This parcel, in three bales, was grown from Sumatra (Deli) seed on the Ranow Estate, the total quantity produced being 58,600 lb., and the approximate yield per acre 1,100 lb. The entry was made by the British North Borneo Company.

Remarks of the Judges.—Taking the three bales as a whole, the leaf naturally resembled Sumatra tobacco; the colour varied from medium brown to light brown, and there were some urripe spots; the veins were hard and wiry, but the leaf was thin, silky and tender. The proportion of stalk was about 16 per cent. Commercially considered this tobacco was the most valuable submitted to the judges, on account of its productiveness, and suitability for cigar covers. According to one estimate, about one pound, if carefully worked, would be sufficient to cover about 450 middle-size cigars. Made up into cigars by itself, the flavour of the tobacco was pungent; neutralised by mixture with other tobacco, so as to overcome the Sumatra flavour, it would probably be better liked. Generally speaking, however, it lacked the rich aroma peculiar to the finer classes of West Indian tobacco. The burning qualities of the leaf were good, there being a clean ash, and cigars made from average samples kept alight for at least five minutes. The specimens submitted were part of a large consignment, and apparently did not represent all the classifications of the crop, and for this reason the judges have not been able to form an opinion on the merits of the entire growth.

3. EAST INDIAN TOBACCO (514 lb.).—Grown by the Superintendent of the Government Tobacco Farm, Ghazepore, Bengal, of which Messrs. Begg, Sutherland and Co., of Cawnpore (Begg, Dunlop and Co., London), are the lessees. The sample weighed 1,133 lb., and it was one of 91 hogsheads shipped for sale to the United Kingdom, and not put up specially for the competition. The tobacco was raised from 'Pryor' seed, and about 60 tons were produced. Messrs. Geo. D. Wishart and Co., of Liverpool, who made the entry, believe the hogshead to be 'a fair representative sample' of the entire growth, and state that 'for some years past the produce has shown steady progression especially in the handling and curing. Only at the last minute did we decide to enter this competition, and we regret that we are unable to give any exact details as to the total quantity grown, or cost of production. The quantity shipped, however, shows that the tobacco is grown on a considerable scale, and that it has passed the experimental stage.'

Remarks of the Judges.—This tobacco was only suitable for cutting purposes, and of a common quality. The leaf was coarse, though bright, and the stalks large. Nevertheless, the strength of the leaf pointed to the capabilities of the soil on which it was grown for the cultivation of tobacco suitable for the pipe, provided there is a judicious selection of seed and the conditions of scientific culture are observed. The tobacco submitted resembled the lower American grades; in fact, with proper cultivation, it would be a good substitute for such kinds in the event of any stoppage in the supplies from the United States. It was estimated that in its then state the tobacco would be worth in the English market about 3s. per lb., and perhaps more to buyers requiring it, on account of its colour for blending with other varieties. The fact that during the American war large quantities of tobacco grown from American seed were imported from the East Indies should be some encouragement to growers there.

GENERAL OBSERVATIONS.

In conclusion we have to repeat our expression of regret that the prize offered by the Section has failed in its object to stimulate further attempts to develop a lucrative branch of production in the British colonies and possessions. This is the more to be regretted, because, in the great varieties of climate and

soil embraced in those localities—so many of them in sub-tropical situations favourable to growth of the finer descriptions of tobacco—there is an element of successful cultivation which has not been utilized, as yet, to any extent.

It might certainly have been expected that the offer of a prize for a competition of this kind could not fail to draw more attention to the possible capabilities of our dependencies in this direction. Every effort has been made since the conditions were decided upon to bring them under the notice of Colonial and Indian growers, and we are informed that numerous communications on the subject have passed between the London Chamber, Colonial Government representatives and individuals. Yet the result, as we have already pointed out, has been confined to three entries.

It can hardly be thought likely that in both hemispheres with few exceptions, the only places where fine tobacco can be grown are those inhabited by the Spanish race. We think it more reasonable to conclude that intelligently conducted trials would have led to the discovery in the British colonies and possessions equally well adapted for the purpose as any in the Spanish or Dutch possessions.

(Signed) WILLIAM HENRY WILLS,
(Chairman of Committee of Judges).

Appendix B.

EAST INDIAN TOBACCO.—Grown by Mr. H. Caiu, Superintendent of the Government Tobacco Farm, Port Blair, Andaman Islands. The sample weighed about 514 lb. nett, the tobacco being raised from Virginia seed on the Government farm, and the total crop being 3,000 lb.

Report on one Hogshead of Tobacco.

EXAMINED FOR THE LONDON CHAMBER OF COMMERCE.

MANIFEST MK.	LANDING MK.
LB	No.
X	TF 782

Remarks.—Small part leafy, but rather narrow for the length, large part short and more or less blistered throughout, very imperfect, and with large bare stalks and butts attached. This tobacco in its present state has the general appearance of being only partially fermented, and will not hold fire, and has little or no flavour of tobacco. As a whole, it is not of such a character (in its present condition) to be an article that would meet a ready sale, except at an extremely low price.

GRANT, CHAMBERS & Co.,

37, Fenchurch Street.

London, November 15, 1889.

—Tobacco.

OUR REVIEWER.

ENGLISH VEGETABLES AND FLOWERS IN INDIA AND CEYLON*

Is the title of a very complete and valuable Manual, compiled from authentic sources by Donald McDonald. It is a square volume of 60 pages, good toned paper and clear type, and gives directions easy for an amateur to understand and to follow. In the introduction the writer shows how great the influence of Europeans in India has been in developing among the educated natives a taste for flowers and for gardening, and speaks of the help afforded through various Government Botanic Gardens, to those who are establishing a garden. The 1st chapter treats of "The Climates and Physical Features of India," and regards that land as having three distinct climates, those of Northern, Central and Southern India. The 2nd chapter is on "The Soils of India," the 3rd on "The Formation of the Garden," giving directions as to the slope, shape, preparation and drainage of beds, with quotations from various authorities. Then follows a very complete table showing "The proper months to sow and plant English vegetables in the Plains"; fifty-seven different vegetables are tabulated, and opposite to them we find the months marked when they should be sown on high and on low-lying lands. Next we have "Monthly reminders for cultivating English vegetables and flowers in the Plains." Thus we find "March in the Vegetable Garden," "March in the Flower Garden," and under each heading you have directions for Northern, Central and Southern India respectively. We will quote by way of illustration the directions for March in Southern India:—

"The great heat generally prevailing at this season prevents much sowing or planting being done, therefore pay attention to trenching, digging, and ridging up ground. In commencing to subsoil or trench a piece of ground, let an opening be formed, of two feet or twenty inches in breadth, to the full depth of the surface or active soil, and the entire length of the bed, and let the stuff be removed and left at the opposite side, in order to have it to fill up the last opening, when the ground or bed will have been entirely turned over. Let the subsoil, to the depth of a foot or fifteen inches, be loosened and well broken, with a pick or spade; but let none of it now be brought to the surface. A second trench must now be marked out, the same breadth as the first, and the surface sod of it turned over on the broken subsoil (upside down), and finished off in the form of a small ridge or drill. The subsoil in the second opening is now loosened and broken as the first, and a third line or opening marked out, the surface sod of which is turned over on the broken subsoil of the second, and finished off in the form of a drill, like the first, and so on to the end. The ground can be manured as the work is being carried on; but the manure should not be laid on the bottom nor on the surface, but in the middle of the drill, between the first and second spits, or between the digging and shovelling. Ridged up or drilled in this form, let it remain to pulverize, and there will be very little trouble in levelling it down for cropping in the proper season. At each succeeding digging a portion of the broken subsoil should be turned up and well incorporated with the surface soil; and by repeated digging, and taking up the subsoil in regulated proportions (not more than an inch or two of it at a time), the texture of the entire mass will be changed from a poor sterile, to a rich, fertile soil. This is the true method of deepening and enriching the soil, which, with effectual drainage, is certainly the best preparation to ensure good crops in the garden; and should be attentively studied and industriously persevered in."

* To be obtained at the *Observer* Office. Price! cloth covers, cash R4.50, credit R5; in paper covers cash R2.50, credit R3; Postage 10c.

Then we have a table of "Average Seasons at various places." Next, a chapter on "English Vegetables, the best sorts to grow and quantities to sow." Concerning "Carrots," for instance, they tell you:—"One ounce will sow a row 100 feet long and twelve inches apart; thiú out to six inches from plant to plant. Mix the seed with moist sand the day before sowing. The best sorts are Early Summor Favorites, the new Scarlet Perfection, Intermediate, Early Horn, and White Belgian."

Or concerning Tomato:—

"One ounce will give about 800 plants. Sow in boxes, and transplant to three feet apart. As they mature, cut out all superfluous growth to expose the fruit to the sun. Such varieties as the Smooth Perfection, Dedham Favorite, Holborn Ruby, and Golden Gem, give marvellous returns of the most delicious fruits in most parts of India. The plants will require support unless against a fence or wall. A plan that might be tried with success in India is the placing of a piece of trellis shaped thus ^ over the plants, push the growth through it, and let the flowers and fruit lay on the top. The foliage will assist in keeping the roots shaded and cool, while the fruit will get the full benefit of the sun. It is a great mistake to feed them too much at the earlier stages of growth. They will set their fruits more freely on pure water and good garden soil, if a start is given them in something richer, and repeated when the fruit is forming."

The remaining chapters are headed "Hill Stations, Garden Cultivation in Upper India; Notes on Ceylon; English Flowers from Seed; Popular English Flowers, including shrubs and other plants that do well in India; & Select List of Foliage Plants for subtropical gardening (all of which can be grown from seed); The Rose; English Bulbs; English Fruits; On Manures, Watering, Vermin, &c.; Average Rainfall at various places; English Seeds and how to treat them; Average Altitudes at which various trees grow in India; The Rotation of Crops in the Vegetable Garden (a table)."

The list of Popular English Flowers includes 113 names, and the descriptions run somewhat as follows:—"COCKSCOMB.—A variety of the Celosia, ranging in colour from bright yellow to deep crimson. Sow in pots and transplant singly as soon as large enough to handle; re-pot as required, and keep the plant well fed, and with plenty of root room. The fine Empress variety produces combs of colossal proportions. The plumosa varieties can be bedded out.

"Sow in the Hills, March to May; in the plains everywhere, June to September."

INSECT PESTS AND REMEDY.

Although the following is properly an Advertisement, we quote it into the *Tropical Agriculturist*, as the information may be useful to our readers:—

CASPER SCHNEIDER'S ARSENITE OF AMMONIA. U. S. PATENT. PREVENTS DAMAGE OR DESTRUCTION TO COTTON PLANTS AND ALL OTHER CROPS OR DELICATE PLANTS BY INSECTS, &C.

Distinctly superior, more convenient and considerably cheaper than Paris Green.

Stapleton, N. Y., April 5, 1890.

Gentlemen.—On the 11th Day of February 1890, I obtained from the U. S. Patent Office a patent for a Substitute for Paris Green which I have named "Arsenite of Ammonia." It is designed for all those uses on the Plantation, Farm, and Garden to which Paris Green is now applied; and it has been adjudged decidedly superior to the latter article by farmers in all parts of the country who have tested in with the most satisfactory results. With their letters of commendation before me, I have no hesitation in introducing it to the public at large.

A few of the advantages I claim for Arsenite of Ammonia over Paris Green are as follows:—Being a fluid, it will raise no dust and is entirely free from sediment when dried out. It is particularly beneficial

to Cotton Plants, but is also decidedly superior to Paris Green for use on fruit-trees, currant-bushes, grape vines, and general garden truck. Having no sediment it will not, like Paris Green, leave a deposit on the plants to which it is applied that will retard their growth. On the contrary, plants treated with this solution are of quicker growth and of decidedly improved appearance.

It will enter into every crevice of the plant—which cannot be said of Paris Green: at the same time it is not necessary to saturate the surrounding ground.

DIRECTIONS.—To an ordinary pailful of water take one large tablespoonful of the solution. Mix and apply with an ordinary Sprinkler, or hand pump, or even with a small broom. In the case of cabbage plants, care must be taken to apply the mixture before they close or form the head. As a general rule one application will be found sufficient to destroy all insects and germs.

In using large quantities it requires no more of the Arsenite of Ammonia than of Paris Green, that is to say, where one pound of Paris Green would be required, take one pound of my substitute and secure sure results.

The experience of those agriculturists who have put my invention to a practical test warrants me in claiming for it:

1st. That it is more convenient to use than Paris Green.

2nd. That its effects are more satisfactory.

3rd. That, unlike Paris Green, positively no injurious results can come from its proper use.

4th. That it is considerably cheaper.

With my fifty-five years' experience in this line I am known all over the world as a reliable Chemist and the oldest manufacturer of Paris Green in the Country. My goods have the reputation of being the best made anywhere. I know the danger of using Paris Green on Plants etc. for the destruction of insects and have been experimenting for years to find an article equally as effective but not so dangerous: and I am fully convinced that in offering to the Public my new invention Arsenite of Ammonia, I offer an article that is sure to give entire satisfaction to all who use it.

Hoping you will give the circular your kind attention.

I remain, yours very respectfully,

CASPAR SCHNEIDER, Chemical Works.

Sole Agency: Fr. Jac. Andres, 25 Pearl Street, New York.

—Quotations on application.—

Prof. Charles Ripley of the U. S. Department of Agriculture writes:—

"If your mixture is valuable for the cotton worms, it will be also useful for many other insects."

He has instructed me to ship a Keg each to several agents of the Division of Entomology in U. S. who are now experimenting with it.

Arsenite of Ammonia has also been found useful on potato fields and other purposes, and the following are copies of letters received:

1. I have tasted your insecticide on my potato plants with very good results, as compared with Paris Green. A single application of your compound upon several rows of plants killed all the bugs in one night. Adjacent rows of plants were treated with Paris Green, and as the first application had no perceptible effect upon the plants, a second dose had to be applied, which had the effect of killing the bugs, but had a perceptible had effect on the plants; while your compound had a decidedly beneficial effect upon them.

2. I hereby thank you for the bottle of your Arsenite of Ammonia you gave me as an exterminator of potato bugs and other vermin; it has been the best remedy I have ever used.

3. I have used your Arsenite of Ammonia on my rosebushes according to your directions, and found that even half the quantity will be sufficient; it killed all the bugs almost instantly, I found them dead under the bushes.

Correspondence.

To the Editor.

TEA-DRYING—THE BLACKMAN SYSTEM.

DEAR SIR,—I believe the "Blackman Air Propeller" has been introduced on one or two estates. Would the managers of such estates kindly favor your readers with their opinions of it and what alteration, if any, is required in an ordinary withering loft to work it successfully? S. A.

FURTHER INFORMATION WANTED ABOUT A NEW FOREST CLEARER.

DEAR SIR,—The March number of the 9th vol. of the *Tropical Agriculturist* contains at page 642 an article headed "A New Forest Clearer." Does any of the numerous readers of the periodical know anything more about the invention, or is the whole simply a humbug? By all means the information is not taken from an American paper.

For any informations in the *T. A.* which may lead to know more about the matter, eventually to get at the composition will be very thankful one who is about to become on a large scale a forest clearer.—Yours truly, EUGENE KASSEL.

A PROLIFIC COTTON TREE.

P. W. Bungalow, Delmar Estate, Sept. 20th.

DEAR SIR,—In one month—20th August to 17th Sept.—I collected from ONE TREE 7 oz. cotton, the seed 1½ oz. There has been no rain for some time; the tree is not at all a fine tree. I had to cut a large piece about 3 feet off, it was so overweighted with pods, and had been neglected. I would like to know what quantity of oil can be got from 1 cwt. seed; also pounce, and their value and use.—Yours faithfully, JAMES ROBERTSON.

P.S.—The same cotton as I sent you—"kidney" or "Pernambuco"—I gave a good number of this seed to the Hon. J. Grinlinton. I would like to see a deal of information given about this sort, for I feel sure it is the proper kind for Ceylon, if some fresh seed could be imported. [We commend this letter to the special notice of the Secretaries to the Cotton Spinning Company.—Ed. *T. A.*]

LIBERIAN COFFEE &c. IN JAVA.

Pussellawa, September 23rd.

DEAR SIR,—I send you a translation of the conclusion of what seems to me a very interesting amount of Liberian coffee in Java—where according to Mr. H. J. Wigman it is to play a conspicuous part. There is in the same number an article on the production of camphor in West India by Dr. M. Greshoff which I think worth publishing.—Yours truly, JOHN DENT YOUNG.

"*Liberian Coffee.*"

"At the present time, the cultivation of Liberian coffee is being extended with great energy in the subdivision of Buitenzorg alone. Tehre has to my knowledge, already been an extent of over 3,000 acres those cultivated and there is still an immense extent of land in the lower districts, now lying waste, which can by suitable culture be converted into productive coffee estates."

The above is the concluding portion of an interesting article by Mr. H. J. Wigman in the 5th No. of the "Teysmannia." The article contains an account of the Republic of Liberia, and in my opinion is of much interest. Shall I send you a

translation of the whole? How beautifully got up is the "Teysmannia"—paper, type and all well worthy of the countrymen of Laurens Koster. As far as I can learn the name of the work is adopted from the name of a botanist called Teysman, with a Latin termination.

[We shall be glad to have translation of both articles for our *Tropical Agriculturist.*—Ed. *T. A.*]

THE STAMPING-OUT OF CATTLE MURRAIN

Belgravia, Sept. 23rd.

DEAR MR. EDITOR,—If not too late, in reply to your excellent editorials, beginning in your issue of 5th August last, evidently called out by your correspondent "Truth"'s remarks on cattle disease and its prevalence and causes, I agree with every word "Truth" says, and would if able say far more and severe things regarding those who have so long stood aside and allowed murrain period after period to sweep over the land, kill out its herds, impoverish the poor cultivators and bring them by many thousands to misery, want and ruin.

I at least am convinced, after an experience of more than 30 years, and maybe with better opportunities than many, while at the same time my early training fitted me to see and appreciate, and watch the progress of disease during this long period;—I now say no more fruitful cause of poverty prevails among the native cultivators of the soil than that of cattle murrain, call it by what name you may. Cattle are the chief wealth of the rice cultivator, while they are the mainstay of the numerous cart drivers and tavalam men.

The cry of improvement of the breeds, of their degeneracy, of better housing and feeding are all to me mere surplisage. The better you breed, the more you feed, the more you lay your herds open to contagion, as long as the disease is allowed to go rampant over the land.

It has ever been, in the matter of cattle here, "a survival of the fittest." Hardy and untended, a remnant has always escaped, and pray who but A MADMAN would go to any expense to improve stock, without the security of a single month's freedom from the ravages of disease let loose on him at any moment and at any point of his surroundings?

Your valuable discussion of the whole question has not, in my opinion, improved the condition of things one *iota*. Strike at the roots of the evil, "suppress the disease," and render it manageable and then think of improving, feeding and housing; and not till then. I shall in another article follow all your reasoning so well and full and exhaustively done; yet you have not touched on the main cause of all the evil at least with a practical suggestion.

You represent me as "bloodthirsty," standing with a poleaxe ready to destroy half the cattle in Ceylon. You quite misunderstand me. I no more want the disease to gain a footing than does our admirable C. M. staff *in re* cholera when it appears. W. S.

[By all means let us hear our correspondent's scheme for stamping out murrain. No one would more heartily rejoice at the success of such a scheme than we. The difficulty is that here in Ceylon, as in continental India, rinderpest is not merely an occasionally imported pest, but an indigene of the land, lurking in the byplaces of bad shelter and insufficient food and every now and again vivifying into virulence. If the Madras Government has failed to extirpate the evil, we fear we cannot be much more successful. But let us have our correspondent's remedy for what is, confessedly, one of the greatest of evils.—Ed. *T. A.*]

A FEW TEA NOTES.

SIR,—Some little time ago there was a discussion between tea planters and tea buyers, many of the former asserting that they do not get full value of teas sold at the weekly auctions, and in consequence ship direct to London. On the other hand tea buyers maintain they have orders from various parts of the globe which it is impossible to fill, even though they are prepared to pay more than the London valuations. There is no doubt whatever that much business from foreign countries, formerly passing through London, is now coming direct to Colombo, but if these orders cannot be promptly fulfilled they will again revert to Mincing Lane to the detriment of local firms and the growers themselves. I cannot by any means agree with the latter as to the local market not being so good as Mincing Lane. There may be exceptional cases where monies have realized higher prices at home, but in the long run I feel sure planters will benefit by supporting the local sale room. It is well-known by Colombo tea men that large sums have been dropped by buyers at local sales who have resold in Mincing Lane. Many firms have bought tea as a speculation, or as a form of remittance hoping to save something in exchange, and those who study the Mincing Lane Circulars can see that losses have been made to the extent of even 5d per lb. Of course where they have private outlets they come out alright, but I think I can safely say, that those who have bought teas here and sold at London auctions have lost money somewhat heavily, taking the year all round. On an upward market they may now "score" for a time, but as a rule any upward tendency is fully discounted in Colombo, as witness recent sales.

I know of two cases where local firms have received foreign orders for particular brands. In one case the sellers wanted over a rupee per lb. for that which has only been fetching about 10d per lb. in Mincing Lane. In the other instance the difference was not so marked, yet quite sufficient to prevent the order being placed in Ceylon. In both these cases the orders will revert to London, so that the planters will lose a good market and the merchants their commission.

It follows, therefore, that those planters availing themselves of the services of local brokers have invariably reaped higher prices for their teas through the spirit of speculation or competition amongst buyers in Colombo, than they would have done had they themselves speculated by shipping their produce to a market 6,000 miles away.

UPIDU.

INDIAN TEA EXPORTS.

Indian Tea Association, Calcutta, Oct. 11th.

DEAR SIRS,—The General Committee have the pleasure to hand you their usual Monthly Return of shipments of tea from Calcutta, and also a Return of Exports of Ceylon Tea for four years up to the 18th September 1890.

EXPORTS OF INDIAN TEA FROM CALCUTTA.

	1890	1889	1888
	lb.	lb.	lb.
Exports to Great Britain in Sept. ...	14,263,059	16,253,978	12,188,328
Exports to Great Britain from 1st May to 30th Sept. ...	40,415,251	40,761,931	40,025,482
Exports to Australia and New Zealand in Sept. ...	712,200	806,863	495,061
Exports to Australia and New Zealand from 1st May to 30th Sept. ...	2,293,446	1,807,392	1,344,564
Exports to America in Sept. ...	25,837	23,586	19,990

Total Exports from 1st May to 30th Sept. ...	43,297,046	43,721,777	41,897,382

—Yours faithfully, S. E. J. CLARKE, Secretary.

RUTHERFORD'S AND STREET'S TEA TABLES.

Oct. 1st.

SIR,—Attention having been called in your columns to the alleged incorrectness of Mr. Rutherford's figures, I have taken the trouble to compare them with those of Mr. Street, and I must confess that I am somewhat mystified as to the manner the calculations have been made: they do not appear to agree with each other at all, and both are at variance with the true equivalents in Ceylon currency—for instance, in *Rutherford's Tables* it is stated that at

London price.	Exchange rates.	Equivalent in Colombo.
per lb.		Cents.
1s 4d	1s 2d	101
1s 4½d	1s 2½d	100·50
1s 5d	1s 3d	100
1s 5½d	1s 3½d	99
1s 6d	1s 4d	100
1s 6½d	1s 4½d	100
1s 7d	1s 5d	100
1s 7½d	1s 5½d	101
1s 8d	1s 6d	100
1s 8½d	1s 6½d	99·50
4s 9d	1s 7d	100

Clearly if we take off the 2d per lb. (allowed for by Mr. Rutherford for freight insurance charges) from the London prices for tea mentioned above we have figures remaining exactly the same as the rates of exchange placed alongside them, and the result must, of course, in each of the above instances, be neither more nor less than 100 cents (by taking off 19 cents allowed to buyers of leaf and dividing the result by 4 the correct price of green leaf as calculated by Rutherford is arrived at.) In Mr. Street's tables it is stated that

Colombo price	Exchange rates	Laying down cost in London per lb. in pence.
	s d	
100	1 2	1s 4·61d
100	1 2½	1s 5·16d
100	1 3	1s 5·74d
100	2 3½	1s 6·28d
100	1 4	1s 6·83d
100	1 4½	1s 7·40d
100	1 5	1s 7·94d
100	1 5½	1s 8·50d
100	1 6	1s 9·05d
100	1 6½	1s 9·63d
100	1 7	1s 10·17d

The differences between Mr. Street's "laying down cost in pence in London" of the above as compared with Mr. Rutherford's system of *always* calculating 2d per lb. to cover all London charges for freight, insurances, selling, commissions, &c., &c. (and which is a very convenient plan, for he gives at foot of his tables the cost equivalents of each farthing of these charges, under each rate of exchange so that with low freights or high freights, the exact calculation can always be readily arrived at when ever London charges amount to more or less than 2d per lb.) is very considerable, thus—by Mr. Ruther-

ford's system (not his figures!!) 100 cents give selling price in London
 Exchange..... 1s 2d, 1s 2½d, 1s 3d, 1s 3½d, 1s 4d
 1s 4½d, 1s 5d, 1s 5½d, 1s 6d, 1s 6½d,
 1s 7d.
 H. K. Rutherford... 1s 4d, 1s 4 5/10d, 1s 5d, 1s 5 5/10d,
 1s 6d, 1s 6 5/10d, 1s 7d, 1s 7 5/10d,
 1s 8d, 1s 8 5/10d, 1s 9d.
 F. F. Street 1s 4 6/10d, 1s 5 1/10d, 1s 5 7/10d, 1s
 6 2/10d, 1s 6 3/10d, 1s 7 4/10d, 1s 7 9/10d,
 1s 8 5/10d, 1s 9 0/10d, 1s 9 6/10d, 1s
 10 1/10d.

Evidently Mr. Street's tables are intended for buyers of tea in Colombo, and thus include a good FAT commission sufficient to make a tea grower ENVIOUS.

TROPICAL PRODUCTS IN BRITISH NORTH BORNEO.

Kandy, Oct. 3rd.

DEAR SIR,—I send a pamphlet on coffee, cacao and other tropical products grown in British North Borneo, compiled by Mr. Henry Walker, the Commissioner of Lands, an old Ceylon resident. Mr. F. G. Callaghan and Mr. P. Christian, whose names appear in the pamphlet, are also old residents.

I have lately received from Mr. Christian an estimate of the cost of forming a Liberian coffee plantation in British North Borneo of 200 acres, in which he estimates the total cost inclusive of the purchase of land for the first 3 years and laying down the produce in London at R50,000

At the end of the 3rd year, he estimates a crop from these 200 acres, cwt.
 1,000 at £4 10s = £4,500 at 1s 8d
 exchange R54,000

Net profit R4,000

For the 4th year such an estate would probably give from cwt. 6 to cwt. 8 per acre, say cwt. 1,400 laid down in London at a cost of R16,000.

The above information I hope will be interesting to your readers, and I remain, yours faithfully,
 W. D. GIBBON.

CEYLON TEA AND ITS NATURAL MARKET.

SIR,—“Vendor” in your issue of 3rd instant concludes his letter by calling upon Mr. Street to revise his table “a little.” I second that suggestion, but I would say “a good deal” instead of “a little.”

It is patent to anyone making use of that table (F. F. Street's) that it includes not only the very full allowance of 2d for London charges, i.e. freight, insurance, landing, rents and selling commissions of brokers and agents in London, but also a Colombo buying commission of from 4 to 6 per cent or it may be more. Having bought Mr. Street's tables and used them, never thinking that they contained any item such as Colombo buying commission. I would now ask Mr. Street through your columns to state what percentage of Colombo commission his figures include.

We want new tables based on 1½d which now-a-days covers every charge in London account sales. Vendors of green leaf would then deduct (not 19 cents as allowed by Rutherford, but) 13 cents to cover all cost of manufacture, &c., and the remainder divided by 4 would give the correct value of LEAF.

P.S.—On the new basis of 1½d off only for London charges, vendors would then expect to see 100 cents precisely marked in the tables whenever the selling price of tea in London was say 1½d per lb,

more than the rates of exchange mentioned in the tables, thus:—

Selling Price.	Exchange.	Cents.
s. d.	s. d.	
1 11½	1 10	100
1 10½	1 9	100
1 9½	1 8	100

Rutherford's tables (based on 2d London charges) do not bear this test—he is often out 1 and 2 cents—100 cents being by him stated sometimes as 101 and at other times as 99.

CUBEB CULTIVATION.

Colombo, Sept. 15th.

To the Secretary of the Ceylon Planters' Association, Kandy.

Dear Sir,—At the request of Mr. H. VanPrenh of Plaver, I beg to enclose translation of a letter for your perusal and trust it may prove of interest to your Association,—I am, sir, yours faithfully, (Signed) RICHARD REMMERS, Consul for the Netherlands.

Plaver, near Salatiga, Java, Aug. 17th.

The Consul for the Netherlands, Colombo.

SIR,—Having read in one of the Indian papers that the planters of Ceylon are trying to secure Cubeb plants from here since those planted some years ago by them did not grow, I beg to inform you that I can supply these plants during November next at fl. 0 15 ea. delivered on my estate and fl. 0 20 per plant delivered at Samarang, and should wish to know whether you will be good enough to advertise the sale of them in one or more of your local papers at the prices above stated. It is my intention in the meantime to advertise the sale of these plants in the Java newspapers towards the end of next month, and should any of the Ceylon planters require them they must send their orders in time. I may mention that the plants are placed in bamboo pots so as to secure them from damage.

Thanking you beforehand for the trouble I am giving you, I remain, sir, your obedient servant,
 (Signed) H. VAN PREHN.

THE REPORT of the Cinchona plantation and factory of the Government of Bengal, under Dr. King and Mr. Gammie, shows a falling off in the profits as compared with the previous year. The loss was partly due to a general depression in the cinchona industry, and to the large exportation from Ceylon having reduced prices. The year marks an era in the manufacture of the febrifuge, for during it the new fusil oil process for extraction entirely superseded the old acid and alkali process. The sales of febrifuge and quinine during the year were in quantity between 7,000 and 8,000 pounds at R14 per pound for cinchona and R17 per pound for quinine; and the sum realized was R1,13,000, roundly, as compared with R1,29,000 the year before.—*Madras Times*.

AERATED TEA.—It is said we may shortly expect to see a company launched for the manufacture and sale of the aerated tea respecting which my letters a short time back gave you some account. A specimen of the bottles in which this new competitor for public favour is to be sold has this week been shown to me, and from the label it bore I see the proprietors have chosen as the name by which the beverage is to be known “Theafoam.” Not a bad name, we think, for a liquor which pours out with a fine, sparkling, frothy head. Some of us venture to predict for this liquor a very large amount of popularity, and in that case, should its consumption ultimately at all approved that of some other well-known effervescent beverages, its manufacture may have a sensible effect upon the consumption of your island grown teas.—*Cor.*

NOTES ON POPULAR SCIENCE.

By DR. J. E. TAYLOR, F.L.S., F.G.S., &c.,
EDITOR OF "SCIENCE GOSSIP."

In a few years the world will be one botanical parish. The distribution of plants, and their localisation here and there, is one of the most suggestive of scientific generalisation. How did special plants get to special places? None even of the ingenious authors of the over-estimated "Lux Mundi" endeavour to explain it. But steam and increasing population are giving the finishing stroke to the phenomenon. Plants characteristic of different countries are getting dreadfully mixed up. Certain "hush" seeds reach us from Australia, the Cape, the Argentine, &c., brought in the uncleaned fleeces of wool. The latter are washed and combed in Gloucestershire and Yorkshire, and the seeds are stranded on the river banks, or distributed by the agency of birds, so that they are spreading over the country, or they are brought in ships' ballast, and afterwards disseminated. In the north of England farmers are in the habit of putting the screenings of foreign wheat on the land, and a host of foreign weeds has sprung up in consequence.

Now that unknown Africa is becoming known, and a new and vast field for colonisation is likely to be opened out by the recently-founded East African Company, it is well to learn what science has to say upon that pest of the Dark Continent—the African fever. This is the unseen demon which haunts the European traveller in tropical and equatorial Africa by night and day. Once the system has been thoroughly steeped in it, it becomes chronic. He may have left Africa for ever, but the African or malarial fever will not leave him. Dr. Crumie Brown, of Edinburgh, has just issued a *brochure* on the subject, which he has addressed to the secretaries of all British and American missions in hot countries. One of the newly-acquired territories of the above company has been very properly named "Livingstonia," after great traveller. Professor Drummond, in his delightful work on *Tropical Africa*, says of this place:—"It is one of the loveliest spots in the world, and it was hard to believe, sitting under the tamarind trees by the quite lake shores, that the pestilence which wasteth at midnight had made this beautiful spot its home." Dr. Brown is of opinion that the Australian blue-gum tree is the antidote to malarial fever. There is no worse place for malaris, even in Africa, than the Campagna at Rome. Few visitors to Italy dare bide there in the summer months. But the blue-gum tree was planted in the Roman marshes a few years ago, and the results have been remarkably successful. The microbe of malarial fever and the gum tree do not get on well together. The Trappist monastery in the Campagna had to be abandoned on account of the fever in 1863, but since the gum tree woods have been planted it has been reinhabited, although the place had previously gone by the name of "The Tomb." The Trappist brotherhood, aided by the Italian Government, are extending the cultivation of gum trees in the Campagna. When we have got real possession of tropical Africa, our first duty will be to plant forests of gum trees there.—*Australasian*.

SACRED TREES OF THE WORLD.

The palm, the oak, and the ash are the three trees which since times immemorial, were held to be sacred trees. The first among them, which figures among them, which figures on the oldest monuments and pictures of the Egyptians and Assyrians, is the date-palm (*Phoenix dactylifera*), which was the symbol of the world and of creation, and the fruit of which filled the faithful with divine strength, and prepared them for the pleasures of immortality. "Honour," said Mohammed, "thy paternal aunt, the date-palm, for in Paradise it was created out of the same dust of the ground." Another Mohammedan tradition of a later period says that when Adam left Paradise he was allowed to take with him three things—a myrtle, because it was the most lovely and the most

scented flower of the earth; a wheat-ear, because it had most nourishment; and a date, because it is the most glorious fruit of the earth. This date from Paradise was, in some marvellous way, brought to the Hejaz; from it have come all the date-palms in the world, and Allah destined it to be the food to all the true believers, who shall conquer every country where the date palm grows. The Jews and the Arabs, again, looked upon the same tree as a mystical allegory of human beings, for, like them, it dies when its head (the summit) is cut off, and when a limb (branch) is once cut off it does not grow again. Those who know can understand the mysterious language of the branches on days when there is no wind, when whispers of present and future events are communicated by the tree. Abraham of old, so the rabbis say, understood the language of the palm. The oak was always considered a "holy" tree by our own ancestors, and, above all by the nations of the North of Europe. When Winifred of Devonshire (680-754 A.D.) went forth on his wanderings through Germany to preach the Gospel, one of his first actions was to cut down the giant oak in Saxony, which was dedicated to Thor and worshipped by the people from far and near. But when he had nearly felled the oak, and while the people were cursing and threatening the saint, a supernatural storm swept over it, seized the summit, broke every branch, and dashed it, "quasi superni motus solatio," with a tremendous crash to the ground. The heathens acknowledged the marvel, and many of them were converted there and then. But the saint built a chapel of the wood of this very oak, and dedicated it to St. Peter.

The sacred oaks, it must be admitted, do not seem to have always done their duty. Thus, for instance, a famous oak in Ireland was dedicated to the Irish Saint Columban, one of the peculiarities of the tree being that whoever carried a piece of its wood in his mouth would never be hanged. After a time, however, the holy oak of Kenmare was destroyed in a storm. Nobody dared gather the wood, except a gardener, who tanned some shoe leather with the bark; but when he wore the shoes made of this leather for the first time he became a leper, and was never cured. In the abbey of Vetrou, in Brittany, stood an old oak tree which had grown out of the staff of St. Martin, the first abbot of the monastery, and in the shade of which the princes of Brittany prayed whenever they went into the Abbey. Nobody dared to nick even a leaf from this tree, and not even the birds dared to peck at it. Not so the Norman pirates, two of whom climbed the tree of St. Martin to cut wood for their bows. Both of them fell down and broke their necks. The Celts and Germans and Scandinavians, again, worshipped the mountain ash (*Fraxinus*), and it is especially in the religious myths of the latter that the "Askr Yggdrasil" plays a prominent part. To them it was the holiest among trees, the "world tree" which, eternally young and dewy, represented heaven, earth, and hell. According to the Edda, the ash yggdrasil was an evergreen tree. A specimen of it (says Adam of Bremen) grew at Upsala, in front of the great temple, and another in Dithmarschen, carefully guarded by a railing, for it was, in a mystical way, connected with the fate of the country. When Dithmarschen lost its liberty the tree withered, but a magpie, one of the best prophesying birds of the north, came and built its nest on the withered tree and hatched five little ones, all perfectly white, as a sign that at some future time the country would regain its former liberty.—*Deutsche Rundschau in Public Opinion*.

DOMESTIC USES FOR AMMONIA.

A little ammonia in tepid water will soften and cleanse the skin.

Spirits of ammonia will often relieve a severe headache.

Door plates should be cleansed by rubbing with a cloth wet in ammonia and water.

If the color has been taken out of silks by fruit stains, ammonia will usually restore the color.

To brighten carpets, wipe them with warm water in which has been poured a few drops of ammonia. One or two tablespoonfuls of ammonia added to a pail of water will clean windows better than soap. A few drops in a cupful of warm water, applied carefully, will remove spots from painting and chromo.

Grease spots may be taken out with weak ammonia in water; lay soft white paper over and iron with a hot iron.

When acid of any kind gets on clothing, spirits of ammonia will kill it. Apply chloroform to restore the color.

Keep nickel, silver ornaments, and mounts bright by rubbing with woolen cloth saturated in spirits of ammonia.

Old brass may be cleaned to look like new by pouring strong ammonia on it, and scrubbing with a scrub brush; rinse in clear water.

A tablespoonful of ammonia in a gallon of warm water will often restore colors in carpets; it will also remove whitewash from them.

Yellow stains left by sewing machine oil, on white, may be removed by rubbing the spot with a cloth wet with ammonia, before washing with soap.

Equal parts of ammonia and turpentine will take paint out of clothing, even if it be hard and dry. Saturate the spot as often as necessary, and wash out in soap suds.

Put a teaspoonful of ammonia in a quart of water, wash your brushes and combs in this, and all grease and dirt will disappear. Rinse, shake, and dry in the sun or by the fire.

If those who perspire freely would use a little ammonia in the water they bathe in every day, it would keep their flesh clean and sweet, doing away with any disagreeable odor.

Flannels and blankets may be soaked in a pail of water containing one tablespoonful of ammonia and a little suds. Rub as little as possible, and will be white and clean and will not shrink.

One teaspoonful of ammonia to a teaspoonful of water will clean gold or silver jewellery; a few drops of clear aqua ammonia rubbed on the underside of diamonds will clean them immediately, making them very brilliant.—*Scientific American.*

THE MODEL DUKE ESTATE, TAVOY, BURMA.

Dear Sir,—In your paper of the 5th instant I see you have written a long leader on "Exotics," which does your paper great credit, and will be read with interest by all those interested in new products.

But you have been led into a mistake by the report on the experimental cultivation in Mergui, which I shall be much obliged to you if you will correct. You say in your first paragraph that you cannot allow the fact of the first *Tea* being produced in lower Tenasserim, by the officers of the Forest Department, to pass unnoticed. Now, I beg to inform you that the 172 plants remaining in the Mergui garden were made a present of by me to the "Local Government," through Mr. Palmer, then in charge of the Mergui garden. I gave over 300 splendid hybrid plants to Mr. Palmer in July 1886, and the remaining 172, are what have succeeded to grow, with the treatment they have received since! In October 1885, I got two maunds of *Tea* seed from Seaforth, Ceylon, a place opened up and planted by me.

The seed was selected from the finest trees on Seaforth and forwarded on here by Sir Graeme Elphinstone to me, so that I knew I have the best hybrid that could be produced in India, as I myself got the Seaforth *Tea* seed from there. This I shall prove to you by facts.

All the same, the greatest credit is due to Mr. Palmer, and Capt. now Major, Butler, who first started the garden. Capt. Butler first started a small place on his own account, which drew the attention of Sir Charles Bernard when down there. Capt. Butler produced good tobacco, "Coffee Arabica," and had a few varieties of other products, which drew the attention of the worthy Chief Commissioner, and when he saw

what success Capt. Butler had attained, he gave a grant at once to start on Government account, on a small scale, so that Capt. Butler had a good 3 years' start ahead of me here.

When I came here Mr. Palmer took charge of the garden and took the greatest interest in it. I went down twice to Mergui, when he was in charge, and gave him advice what to do, which he carried out to the letter, and with good results. Mr. Palmer went down and lived for months in the garden and worked hard, for which I fear he never got the credit.

I went down last year and saw the garden: the oldest coffee was simply splendid and bearing a heavy crop. The gentleman in charge asked me to estimate the same, and I put it down at the lowest figure, viz. 8 cwt. per acre; but many of the trees were bearing a good round ton per acre. The trees had been neglected, and not handled out after last year's crop. Of course this means discredit to me one, as officers being changed so often, they do not know better. Planting, like anything else, is very simple when once you know it.

The Liberian Coffee is a decided success. I have trees here now 12 feet high and 27 feet in circumference, and loaded with a crop of fine bright Jolayan resembling a young Jack tree. I have planted up in all, in mixed products, 39 acres. I have Liberian Coffee, Tea, Divi Divi, Annatto, "Bixa Orellana," Oron Oil trees, Pepper Nigrum, Pepper Cubeb, Vanilla, Rubber of three varieties viz. Hevea, Ceara and the "Tavoy Rope Rubber," indigenous to Tavoy district, Cocea, and Jacks of three varieties, viz. Penang, hybrid and common. The Jack is a most valuable shade tree, as well as other value in itself, also mangoes of different kinds, oranges, lime and lemons, Leeches, guavas of 3 varieties, China and common plantains of 8 different kinds, also the China Banana, coconuts, and betelnut trees, now in bearing, Chestnuts just beginning to bear, fine large trees of a good kind, "Cotten" Pernambuco, or what is better known as "kidney cotten." One tree gave me over 3 lb. of produce this year! Cocea must have shade to be a decided success, but this will be overcome in time, as the soil and climate are perfection for all the products now enumerated. Tobacco I have grown from Sumatra seed, and produced a fine, delicate, well marked leaf. Indigo grows wild in the Tavoy district. Cardamoms also grow wild here. This shows that the Tavoy district is to be the "Eldorado" for planters. Silvestre, formerly Editor of the *Indigo Gazette*, while down here prospecting, found the indigo plant growing wild near Niadoung and brought some in and manufactured a small piece. He took the same away with him. Silvestre came here to prospect, which I hope to hear more of it soon.

Coffee, Liberian, is to be one of the greatest successes in this district, and Tea, and Cocea, also Arabian Coffee will grow at higher elevation. I never predicted, or said that Arabian Coffee would succeed at a low elevation, and it is only a matter of time and a selected variety from India, Mysore. To gain this end we only want roads up the mountain sides. I planted about 7 or 8 acres with Arabian Coffee here, but of course I had not sufficient elevation. It grew fine. I got the seed from Mr. Petley in the Teungoung Hills, so that I might be clear of leaf disease. It gave a good crop, in fact too much the second year, and then went out. I sent home a hundredweight in 1887 to Mr. Marlin Leake in London, and it was well reported upon and sold at a fair price.

You will see by this, Mr. Editor, some of the difficulties a planter has to contend with in the beginning in a new country. No one has any idea of the many losses and disappointments one has to contend with at first, even to get seed in a fit state to plant, often rotten before I saw it, seed sent on to Calcutta, from Calcutta to Rangoon, and from thence to here, and often delayed en-route.

When the thing is once set agoing there's no more such risks and losses.

The pioneer has the great battle, and should he not succeed in all, he gets all the blame and lots of kicks behind his back. They do not come forward

as honest men and argue the point. It is also hard to do any business with men that do not know the work to be done. No man can make a silk purse out of a sow's ear; money must be first sunk and wait patiently for returns. Coffee and tea planting are not like a crop of potatoes, more especially in a new country. *Exotics* must be acclimatized, and it takes longer in a new country for a new product to the country to come into full bearing. This is clearly shown by the Liberian coffee in Mergui, the same coffee only in full bearing in Mergui planted 3, or you may say 4 years before mine here from seed. People ask me of course—Where is your coffee, where are your returns, is the thing a success? This is the sympathy one gets as a pioneer. What is that *fe-l-l-o-w do-o-ing* down there; is he a planter I wonder or what? Well, I fancy I know the ropes now. But in this climate and with such strong soil, the Planter has nothing to fear; only he must be prepared to wait for returns longer, than one would do in a poor but forcing climate. Coolies will flock to Burma whenever the demand comes. No fear of labour, none in the least. I have a command of labour ready at my call at any moment. Why rice here is only one *half the price in Ceylon*, now only Rs 1.12 per basket, a basket about the same as a bushel, and in Ceylon rice is never cheaper with the planter than Rs 4, and it is impossible to predict a famine here although one had to get rice from Moulmein and carriage to the estate at a distance, it would never overreach Rs 3 here on an average. "Curry-stuffs," fish and fowls, and all necessaries are only about half the price from that in Ceylon, and the district is a healthy one. Opening up new land, of course, is not healthy for a short time, but much can be done by the planter to prevent sickness; all depends on good pure water and an elevated place for their habitations.

Besides, the Burmans work well when one once knows well their ways and treats them kindly and does not bully them. Jack Burman won't stand bullying; he has some pride in him. This is a good part even in poor despised Jack Burman, and he delights to work in the rain, and keeps in good health. I have sometimes as many as 200 working at one time and never had trouble with them in their work. Women and boys get annas 3 per *diem*, the rest 6 annas, and I could get hundreds.

Money is only wanted; all the elements are ready at hand, and coast coolies are ready to be called to Burma at any moment. Labor gives me not a thought. I see and know the way. Labor Laws, of course are much wanted for all Burma, but then you have to go to "India" to ask for this. This will come straight in due course.

Planters have nothing to fear here; I have received the greatest kindness and consideration from all the heads of the different departments, from Sir Charles Costhwaite downwards; they are as good a set of men as could be found in any other part of the world, and ever ready to give assistance and information as far as lies in their power, and Burma will 'hang fire' until power is given to the Head administrators, not only to the Chief Commissioner, but Governor of Burma or Lt.-Governor with power to act on the spot. I have not the slightest doubt but that this project is near at hand, and then Burma will move forward quickly and staunchly.

I trust this long letter will not weary you, and I shall be much obliged to you, if you do not put it into your waste, paper basket or give it over to your Devil.

I remain, Dear Sir, Yours Sincerely,
JAMES D. WATSON.

4th September, 1890.
—*Rangoon Times.*

A METHOD of clearing forests by poisoning the trees has been introduced in New Zealand. An auger hole is bored into the trunk, and filled with a chemical composition, of which the secret is guarded. In two or three months the tree dies and rots, so that it can be easily removed. In one of the trials recently made no fewer than 700 acres were speedily cleared by this plan, but of course, with the loss of the timber.—*Globe.*

THE largest wheel in the world is being constructed by the Dickson Manufacturing Company, of Scranton, Pennsylvania, for the Calumet and Hecla Copper Mining Company, of Lake Superior. It is intended to lift the "tailings," or waste, from the mines of the company, and discharge them into the lake. The wheel is 54ft. in diameter and weighs 200 tons. On its rim are 448 steel buckets, which catch up the "tailings" as the wheel revolves. The velocity of the wheel at its tyre is 600ft. per minute, and it is capable of elevating enough sand in 24 hours to cover an acre of ground with a layer 1ft. deep.—*Globe.*

RECENT experiments by M. Georges Ville at Vincennes, and communicated to the French Academy of Sciences, show very clearly the value of nitrogen in manure for promoting the growth of vegetables. Plants grown with manure containing nitrogen were taller, heavier, and of a darker green than those grown in manure without nitrogen. The same plants grown in earth without manure were conspicuously dwarfish and feeble. The general result of his experiments is that the nature of the soil affects the plant in height, and shape, and colour, as well as in weight of the harvest. With regard to the question of height, it has long been known that Jersey cabbages require a particular soil in order to become very tall.—*Globe.*

WHEN Darwin and other naturalists made their experiments with so-called carnivorous plants, the importance of micro-organisms was not realised, and hence their results are questionable. In 1875, M. Edouard Morren investigated the behaviour of the *Pinguicula* and *Drosera*, and arrived at a conclusion quite different from the opinions of Darwin on these interesting plants. Another series of experiments on the *Nepenthes* has been undertaken by M. Raphael Durbois, whose results have just been communicated to the Académie des Sciences, Paris. Sir Dalton Hooker considered that the carnivorous attributes of the *Nepenthes* was beyond a doubt, but M. Dubois has found reason to differ with him. His observations were made on a great variety of these plants at the botanical garden of the Tête d'Or, Lyons, for example the *N. Rafflesiana*, *Hookeriana*, *coccinea*, *phyllanthophora*, *distillatoria*, *hybrida*, and *maculata*.—*Globe.*

"A WAIL FROM FOOCHOW" might well describe the following which we find in the *N.-C. Herald* of Ang. 22nd:—

From Foochow we have the following tea news, under date the 16th instant:—The shipments during the past fortnight have barely reached a million of lb. The calling steamers have been the "Palamed," "Ajax" and "Peking." The export to London and the Continent stands today at 10½ millions against 11 millions last year and 17½ millions in 1888. The tone of the market remains quiet. The settlement of 21,000 chests Congou for two weeks is again very small; and, but for the demand for Australia, it would have been very much smaller, as the telegraphed advices regarding Foochow Congou in the London market are sufficiently bad to cause a stoppage of shipment to that quarter altogether. Souchongs have continued in demand and there has been some business in Oolongs and Scented teas. Comparing the latest prices paid with those ruling a fortnight ago, there is no change of importance to note. Tael prices, as lately remarked, are low; but the laying down cost, with the high exchange, is too near London quotations while that market is reported as declining. And in some cases costs are distinctly above Mining Lane prices; common teas for example are Tls. 5 or 5½ here, and in London only 4½ to 4¾ per lb. As the inanimation in this market grows more prolonged, so the estimates of the total supply for the season become smaller. Whereas a fortnight ago a total approaching 380,000 chests was thought likely, 360,000 chests is now looked upon as the probable season's supply. The settlements of Congou to date are 177,000 chests. For the corresponding eleven weeks after the opening of the market last year 274,000 chests had been settled, and during the same period in 1888, 336,000 chests. The stock of Congou today is 156,000 chests against 168,000 chests last year, and 13,000 chests in 1888.

PLANTING IN CENTRAL AFRICA.—An ex-Ceylon planter now in Queensland writes that a relative—a trained arboriculturist—has just gone to Mandala near Lake Nyassa under an engagement to the African Lakes Co., to conduct experiments in the growing of tropical products. Mandala and Nyassaland have one of the finest climates in the world. "The Moirs" have already a flourishing coffee plantation there.

NUTMEGS.—The cultivation of nutmegs in New Guinea is described by one who has witnessed it as a very interesting progress. The aroma of the nutmeg is so penetrating as to make the country for a long distance delightfully fragrant. The trees grow luxuriously and the fruit resembles a pear. When it ripens it opens and displays the nut with its beautiful red coating of mace. At this stage the nuts are picked off and carried in baskets into the house, where they are husked and put on shelves. Then they are partially roasted over a slow fire until all the moisture is extracted. Afterwards they are cooled and carried to the village in nets to await the traders. The nutmeg grows in perfection in the West Indies and Brazil, and may some day prove to be a valued product of some sections of this country.—*Madras Times*.

THE MUTURAJAWELLA PADDY FIELDS.—Mr. de Mel's scheme to irrigate and successfully cultivate the fields at Mutturajawella is now an accomplished fact. Harvest operations have already begun, and the work is now in full swing. A good quantity of the paddy has turned out *Bol* or devoid of seed. This was due to the want of rain during the ripening season (July). The enterprising and genial proprietor of the fields, it is to be regretted, is unable to be present at the spot during the harvest owing to illhealth. Mr. de Mel is still confined to his room with an attack of fever, which he contracted soon after his return from Rakwana, whither he went in company with Mr. Oheysekere, as Directors of the Ceylon Gem Mining Company, Lionited, to report on some Gem lands. It appears that during the journey both up and down the weather was very wet, and Mr. de Mel was considerably exposed to it. He caught a chill then, and is still suffering from its effects. Under Dr. Garvin's able treatment, we trust Mr. de Mel will be quite well before long.—*Cor., local "Examiner."*

ORIENTAL COFFEE COMPANY.—The fourteenth annual meet'g of the shareholders of the above-named Company was held on Thursday week at the offices, No. 32, Great St. Helens, E.C., under the presidency of Mr. John Young. The Chairman moved the adoption of the directors' report and statement of accounts. The board expressed regret that the year's working had proved less favourable than was expected at that date of last meeting. The monsoon, then prevalent, proved abnormally heavy, rain and gales having been experienced for four months almost without intermission, doing much injury to the crop, which turned out only 53 tons 2 cwt. The deficiency, however, was to some extent compensated by higher prices, the average reached being 92s 3d per cwt., against 86s 9d the previous year. The balance sheet showed a net profit for the year of £660 16s 3d, and an available balance at the credit of profit and loss of £974 7s 5d, out of which the directors recommended the payment of a dividend of $\frac{2}{3}$ per cent, carrying forward £224 7s 5d to next year's account. The recent rise in the price of silver and rates of exchange affected the result of the year to some extent, and would, so long as it lasted, be very prejudicial to the planting interest. The prospects of the coming year had unfortunately been much affected by the unusual season above mentioned, rain having continued close up to picking time, and delayed it beyond the usual period, not giving the trees time to recover themselves before the blossoming season. The superintendent advised that he could hardly expect the coffee crop to be better than the last, and in this respect the district would be more favoured than Wynaad, where the crops were the most disastrous ever known. So far as could be judged at present, the prospect was in favour of higher prices than last year.—*Home and Colonial Mail*, Sept. 26th.

BANANAS.—The *Panama Star and Herald* says:—"We have received from New York a tabulated statement of the banana trade during 1889 between Central American and West Indian ports and the United States, which is full of suggestive interest to all who are following the development of this trade. Taking the New York branch of the business, which is the largest, we find that the total imports for the year aggregated 3,639,593 bunches, to which Jamaica contributed about one-third, or 1,346,062, whilst Colon only sent 216,528. The other shipments were as follows:—From Baracoa and Banes, 1,190,478; from Port Limon, 609,798; from Honduras, 276,727. The New Orleans banana trade for the same time was as follows:—From Honduras, 1,867,429; from Bluefields, 563,382; from Port Limon, 376,401; from Boca del Toro, 135,946; from Jamaica, 2,900—total, 2,946,058. Boston received during the same time shipments from Jamaica and Baracoa amounting to 1,292,946 bunches, whilst Philadelphia from these places and Bluefields received 853,183 bunches and Baltimore 358,294, making the entire annual importation of bananas to the United States 9,090,074 bunches, plus another 100,000 bunches estimated for other ports not specified in the statement."—*Colonies and India*, Oct. 1st.

THE MAGAZINE

OF

THE SCHOOL OF AGRICULTURE,

COLOMBO.

Added as a Supplement monthly to the "TROPICAL AGRICULTURIST,"

The following pages include the contents of the *Magazine of the School of Agriculture* for November:—

VEGETABLE MANURES AND CHEAP FERTILIZERS.

VEGETABLE manures, like cattle manure, contain all the ingredients of ordinary crops, and hence may be called general manures, though they are more slow-acting than cattle manure, and contain a larger percentage of water. They may be applied alone or mixed into a compost with cattle manure. Many of them contain an excess of nitrogen, and are sometimes classed under nitrogenous manures. The action of green manures may be said to be three-fold: they act mechanically, rendering the soil more open; they supply humus; and lastly, they act as true manures, contributing the soluble ingredients of plant food to the soil. The value of vegetable manures depends on the kind of plant as well as the part of the plant used. When crops (such as the legumes) are ploughed directly into the land upon which they are grown for the special purpose of supplying a green manure, it is as a rule advisable that they should be taken out of the land just before flowering, as at this stage they contain the maximum of valuable ingredients in leaf and stem. For green manuring by burying in the whole crop, rapid-growing plants are most suitable. Sometimes the crop-residue only is used after the harvesting of the crop, and in the case of leguminous crops it has been often found that the root-system is equal in weight to the weight of the crop above ground. The roots of this order

of plants when buried in the soil have a very beneficial effect on poor soils. Whatever may be the doubts that exist as to the exact manner in which the leguminosæ improve the soil by accumulating nitrogen in the land, that they do so, and that the ploughing in of them or any part of them improves the condition of soils, there can be no doubt of. Where the crop grown on the land is ploughed in, the main advantage derived is that the ingredients of plant food are collected and placed in a proper position and condition in the soil. Where, however, the green crop is transferred to the land, there is a distinct importation of plant food into the soil.

Peat is useful for soils deficient in organic matter, good dry peat containing about 1 per cent. of nitrogen and from 5 up to 20 per cent. of mineral matter, which contains fair proportions of phosphoric acid and potash. Peat decomposes very slowly, and is best composted with lime. It is sometimes charred, and the residue used as a fertilizer either directly or after absorbing liquid manure. The charring process, however, causes the loss of almost all the nitrogen. Peat often contains injurious ferrous salts, and hence it is a good plan to treat it with lime before applying it to land.

Coconut husk should be applied in as fine a state of division as possible in the form of coir dust. The so-called coir dust as supplied from mills is often found to consist of husk for the most part in a long fibrous condition. It contains from 2.5 to 5 of nitrogen and a fair proportion of mineral matter. Coconut fibre is a good mechanical agent and a splendid absorber and retainer of moisture.

Tanner's bark, owing to its hardness and thickness, decomposes with very great difficulty, and is therefore best applied after burning in spite of the loss of nitrogen which results.

Sawdust has little value as a manure since it is so slow-acting, though it is a good mechanical agent and an excellent absorbent. It should form a good medium for taking up the ammoniacal liquor of gas-works.

The leaves of trees may be said to contain nitrogen from .5 to 1, phosphoric acid .1 to .5, and potash from 1 to 3 per cent. They are either ploughed in directly or first composted. Some of the trees of which the leaves are used among native cultivators in the villages, are *Cerbera Odallam* (Sin. Kuduru), *Taprosia Purpurea* (Sin. Pila), *Croton Lacciferum* (Sin. Keppitya), *Pongamia Glabra* (Sin. Magulkaranda), and *Callicarpa Lantana* (Sin. Illa).

Sea-weed is another form of vegetable manure which was at one time much in vogue. In some soils it has been known to double the produce, and its use in potato cultivation is still kept up in Ireland, while in our own Island it is favoured in the Northern Province. In the Channel Isles there are certain restrictions placed on the collecting of sea-weed. The great objection to sea-weed is the large percentage of water (about 90 per cent.) it contains. It is found to consist of from 5 to 10 per cent. of mineral matter, the rest being organic matter which yields from .2 to .5 per cent. of nitrogen. Sea-weed, if heaped moist, decomposes tolerably readily, and is, where at hand, used with advantage for improving poor soils. Shells are generally composted with the weed, and this addition slightly increases the proportion of phosphoric acid and nitrogen derived from the remains of animalculæ in the shells.

Straw improves the mechanical condition of heavy soils, but decomposes exceedingly slowly, and is of little value as a manure. It is best used in the form of litter after having soaked in the liquid manure in cattle sheds or stables. Composts formed of the store of all refuse matter on cultivated land are of much value, and should be found on every property. These composts should be kept moist, but care should be taken that an excess of water should not be added. The heaps must not be allowed to become acid, as by this putrefaction is prevented: hence lime should be added which also promotes nitrification. Liquid matter must not be allowed to escape from the compost heaps which should be protected from the weather. Liquid manure and urine generally, as well as blood, are useful in soaking the heaps. The various forms of cakes used as manure, though coming under the head of vegetable fertilizers, are generally classed as nitrogenous manures.

OCCASIONAL NOTES.

We have on more than one occasion referred to the carelessness of cattle-owners in taking no precautions in times of diseases, to prevent their animals falling victims to fatal disorders. During the late outbreak of murrain along the Cotta road, the owners of cattle continued to allow their animals to wander about and pick up grass wherever they could find it, only bringing them home in the evening to be tethered to trees in the open air. Within a very small area in the vicinity of Borella some 70 animals died from murrain, and yet the cattle-owners in this part were making no attempt at segregating their

stock. Though they were glad to accept or pay a limited sum for disinfectants, they objected to incur the small expenses of erecting sheds for the cattle to be kept and disinfected in. It is just here that the need is felt for Government interference through inspectors who should see that village cattle are not allowed to wander about in times of disease, or indeed at any time. In another column we note the restrictions which are placed upon the grazing of cattle on Government land in the Madras Presidency. The efficacy of disinfectants and other preventative methods (the only means of saving the lives of cattle exposed to contagion) has been amply demonstrated in the case of the cattle at the School of Agriculture escaping when murrain was raging all around them. A large cattle-owner in the vicinity of the school was unfortunate enough to have the disease imported among his herd, and lose some valuable animals, but judicious management even after murrain had gained a footing among his stock, was the means of effectually staying the plague. A poor milk supplier, who lost his herd of six cows, hesitated up to the last to lay out less than the value of one animal in erecting sheds and purchasing disinfectants. It is hardly credible that such conduct is the result of laziness which prevents these men from feeding their animals in their sheds instead of letting them loose to pick up their own food, and attending to both animals and sheds in a proper manner. It is rather the result of ignorance which engenders doubt as to the efficacy of disinfection and segregation in contagious and infectious diseases; and the evil results of this ignorance can only be minimised by enforcing some such measures as are adopted in the case of contagious and infectious diseases in man.

Professor Shield Nicholson, who was lately discovered to be an aspirant to literary fame, is Professor of Commercial and Political Economy and Mercantile Law in the University of Edinburgh, and author of "Tenant's gain not landlord's loss, and some other economic aspects of the land question." Professor Nicholson is a young man of a modest disposition, and a favourite among the students. About two years ago the Professor inaugurated a short course of lectures on Economics as applied to agriculture in connection with the agricultural curriculum at the University. He is a fluent speaker and a clever exponent of his subject.

"Trade Prospects in the United States" and "A Central Normal School of Agriculture" are the titles of two short pamphlets published by Professor Wallace of the Edinburgh University. The former is reprinted from the *Glasgow Herald* and the latter from the *Times*. In the one the Professor declares that the breakdown of the protective system in America is at hand, and goes on to show that a declaration of free trade by America would prove to be the most unfortunate event that England has seen for the last half-century. In the other he demonstrates that a Central Normal School of Agriculture will turn out a most expensive concern for which there is no necessity whatever in Great Britain. We hear that the Professor's new book on Australia will be published shortly.

INDIGENOUS FOOD PRODUCTS
CULTIVATED AND WILD.

BY W. A. DE SILVA.

31. *Bryophyllum, Calceinum*, Salisb. Sin.
Akkapana, Embulbovi or *Ratagowa*.

This is a succulent plant which grows in all parts of the Island up to high elevations, and it is a weed found both in cultivated and uncultivated places, growing to the height of from 3 to 5 feet, and bearing panicles of peculiarly-shaped flowers. Its stem is round, thin and green, and its interior is filled with a succulent pith. Prominent scars are left at the places where leaves are broken from the stem. The leaves are thick and succulent, of an elliptical shape, and having crenulated margins which are of a brownish red colour.

The flowers, which are borne in large panicles, have a light greenish-coloured long tubular calyx having a beautiful delicate appearance. Before opening, the whole flower is enclosed in this calyx. The corolla is of a deep red colour, and the flowers contain a sweet nectar.

The leaves of this plant give out buds from their margins, and hence it propagates and spreads very quickly. The hardness and the ease with which these buds come up are so marked that even a leaf plucked from a plant and nailed to a wall gives out small plants.

The leaves are of a sub-acid taste and are used in making salads as well as curries. The name *Ratagowa* has evidently been given to this plant, as its leaves are edible like that of the common *gowa* (cabbage).

Myrtaceae.

32. *Eugenia Aquea*, Brum. Sin. *Jambu*.

This is a tree commonly met with in the Island up to a high elevation. The trees attain somewhat large dimensions. The stem is thick and round, and like most dicotyledonous trees it is much branched. The leaves are lanceolate, long, and dark green, with entire margins; and they have an acid taste. The flowers are large, often purple, and contain a large number of stamens arranged in the fleshy calyx. The fruits grow to the size of an egg, and are white when unripe, but attain a reddish hue when fully ripe. The pericarp is of a fleshy nature and covers a seed the size of an ordinary marble. The fleshy pericarp is of an acid taste when raw, but the ripe fruits have a sweetish sour taste. The fruits are much eaten, and the flowers and sometimes the young leaves are also eaten by children. The fruit makes a very good preserve.

The juice of the green leaves of this plant is used in cases of dysentery by native medical practitioners, while the bark is also employed in making decoctions.

33. *Eugenia Zeylanica*. Sin. *Maranda*.

Is a medium-sized tree growing in the hot drier parts of the Island. This is very commonly met with in cinnamon land. The tree is much branched, and the leaves are lanceolate with acute apices and entire margins. The young leaves are pink-coloured and give a very pleasing appearance to the trees. The flowers are small with glandulose calyces, and the fruits are about the size of peas, and white. The pericarp is fleshy and has a sweetish taste. This is generally eaten

by boys. Except for this trifling use this plant can hardly be classed as a food product.

34. *Eugenia Caryophyllata*, Wight. Sin. *Dan*.

This is a common shrub growing up to an elevation of 3,000 ft. It is generally met with on the sides of ditches or rivers, or in marshy places. The shrubs grow from 6 to 10 feet in height, and are covered from the base with branches. The leaves are elliptical with a prominent midrib of slightly dusty colour. The fruits are borne in clusters and are a little larger than peas; they are green and hard when unripe; but the ripe fruits are soft and jet black, and when bruised give a violet colour. These fruits are eaten, and in some places they are even sold in markets. They have a slightly astringent sweetish taste.

The bark and leaves are occasionally used in native medical practice.

35. *Eugenia Jambolana*, Lam. Sin. *Madan*.

This is a tree growing in the drier parts of Ceylon. It grows to a medium size and is generally common in cinnamon land, and land containing fine soil. The trees are much branched on the top. The leaves are green with prominent nerves, and are leathery, entire, and of an elliptical shape. The flowers resemble the other myrtaceous plants. They bear oblong fruits about double the size of an ordinary pea. These when raw are of a green colour, but when ripe they become jet black, giving a deep violet colour when bruised. A single tree bears many bushels of these fruits in a season which are relished much. They have a sweetish aromatic taste. During the season they find a way into the markets. The timber of this tree is hard and elastic, and is used for various purposes. It is said that it has been successfully tried as railway sleepers, and there is a movement on foot to plant them extensively for this purpose in Victoria.

The bark contains a good deal of tannic acid, and has proved to be a good tanning material. The bark and the leaves are used medicinally by the native practitioners of Ceylon. It is stated that some German physicians have found out some remarkable properties in the seed, which has proved to be a remedy for diabetes; and experiments are being made to test its value as such more fully.

CEYLON BEE CULTURE. VI.

BY ABA.

Since writing my last article on the above subject, I was agreeably surprized to read in the *Ceylon Observer* a very interesting account of the domestication of the Bambara by Mr. J. Holloway of Wategama. That gentleman says that a swarm of the Bambara lived for months in 1883 in a hive sent out from Germany and kept in the verandah of his house. He also mentions a very nearly successful attempt to import the Bambara into Germany, where it is said that a colony of this bee would be worth £50.

The fourth species of Ceylon bee is the *Kana Veyiya*, a tiny bee belonging to the Trigona. This insect produces only a small quantity of honey, of rather an acid taste, which is used in native medicine. The combs are about 4 or 5 inches in circumference, and are built in the hollows of trees, crevices of rocks, buildings,

&c. The wax is dark-coloured and softer than ordinary bees wax. The bee is stingless.

So much for the different species of bees found in Ceylon. Now we come to consider about the cultivation or management of bees. The first thing necessary to be done in the formation of an *apiary* is the providing of a stock of bee-hives. As to the form and the materials out of which hives should be made opinions differ very widely both in theory and practice. In England hives made of either straw or wood have always been found the most profitable for bee-keeping, but those who wish to observe the movements of the bees employ glass hives or hives provided with glass-windows. Hives made of wood are neat in appearance and more durable than straw ones, but it is said that unless they are protected from the sun, the combs are liable to get melted and fall off. Earthenware hives are said to be in use in Turkey and Greece, and in our own country, as my readers are aware, a useless earthen pitcher or pot is the only hive provided for a swarm of bees to settle in.

The form of the hive may be of any shape, but it is important that there should be sufficient room provided for building combs, &c.

At the Fairfield Apiary, Mount Barker, Australia, where they have more than 200 hives, the hive in use is the "Standard Langstroth," an American pattern, simple in construction and producing good results.

(To be continued).

NOTES FROM A TRAVELLER'S DIARY.

The country beyond Wahakotte is comparatively free from hills, and the villages are scattered irregularly amidst vast forests of timber trees. Each village has its own tank and grove of coconut palms close to which the dwelling houses are built.

On my visit to the famous rock-cave at Dambulla, my attention was drawn to the continual drip of water into the cave from a crevice in the rock. The water appears to be of the purest description, and is collected in an earthenware vessel left for the water to drip into. This water is reserved for the use of the priests.

Palugaswewa, where I made a halt, is about 20 miles from Dambulla. The village has its tank and a large tract of paddy land; but owing to a prolonged drought I found the tank dry, while the fields had been uncultivated for 3 or 4 years. From this place the Ritigala rock, reported to have been the Sanitarium of the Native Rajas who reigned in Anuradhapura, is visible. The summit of the rock is said to be occupied by some ruins as well as by the King's Garden.

I touched at a place called Andiyagala, where I heard for the first time of the experimental cultivation of potatoes in the North-Central Province. The schoolmaster of the place first experimented with potatoes on a very modest scale. He took only a single tuber, and having divided it into four sets, planted them during the rains of December. The plants came up well, and after 4 months, tubers to the weight of half-a-

pound were dug up. The soil is rich in these parts, but the great want is rain. Arrowroot ought to be grown very successfully here, but up to now paddy and kurakkan are the only crops cultivated by the natives.

At Palugaswewa I saw for the first time the process of extracting lime from the kumbuk tree (*Terminalia glabra*). There is no limestone from which to obtain lime in the neighbourhood, and lime is much needed for chewing with betel. About two baskets of the ash of this tree give one of pure lime. The ash is obtained by burning the stem and then sifting the residue to remove any impurities that may be mixed up with it. Next a paste is made by mixing the ash with the juice of the Hinguru plant (*Acacia concinna*), and also that of the keliya (*Ircia microcos*). The paste is dried into balls, or cakes like cabin-biscuits and burnt in a heap of dry cowdung either by placing in coconut shells or after wrapping in plantain leaves. The heaps of dung are sometimes made so large that they continue to burn for over 8 hours. The residue from this second burning is put into hot water where it remains for several hours. The water is afterwards poured off and the residual is lime. This lime is mostly used for chewing with betel-leaf, but in one place I actually found a house whitewashed with it.

THE CULTIVATION OF TOMATO.

(*Lycopersicum Esculentum*.)

By W. A. DE SILVA.

The tomato or the love-apple is a native of America, and was introduced to Europe at an early period; from Europe its cultivation as a garden product has extended to the Eastern countries.

It is at the present day grown to a large extent in Southern Europe as the climate is favourable there; and as the demand is great both for daily use and the manufacture of preserves it has become a paying crop.

The tomato is one of the common foreign vegetables grown in Ceylon both in the lowcountry and the cold hilly districts. The demand is fairly large, as all classes are fond of this fruit.

There are a great number of varieties of the tomato, known under different fancy names which are given to them by gardeners, and particularly by seedsmen; but the varieties which can be grown with advantage in Ceylon are those known as "the large red," "the yellow," and the "red currant." The last-named variety bears small oblong fruits, and the plants are hardy, grow well and produce abundantly, the only objection to this variety is the smallness of the fruit.

The first two varieties, the red and the yellow, grow well and also produce good crops. These two varieties are generally the favourites of the cultivators.

There are also varieties of tomatoes producing very large fruits, for instance 'the giant red' producing fruits weighing from 4 to 6 lb., but such varieties are not adopted for general growth as they produce very few fruits.

In the cultivation of the tomato the seeds have to be first put in a nursery. It is very important to test the germinative properties of the seed by growing a few first, and then putting down a quantity to obtain sufficient plants.

A flower pot or some vessel filled with fine earth and well-rotten dung would form a suitable nursery. After sowing the seeds they should be kept in a place not exposed to vertical rays of the sun. The nursery should be daily watered and weeded. The plants will be ready for putting down in the land, in three or four weeks.

The land should be well prepared by weeding, digging and levelling, and holes should be made three feet apart for the ordinary variety. These holes might be manured with well-rotten dung, ashes, &c. Care should be taken not to apply unfermented manure in the cultivation of tomatoes as such manure has a tendency to spoil the crops. The young plants should be carefully planted in these holes and watered daily when there is no rain. As the plants are growing the land should be carefully weeded, and the earth near the roots should be loosened once a week or so. When the plants grow to the height of about one and a half to two feet, sticks ought to be planted around them, so that they may grow erect.

A dressing of manure as before should be applied, when the plants have grown for a month or six weeks in the garden. In two months they show signs of flowering. All plants should be pruned above the third branch of flowers so as to obtain good fruits. The side shoots should always be suppressed and a single stem aimed at. The pruning and the suppression of the side shoots preserve materials which otherwise would be wasted in the formation of useless leaves and stems, for the formation of fruit.

The application of liquid manure to the plants at the fruiting stage helps to increase the crops. Liquid manure for this purpose may be advantageously prepared from any dung, or a mixture of dung and bone dust. In order to prepare the liquid manure, the dung should be kept in a vessel, with as sufficient water to keep it in a semi-liquid state for two or three days, so that it may ferment. A pound or two of dung thus prepared may be mixed with a can of water and applied to the plants.

It has also been found that a dressing of saltpetre mixed with earth applied to the plants makes them bear well. A pound of saltpetre reduced to powder and mixed with dry earth is sufficient for applying to a hundred plants.

The tomato, like all other plants, is subject to disease, and it is a pitiable sight to see a plant which was vigorous the previous day, drooping all its leaves and dying off, with flowers, buds, and young fruits on it. This occurs owing to an excess of moisture in the land. With well drained gardens and the occasional loosening of the soil to remove the excess of moisture this could be prevented.

As a food product the tomato is well known, while it is also believed that it possesses certain medicinal properties.

WAYS AND MEANS.

No insect can live under the application of hot alum water. It will destroy red and black

ants, cockroaches, spiders, bugs, and a whole host of others. Take two pounds of alum and put it in three or four quarts of boiling water; let it stand over a slow fire until the alum is all dissolved, then apply it with a brush while nearly boiling hot to every part of shelves, closets, &c., where you suspect vermin to harbour.

A mixture of copperas and glue will protect trees from rats and mice.

Half-a-pound of Paris Green or London Purple to fifty gallons of water is sufficient. It needs to be kept stirred while being sprayed, otherwise the poison will sink to the bottom, as neither dissolves in water except to a slight degree.

The French say that when a large onion is planted by the side of a rose tree in such a manner that it shall touch the root of the latter, it increases the odour of the flowers. The roses thus produced will have, they say, an odour much stronger and more agreeable than such as have not been so treated, and the water distilled from those roses is very superior to that prepared by means of ordinary rose leaves.

The green ears of maize or Indian corn form a most delicious vegetable. The cobs should be plucked just as the styles, that elegant silky-looking appendage to the ears are beginning to turn brown and wither. The corn is then of a delicate cream colour. The cobs are stripped of their covering and boiled for about three quarters of an hour, and eaten with a little butter, pepper, and salt.

Tobacco water for killing insects, &c., is made by putting a pound of tobacco into four gallons of boiling water, and placing the vessel over a slow fire where the water will continue warm for some time.

Plants cannot live indefinitely deprived of their leaves. Hence preventing their appearance above the surface will kill them sooner or later.

Plants have greater need for their leaves, and can be more easily killed in the growing season than otherwise. Cultivation in a dry time is most injurious to weeds and beneficial to crops.

Avoid the introduction of weeds in manure or litter from weedy surroundings.

After a crop has been reaped, instead of allowing the land to grow up to weeds it is often well to sow some crop to cover the ground and keep them down.

Give every part of the farm clean cultivation. If the ground is kept well occupied with other crops, weeds will give much less trouble.

Keep meadows and roadsides well weeded.

THE POULTRY YARD.

BY ABA.

Poultry Keeping and Management.

The advantages of poultry keeping are very great, as most of my readers know, and if one has the time to take good care of fowls, they can be made as profitable as any other business. It is, however, very foolish to suppose that immense profits could be made by keeping fowls, and those who have started with this idea in mind have very naturally met with disappointment and given up poultry-keeping in disgust.

In poultry-raising as in many other kinds of business, a strict attention to details is necessary in order to insure success. The poultry-keeper

must take an interest in his fowls; he must be on the look-out to see what they lack in the way of comfort, and supply that lack; he must be thoughtful for them. A thoughtless, careless person is less likely to succeed in this business than in many another.

There are few households, except in the most densely-populated parts of our towns where a greater or lesser number cannot be kept with advantage and profit. I do not advise my readers to keep fowls under conditions rendering life a misery to the poor creatures, and a discomfort, if not a positive danger to the health of their owners as is sometimes attempted; but in connection with a great number of town houses, room can be contrived for a few.

Fowls in confinement require more care and attention than those that have their liberty, and in those cases overcrowding should be specially guarded against. In small runs the number of birds kept must be limited in accordance with the available space, but where they have an unlimited range a much greater number may be kept, and at a cheaper rate, as they find for themselves much necessary food when allowed to roam about, but even here overcrowding under the most favourable circumstances must be avoided for fear of bringing on contagious disease as chicken cholera, &c.

Perhaps the greatest blunder the ambitious poultry-raiser can make is trying to raise too many fowls. Because a farm contains a hundred acres, the owner may think that he cannot overstock it with poultry, and so try to raise from five hundred to one thousand fowls. Where fowls have unlimited range they will go quite a distance in search of insects. About a quarter of a mile, however, is the limit of their wanderings, and when fowls are left to their own inclination they will separate in flocks of perhaps a dozen to each flock. This should teach us a lesson. We can learn many lessons from nature, and in their natural state fowls never move in large numbers while foraging, and would not at any other time if they could have their own selection of roosting places. But the owner thinks to economize in space and material, and will crowd a hundred into one house, and then wonder why they get sick.

Poultry-raising on a large scale will not succeed from year to year on a small area. Even on a large farm each flock of twenty-five fowls should have its separate roosting-place. They will manage for themselves during the day if allowed their freedom. Plenty of range is absolutely necessary to the well-being of fowls, all the advice to townspeople to keep a few fowls to the contrary notwithstanding. Fowls may do well awhile in a cramped city cot, but time will prove that it cannot be successfully continued from year to year. Besides, the keeping of poultry in cities only adds much more impurity to the air where too much cleanliness cannot exist if we have any regard for human healthfulness.

HEREDITY AND SEXUALITY.

According to M. Kiener of Haute-Alsace, heredity influence is controlled by two factors—the parents whose characters are transmitted to the offspring, and the environment, which aids in moulding or modifying the latter. As an instance of the influence of environment is

mentioned the difficulty of replacing a local race or breed by an imported one. The imported stock becomes gradually modified and assimilated in character to the local race, though by the exercise of care and selection on the part of the breeder the original characteristics may be preserved. It is inexpedient, thinks M. Kiener, to mate together large sires and small dams, whilst it is beyond question that the use of small sires upon large dams has yielded excellent results. Many examples are quoted to show that neither of the parents enjoy a monopoly in the transmission of characters. In other words the offspring may derive its peculiarities from either parent, or from both parents. Thirty years' observation has convinced M. Kiener that the milking propensity, for example, is quite as transmissible through the male as through the female line, and, in view of the large number of offspring of one bull as compared with those of one cow, he argues that the milking aptitude is preferably propagated through the male. He adds that bulls of good dairy character are distinguished by the possession of fairly developed teats. Ancestral influence is undeniable, though under what combination of circumstances it is most likely to manifest itself it is difficult to say. The influence of the male in close in-and-in breeding is of the highest importance; and many striking instances are given in proof of this statement. For the transmission of hereditary disease it is not necessary that more than one of the parents should be the medium. The experience and observations of many years has led M. Kiener to the conclusion that it will never come within the capacity of the breeder to control the sex of the offspring, though some consider that more than one circumstance can be made to rule the sex and cite instances in proof of their theories. The age of the parents does not appear to M. Kiener to exercise any influence on the sex, and he considers that the more robust parent does not necessarily determine the sex.

The progress of the study of Embryology has placed beyond doubt the circumstance that in the animal kingdom the bisexual or hermaphrodite condition is the usual and primitive state, the unisexual condition being the result of more or less suppression of the one kind of sexual apparatus in favour of the other, which consequently develops the more fully. The embryos of vertebrate animals are first hermaphrodite—a condition which is very commonly permanent among invertebrates, and is occasionally more or less so in the case of vertebrates. In plants hermaphroditism is the rule—the unisexual condition the exception.

If the proportions of the sexes at birth be taken as a standard, it is found that normally the two sexes about balance each other in case of the human species and the domesticated animals, though with a slight preponderance of males. Statistics of the European countries give an average of 105 boys to every 100 girls. According to the observations of M. Cornevin (Professor at the Veterinary School at Lyons) the ratios in the case of farm animals are:—Horses 101 males per 100 females, cattle 104.6 males, sheep 115.4, pigs 104.9. Change in the environment appears to be one of the most potent causes in the determination of sex, and, as regards the human race, observations on this point are easily made. In hot

countries to which white people have migrated there is a preponderance of girls at birth. Horses equally serve to afford evidence that, in an environment different from their native one, there is an excess of female births.

The results of the observations of M.M. Kiener and Cornevin, as given in their papers on this subject, and reproduced in the *Royal Agricultural Journal*, strongly support the statements given on their authority in this note.

GENERAL ITEMS.

Attention is being prominently called to an alleged cure for Pleuro-pneumonia, which has already been tried and found effective. This cure was discovered by a Mr. Dawson, who argued that as Pleuro was caused by a species of microbe infesting the lungs, and as paraffin oil was found very effective in destroying minute pests which infest vegetation, it might also be equally effective in destroying microbes in the lungs. Mr. Dawson solved the difficulty of getting the paraffin oil "sprayed" over the lungs by putting a small sponge saturated with oil into one nostril of the affected animal, and holding the other nostril tight, and at every inspiration of the beast he gave the sponge a squeeze. The plan proved quite successful, and in every case resulted in the cure of the animal. The system has been tried in a large number of cases in different localities and always proved a complete cure, the result being testified by veterinary authorities. The whole facts in connection with the discovery will be brought before Parliament shortly, so that this most simple and inexpensive cure may be fairly and thoroughly tested.

A new and enlarged edition of Miss Ormerod's work on insects, entitled "Injurious Insects and Methods of Prevention" has been lately published. The volume is tastefully got up, and is illustrated by a portrait of the distinguished authoress whom one *Agricultural Journal* designates "the queen of Entomological Science." Simpkin, Marshall & Co. are the publishers, and the book is priced at five shillings.

Dr. Babcock, an American chemist, has discovered a new method of estimating the amount of fat in milk. The new plan consists in putting equal quantities of milk and sulphuric acid into a test bottle having a long narrow neck. The bottle is then placed on a wheel which revolves at the rate of six to eight hundred times per minute. In the course of six minutes the fat of the milk which has been set free by the acid will have risen to the top. Some hot water is then poured into the bottle, so as to fill it up to a certain point; and after other two minutes whirling at the same rate, the cream will have again risen to the top, and its percentage can be read on the graduated neck of the bottle.

A new college farm has been established in the north of Scotland where all the branches of agriculture will be taught—the instructors being all members of one family. These consist of Mr. Ledingham, senior, who will be assisted by his eldest son who studied at the Edinburgh

University, and is at present a lecturer at the Tamworth College, his youngest son trained in America, and by his daughter who is an adept in dairying.

Paddy occupies an area of 1,272,100 acres this year in the Madras Presidency, a little under the normal area. Cotton is cultivated over 71,300 acres, Indigo 14,200, and Gingelly 339,200.

According to analyses made by Dr. Barry, Government Analyst at Bombay, buffalo's milk has 18.67 per cent total solids, that of the Indian cow 12.88, that of English cows 13.20. The fat in the milk of the three varieties of animals respectively, were, 7.78, 2.87, and 3.82 per cent. The difference was also borne out in the results of butter-making, and goes to show how valuable the buffalo is as a butter and *ghee* producing animal.

As to the soil for grapes, *Food, Home and Garden* says:—"The old idea that grapes thrive best on light land is mainly due to the fact that such soils are naturally dry. While a heavy clay is not best for the grape, it is no insuperable obstacle to success in vineyarding, provided it be thoroughly underdrained. In fact, grape growing is possible under a wider range of conditions and soil than is the case with any other crop. The one thing that the grape roots cannot abide is stagnant water. No matter if this dries out in midsummer, it is then past the power of the vine to regain lost time. Land thoroughly drained to the depth of three feet warms quickly and makes a difference in temperature of five to ten degrees or more at the time when the vine most needs warmth."

According to the *American Agriculturist*, a sandy loam is the best soil for sweet potatoes, and well-rotted stable manure the best fertilizer.

By reservation of forest-land and the restricting on cattle grazing the Madras Government thinks that it is doing its best to eliminate deteriorated cattle, and render the conditions of life easier for cattle of stronger growth. A fee is charged for each head of cattle admitted to the forest reserves.

According to the *Indian Agriculturist*, the study of elementary agriculture has been much attended to in primary schools in the Central Provinces of India during the past year. School gardens are to be established for the boys to learn the industry practically. Both these plans have formed part of the policy of the late Director of Agriculture in Ceylon in the appointment of Agricultural Instructors.

The leaves of *Daboisia Hopwoodii*, a shrub growing in Australia, which are chewed by the natives in the same way as tobacco is chewed, bid fair to be a rival to tobacco. The leaves of this tree contain an alkaloid piturine which is identical or closely allied to nicotine. At least it has been proved that the actions of nicotine and piturine are in every respect identical.

Erratum.—In October number, the title of first article should be "Liquid Manure."

SCHOOL NEWS.

Mr. H. W. Green, late Director of Public Instruction and the founder of the Colombo School of Agriculture, has been confirmed in the appointment, in which he has more than once acted, of Assistant Colonial Secretary; and Mr. Cull, late Principal of the Royal College, succeeds him as Director of Public Instruction. In spite of Mr. Green's translation to another department, where he will have more than enough to occupy his time and attention, we doubt not he will maintain his interest in the cause of agricultural education in Ceylon, and the success of the school with which his name will always be associated.

Mr. J. S. De Saram is back again in Colombo in the capacity of Commissioner of the Court of Requests, the duties of which he fulfilled with so great satisfaction on a previous occasion.

Mr. H. D. Juanis, who passed out of the school last year, has been appointed Agricultural Instructor of the unfortunate Walapane district, the condition of which the Assistant

Government Agent of Nuwera Eliya is doing all he can to improve.

Among the subjects discussed at the Agricultural Improvement Society was the much written about "Need of Technical Education in Ceylon," the subject of a paper read by Mr. W. A. de Silva. At the last meeting five new members, unconnected with the school, were elected.

Mr. Jayasinghe, an old boy of the school, has settled down as a sugar-cane planter in the Southern Province. He has already planted up 100 acres, and intends opening about the same extent of land with the object of extending the cultivation of the cane.

The final examination for the Seniors, as well as the Junior class examination, comes off about the 15th of the month; the distribution of prizes and certificates will follow at the end of the month; and the long Christmas holidays begin from the 1st December.

THE TROPICAL AGRICULTURIST MONTHLY.

Vol. X.

COLOMBO, DECEMBER 1ST, 1890.

[No 6.]

ANALYSES OF TEA, TEA SOILS AND TEA MANURES.

R. JOHN HUGHES analysed specimens of soils of a large proportion of the hill districts of Ceylon, in which tea is now grown, but with reference to their suitability for coffee culture, indicating the

mechanical treatment and the nature of the manures best calculated to improve the soils and help our then staple product. But since Mr. Hughes was here on the requisition of the Planters' Association, tea has been grown in localities, such as the Kelani Valley, which were not even conceived of as suitable for coffee. Tea also flourishes in stiff and ferruginous soils, not so well adapted for coffee, and tea, being a leaf-producer and not cultivated for fruit as coffee was, is not so much benefited by the application of lime as coffee and coffee soils were. It seems to us, therefore, that not only ought our Planters' Association to respond readily to Mr. Hughes's offer to analyze specimens of Ceylon teas, but that the scope of the chemist's examination and report should be extended so as to include reports on the soils in which the teas are grown and indications of the nature and quantity of fertilizing matter necessary, or likely to improve the quantity and quality of the produce. More than two years ago the Agricultural and Horticultural Society of India formulated an exceedingly comprehensive scheme of dealing with teas, soils and manures, and also the technical details of the manufacture of tea. The proposed scheme originated in a letter from Messrs. Jardine, Skinner & Co. pointing out the very haphazard manner in which tea in India and Assam was manured. The letter was accompanied by specimens of oil cakes used on various estates (one of which, by the way, bore the elegant name of "Rose Kandy") and asked information as to the fertility of each as a leaf-stimulator. It was added that managers, as a rule, had little idea of the comparative manurial value of oil cakes,

although a lakh of rupees and upwards was spent annually on oil cake in Cachar alone. On this letter the comment of the Secretary is:—

"The information which is required for basing an opinion on the merits of different oil-cakes as a manure for tea, does not appear to exist. This should include analysis of the soils on which the tea is grown, of tea leaf, of the manures accessible, and other points of the like nature, without which the scientific treatment of the subject is impossible. The Society, and indeed all who are interested in the great Tea industry, are therefore greatly indebted to Dr. Warden, who has expressed his willingness to make a set of the required analyses which, when tabulated, will show at a glance what the different soils require. The importance of the data which will thus be collected can hardly be over-estimated, for much of the information will be as useful to cultivators of sugar-cane, indigo, &c., as to Tea planters. Messrs. W. O. Bell-Irving and P. Playfair are appointed as sub-committee to give Dr. Warden such assistance as he may require."

At a meeting of the Indian Tea Association:—

"An unanimous opinion was expressed that Dr. Warden's report on Tea Manures and Tea Garden Soils would be likely to prove most instructive and valuable, and as such, sure to be much appreciated by all interested in tea growing. On receipt of details as to the manner, &c., in which the samples should be collected, the Tea Association will be only too pleased to do the needful. It is suggested that samples be sent from three or four representative gardens in each district, say Cachar, Sylhet, Assam and the Dooars, and that gardens possessing different descriptions of soil be selected. One garden to send, say black peaty bheel soil, another plateau mould, a third stiff soil, and a fourth a specimen of Teelah formation. Some idea should be given as to the amount of earth (surface and subsoil) required as a sample, and the depth at which the latter should be taken, also as to the quantity of oil-cake, bone-dust, cow-manure, &c., necessary for a fair test muster."

It will thus be seen that Indian Tea Gardens embrace all the varieties of soil which exist in Ceylon, although the terms "bheel" and "teelah" do not enter into our vocabulary, as descriptive respectively of swamp and hill land. Samples of soils and plants were actually sent to Dr. Warden, but the illness of members of his staff prevented the analyses, and details of the wider scheme were specified in the journal. The necessity for action was shown by the statement that in Cachar, Assam, and Sylhet there were many "concerns" still of the highest class and remunerative with a yield of from 4 to 6 maunds (320 to 480lb.) per acre; but since gardens were being opened out which yielded 6 to 8 maunds (480 to 640 lb.), the old estates, if not

renovated would fall back into the third or fourth class. The proposal therefore was that

"A competent chemist should be employed for the purpose of making the investigations indicated above, viz., the analysis of the tea plant, the root, stem, branches, leaves and seed; the soils on which the plant is grown and the manures, both such as may be available on the spot, and those it is possible to transport with sufficient economy to make their use practicable. Linked with the enquiry as to the fertility of soils would be questions relating to the treatment of the tea plant, and of the leaf in the process of manufacture, points on which most useful information may be obtainable by careful scientific enquiry. As for example, the causes which tend to variations of quality in the teas produced, the chemical changes which take place in the leaf during the process of manufacture, and a number of similar points which if they cannot be dealt with chemically may, when a full record of all local circumstances is available, be referred to the leading authorities in different departments in Europe." It was resolved that a competent chemist should be engaged for the purposes indicated for a period of at least two years; that the results, as obtained should be published; that £10,000 should be guaranteed by the Indian Tea Association; that portions of the necessary expenditure should be recouped by fees levied for special reports on soils of individual gardens and soils submitted for analysis. There are other details of minor importance and the memorandum concludes as follows:—

"At present the tea industry is regulated by more or less empirical methods; the precise conditions which influence the commercial value of the teas are practically unrecognised. A high priced tea and a low priced one, as far as is at present known, are chemically indistinguishable. The tea plant can be made to yield a larger crop by the return to the soil of certain principles abstracted by the leaf, and which is at present given back by the indiscriminate use of manures, while those which influence the quality of the leaf are, from a chemical point of view, an unknown factor. There are general rules regarding the restoration to the soil of constituents abstracted which are as applicable to the tea plant as to any other crop, and the systematic application of which will most certainly improve the yield. But although it cannot with certainty be predicted that any special rules will be deduced as an outcome of the enquiry, the application of which will certainly improve the quality of tea, yet there is every reason to believe that general deductions will be arrived at which will indicate to some extent the system which should be adopted to this end."

The memorandum is dated Sept. 1889, but up till now, we have not seen in the proceedings of the Society that the Indian Tea Association has taken any more active steps to carry out the scheme, than our own Ceylon Planters' Association has done in the case of Mr. Hughes's proposal. Mr. Hughes is now well enough known in Ceylon to justify us in saying that no better qualified chemist could be chosen to carry out analyses and experiments such as are contemplated in the Indian memorandum.

Our planters know generally that tea requires more nitrogenous manures than coffee did. That no better fertilizer could be used than cattle manure, provided it were easily obtainable from extraneous sources, or if the keeping of cattle on estates, largely for the sake of their manure could be made to pay. We also know that no better oil-cake can be used to supply nitrogen largely and potash in an appreciable degree than white castor cake, while coconut ponnac is good, but not so valuable as a fertilizer, especially where wild pigs and similar animals abound. We know that by a very large number of authorities it is held that to supply tea with the desiderated proportions of nitrogen, potash and phosphate of lime, a perfect combination is that of white castor cake and bones broken small.

If the latter are steamed so much the better, perhaps. But so highly nitrogenous a substance as fish must be valuable, if only its effects are lasting. Kainit, too, might be found valuable. In a recent experiment fish manure alone put luxuriant leaf on the tea bushes and no blossom, while fish manure with an admixture of bones, stimulated blossom (which is undesirable,) as well as leaf. A small quantity of super-phosphate added to the fish would probably have been preferable. Such questions and others regarding manures, in connection with knowledge of the constituents of the tea plant and the soil in which it grows, a competent chemist could settle. And surely it is more than probable that such a man as Mr. Hughes, watching, repeating, and experimenting on all the processes of the manufacture of the leaf, under different circumstances of elevation and weather and of the leaf itself as to degrees of withering, rolling, fermentation, roasting, &c., would be able to help planters to obtain uniformly those good results, which at present are obtained only occasionally. We believe, therefore, that a portion of the funds of the Association, with, perhaps some help from Government, would be well spent in securing the services of Mr. Hughes, or some other competent chemist, if that gentleman cannot accept the mission, to conduct in different districts of Ceylon, and on a series of typical plantations and in their factories, a series of experiments in cultivation, the application of manures, and the manufacture of the gathered leaf, such as we have indicated in quoting and commenting on the comprehensive Indian Memorandum. We submit the question for the serious consideration of the producers of tea in our island. Our teas have a high character for their fine quality. Our efforts ought to be directed to sustaining and even improving the character of what is now the staple product of Ceylon.

RECENT GEMMING FINDS.

Several valuable gems have recently been found in Rakwana and the Morawak Korale, which are likely to have an appreciable effect on the market, especially amongst London capitalists. *Apròpos* of a para. in our contemporary the "Times" yesterday headed "Gemming in Morawak Korale," which says:—"We are told that a cat's-eye was recently discovered on Rangwelltenne which has just been sold for £12,000,"—we are informed that it was not found on Rangwelltenne, the mining rights of which belong to the Ceylon Gemming and Mining Co., but it was found in the Morawak Korale, and Rangwelltenne is in Rakwana. This catseye was sold in Colombo three days ago to a Moorman for the sum named. An experienced man who has had an opportunity of inspecting the stone says it is one of the finest that has been found of recent years.

Another very fine stone of 26 carats. was recently found on Knowhill estate, adjoining the Ceylon Gemming and Mining Syndicate's estate, Golden Grove.

THE HARDY WHITE PASSION-FLOWERS.—Messrs Fuller, Courtenay Nursery, Newton Abbot, write to protest against a doubt raised by a correspondent as to the correctness of the statement that the plant in question originated in their nursery as a seedling from *P. cœrulea*. Although the plant was first described in these columns, we were of course dependent upon others for a correct statement as to its history. Messrs. Fuller say they raised the plant, and there is, so far as we know, no reason whatever to doubt their accuracy; but, if it be a seedling, other people may have raised it before, and others may raise it again. —*Gardeners' Chronicle.*

REGULATIONS FOR LAND SALES. IN CEYLON.

A new set of regulations for sale of unreserved Crown lands is published in the last *Gazette* and will come into operation from the 1st proximo. They are much the same as those given in our latest "Handbook and Directory" with the exception of a few amendments; while several new clauses have been added to them. Clauses 1, 2, 12 and 13, and the last part of clause 4 commencing from "For the opening" &c., and that of clause 9, from "and the amount of stamp duty chargeable" &c., have been expunged, and clause 11 has been made to read "On receipt of the purchase money in full, the Government Agent will apply to the *Colonial Secretary* for a grant in duplicate," &c. In the table of fees the progressive increase of R40 per 100 acres will in future be for lots between 2,000 and 6,000 acres and not 5,000 acres as hitherto. The following are the new clauses referred to:—

As a general rule, all unreserved Crown lands will be sold by auction, and at a price not less than 10 rupees per acre.

Sales of unreserved Crown land are classified as follows:—

(a) Those of forest, jungle, or patana not hitherto cultivated.

(b) Those of land already occupied, but the possession of which the occupants desire to regularise.

(c) Those of land which the occupants fail in acquiring, or that have been seized in default of payment of tax.

Under class (a) fall:—

(1) Land sales initiated by the Government to advance the progress of agricultural or planting enterprise.

(2) Lands the sale of which is applied for by parties desirous of adding to existing holdings or of possessing land in a district of their own selection.

To class (b) belong:—

(3) Lands occupied originally without deeds of title and improved for a period of less than 5 years, but sold to the occupant on payment of the appraisal value.

(4) Lands occupied originally without deeds of title and improved for a period of more than 5 years and less than 10 years, but sold to the occupant at the rate of 10 rupees per acre, and lands held on permit or license continuously for not less than 2 years.

While under class (c) come:—

(5) All lands under (3) and (4) which the occupants fail to acquire under the conditions therein stated, besides those seized in default of payment of tax.

When lands exposed for sale under rule 2 (a) and (b) exceed 50 acres in extent, or in cases where small contiguous blocks aggregate 50 acres or more, the same shall be advertised in the *Gazette*, with the name of the applicant, if any; and these and other advertisements may be inserted, as at present, by the Surveyor-General in the Local, Indian, or Home papers, under such limitations as the Government may from time to time appoint.

Before any block of unreserved forest, mnkalana, lands adjoining forests and lands adjoining river or streams, or chena over twenty years' growth can be brought forward for sale, the opinion of the Conservator of Forests shall be taken as to the desirability or otherwise of the alienation before publication of intended sale in the *Gazette*; and in cases where the block exceeds 50 acres in extent, a report on the land, with explanatory sketch, shall further be submitted to His Excellency the Governor, showing its situation, altitude, proximity to existing estates, drainage of watershed, extent of forest reserves in the neighbourhood, and probable existence of minerals or gems.

Land over 5,000 ft. elevation shall not be alienated, and land of any elevation whatsoever, which, in the opinion of competent authority, from its position upon or at the side of a ridge, or at the source of streams, or on the banks of streams, or for any other cause, should not be alienated, may be permanently reserved and marked in the record maps "Not to be sold."

When any block or lot of land has been reserved as above by order of Government, such block or lot shall not be brought forward for sale at any future time unless the conditions under which it was reserved have in the opinion of the Governor ceased to exist.

Reservations on rivers or streams should be carefully demarcated and preserved, more especially when there is dependent paddy cultivation below; while in the case of estates bordering on villages, suitable reservations round the village should be allowed for the wants of the inhabitants in forest produce, grazing, and so forth. The land abutting on paddy fields should, as a general rule, be reserved for the villagers.

Rules for the Guidance of the Government Agents and Surveyor-General in bringing forward unreserved Crown Lands for sale.

In respect to land sales under 2 (a) of the Regulations for Land Sales dated September 13th, 1890, the Government Agents, under instructions from Government, will make arrangements for bringing forward for sales suitable blocks of land in such district or districts as the Government may deem expedient. With regard to sales under 2 (b) and (c), the necessary arrangements will devolve upon the Government Agents in conjunction with the Surveyor-General.

When Crown land exposed for sale at upset price has any standing timber or other forest produce upon it, it shall be optional with the crown on its own behalf to fell and remove the same, or to sell all or part of such standing timber and produce to the purchaser, at a valuation to be made by the Forest Department.

Government Agents and officers of the Survey Department are enjoined, when dealing with applications, to be particularly on their guard against any attempt on the part of applicants to select the pick of the land in separate blocks, or to obtain allotments in such positions as to detract from the value of neighbouring unsold land, and by rendering this latter inaccessible in the future to other applicants, to obtain command of the market. To prevent these attempted deteriorations of crown property, frontage to routes of communication (roads, rivers, &c.) should be evenly distributed, means of access to all lots provided by suitable road reservations, and the land blocked out as the configuration of the ground and not as the desire of the applicant dictates.

Forest and woodland being of vital importance to the interests of the community, whether for the supply of material wants, for grazing, for assuring the water supply, for maintaining the balance of bird and insect life, or for preserving the beauty of the landscape, the Surveyor-General and Government Agents are held responsible that in bringing forward lands for sale due attention is paid to these important considerations.

Sales of land under rule 2 (a) will be held from time to time at such place and on such date as the Government may by Notification in the *Government Gazette* appoint. Sales under rule 2 (b) and (c) will be held when practicable at the different kachcheries twice a month, after six weeks' advertisement by Notification in the *Government Gazette*, and care will be taken to prevent the days of sale in the several Provinces from clashing with each other.

SOME INFERIOR MADRAS TOBACCOS.—In May last the Commissioner of Agriculture forwarded to Messrs. Corry, Soper, Fowler & Co., of London, for report, samples of certain tobaccos grown in this Presidency. Of these tobacco grown in Chebrole, Kistna District and Cuddapa, Cuddapa District, are reported to be of no value and not worth sending to Europe. That grown at Medur, in the Kistna District, the firm offers to buy at 2d per pound in London, and the tobacco from Pannatola in Jammalamadugu in Cuddapa District at 1½d delivered at London. The tobacco growers in these districts are not likely to accept the offer of Messrs. Corry, Soper, Fowler & Co., as the rates offered by them are lower than the local selling prices of the leaf.—*Pioneer*, Oct. 12th.

LETTERS FROM JAMAICA: NO. 32.

WEATHER—COFFEE CROPS—PRICES FOR COFFEE IN LONDON—CEYLON VERSUS JAMAICA—LABOUR SUPPLY—THE FORTHCOMING EXHIBITION—RAILWAY EXTENSION.

Blue Mountain District, for Packet of Aug. 12th:

DEAR SIR,—It is quite six months since I addressed you: the only excuse I can make is that I have not had sufficient materials for a letter.

First, as to weather among these Blue Mountain hills: we had during the five first months of the year, more rain than we needed—not that it was heavy, but continuous showery weather with very few intervening fine days, so that it was impossible for us to do much coffee preparation till June, for as you know we have to prepare our coffee on the estate ready for shipment. On the other hand other parts of the island, even those below us and not far off as the crow flies, have suffered from drought, and I fear it will cause light and short crops in the low-lying districts of the island which are mostly owned by *settlers*, and would in Ceylon be termed native coffee. My own coffee in the high fields in exposed places suffered very much from the cold cutting N.-E. winds, and the constant showers; the ends of the branches turned black and had quite a frost-bitten appearance. It was only in the highest coffee in Ceylon, and in hollows, that I have seen the like. It is evident that 4,000 should be the limit at which Jamaica coffee should be planted; 3,000 feet is by far the best height, as we are so much more to the northward, and have quite a marked winter. I am glad to say that most of my neighbours had good crops and did very well; on old Jamaica properties crops seem to alternate: after a large yield. One must look for a shorter one the coming year.

As to prices, Ceylon appears to have done better in London than Jamaica in Liverpool. I saw in the *T. A.* list that one Ceylon property had touched 132s and 133s: this is what our best marks usually obtain for number one quality. I fancy the highest price is given in London for "peaberry," but this is seldom separated in Jamaica, as the sizers do not seem to be perforated to extract the peaberry: my sizer, one of the old fine sort, does not. Some little time ago I noticed in one of the *Tropical Agriculturists* a letter from a Jamaica planter, who was evidently not a Blue Mountain but a Manchester coffee planter. In one of my previous letters No. 22, I described Manchester coffee, and how totally it differed from ours, being grown under the shade of trumpet trees, without which shade it strangely cannot thrive: the land is flat, the soil red, as in parts of Devonshire; and there is a subsoil of marl which is fatal to the coffee tree if the roots reach as far. On the other hand our hills are very steep, suitable land has to be picked out, and the conditions far more favourable than those of Udupussellawa and Haputale in Ceylon, but we have no open patanas, the sea is only some ten miles off, and the hills altogether are very much more scarped and abrupt.

As regards Immigration, it is to be again resorted to, but not before an attempt has been made to obtain indentured labour *locally*, by a system of yearly contracts, the employer to pay Government the sum £2 10s for each labourer so supplied, over and above his daily wages. £2 of this sum is to be handed to the labourer as a premium at the end of his contract. I am not of opinion that this plan will meet with much success, and it certainly will not be popular amongst the planters and other employers of labour, who will not care to pay the £2 10s extra yearly for labour procured locally. In the case of East Indian coolies it is different, as it is natural the planter should bear the

principal cost of importation. Neither do I think the 3s 4d extra a month will induce our local Jamaican to bind himself to any such arrangement, as he loves his liberty too dearly, and might fancy it was a dodge to introduce a species of slavery. As to the local coolies who have served their time, a few might be induced to tender for the sake of the £2 bonus, but they mostly prefer to become keepers of rum and other shops. As to such coolies who are free and are now working on some of the sugar estates, this new plan ought to suit them, as by binding themselves for a year they would get two pounds a year in addition to their present wages. It would in my opinion be best to send for coolies at once, and if they could be got from the Madras Presidency instead of Bengal, a much better working man and physically stronger, would be obtained, some perhaps with experience of Ceylon or Mauritius.

Our Exhibition buildings are, from the account I read in the newspapers, progressing satisfactorily and there is the hope that they will be all but completed by the middle of January. The Governor has been visiting various parts of the island and stirring up the people to action. The consequence is that two or three local exhibitions in other towns in the island are to be held so that the people will get a good idea of what the large Exhibition is intended for. That the Exhibition will draw attention to Jamaica and her products, and make her to be better known all over the world, there is no doubt; but no one seems to expect a financial success, as our own population is not sufficient to make it pay, the expense of travelling will deter many from visiting it, and it is too long and expensive a trip to expect many to come from Europe where they can see very much finer exhibitions; but no doubt it may induce many Americans and West Indians to visit us, if sufficient accommodation is available. With this view a law has been passed to induce people to build hotels without delay, Government guaranteeing 3 per cent interest on sums so legally invested, so it is hoped sufficient accommodation may be available by the time the Exhibition opens, towards the end of January. I hear also that the railway is being pushed on, and that the first 12 miles will be ready by contract time, *i.e.*, one year after commencement; this is the section of main line to Montago Bay; the branch to Port Antonio has not yet been commenced. W. S.

GEMS GALORE!

The big catseye found in the Morawak Korale has been purchased by the same Moorman dealer who had collected together the fine gems recently described in our columns. His offer of R16,000 for this latest find has been accepted and the Moorman has started off for Galle to take over this precious stone.—The Rangwelletenne sapphire reported to us as worth £100, is now being cut under Mr. Siedle's care and is pronounced worth at least £200. A few more of such stones will make a handsome dividend for the "Gemming and Mining Company of Ceylon Limited" apart from their other returns.

THE EXPERIMENT which has been made to cultivate tea in South Africa has not been successful. The Natal Tea Company has decided to perform a "happy despatch" by voluntary liquidation. The first subscription of £3,000, it appears, is all spent, while the tea produced last year did not pay the working expenses. The chairman's explanation was the familiar complaint—insufficient capital.—*L. and C. Express.*

CEYLON TEA: HOW TREATED IN LONDON TEA WAREHOUSES.

A well-known proprietary planter favors us with the following account of his experience in this matter:—

Oct. 16th.—I can't agree that in the "great Bonded Warehouses," our teas are treated in a sensible fashion! for during my last "holiday" at home, I spared no pains in watching the treatment tea received in London. In the "Bonded Warehouses" referred to, each and every chest and $\frac{1}{2}$ chest is ripped open; then a man comes along with a knife and slits the tea lead, right along the full length of every chest; a handful is then taken from each chest and submitted for examination to the selling brokers' representative, who decides whether or not the teas are to pass as "Factory bulked"; if they are not so passed, out on to the floor it all goes, to be bulked by the warehousemen. Navvies in fact; who turn it over and over with iron shovels, when sufficiently bulked it is most roughly repacked, and stamped down by the navvies in their lobnailed boots. From the time the lead is first slit open, days may elapse and do elapse, before any steps are taken to in any way protect the teas from the air. One time when I was being shown round, I noticed a strong smell of coffee roasting, which was being carried on close by; large quantities of tea were at the same time being bulked! So much for the sensible fashion in which our teas are treated in the "Great Bonded Warehouses"!

HILLCOUNTRY PLANTING REPORT.

THE WEATHER—A VISIT FROM MR. NOCK—THE BATTLE OF THE WATTLES—ACACIAS AND EUCALYPTS—OTHER TIMBER AND SHADE TREES—GRAND VIEWS—THE TREE TOMATO—HINDRANCES TO PROGRESS ON THE RAILWAY EXTENSION—ANOTHER CALM DAY.

NANUOYA, Oct. 18th.

Yesterday was a beautiful day, and there was a gentle deposit of rain during the night which is indicated this morning by the rain-gauge as equal to 16 cents. The fears of those who are planting have been thus dissipated for the time. As a consequence, no doubt, of the rain falling on ground heated by yesterday's strong sunshine, there are masses of white vapour on the mountains, but the sun is shining brightly down into the valley. "Every leaf is at rest," and there is the promise of another fine day. [Which has been amply fulfilled.]

Yesterday we had a very interesting visit from Mr. Nock of Hakgala, who came for the purpose of obtaining information and specimens to enable Dr. Trimen to identify some of the many exotic trees growing here and especially to clear up, if possible, the confusion existing regarding the numerous and variable species of Australian acacias or wattles: About *A. armata*, with its thorn-like leaves and its primrose-coloured, catkin-like blossoms, there is no question: it is simply ornamental. The difficulty has been about *A. decurrens*, with its two varieties (at least), and *A. dealbata*. We are about certain that we have the best varieties of both, grand trees of a dozen years' growth on a quartz ridge. What we take to be *A. decurrens*, and what Mr. Nock thought was its superior variety *mollissima*, agrees in foliage with Mr. Kellow's specimen sent to us, its warmer golden colouring of flush in ours being probably due to its more mature age. Indeed our trees look as if they had reached full maturity, the large quantity of gum they secreted having led to considerable decomposition of the bark and the formation of a series of curious round knobs, some of which

were detached and handed to Mr. Nock, while others, being connected with the wood of the trees, could not be removed. The specimens of both trees show great growth for their age, but their mode of growth differs exceedingly. What we take to be *A. decurrens* has grown umbrageously, throwing out a large number of thick branches; so that, as Mr. Nock remarked, a tree, if cut down, would yield a large quantity of "cord-wood,"—that is timber for fuel. Its mode of growth certainly seems to indicate that it is more suitable for firewood than timber for house building or other purposes, although the trunk and even some of the enormous horizontal branches would yield planks and deals of good size. What, from its silvery foliage, we take to be *A. dealbata* grows into straight tall handsome trees, with a moderate array of branches, which are not spreading, but assume more of the semi-perpendicular form. There can be no question as to this being the finer tree of the two, while, from the absence of gummy and other secretions, it shows no sign of having reached anything like the termination of its fresh and growing existence. The sending up of suckers by this tree seems to depend on circumstances. Until yesterday we called our tree "the *A. dealbata* which does not send up suckers." But we found that one specimen had sent its roots out into loose soil and that from these roots suckers were springing. For yielding a large supply of firewood, it will probably be advisable to encourage rather than suppress the tendency of *A. dealbata* to send up suckers. Mr. Nock took away specimens of other acacias, as well as of the numerous varieties of eucalypts growing on Abbotsford. One of the latter, of exceeding rapid growth, closely resembles *A. decurrens* in its branching habit, some of the branches, indeed, vying with the trunk in size. The blue gum, *Eucalyptus globulus*, of which we have many, are not trees to be proud of, except in specially favourable localities; but the red and white gums grow well. *E. robusta* is here as in all these districts a very luxuriant grower, while, rather to our surprise, one of our best and quickest growing trees is the famous jarrah tree, *E. marginata*. Mr. Nock admired our truly noble specimens of *Albizia moluccana*, so prized in Java as a shade tree. When covered with snow-white flowers, as some of ours have been, these trees are beautiful objects. But they are brittle and the timber poor as firewood, although, doubtless, it would prove suitable for tea chests. Greivileas do well here up to close on 6,000 feet, but Nuwara Eliya seems to be beyond their limit. A few planted near the bund in good soil, have grown fairly well, but their tops were broken by wind. Mr. Nock much admired our *syncarpias*. As one of the best firewoods we have large numbers of different species of casuarinas, and for the same purpose we are growing the luxuriant bushy frenelas, trees which for shelter and shade purposes could scarcely be surpassed. Mr. Nock was in great admiration of our young plantations, in which, wattles, casuarinas, eucalypts and cryptomerias are conspicuous, while other trees are being tried, as well as with the large number of older trees scattered about the estate. We have now found that, with the exception of wattles, casuarinas and above all bamboos, trees grown amongst tea do little or no harm to the principal culture. Indeed we rather think that at our higher elevations the shelter of trees is useful. Never having been here before, Mr. Nock was enchanted with our grand and extensive views, as of mountains, valleys and patanas, terrace after terrace, between 1,600 and nearly 6,000 feet altitude, was attained near our beautiful lakelet, which supplies water for working tho

"tandem wheels" at the factory. *En passant* I must express my admiration of the grand leaf, as well as the fine fruit, of the tree tomato. A leaf from plants grown on a trellis at 4,700 feet measured 21 inches by 15.

INDIAN TEA NOTES.

Dehra Dnn, Sept. 30th.—On the 23rd we had 1.25 inches of rain, and since then it has been cloudy but no rain. The rain has done a lot of good. Luckimpore, Sept. 22nd.—Rainfall for the week 4.71 inches. Mosquito blight very prevalent and general in the district, and it is a struggle for most gardens to keep up with last year. Increases on last year are diminishing slowly with little hope of pulling up again. The mornings and evenings look very much like an early close. Rainfall to date 142.98 inches.

Dooras, Dam Dim, Oct. 4th. The weather during the past week has been very unsettled and varying. Showers have fallen at night, and days are fairly warm. Snow fell on the lower range of Bhootan hills, which is uncommon for this time of year. Rainfall from 20 to 30 inches ahead of last year on same date, Outturus going further behind, but quality showing some improvement.—*Indian Planters' Gazette*.

NOTES ON PRODUCE AND FINANCE.

THE DEALERS AND THE DUTY.—The tea dealers have carried their point about the proposal to weigh tea to the half pound, and the Customs authorities will not insist, at least for the present, on any departure from the old plan. All over the country tea dealers had protested against the new order, and now that it is temporarily rescinded it will probably never be heard of again. The tea trade of the country is a powerful interest, and the Government cannot afford to add to the ranks of its enemies.

TEA AT THIRTY SHILLINGS PER LB.—Commenting on the remarkable price paid for some small boxes of Ceylon tea, as recorded by our "Commissioner in the 'Lane,'" last week, the *Grocer* says:—"One of the rarest and most curious kinds of tea that has been imported into this country in modern times was offered by auction in Mincing Lane on Tuesday last, when a small parcel of three boxes Ceylon, weighing only five pounds each, very showy, and described as "choicest gold n-tipped flowery Pekoe," fetched the astonishingly high price of thirty shillings and sixpence (30s 6d) per pound. Just fancy seeing tea marked up at such an extravagant figure in a grocer's shop window! and the effect, we should think, would be to scare away customers, instead of inviting them to buy, for no one surely but some magnate or a crowned head would ever think of drinking tea that cost so much money, as, at the rate of nearly twenty-three pence (1s 11d) per ounce, it would be dearer than many bottled wines of the finest vintages. The estate or garden in Ceylon where the said tea was grown is named 'Hethersett,' and it is probable that the proprietors and owners there may be stimulated to fresh exertions to produce a larger quantity of the same sort, and then perhaps further consignments may be sent forward for the approval of those who pride themselves in being connoisseurs in drinking tea of the greatest excellence."

PUSHING THE SALE OF TEA.—A correspondent of *The Times* writes: "Whilst my wife was entertaining a number of friends at her afternoon tea, the servant announced 'Mr. —,' who walked into the room, and, seeing a lady without a bonnet, asked her to patronise his tea, at the same time offering her circulars of 'The — Company,' Tower Hill. The lady happened to be a visitor staying in the house. My wife had some difficulty in getting the intruding tout to withdraw. Publicity may, perhaps, tend to abate a nuisance of this offensive kind. I may mention that twice within the past twelve months my privacy has been intruded upon by touts. They came to the door in broughams and took the servant in by asking for no by name. My servants are pretty wide-awake now, but 'Mr. —' managed on this

occasion to elude the vigilance of the one who answered his double knock and ring."

HOP TEA.—Mr. Patrick Macgregor, late of Assam, is, as will be seen from a reference to another column, showing the men of Kent how to make hop tea. Although less hopeful than the promoters of this new industry as to its success we feel sure that Mr. Macgregor will bring the necessary energy to bear upon the new undertaking, and he may succeed in making hop tea popular.

TEA LABELS IN RUSSIA.—We referred recently to the quantity of adulterated tea sold in Russia. In order to protect the public and to assist those who wish to sell pure tea, the Government now permit tea dealers in Russia to sell their wares under Government labels, which are placed on packets of tea of various weights, by persons employed by the Government for that purpose, and who work under the control of official inspectors. The cost of labelling, which is small, is defrayed out of the money realised by the sale of the labels. The labelling is not imperative, but most of the tea merchants in the retail trade have recourse to this expedient to increase their sales.

COFFEE AND ITS ADULTERATION.—Public analysts complain with justice that there is no unanimity on the magisterial bench on the important subject of food and drug adulteration. One analyst finds that 57 out of every 100 samples of coffee he examined contain on an average 40 per cent. of chicory. On this point the difficulty of the magistrates is not to be minimised. Some people prefer a mixture of coffee and chicory, and if anywhere in the packet carried away by the customer the words "sold as a mixture" are found, one magistrate may hesitate to inflict a fine. Another, bearing in mind that coffee is worth at least sixteen pence a pound while chicory costs but four pence, will hold that the purchaser is not bound to stay in the shop and read the printed wrappers of each article he buys. If he asks for coffee and gets coffee and chicory the seller is punished. The more lenient magistrate, it is complained, will make no distinction between the case of a man whose packets are one-half chicory and another who only makes them one-third chicory and gives two-thirds of the weight in genuine coffee. Some uniformity of practice among magistrates on this subject would tend to minimise confusion.

THE INDIAN GOLD MINE BOOM.—By way of preparing people on this side the *Financial News* has the following:—"Private advices from Calcutta report that a gold fever has broken out in India, and that great preparations are making for the floating of companies in England. The Western Bengal Prospecting Company has been got up by Mr. G. Tosco Peppe, one of the most active promoters, who will shortly offer it here for £200,000, in return for which the English purchasers are to have the right to prospect 1,500 square miles of territory. The Souppet Company has been floated in Bengal, and has begun buying up adjoining properties, including the Chota Nagpore. Messrs. Ogilvie, Gillanders, and Co. are credited with the intention of introducing the Kapurgadh Gold Mines on this market, and Messrs. Jardine, Skinner, and Co. are reported to have acquired the Patcom for a London syndicate. Other properties, of more or less value, destined for English investors are the Kharasawan, the Pat Pat, and the Tamar, of which more anon."

BURMAH RUBY MINES CO.—The company, for which there was such a rush for shares, was floated in February, 1889, and was formed to acquire a concession granted by the Secretary of State in Council of India for the Ruby Mines of Burmah. The grant was fixed for seven years only, from November 1889 (with certain provisions for renewal), at a rent equal to about £28,000 per annum, the Government, in addition, receiving one-sixth of the net profits. The price paid for the transfer of the grant was £55,000 in cash. No dividend has as yet been paid. The market quotation, which carried a good premium all last year, and retained some of it during the first months of this, now shows a discount.—*H. & C. Mail*.

CEYLON AND CHINA TEA IN RUSSIA.

The decline in the export of tea from China to Great Britain has been partially counterbalanced by an increase in the export to Russia, a circumstance from which the apologists for China's suicidal policy in regard to her principal article of trade have derived more consolation than is fairly warranted. It is only a question of time how soon China tea will be relegated to the same relative position in the Russian market that it occupies in the English market. Russian buyers will find out sooner or later that they can get tea of equal quality at much cheaper prices. Ceylon planters are taking active steps to bring this fact prominently before the subjects of the Czar, and when they have succeeded Russian tea drinkers will not be slow to take advantage of it. At present the Ceylon Planters' Association has a Commissioner in Russia, and an interesting letter from him giving particulars regarding his mission was recently published in the Ceylon papers. From St. Petersburg he writes that from all the information he has been able to collect since his arrival there is a great future before Ceylon tea in Russia, where it is already pretty well-known and appreciated for its purity and cleanliness of manufacture. It is not the fact, he says, that the teas are found too strong and dark in infusion, as the Russians like a somewhat strong tea and do not at all object to a dark reddish colour, but what they do not like, at least in St. Petersburg, is the sweet raspberry taste given to Ceylon teas by the water of the Neva. Whether any alteration may take place in the popular taste in this respect or whether the objection can be removed by some alteration in the manufacture of the tea remains to be seen, but at all events all the dealers, both wholesale and retail, were desirous of seeing and tasting the samples. These samples were to be distributed with a short circular printed in the English, German, French, and Russian languages. From St. Petersburg the Commissioner proposed to go to Moscow and Nijni Novgorod, to push Ceylon tea there.

But to secure success in Russia "tips" are necessary. "To get the key of everything," he says, "of every door of success in business or otherwise, you must tip everybody, from the lowest moujik to the most influential swell; and it is only by doing so that we shall introduce our Ceylon teas in this country. I have been told that a Chiuanan, last year, spent something over 30,000 roubles in opening a large tea retail warehouse on the Newski Prospect (the largest and most central street here); he has now made his fortune. The Brazil Coffee Company spent three years ago, roubles 50,000 to introduce their coffee here, and are now doing all over Russia, a very considerable and paying business, as their coffee is known to and drunk by almost everybody. Another Coffee Company of the same kind, who would not spend the necessary currency in tips or otherwise and tried to do without it, did nothing at all and failed." Presumably the Ceylon Tea Fund will not let a small expenditure for "tips" stand in the way of their tea, whatever opinion the members may entertain individually as to the morality of tipping in the abstract.

The prospect for China tea seems bad enough from whatever point of view it is looked at, and when we see the Ceylon planters making such vigorous efforts to wrest from it another of its chief markets one is compelled to believe that, with all their advantages, they are bound in the long run to succeed. It is interesting to note the enterprise of the Chiuanan mentioned above, who opened a retail tea warehouse in St. Petersburg and succeeded so well in his venture. But, granting there were many like him amongst his countrymen, what possible chance can China tea have so long as the Government continue to handicap it with heavy export duties whilst its competitors can be exported free or, as in the case of Japan, on payment of a very mild duty? The total extinction of the China tea trade is merely a question of time if the Peking Government continues to pursue its present policy. The decline in the total export of tea from China this season up to date is about twelve million pounds.

Ceylon, on the other hand, has gained about nine million pounds; India, we believe, will show a still larger increase; and in Japan also there has been a forward movement. If China would adopt a bold policy and sacrifice the revenue derived from tea the export would immediately begin to expand and a good deal if not the whole of the lost ground would be recovered. There is just a possibility of the demand for China tea being revived by another cause, which, however, is not a pleasant one to think of. There has lately been some talk of the plant in India being attacked by blight. So far this does not seem to have done any great damage, but as high culture often seems to invite disease from which plants have been free in their more natural state the progress of the tea industry in India and Ceylon may in time be arrested by blight, as was the case with coffee cultivation in Ceylon.—*Hong Kong Daily Press.*

CINNAMON CHIPS.

While Mr. Jardine was in Colombo today our representative took the opportunity of asking him whether the combination entered into about twelve months ago by cinnamon growers as regards cinnamon chips was receiving general observance, and whether the agreement had had the desired effect. Mr. Jardine replied to the effect that he was constantly receiving letters stating that the combination was not being adhered to by certain growers, but his correspondents would not mention names, and expected him to act the part of detective and then take upon himself the risk of exposing the delinquents. This Mr. Jardine does not feel himself called upon to do, and notwithstanding the letters he has received he himself is convinced that three-fourths of the cinnamon growers who entered into the combination have honourably adhered to it. But it is a strange and puzzling fact that though all these men agreed twelve months ago not to make chips the exports up to date show no decrease. As the price of cinnamon has gone up considerably so has the price of chips advanced to nearly double what it was a year ago. This may perhaps be regarded by some growers as an opportunity too good to be lost, and the question is—have any of the big growers retired to some distant part of the jungle for the purpose of making chips "on the quiet"? The failure of the rain which is generally characteristic of the south-west monsoon in the cinnamon districts has had a bad effect upon cinnamon generally, and rain is very much wanted for the November crop.

RAISING TOBACCO in California is by no means an experiment. It can be grown very successfully over a wide range, but the process of curing has been a stumbling block in the way of success as a business venture. It was thought some years ago that the Oulp process was a solution of the difficulty, and quite a large amount of tobacco was raised in Pacheco, and worked up for the market in accordance with that formula, but the manufactured article did not find favor with consumers and the business died completely out wherever it had been started. We are reminded of this experience by receiving a few leaves of the plant grown by José Roges on the land of S. Blum & Bro., near Pinole. They show a thrifty growth, and give evidence of the adaptability of the soil and climate for its cultivation, and if Mr. Roges succeeds in curing it, as we learn it is his intention of doing, so as to make a good merchantable article, he can make a fortune for himself and add a valuable industry to the State.—*Contra Costa Gazette.*

THE AMSTERDAM CINCHONA AUCTIONS.

AMSTERDAM, Oct. 2.—At today's cinchona auctions 2,301 packages Java bark sold, with a rather weak tone, at an average unit of 9 cents (about 1 $\frac{1}{4}$ per lb.), prices on the whole being scarcely maintained as compared with the preceding sales. Manufacturing barks in quill, broken quills, and chips realised from 9 to 78 cents (1 $\frac{1}{2}$ to 1s 2d per lb.); and root from 28 to 69 cents (5d to 1s 0 $\frac{1}{2}$ d per lb.) For druggists' barks in quills and chips, from 6 to 103 cents (1d to 1s 6 $\frac{1}{2}$ d per lb.), and ditto root, 9 to 24 cents (1 $\frac{1}{2}$ d to 4 $\frac{1}{2}$ d per lb.) was paid. The principal buyers, in order, were Messrs. C. L. Schepp & Zonen, Rotterdam; Matthes & Bormeester, Amsterdam; the Anerbach factory, and the Amsterdam Quinine Works.—*Chemist and Druggist*, Oct. 4th.

PAPER PACKING FOR TEA.

We are interested in learning that so satisfied are the proprietors of the Elkaduwa group of tea plantations with the prepared paper introduced as packing, instead of tea lead, by Mr. Maitland-Kirwan, that they are continuing to use it. Some time ago we announced the despatch of a break of tea so packed, but made up in 20 lb. boxes. This was pronounced quite a success in Mincing Lane. The Manager of Elkaduwa is now despatching another break, but in full chests of 95 lb. packed with the paper in place of lead. If this also meets the approbation of the buyers at home, the saving will be considerable, and Mr. Maitland-Kirwan will then no doubt take steps to advertise and sell the new packing, giving prices and his own experience of the economy effected.

BAMBOO CHARCOAL.—It is generally thought that bamboo being so light and small make a bad fuel wood, and no one would think it of any value as fuel for forges; yet it is considered the best material for making charcoal for blacksmith work, and is in large demand all over Mysore. It is said to give off more heat than the best coke and to require less blast. A maund of bamboo charcoal fetches twice as much in the village-markets as the best charcoal than any other fuel. The method of charring bamboo is different to that used for harder woods—the stacks or kilns being carefully covered with green leaves and then plastered with wet clay. While the burning is going on, care is taken to exclude air as much as possible, without extinguishing the fire.—*Bangalore Spectator*.

MR. KELLOW'S WATTLES: "ACACIA DECURRENS."—When adding a note to the letter "From the Hills" the other day on this subject, we could not lay our hands on the dimensions of some of his fine wattles (that do not send up suckers) furnished to us by Mr. Kellow. Here is the memorandum—one which ought still further to encourage planters to go in for "acacia decurrens," especially the Uva men with patana reserves. Mr. Kellow wrote:—

"Dimensions of some of my Acacia decurrens:—
Circum. Height. at base.
ft. in. in.

No. 1—Acacia decurrens planted out in Nov. '87	.. 42 3	high	33
No. 2—Do do do do	.. 36 0	"	24
No. 3—Do do do do	.. 33 6	"	24
No. 4—Acacia germinated seed put into supply baskets June '89	27 6	"	20
No. 5—Acacia germinated seed planted in Nursery June '89 and not removed	.. 24 7	"	—

Number five is one of a batch of plants sold to the Forest Department 12 months ago but not removed so that it has not had fair play (all patana land). If you want a successful belt I should strongly advise supply baskets as then the plants receive no check."

THE MAGAZINE OF THE SCHOOL OF AGRICULTURE for November opens with an article on Vegetable Manures and Cheap Fertilizers, dealing with green manures, peat, coir-dust, saw-dust, leaves, sea-weed and straw. Mr. W. A. de Silva continues his paper on indigenous food products and also writes on the cultivation of the Tomato. "Aba" supplies another instalment of "Ceylon bee culture," and takes up the subject of poultry in a separate contribution. The rest of the contents consist of a note on heredity and sexuality, general items, occasional notes, and school news.

TEA COMPANIES' SHARES continue in the same dull and neglected position, and the latest accounts from many gardens do not lead one to expect that they can do otherwise than badly this season. The crop continues to be an unusually poor one as regards quality, for extremely little really fine tea is offered at our weekly sales. Prices here continue on an unsatisfactory level and will not be compensated for by an increased outturn as many gardens are already behind in this respect. All round the prospect before tea companies looks very gloomy, and at a time like the present it is very necessary for managing agents and secretaries to exercise the greatest economy and to cut down expenses to the very lowest possible limit. A determined attempt ought to be made to reduce the brokers, charges here, which have always seemed to me enormous and utterly unjustifiable. Brokers charge gardens at present 1 per cent for selling their tea, and buyers have to pay them 1 per cent for buying the same tea, so that every chest of tea sold at public auction goes home burdened with a broker's charge amounting to 2 per cent. Is it to be wondered at therefore that much tea is now diverted from the Calcutta market and shipped direct home by the grower or on the garden's account? In these days of competition and reduced profits merchants are willing to move goods or money from one side of the world to the other for a certain profit of 1 per cent, and I cannot see that any justification can be offered for the enormous brokerages paid here on tea and indigo which are certainly doing much to cripple the trade in both these articles.—*Pioneer Cor.*, Calcutta, Oct. 4th.

POTATO DISEASE.—It is a recognised fact, that high moulding will save a large percentage of Potatoes even when the conditions seem very unpropitious. Sulphate of copper also has great power in checking the disease. PAILLIEUX, in his experiments, obtained 115 sound Potatoes by the use of a six-per-cent. solution of sulphate of copper, while from an equal area side by side, but where the copper solution was not used, only fifty-three tubers were produced, 32 per cent. of which were diseased. In 1888, M. A. GIRARD conducted two sets of experiments on different farms, using a mixture in water of 2 kilogrammes of sulphate of copper and one of quick-lime per hectolitre. A single application, as a curative treatment, largely reduced the disease, while as a preventive treatment it was a complete success. The solution was applied through an ordinary sprinkler. The increase in healthy tubers on each farm, by the use of the copper sulphate, was:—

A.	B.
14.3 per cent. per cent.
22.9 "	2.7 "
13.5 "	20.2 "
17.2 "	4.4 "

From all the figures presented it is concluded—1st. That the application as a curative treatment does not ensure absolute immunity. 2nd. However, in these cases, treatment diminished in a notable degree the number of diseased tubers, and at the same time increased the weights of the healthy tubers in a very different proportion according to the variety used. 3rd. That the varieties treated, in respect to their receptivity of the disease, differ widely. A 2 to 3 per cent. copper sulphate solution is recommended. It is mortifying to see no steps taken to combat the disease, while no means is neglected to ensure the propagation of the disease. The apathy is from no lack in the supply of information.—*Gardeners' Chronicle*.

THE DEVELOPMENT OF MADAGASCAR.

In a letter recently to hand from Antananarivo, the Editor of the *Madagascar News* says:—

"Madagascar by reason of the Anglo-French Treaty on African partition is now prominently before the world, and the course of events here will doubtless be of interest to your readers, especially as there is every reason to expect that the vast mineral resources of the country will very soon, if not immediately, be opened, either by the Malagasy or the French, for development. To push on the approaching development and to forward British interests here, I shall be much obliged if you will exchange papers regularly, and I would impress upon you that the so doing would materially promote British interests in other country by strengthening the only British newspaper published in the island.

Writing to us on Sept. 29th the Editor further says:—

"Many thanks for your notice. Shall be pleased to exchange with you regularly. It is expected here that the Hovas will cave in. The feeling is, the sooner the better if they do not throw the country open. Missionaries as well as merchants are tired of waiting for progress. The country is growing poorer, the people becoming more down-trodden, when under a fair ruler both have great capacities for development. The Hovas have alienated their best friends by their misgovernment; and the feeling, as before said, is, the sooner something is done the better."

THE PREPARATION OF CACAO (COCOA).

In the *Trinidad Agricultural Record* has been published a series of elaborate essays on the fermentation of cacao beans and the other processes necessary to render them fit for despatch to the selling market. Those essays will be reprinted in the *Tropical Agriculturist*, and meantime we are able to present to our readers a review of their contents, by a planter entitled to speak with authority, in which the results of local experience are given in a most able and valuable form, such as must render it acceptable to all interested in the product, here and elsewhere:—

The Essays on Cacao Fermentation appearing in the *Agricultural Record* of Trinidad for March 1890 are exceedingly interesting; and although the methods described all differ much from that pursued by us, which we consider the best, it by no means follows that we have arrived at perfection, or that we have nothing to learn; indeed judging by the range of prices realized by different estates it seems that some of us have yet much to learn in this important matter of curing of cacao. Knowing little of chemistry I cannot fully follow the learned writer of the essay to which was awarded the first prize. I have no doubt that the various changes described as taking place during fermentation are all accurately recorded, and that to those who understand them they will prove most interesting and instructive. To the ordinary planter, however, the fact that during fermentation certain changes take place which suppress the bitter principle and develop the conditions and flavour necessary to render it fit for food and marketable, is all he cares to know; and to afford the desirable information as to which method is the best to gain this end is the object of the essayists. The various methods in vogue in Trinidad and Grenada are fully described, and preference seems to be given to that introduced by a Mr. Strickland. The writer of the first essay says that the Criolo cacao requires only 3 days' fermentation (we allow 5 to 7), and as Ceylon cacao is the Criolo or Caracas variety, it may in some degree perhaps account for the fact that the elaborate and lengthened fermentation, said to be necessary to

the full development of the flavour and requisite colour of the forastero or Trinidad cacao, has never been tried here. It is only within the last five years—after the scare caused by drought and *helopeltis*—that these hardier varieties have found favour with some, most still standing by the delicate criola as the best paying. Ceylon planters object to "dirt in the wrong place," and hence have never adopted the practice of drying cacao by mixing earth or any other substance with it. On one occasion an experiment was tried with a few lots by drying without washing, but the result every way was so unsatisfactory that it was never repeated. It is just possible that the curing of the forastero beans may not be such a simple matter as is that of Criolo, and someone or other of the best methods described by the essayists might be tried with a view to determining whether or not they are improvements upon ours.

I may here state that I have sold in the local market forastero cacao cured in the ordinary Ceylon fashion at from R1 to R2 per cwt. more than that realized by Criolo. Two lots of forastero fetched R55 and R51.50 per cwt., while Criolo sold at the same time brought only R54 and R49.50 per cwt. I have not yet tested the home market with it, but I believe that others have, and that prices equal to that obtained for the best criola have been realized. The plan of curing generally adopted by Ceylon planters is as follows, and is simple, expeditious and cleanly; as a rule no cisterns are built, though boxes or troughs are sometimes used, and there is no testing with a thermometer to ascertain the degree of heat in the mass. Pods are always gathered ripe and are brought and heaped on the nearest roadside; an hour or two before knock-off time they are broken with wooden mallets, the beans being scraped out by hand and put into baskets or sacks and carried by the men to the fermenting house. This may be a room or two with mud walls and thatched roof, a lean-to to the store, or the cisterns of an old coffee pulping-house. A wooden cistern is always attached for washing the beans after fermentation is completed. Upon a platform of reapers and coir matting raised a few feet from the ground, and which allows the free escape of the liquor brewed during sweating, the green beans are heaped two to three feet deep, and covered over with old sacks and coir mats. Fermentation is completed in from 5 to 7 days according to the state of the weather and the thickness of the heaps; the heaps being turned over with wooden shovels and recovered on alternate days. This is for Criolo cacao; forastero should have 24 hours less fermentation. The beans are now thoroughly washed in several waters to free them from all trace of the sour mucilaginous matter adhering to them, and if the weather is fine they are spread thinly on coir mats laid on barbecues to dry in the sun, to ensure even drying and to prevent blistering, they are turned frequently by hand, and in three days are dry enough for dispatching. Should the weather be wet the washed cacao is at once taken to the drying-house which is a long ceiled room with two or three lofts of reapers and coir matting; upon these it is spread, and hot air supplied from many iron tubes heated by a furnace outside is drawn over and through the cacao and out at the bottom at the other end by means of a Blackman's or other fan. Twenty-four hours in this drying-house—called a Clerihew—is sufficient to dry it thoroughly. Mr. Jackson's tea drier is highly spoken of as a cacao drier. Mr. R. S. Fraser of Wariyapola says: "Mr. Jackson's tea drier is a perfect cacao drier, both in the very large quantity it will get through in a very short space of time, and the way in which it does it." See vol. V., page 379, of the *Tropical Agriculturist*. The American fruit drier has also been used with success. When there is no drying-house or where the quantity to be cured is only from 3 to 5 cwt. at a time, it is dried on a reaper staging covered with coir matting raised about 3½ feet above the ground; under this fires of dry wood are lighted and kept burning for about 36 hours, the beans being constantly turned. To concentrate the heat the space within the staging is enclosed: when perfectly dry wood is used the colour of the husk is

hardly affected. Cacao fermented and dried as described above is on the outside in the Criolo of a rich brown, and in the forastero of a golden colour; while in both when sectioned, the colour is warm, dark, a ruby red, and the flavour agreeable. I have never seen any cured cacao in Ceylon having, when sectioned, the rich cinnamon colour said to result from fermentation carried out after Mr. Strickland's method. To meet the requirements of some Continental markets, where a lighter colour both inside and out is desiderated, I am told that cacao is fermented for three days only. Our prepared cacao having no substance on it to sour or damp in wet weather fungus does not readily grow upon it. The proof of the pudding is in the eating, and the proof of the value of an article is the price it commands in the market; and as Ceylon cacao generally fetches the highest prices, I think we may fairly claim that our system is a rational one, and, if not superior, is equal to the best that is carried out by our Trinidad brother planters.

CEYLON TEA IN RUSSIA.

THE NEW VICE-CONSUL AT ODESSA.

Lieut. A. P. Murray, of the 1st Battalion Gordon Highlanders, has just been appointed Vice-Consul at Odessa. This is a peculiarly fitting appointment, Mr. Murray's knowledge of the Russian language being so good. The young officer was much liked and esteemed while in Ceylon, and as everything connected with Russia and its trading ports at this time reminds Ceylon folk of the chance of getting their tea more freely taken up, may not this appointment be of some advantage? If Mr. Murray can say a good word, or use any influence, on behalf of Ceylon tea, we feel sure he will not refuse to do so.

"HOP TEA."

Maidstone is in a state of pleasant excitement because the hop-growers, who have been "grubbing up" hop-ground on account of German competition, have found a new market for the *Humulus lupulus*. All Kent is drinking hop tea, because in September all Kent lives almost literally on hops. Mr. Snelling, a well-known tea merchant of Eastcheap, conceived the idea of making hop tea, and bought tons of hops before even the machinery had been laid down for converting the herbaceous twining plant into a product which, before it is mingled with the ordinary tea of commerce, looks like a cross between Bristol bird's-eye tobacco and rough, strong Assam tea. Then Mr. Patrick Eugene Macgregor, who is one of the best known planters in Assam, was called in as expert. He is now making hop tea in a factory on the Medway. We visited the factory, of which I send a view. There Mr. Macgregor was busy at work with the machinery which he was accustomed to use in Assam. The tea-rolling machine represented in our view of the inside of the factory is exactly that which is being exported to Assam and Ceylon by the dozen; but it is the first tea-roller which has been used on English soil, and that is the first "Sirocco" drying machine (in which hops are being made into tea) which has ever been put into motion this side of Colombo. Now, more hop tea is ordered than the present machinery can turn out. The faculty has discovered that the lupulin of the hop counteracts the excessive tannin of the ordinary tea. Is it cheap to produce? No; it costs about twice the price of excellent tea from India or China sold by auction in Mincing-lane. But a proportion of hop tea added to the tea of commerce—the proportion is the secret of Mr. Snelling and Mr. Macgregor—will make a drink which will cheer and not inebriate General Booth

and Sir Wilfrid Lawson, especially if they are dyspeptic persons, and cannot drink finest new Pekoe with impunity.—*P. M. Gazette*. [The illustrations represented "India in Kent," A Tea-House on the Medway," and "Inside the Factory: Roller and Drying Machines."—Ed. T. A.]

COFFEE IN BRAZIL.

According to all accounts the blossoming is so abundant up country that the prospects are exceptionally good for an enormous coffee crop next year, both in the Rio and São Paulo districts. The season has thus far been most favourable, with just rain enough and a continuance of cool weather, to develop a strong and healthy blossom. With anything better than half a show, the crop is sure to be a large one.—*Rio News*.

NOTES FROM EASTERN ENGLAND.

(By an ex-Ceylon Planter.)

Sept. 25th.

The gap made amongst old friends at home since I came home has been heavy, and the end of all flesh has been busy too, amongst those I knew in Ceylon since I left. A death announced (of a European) in your columns when I first arrived in Ceylon was something to talk about; now unless personally known, little thought is given to it. A rev. friend came in lately. I had just laid the *Observer* down. "Oh!" he says: "a foreign paper, I suppose." "Yes," I said, and handed it to him. After turning over the pages. "Bless me," he says, "why it is quite interesting reading; it tells you something about the quinine, cinchona tree, coffee, tea, and many things which people know nothing of here." I was amused at hearing such remarks; it is strange what little is really known of our colonies in the eastern seas, in fact what interest is taken in them is confined to those who have friends or property there. But I must say tea is making the name of Ceylon more familiar now even in the remotest country villages, and many dodges are used by unprincipled parties in dubbing filthy stuff with the name of Ceylon tea, some advertised at 1s 4d per lb! and I saw a red handbill lately stuck into parcels of grocery, setting forth the goodness of the celebrated 'Mazawattee tea' at 2s per lb. I wish I had kept it to enclose to you. I can assure you that 'bluffing' is not confined to America, it may be of American growth, or raising—but it takes very kindly to commercial soil in England as if it was of indigenous growth. It has been said that the weather is a standing topic of conversation in this country, it may well be so with the present summer for an example. A fine summer day has been a rare experience since the end of May to the beginning of this month, but I am happy to say that the farmers have had on the whole a good harvest time, and more than average crops, but still they grumble there is something wrong somewhere. The ground game act and the duty off malt were to set all straight with this class, but I cannot learn that they are a cent the better for either. I have asked many questions of a variety of a people—from large and small occupiers to landlords and labourers—on the subject. Nothing but the rabbit gets a bad word, and he is not at all in the way on waste lands but affords sport which so many crave for. As to the hare, its fast disappearing is much deplored about here, it is getting quite scarce, horses seem to have forgotten what they are. They so rarely see one, for lately a farmer and his wife were driving down a lane, when a hare skipping across the road so frightened the horse that he bolted. Though overturned they fortunately escaped serious injury.—I am sorry to find that the climate has now two, at least, strong competitors in engrossing conversation, viz., drunkenness and the unrest of the labouring classes. The former is fearfully prevalent and an awful curse. I could not have believed half what I have seen of it, had I read of only; and the latter is an ominous dark cloud hanging threateningly over all, and I fear will end in much suffering to the labouring class. I am glad to hear Ceylon is so flourishing. Long may she continue!

NOTES ON PRODUCE AND FINANCE.

POOR CHINA! According to a telegram from New York the prospects of a through trade in tea between China and Europe over the Canadian Pacific line are not progressing favourably. This is short and sweet, at least to planters in India and Ceylon who wish to keep the supply of tea to European markets as much in their own hands as possible. If Ceylon planters conquer as many countries as they have laid siege to, the direct trade in China tea will not be very large anywhere.

NO PRESUMPTION. "Is it presumption in an English man to say that he can teach the Chinese how to grow tea?" asks an evening paper. We should say not, indeed. The planters of India and Ceylon could teach the Chinese not only how to grow tea but where to find the best market for it, but they would much rather not. It pays them better to grow tea themselves, and to beat the Chinaman out of the field.—*H. and C. Mail*, Oct 10th.

"TEA OR COFFEE" IN AMERICA.

[In order that you may know all that is going on as promptly as possible, I send the enclosed which will appear in the *Standard-Union* tomorrow. Copies of the paper containing it will follow by first mail. I am very sorry that in consequence of business engagements I failed to meet Mr. Grinlinton, but I have the best reason for believing that his visit here was pleasant to him and satisfactory in its result.—*New York Cor.*]

AN AMERICAN-CEYLON COMPANY SOON TO GO INTO ACTIVE OPERATION.

WHAT HON. MR. GRINLINTON THINKS OF AMERICA AND AMERICANS—REMARKABLE DECADENCE IN THE PRODUCTION OF COFFEE—GROWTH OF CEYLON TEA EXPORTATION.

The project, of which some account has already appeared in the *Standard-Union*, of handing the teas of Ceylon on a large scale in this market, is progressing favorably, and the enterprise will doubtless soon be in actual and successful operation. The Ceylon Tea Planters' Company (Limited) has been organized under the laws of the United States, and agencies will soon be opened in all the principal cities of the country. Mr. Pineo, formerly a Ceylon planter, and who has exerted himself with much success in making Ceylon teas known throughout the world, will be the general manager of the company with headquarters at New York. Hon. J. J. Grinlinton, of the Legislative Council of Ceylon and for many years a planter in that island, sailed the other day on his way home after a most satisfactory and encouraging visit to the United States in the interest of the proposed new departure in the tea traffic. Before his departure Mr. Grinlinton favored a representative of the *Standard-Union* with an interview, in which some highly interesting facts were disclosed.

"After a residence of over thirty years in Ceylon," said Mr. Grinlinton, "I have the coffee, tea and cinchona business at my fingers' ends. Some few years ago the annual export of coffee from the island of Ceylon was 1,000,000 hundredweight, last year it was only one-tenth as much. The coffee grows there at an altitude of from 1,700 to 5,000 feet above the sea. The chief reason for the decadence of coffee is that some few years ago a fungus parasite attacked the plant and is gradually killing it. Not only is this true of Ceylon, but it is also the case in Brazil and other coffee-producing countries. The consequence of this seems to be that people must learn to replace the use of coffee with that of tea. The price of coffee has been gradually ascending of late and will continue to do so, and the time is not far distant when the production will have been reduced to such an extent as to bring coffee beyond the reach of ordinary people. When this parasite attacked the coffee berry of Ceylon, the planters cast

about for something else to replace the coffee plant. This they found in tea. Only a short time ago the exportation of tea from Ceylon amounted to but 50,000 pounds annually, while this year it will reach the enormous quantity of 40,000,000 pounds, the majority of the higher qualities being purchased in Mincing Lane, London, for the Russian and Irish markets, these being the countries which consume the finest qualities of teas and consequently, preferred that of Ceylon to all others. Our crop of Ceylon teas is increasing to such an extent that we have had to reach farther afield for other markets in order to prevent the supply from exceeding the demand. I trust the American public will appreciate the efforts we have made to place within their reach the superior qualities of teas produced on our island. Heretofore, the formation of such concerns has taken place in foreign countries, formed exclusively of foreigners, with agencies in the United States, thereby virtually asking the American public to lay out their money for the support of a foreign corporation; and we trust that when the fact is generally known that the Ceylon Planters' American Tea Company has been formed in the United States and composed of American, as well as English and Ceylon capitalists, every possible encouragement will be afforded it." Mr. Grinlinton, in speaking of other products of the island of Ceylon, said: "We export much cinchona, and I am glad to learn that your Senate has just decided not to take quinine off the free list. Co'ombo," said he, "is now the emporium of the East, with a population of 150,000 people, but, strange to say, of all this number but one is an American, and he the representative of the United States in the island of Ceylon. The European population is composed chiefly of Englishmen, and the natives are the most honest and respectful of all the natives of the East, and any lady would be perfectly safe in journeying alone from one end of the island to the other." It is not difficult to understand the reasons of Mr. Grinlinton's popularity in his island home, as a more bluff, hearty and genial English gentleman it would be difficult to find anywhere. In speaking of his trip through the United States he commenced by saying, in a quaint manner peculiar to himself: "Why, actually, upon stepping from the steamer to the dock in New York the customs officers insisted on examining all my luggage, which seemed rather strange, as no officer in Colombo would think of to examine my hand-bag; but of course, I submitted gracefully and must say that I found the examining officer the most courteous and polite of gentlemen, who explained that he was but doing what his position compelled him to do, and in all my journey through the country I met with universally courteous treatment, even upon one occasion where it was necessary in making connections to take a train in the middle of the night, and having neglected to secure beforehand a sleeping berth, I was compelled to take the only seat to be found, which was in the smoking car, which was otherwise filled with what appeared to me to be a rough-looking lot of people, an opinion which was quickly shown to be erroneous, as, in order to make me comfortable, some of them insisted upon doubling up, as you call it, in order to place two seats at my disposal; and I am now about to start on my 11,000-mile journey for home, with the kindest thoughts for all of you Americans and a regret that I cannot remain longer with you."

Evidence of the merit of the Ceylon teas is also found in the effort before the Senate to add to the tariff a discriminating duty of 10 per cent on teas grown or produced east of the Cape of Good Hope imported from countries west of the Cape. The claim is made that the section of the bill has been added at the instigation of a few interested tea dealers who wish to confine the importation of tea to those countries where it is the most difficult for the smaller dealer to send orders, and is in reality aimed at the London markets; that Great Britain, against which the section is directed, admit every product of the United States except spirits and tobacco free, and that, therefore, no principle of protection is

involved, and consequently no reason for discrimination against tea other than other products of the Orient, which are largely re-shipped from European countries that the teas imported from London are on a higher average quality than the direct imports and that more than nine-tenths of these teas are bought in London by American merchants before shipment; and finally that section has been enacted before and repealed during a Republican administration, and that its reappearance now is due to the initiative of about five interested persons, while the majority of the trade are opposed to it. The British authorities annually seize thousands of chests of Chinese and Japanese teas and destroy the same as being unfit for human food. A few unprincipled dealers in this country, ascertaining that this stuff could be safely landed here, eagerly grasped the opportunity of purchasing and importing large quantities. The impurity of China teas is further sustained by United States Consul Crowell at Amoy, China, in his letter of Feb. 4th, 1889, page 589, in which he speaks of China tea as "vile stuff" etc., for the American market. In speaking of Ceylon teas, Senator Ewart himself says: "They are the only pure teas in the world," and English enterprise has been struggling for the last two years to introduce them into this country, meeting with much opposition from those wholesale dealers who find there is more money in handling adulterated China teas than the pure ones of Ceylon.

The following official table, showing the annual consumption in pounds, gives the best idea of the progress of Ceylon tea in Great Britain:

	1885	1886	1887
Ceylon ...	3,218,000	6,245,220	9,911,860
China ...	113,514,000	104,229,313	90,581,753
	1888	1889	
	Jan. 1st to Oct. 1st		
Ceylon ...	18,553,054	25,350,000	
China ...	79,792,866	51,800,000	

The English are known to be connoisseurs in teas, and the American taste will doubtless ratify the choice of the mother country.—*Brooklyn Standard Union*.

INCINERATOR REFUSE.—As an experiment, 1 hundred bags of ash refuse from Mr. Harrington's incinerator in Circular Road Calcutta, have been sent up to a tea garden in Assam to test its fertilizing powers and consequent value as a manure.—*Indian Engineer*.

UDAPUSSELLAWA.—The prospects of a good coffee crop next year are looked forward to from this district also, and several good blossoms have been out on all good coffee during the last month. Tea is flourishing but not flushing well just now, and some estates are busy pruning and cutting down the tea bushes. There have been a few days of rather strong puffs of wind lately, but not much rain, the nights are getting colder, and signs of the north-east monsoon being near at hand.

THE SUCCESS of the Colonial College at Hollesley Bay for young men has suggested the establishment of a branch of the Forsyth Technical College, specially devoted to the training of women for colonial life. There being no capital available for the purpose, it will be necessary to raise a guarantee fund for working the experiment for three years, and the board have an immediate offer of 200*l*. for the initial outlay, provided the required total of 1,500*l*. can be raised. According to the Managing Director—Ethel Forsyth—"The training that is proposed will embrace dairy work, poultry and bee farming and horticulture, and the laundry. Cooking and housework of the establishment will be undertaken entirely by the students themselves, under competent supervision. One year's residence will be compulsory in order to gain the college certificate. A suitable house, with farm buildings and land attached, and near a market town, can be had on easy terms if taken at once, and there is no doubt that there is a great and increasing demand for such training as we propose to offer."—*E. Mail*.

COLD SEASON LIFE ON A CACHAR TEA GARDEN.

Delicious weather, morning air exhilarating as champagne, Italian skies, roads hard and dry—it is glorious to get on one's pony and have a rattling canter over ground which till the other day was a series of sloppy, sticky mud-puddles, interspersed with occasional quagmires. Choti haziri is no longer an unpleasant duty, and the daily cold bath is scarcely the luxury it was. A few weeks ago, on coming in from our muddy round of the garden works, we were inclined for nothing but a long chair, a cigar, and a peg. Nowa-days he can tramp all over the country, or wade through bheels for hours after snipe, come home and set to a vegetable gardening (by the way I wish the Agri-Horticultural Society would send us seeds), and never think of anything stronger than claret and soda.

One's enjoyment of the exquisite weather is, however, sadly dulled by the rapid manner in which the gardens seem to be shutting up. The bushes are assuming a regular cold weather appearance, and some sections look as though they intended giving but little more yield. And this is only September. The season has been a complete chapter of accidents, a chain of misfortune from first to last, and until lately, as unpleasant as unfortunate. I fear it is a black look out for many concerns and many managers. A number of gardens, behind in outturn as it was, are rapidly going from bad to worse.

Down below the bungalow teela the green expanse of tea-bush surface, stretching away into the distance, glistens and sparkles with the dew in the morning sun. It is studded and diversified with the white, red and multicoloured garments of the leaf-pluckers. I have just been pitching into the sirdars about some careless plucking, and the sirdars, in turn, giving it to the pluckers. The women are an uninteresting lot, on the whole, with a few exceptions, notably our old acquaintances Rosy (Golabi), Sweet face (Sudamukhi) and Nectar (Amrita). The fresh lightness of the air has culivered them, and they are in high spirits, laughing and joking. An interesting colloquy is taking place between the three young women and a sirdar, who, standing on the road in a hortatory attitude, is getting rather the worst of the argument, and beginning to lose his temper at the chaff. Each of his admonitions regarding leaf-plucking is repeated with the utmost gravity by the two trio in a chorus, and in tones of serious exhortation to one another. It sounds as though the sirdar were conducting a sort of agricultural Litany, and the three girls intoning the responses. It makes the sirdar very worth indeed. "Bobot achcha, good old sirdar," concludes Golabi, "we will remember to pluck beautiful leaf for evermore. Oh, here's the Sahib, come along and show us how to pluck, Sahib." This young woman is in a chronic state of requiring my instruction. Her thirst for information would be most praiseworthy, but somehow my patient teaching invariably proves to be painfully devoid of result when her basket comes to be examined at leaf-weighing time. Sudamukhi has a pain in her finger, and wants me to look at it, and give her a holiday. Amrita would like her temperature taken with my little pocket clinical thermometer, as she thinks she has got strong fever. I tell her she does not look in the least feverish, and that if she really had a strong attack, she would not think so, but would be able to speak with full confidence on the subject.

Changsil and Fort Aijal are holding out pluckily. Captain Cole has sent a letter stating that there has been seven day's continuous fighting, but that the Lushais have retired somewhat. Three hundred and fifty of the 3rd Bengal Infantry have arrived, and the campaign will be a military affair. The detachment of frontier police from Debrughur take up the guards on the frontier. Captain Maxwell returns to Debro. I hope that Mr. McCabe will give the Lushais what the Irish style "taste of his quality."

I hear that the Manipuris have risen in revolt, occasioning the flight of the Raja, who, I believe, subsequently abdicated his throne. Two hundred men are

on their way from Kohima, to quell the disturbance. Altogether we are having quite a lively time, and it is likely to continue throughout the winter season. It is more cold weather than ever. The ground is becoming as hard as bricks, and I expect I shall have to reduce the hoeing tasks in order to get proper work. Five weeks ago the kodallis went up to the head into the soil, with their own weight.

The neem trees are looking dull and wintry. My commission on the season's working begins to look very distant, and I am afraid there is but little chance of the proprietors seeing their way to double my salary. —*Correspondent of the "Englishman."*

CEYLON UP-COUNTRY PLANTING REPORT.

PORCUPINES, CACAO BARK AND TEA SEED—ANOTHER ENEMY OF THE CACAO PLANTER—THE CACAO THIEF AND THE VILLAGE HEADMAN—A MYSTERY SOLVED.

Oct. 21st.

Men who know what havoc a porcupine can make in a cacao garden will be pleased to learn that dearly as that animal loves to tear the bark off the cacao tree, and destroy the pods, yet he is fonder of tea seed. An estate which was surrounded with scrub, infested with porcupines, and which suffered considerably from their ravages, has for some time now been wholly free of this plague. A field of tea has come up close by. The other night a porcupine was shot among the tea. The Sinhalese watcher had for some nights before been hearing a cracking sound among the tea trees, but could see nothing. Watching more carefully, he discovered a porcupine which he shot, and in the morning it became quite clear that it was the tea seed the brute had been after, and on which it had been freely feasting.

A worse enemy of the cacao planter is the Sinhalese rogue. The manager of a cacao garden told me the other day how about half-past six in the evening his watcher caught one of these fellows a little way from the boundary, with several measures of the fruit in his possession. An attempt was made to run the man in, the watcher offering his services to the extent of being prepared to swear that he caught the thief on the estate; but was told that he must stick to the truth. He did this, and the magistrate acquitted on the ground that there was no proof that the cacao had been stolen. The planter felt a little sore, and when his feelings were in this tender condition he had a visit from the local headman. This worthy had come to condole, which he did, adding as a reason for this miscarriage of justice, and perhaps too as a hint for future guidance: "Sir, how can you expect to get the thieves punished in the Police Court, unless you tell lies"! The planter says that the next man that is caught won't be taken before the magistrate, neither will any lies be told about him, but he will assuredly be punished!

There was a row in a cacao garden, owing to a number of branches having been broken. Careless gathering was supposed to be the reason, but yet it could not be satisfactorily brought home. After a bit, the watcher, out after squirrels, found the culprit and shot him. It was not a cooly, but a big scaly creature which had gone up the tree after red ants, and the weight of whose body had caused the damage mourned over. One lives and learns. PEPPERCORN.

THE LEAVES of the *Duboisia Hopwoodii*, an Australian shrub, are chewed by the blacks as a substitute for tobacco. They contain an alkaloid called piturine, which, according to some chemists, is identical with nicotine, or at least closely allied to it. —*Globe*, Oct. 10th.

NILGHERRY TEA DOING WELL.

We notice in Mr. W. G. and H. Thompson's Indian Tea Circular, of the 25th ultimo, that 107 chests Kodanad Nilgherry tea sold at prices ranging up to 1s 7³/₄d the broken pekoe realising that high figure, whilst the pekoe souchong fetched 11³/₄d. These results, which surpasses Ceylon and equal some of the best northern manufactures, should encourage Nilgherry planters. Climatic influences may affect the yield of Nilgherry estates, but when the manufacture is carried out with the best machinery, and in accordance with the most approved processes, the quality leaves nothing to be desired. —*M. Mail*, Oct. 20th.

HIGH AND LOW CINCHONA PRICES.

The now unusually high price of 1s per lb. was realised on Tuesday by a few lots of very fine bark—the first being two bales of renewed officialis shavings from Ceylon, and the next 10 bales bold Ledgeriana stem chips from India. For one small case of renewed quilly *Succirubra* chips from Ceylon the unusually high figure of 8d per lb. was also paid. At the other end of the scale the lowest price realised at the auctions was that paid for 3 bales *Succirubra* twigs from Ceylon, which sold at 4d per lb. Some years ago, when 2s 6d or 3s was a usual price for red chips, such twigs were thought cheap at 10d per lb. This week also 1³/₄d per lb. was the best offer that could be obtained for some damaged soft Colombian bark, imported as far back as May 1880. The broker was not at liberty to accept this bid, and bought in the parcel at 2³/₄d per lb., plaintively observing that when he offered it the last time—ten years ago—he rejected an offer of 1s 9d per lb. for the same lot. The parcel was a small one, and the loss to the importers—apart from the cost of the warehousing of the bark—probably not over 200%. About a decade ago offers of 4s per lb. were more than once refused for a specially fine brand (Z O) of this same variety of cinchona, but the owners of these lots were comparatively fortunate, as they have since been able to clear them at about 8d per lb. The large quantity of *Calissya* bark from the South American plantations formed a feature of the auctions. Nearly 90,000 lb., mostly of recent import via Liverpool or Hamburg, passed the hammer, and two-thirds of this was sold. It must not be forgotten that this bark is nearly twice as rich as the average Ceylon or Indian bark. Most of it is bought by the English quinine-makers. —*Chemist and Druggist*, Oct. 11th.

"THE CEYLON TEA COMPANY LIMITED."

As we fully anticipated the leading gentlemen connected with the local Tea Fund have seen the necessity for organizing a Limited Company to carry on after a commercial fashion the business created through the operations of the Fund's Agents. This was made very clear in the case of Russia the other day, when it seemed so great a pity not to pick up at once the interest and good-will created by M. Rogivue. We therefore highly approve of the new Company, into which we have no doubt, the Ceylon Tea Fund will eventually merge, and we are glad to see it is to be supported by leading planters and merchants. It is proposed to begin with the modest capital of R100,000 and the main object is to deal with the Continent of Europe as may be seen from the list of agencies appended. We quote as follows:—

The objects of the proposed Company are the sale of Pure Ceylon Tea, the pushing, advertising and generally making known Ceylon Tea throughout the world. To enable the question "where can we buy Pure Ceylon Tea" to be answered by and on behalf of Ceylon Tea growers. To supplement and support the action of the "Ceylon Tea Fund" by attending to the execution of orders for Ceylon Tea, and the appointment of Agents,

It is believed that, apart from the general good to all Ceylon Tea Growers and to the whole Island that will result from the undertaking, dividends will be earned by the Company when fully established.

Agencies will be opened in various cities throughout the world as opportunity offers:—

London, Colombo, England, Scotland, Wales, Austria (Vienna), Belgium (Brussels), France (Paris), Germany (Berlin), Russia (Moscow), Turkey in Europe (Constantinople), Australia (Melbourne), New Zealand (Dunedin), Tasmania.

We do not see why every Teagrower in the country should not be a shareholder, for he might in this Company expect a fair dividend for his investment as well as the indirect benefit sure to result to the Ceylon Tea Trade at large.

CAN THE COLOURS OF CORAL BE PRESERVED.

Such is the tenour of a query addressed to us by a correspondent, and it is one to which we do not feel justified in giving a positively negative answer in view of all that is being accomplished in the present day. We believe that efforts have been made to secure permanence to the vivid colour which distinguishes corals when viewed in their native *habitat*, but we are unable to inform our querist as to the degree of success which has attended such efforts. It is suggested that as after much experimenting, it has been found possible to fix the fugitive colours both of grasses and flowers—and in this connection attention is directed to the marvellously preserved grasses, &c., with which many of the oases of stuffed birds in the Museum of Natural History at South Kensington are provided—it might be found possible by some methods akin to those by which that result has been attained, to accomplish what is now desired, namely, the rendering permanent the colours which are so resplendent among corals when viewed from a boat and during their natural growth. Were these colours natural to, and inherent in, the corals themselves, as they are in grasses and flowers, it would seem as if this suggestion might not be wholly wide of the mark; but we believe it to be the fact that the resplendency to be seen while corals are in growth *in situ* is due, not to any pigment contained in the formation of the corals, but to the animalculæ which encrust them. These die almost immediately on exposure to the air, and the vivid colouring which charms so greatly when viewed through the medium of sea water almost entirely disappears when the coral is raised to the surface.

This is, we believe, the fact as regards all the coral found growing in Indian waters. At the same time we are aware that the fishers of the Mediterranean constantly obtain specimens, both of pink, red, blue and yellow coral, which stand the test of exposure and form the material from which the very lovely ornaments, sold chiefly in Naples and its neighbourhood, are prepared. Can any of our readers inform us as to whether the corals so worked up are subjected to any treatment preservative of their natural colour? Our own impression is that they are not, and that the colouring pigment is inherent. If this impression be correct, it is difficult to conceive any reason why, among the many varieties of coral produced in Eastern waters, there should not be some at least possessed of this quality of natural permanence. No one who has once visited the lovely submarine gardens to be seen off the shores around the island of Ramesvaram and in or near to Galle harbour can fail to retain recollection of

them as "a thing of beauty and a joy for ever." We have no hesitation in declaring that a view of these is ample repayment for a journey expressly made to their locality, and we really believe that an excursion trip organized by one or other of our steam launch proprietors would receive patronage and the cost of it be productive of no disappointment to those sharing in it.

This, however, is but a secondary matter. The point just now is whether it might be possible to perpetuate the splendour of such submarine gardens. If this were possible, we are assured that the fringes of our shores would furnish a harvest certain of great remunerative appreciation at home. The much prized pink coral of the Mediterranean fetches, we are told, more than three times its weight in gold for the more sought-after shades of colour. Even supposing that, as mentioned above, the colours are due to living animalculæ rather than to the coral itself, the question naturally suggests itself whether it would be wholly impossible to preserve these coloured creatures upon the coral and so perpetuate the beauty—the extreme beauty—of its appearance. Of grass we are told by the Psalmist that "in the morning it flourisheth and groweth up: in the evening it is cut down and withereth." This, however, has been falsified in a sense, for the grasses at South Kensington above referred to, look as fresh and as lovely as if still growing upon their native soil. Is it looking forward too much, or placing too great faith in the scientists of this advancing age, to hope that some similar method of treatment might be as successfully applied to submarine as to super-terrestrial gardens! Granted that the conditions of growth and the basis of formation are altogether different in the two cases; still in the one decay is but arrested, and such a principle does not seem to be wholly inapplicable to the other. We have seen fishes preserved by Mr. Haly with their natural brilliancy of colour retained. It would not, therefore, seem to be wholly irrational to hope that means similar to those employed in their instance might solve the query in reference to the corals which so freely surround us in this island. On the other hand we are bound to recall the fact that some time ago an Italian who was very eager to commence fishing off our coast for colored, if not pink coral, was discouraged by the then comparatively plentiful supply available in Europe. Has this been worked off and is the price really as high as has been indicated to us above,—are questions we should like to see answered authoritatively

COFFEE.—An anonymous correspondent in the *Journal do Commercio* of the 28th ult. says:—"Trustworthy advices from the states of Rio, Minas and S. Paulo give the future crop (coffee) as without equal; the trees are so covered with blossoms that they appear to be sheets, and from the appearance of the buds a much heavier blossom is expected in the months of September and October."—*Rio News*.

A MAN here has applied for a patent to petrify clay walls and publishes the formula in the *Diario Official* of the 23rd. It is: in 100 litres of water dissolve 1 kilogramme of shell lime, 1 kilogramme of jaggery sugar and 1 kilogramme of *caths*, whatever that is. Mix your clay with the mixture and set up your walls. Perhaps some of our Ceylon friends will tell us what *caths* is?—*Rio News*. [The word is, of course a corruption of *kahuta* astringent fruit,—Ed. T. A.]

FORTUNE-SEEKING IN EAST AFRICA.

Mr. Henry Brown, the Ceylon Police Inspector and formerly coffee planter, who is also known by his book on "Sport in Ceylon," is on his way to East Africa, having obtained six months' leave from the Inspector-General of Police. Writing from Aden on Oct. 14th, he says:—"Here I am vegetating amongst the barren rocks of Aden, and a more wretched place I never saw. I leave here tomorrow by a vessel of the new German line called the German East African Line. The steamers of this line call at all the ports on the coast as far down as Mozambique, and from thence I shall get a Portuguese steamer to Quilimane. I see the Bombay, Madras and Calcutta newspapers, but none of them come up to the *Observer* for news and items of interest. * * * I had to leave Colombo with only four hours' notice, and—what do you think—raised my steamer for the African coast owing to having been put 24 hours in quarantine, which seems absurd, for the 'Navarino' was 24 hours in quarantine at Trincomalee, and brought the General and party round to Colombo, and obtained a clean bill of health from that port. Only myself suffered, however, and I was put on a wretched lights-hip all alone. There is no newspaper published in Aden, but there is much need of one, for the carrying on of some of the official and unofficial residents is scandalous, to say the least, especially as regards their observance of the Sunday."

HOP TEA.

To the Editor of the *Home and Colonial Mail*.

SIR,—I have read with great interest the two accounts of "Hop Tea" in your issue of Oct. 3rd, taken from the *Daily Telegraph* and *Pall Mall Gazette*. The former paper is very misleading, as the produce is sold in packets, all marked in large letters, "India and Ceylon tea, mixed with English hops." The word "adulteration," which is so freely used by the *Daily Telegraph*, is a very ugly one, and quite uncalled for. No man with a single spark of honour would be associated with a company that manufactured an article for adulteration. I am in no way connected with the Hop Tea Company, Limited, further than I received a fixed salary during the hop season, which ends this week. But for my own and the sake of others I state that there is not one iota of truth in the statement made by the correspondent of the *Daily Telegraph* as to adulteration. Further, his statement "that the buyers give the farmers 4d to 61 per lb. for green hops, the margin of profit is obviously great," is misleading, and requires explanation. Your readers will easily make their own calculations from the fact that it takes four to five pounds of green hops to make one pound of dried hops; then add to this cost of English labour, machinery, and all manufacturing charges, &c. The tea planters of India and Ceylon are satisfied as long as it creates a demand for their teas and helps to push China out of the market, and they know that only a very small proportion of the precious hops can be used in their tea. There is no doubt that the mixture is a great improvement. The hop growers like it because it makes a new market for their hops, and some of them are of opinion that the "Sirocco" is likely to prove a successful rival to the old-fashioned way of drying hops. This only shows how many uses that valuable machine invented by Mr. A. C. Davidson, the popular Cauchar planter, can be put to. The tea consumers like it, and repeat their orders, and those that could not drink tea before are obtaining the sanction of their medical advisers to use tea with hops in it. Grocers like it because it is liked by their customers. I know of one grocer in this town who has sold on an average over twenty chests per week. It is with the deepest interest I have read Messrs. Gow, Wilson, & Stanton's most interesting yearly statistics, showing how Indian and Ceylon teas are year by

year superseding China teas, and now your fellow countrymen from the "Garden of England" join hands with those that have invested millions of British capital in India and Ceylon.—Yours truly,

PATRICK E. MACGREGOR.

"Ye Ancient Bell Hotel," Maidstone, Kent.
Oct. 7th, 1890.

NUTMEGS.

An old planter writes:—

"I do not know much about nutmegs. The climate of Hanwella would I think do very well and the soil might be suitable and perhaps those portions with an easy slope might be got to grow them.

"This product wants great care for 4 years, the plants requiring side shade removed every six months. —planted 800 plants near Kurunegala and had them shaded with cadjans, but their growth was very slow. It is now 7 years since he planted them, but I have not seen them for 4½ years. He planted also 300 cloves. I will write to the present owner and inquire how they are."

SOME CURIOSITIES OF THE TEA TRADE OF CANTON.

Mr. Alabaster's report on the trade of Canton for the past year contains references to some odd features of the export trade. Eighty thousand pounds of human hair, valued at £319, appear in the returns, and the Consul wishes it did not, for, as the greater part of it comes from the heads of beggars, criminals, and dead persons, it is not pleasant to think that it is worn by ladies at home, even though it goes through long processes of purification before it is made up into wigs, chignons, waterfalls, &c. The demand for what are called old silk embroideries is unabated; in fact, the majority of these garments are not old, but soiled, and the Chinese must look on the purchasers much as we should regard collectors of discarded teagowns or worn-out tennis suits. "It is true, much of the embroidery is very beautiful, but the association of ideas is not pleasant." The "scented tea" of Canton is the only branch of the China tea trade which the Indian cultivators cannot imitate.* The trade in matting is increasing; last year 228,929 rolls, valued at £123,957, were exported, chiefly to America, where it is largely used for carpets, and in a dry, hot climate nothing can be cooler, cleaner, or better; but it is not so suitable in damp weather, for it gets rapidly mouldy, and breeds fleas to an intolerable extent. An article of export which has come into prominence of late years is glass bangles, of which the value last year was £78,202. These bangles are exported chiefly to Bombay, "and it is strange that Canton should supply a British province with glass-ware." Brass buttons, 560,000lb. in weight, were exported. The manufacture was introduced by foreigners, but has now passed into native hands. "Buttons are the jewelry of China." The magnitude of the export of fans from Canton is shown by the fact that 11½ millions were sent through the Customs in the course of the year. The majority are simple palm-leaf fans, and go chiefly to America, where their lightness and cool appearance have brought them into great favour. For decorative purposes Canton fans cannot compete with Japanese, and for artistic beauty the Canton paper fans are surpassed by those of Foochow and Shanghai; but the feather fans made from the quills of the wild goose are strong, useful, and cheap. Preserved ginger, chowchow (a mixture of ginger, bamboo,

* We do not see why it could not be imitated if there were a sufficient demand for it. In the paper on tea which Mr. Brace contributed to our columns, there is a long list of plants, the blossoms of which could be used to flavour tea, and we have heard of a lawyer-planter in Ceylon treating his lady friend to tea perfumed with rose leaves.—ED. T. A.

oranges, &c.), cumquots, or little oranges, were exported to the extent of over three million pounds, valued at £41,137. In the interest of little boys at home, the Consul thinks it could be wished the export were larger, for, although the ginger may not be as pungent as that of the West Indies, the preserves are wholesome, agreeable, cheap, and, as far as the leading firm of Chyloong is concerned, cleanly made. As to Chinese medicines, peppermint oil and rhubarb have established their fame abroad, and when better known Pu-èrh tea will probably take the place of senna, as it is equally effective and far more agreeable. Of general medicines 2,992,533 lb. were exported last year, exclusive of special drugs, and 2,088 cwt. of pills. Another Canton speciality is teapots encased in wadded rattan cases. "They are not particularly handsome, but for a traveller, who wants to take a warm cup of tea to solace him during a long railway journey, they are invaluable, as they keep the tea warm for a considerable time, and keep the teapot from upsetting or getting broken." Woollen blankets, as an article of import, are increasing; white blankets are naturally not greatly in demand in a country where seap and water are rarities, and blue, being suggestive of a funeral pall, are not in favour; but every passenger by night boats seems to have a red blanket. Otherwise woollens are used chiefly for uniforms and table and obair covers. Gloves are not in demand, for the long nails are endangered by them.—*Times Weekly Edition.*

RATS DRIVEN INTO COCONUT TREES BY MONGOOSE.

Under this heading the *Jamaica Gleaner* reports evidence taken which goes to prove that the mongoose, introduced to destroy the cane rats, has become almost as great a plague in Jamaica as the rabbit is in Australia. As a sample of the statements made, we quote as follows:—

The Commissioners met at Headquarter House yesterday at 11 o'clock. The first evidence taken was that of Inspector H. Thomas of St. Thomas:—He said that the mongoose had destroyed all the quails in the district, all the poultry, and had destroyed the booby duck in the high mountains and blue dove. They killed the black crabs which were always to be found in the swampy lands. They had driven rats into the coconut trees, but he could not say if they were the cane piece rats. It was common to see the rats eating the coconuts. He has seen the mongoose climb trees like a cat. They were fond of fruit, especially the naseherry and mango. The small settlers were anxious to get rid of the mongoose. He had recent cause to believe they devoured their own species and had proved this by trying a dead one and watching and seeing a mongoose come for it and cut the cord to drag the dead one away. He believed they colonized, at one time you would see large numbers, and if persistent efforts were made to destroy them they would go away and come back again. He thought the male foraged while the female remained at home. He had been assured by penkeepers in Hanover that newly born calves had been attacked and killed. At Shettlewood Pen the overseer had told him that more than one newly born calf had been found with his throat cut and this was attributed to the mongoose. Pigs were destroyed in the same way. He never heard of them attacking infants. The peasantry could not preserve their poultry from them. He had 80 chickens destroyed in three weeks by the mongoose. He had known one to attack a rooster in the lush. The mongoose was averse to cross an open space. They bred in hollows of stone wall and penguin fences. Sharp dogs would keep them away. He knew a gentleman at Yallahs who caught 150 in a month. For a fair amount 1000 could be trapped in a month in his parish. He thought to get them trapped it would be better to give 1d per head or tail rather than only accepting them at that rate in exchange for taxes. He did not think people had more rats in their houses now than formerly, and had not noticed any diminution in the number of john-crows.

George Nethersole said: They did much mischief. He could not raise fowls. They drag cocoa from the grounds and eat the corn, breadfruit and red peas,

green corn and plantains. Had never seen them eat canes. The rats were as numerous as ever. They eat coconuts. Had never heard of a mongoose attacking children. They had destroyed the snakes. Mr. J. P. Walsh thought the ticks should be attributed to the mongoose as they had destroyed the blackbird, the great tick eater. He had seen mongoose among the crows on the beach eating fish offal but had never seen a black head crow—these were the young ones. Had seen john-crows eggs broken and thought it probable they had been eaten by mongoose. In a short time he believed there would be no crows left as scavengers. The poor people complained they could not pay their taxes because the mongoose ate their poultry. Fowls that used to be 4½d per lb. were so scarce that people had to pay now 9½ to 1s.

Mr. E. S. Salmon said the mongoose destroyed poultry, climbed banana trees and ate ripe bananas and pines.

WYNAAD PLANTERS' ASSOCIATION.—At the general annual meeting held at Meppadi Reading-room; on 1st Oct. 1890, there were present, Messrs. Abbott, Atzenwiler, Hockin, Jowitt, Lsmb, Mackinlay Malcolm, Morres, Powell, Puedzieux, Taylor, E. Trollope and G. Romilly, Hon. Secy. Mr. J. R. Malcolm in the chair, and the Hon. Secretary read the annual report, from which we make extracts showing how the Wynaad planters complain of want of labour and how they deem their prospects not very bright:—

The great question of the year has been the want of labor. Many Mysore maistries and coolies have not come in, owing it was said to the prevalence of influenza in their villages. The same reason has been given for the desertion of the Tamils, but in this case it is without doubt the fact that many maistries under advance to planters in this District have taken their coolies wholesale to Coorg. They unfortunately realise that owing to the rulings of the High Court with regard to Act XIII. of 1859, they can do this with impunity. Unless the maistry can be caught before the expiration of the term of his contract, (which he takes good care to prevent) he escapes without any punishment. If he is caught, he is merely ordered to fulfil his contract and thus given another chance of escape. We have appointed a committee to inquire into the grievances of the district owing to this useless Act and we hope that by a combined representation on the subject from all planting associations, we shall get Government to acknowledge the disabilities under which we are working and to grant us redress. Last January we requested Government to send an expert to report on the great mortality of Cinchonas throughout the district. Mr. Lawson the Director of Government Cinchona plantations was at once sent. He has reported that there is no specific or infectious disease, but that in his opinion the mortality is due to starvation. Unfortunately the mortality continues even in well-manured fields. As to our prospects I fear that notwithstanding the present high prices, the outlook is not bright. A terrible attack of leaf-disease has succeeded a very short crop, and Cinchonas in many parts of the district are still dying wholesale. Notwithstanding the letters that periodically recur in the newspapers, everything that science can do to determine the character of the *Hemilia Vastatrix* and everything that science could suggest to arrest its progress, was tried years ago in Ceylon, and yet in the face of science the disease has practically driven coffee out of the island. Now for the first time we, here, are realizing the possibility of such a danger. In Ceylon they turned their abandoned coffee lands into tea and prosperity returned. Here though we have abundant proof that tea will thrive luxuriantly, where both coffee and cinchona fail, owing to an apathetic Government we cannot command the labor. We have not sufficient even for our coffee; and tea requires double the quantity. So that unless we can get legislation to assist us without delay in enforcing our labour contracts, the end will be that we shall have to relinquish the land, in which we have sunk many laes of rupees into the hands of a short-sighted Government with diminished revenue.

HILLCOUNTRY PLANTING REPORT.

A SOUTH-WEST RAIN-STORM—FOREST AND RAINFALL AND GOVERNMENT RESTRICTIONS—A MORE LIBERAL POLICY REQUIRED—IMPROVED PREPARATION OF CEYLON TEA. NANUYA, Oct. 28th.

To revert to the question of forest and rainfall in mountain regions and the regulation prohibiting the sale of lands above 5,000 feet altitude, I take it for granted that the prohibition does not extend to the vast stretches of upland prairies, which are treeless or nearly so. And as regards forest land above 5,000 feet elevation, which all the remaining forest on the dividing ranges is, I strongly deprecate any hard-and-fast rule. Ever since my attention was attracted to the subject by a deputation from Kataragama when I was pioneering in Uva (half-a-century ago!) requesting me to spare the mountain forest for the sake of the sacred river, my opinion that, in mountain regions at least, the denudation of forest has not the slightest effect in diminishing rainfall has been but strengthened with the effluxion of time and the results of reliable observations. I was sorry to see a man like Mr. Moir, in his report on the Walapane distress giving currency to the proposition that the clearing of forest by planters had lessened the supply of rain for the paddy fields. There are regions of recurring drought on the outskirts even of mountain regions, owing to the position of such localities with reference to the monsoon currents; and all the records available show that in all history Walapane has experienced the effects of being situated in such a region. Mountains are nature's great agencies for cooling moisture clouds and currents and compelling them to part with their contents. But there are in Ceylon as in India portions of mountain ranges beyond the reach of our greater monsoon, the south-west, and from which, by topographical features, even the currents of the north-east monsoon are either deflected or have been previously deprived of their moisture. On the rainfall in such regions the process of felling forest about 40 feet high and substituting cultured plants about 4 feet in height, within a good many cases, cultivated trees of taller growth (cinchonas and timber trees, for instance), cannot have, and we know from extended observation has not had, any diminishing effect. There is more to be said in favour of the statement that the denudation leads to floods and the deposit of silt. But any tendency in the direction of floods is very largely counteracted by the tillage which the soil receives on estates and which renders it specially absorbent of moisture. One of the greatest floods in the Kelani river in modern times took place in 1837, when only a few hundreds of acres had been felled of the vast tracts of forest at its sources and along its course. Silt in rivers and streams is speedily disposed of by scour, and in the rare cases where paddy-fields lie beneath European plantations (there are no such cases in the region whence I write) damage by silt to the former could easily be obviated by the cutting of a trench between the two. This might be rendered imperative on the planter, instead of the course now frequently pursued of refusing to entertain applications for forest land, the clearing of which may possibly lead to damage of rice lands by descending silt. By all means let us have forest and fuel reserves in reasonable proportion and within reach of railways or other means of communication. And let rice cultivation be duly protected and encouraged. But surely it is an unwise policy to restrict further extension at high altitudes of the one enterprise on which the

Prosperity and progress of Ceylon so overwhelmingly depend. In the region around me as I write there are elevated ranges connected with such mountains as Pidurutalagala, Kirigalpotta, Totapala, &c., which ought not to be invaded by the clearing axe and with which no planter in his senses would tamper. But below these, at from 5,000 to 6,000 or 6,500 feet, are vast expanses of forested valleys, hollows and ravines specially suitable for tea culture and which cannot be utilized as reserved forest or fuel for the railway, owing to their distant and secluded position. If blocks in such valleys were laid out for sale, proportions of patana land being added for the growth of timber trees, there would be room for expansion of enterprise, culture and population; means of communication being provided under the operation of the Branch Roads Ordinance. To say absolutely that no land above 5,000 feet will be sold, is to say to progress in Ceylon "Hitherto shalt thou come and no further," and to divert capital and enterprise to lands which are our rivals in the production of tea: And this at a time when Ceylon tea is, above all others, finding favour in the markets of the world, and when its culture and preparation have come to be so much better understood than ever before. Apart from such details of manufacture as leaf-sorting,—first a light rolling of the leaf, succeeded by a heavier; the provision of "roll-breakers," and drawers for "fermentation";—planters now understand that the first flushes after pruning yield weak tea. Arrangements are, therefore, made for having fields of pruned and unpruned tea in due proportion, so that the leaf from each may be mingled. Then, at high elevations, it has been found that bushes can be plucked for two years in succession without being pruned, provided the previous pruning was low enough to prevent a tendency to blossom and leaf. In these directions and others knowledge has been obtained and improvements made calculated still further to add to the high quality of our tea and to the earnings of "poor but industrious planters."

DARJILING AND TERAI TEA SEASON.

Since the deluge, or more plainly speaking, since the heavy rains, there has been very little to record in favour of the tea prospect. The weather in the district has undoubtedly improved but beyond that the tea manufacture continues very much in the same groove that it did when things were in a perpetual state of mildew. As to the future it is very difficult to foreshadow the results of this season's working, but from recent accounts the hill gardens have considerably improved in quality of outturn. This is gathered from the last London market sales to hand, which show prices not only better than usual, but far exceeding those obtained last year for the same quality of tea. Although the hill gardens are favoured with what one might call tea-making weather just at present, the season is too far advanced for any material change to take place as far as quantity is concerned, and it is feared that many will close with a very short crop. There is, however, a chance of the season being late, with this wild weather. In that case it will be a considerable help to those who suffer the most from the effects of the spring drought.

The Terai gardens have had an unfortunate season all round. To commence with, they required moisture; this was followed by excessive rains in the hills flooding the rivers, and for two months many of the gardens in the plains were entirely under water. So, practically speaking, the factories have almost been closed for the latter half of the season. As soon as brighter weather favoured the place, it became enveloped in an overwhelming blight such as has never been known in the Terai, and there is very little chance of matters improving at present.

One or two of the gardens have done better than others, but on the whole the season will be a deplorable one to proprietors: some say that many of the small estates will close at the end of the season for want of financing. It is very difficult for small factories to exist in a place like the Terai. The climate is such that few proprietors would care to settle down in it, and the price now obtained is not sufficient to secure good management; consequently those places started in better days, have not a very bright future, unless amalgamated with each other to ensure good management at a minimum expenditure. It is estimated that the crop is twenty-five per cent. less than usual, some of the factories being as much as fifty per cent short of the outturn. Several changes in the managements are pending, both in the Terai and in the Hills. This is poor satisfaction to the proprietors, but it seems to suit some people to be in a constant state of change.—*Correspondent of Calcutta "Englishman."*

AFFAIRS IN MADAGASCAR.

Writing to the editor of the *Tropical Agriculturist*, the editor of the *Madagascar News*, in a letter somewhat similar to one from which we published an extract some time ago, says:—

"Madagascar is on the eve of a great development of her vast pastoral, agricultural, and mineral resources, and that the course of events here during the next few years will doubtless be of interest to you, especially as the resources of this island are very similar to those of yours. Beyond that, however, there is the French policy here to follow, the result of which were those directly associated with the Government cannot today forecast. Her Majesty the Queen, the Prime Minister, and the Court have been in the forest country ever since the Anglo-Franco Convention began to be negotiated, and the few people remaining in town are embodied with the Government; the town, however, desires peace at any price."

COCONUTS AND CINNAMON.

Kadirana, Oct. 30th.

It is a trite saying that all things come to those who wait; and to us at last has come the long delay, and therefore all the more welcome rain. Since the 26th it has rained every day with only short breaks of rest, but the rain till last night was so gentle that not a drop ran off the ground; during last night, however, the rain was very heavy, and the gauge measured 3.30 inches. The total for four days is 6.81 inches. There is a marked absence of electric disturbance. Gladness is in all hearts, but as for thankfulness that can come from only the Christian or the theist. The Buddhist can feel none, for to him there is no one to be thankful to except perhaps to himself; for must it not be due to his own good deeds—Karma—in some previous birth that the rain has come when it did! It strikes me that there must have been a good many whose merit is pretty equal to bring down the rain almost everywhere just at the same time! How would the Buddhist account for its falling equally upon the bad?—A bud is showing on the cinnamon, and will be well out in a few more days.

TEA IN FOOCHEW.—The news of the large settlements of tea during the last month have produced some sensation in the principal districts in the country, but owing to the lower range of prices offering they prefer to leave the leaf to grow old instead of picking it. It is believed by growers that a clean picking off of the leaf every year does harm to the plants, and that the short picking of last year has greatly added to the strength of this season's tea in the cup; for this reason, coupled with the low prices, they almost unanimously refuse to pick any further quantity, so the supply for the season may now be computed at no larger amount than 370,000 chests.—*Hongkong Daily Press*, Oct. 14th.

PLANTING AND NEWS REPORT FROM PANWILA DISTRICTS.

EXCELLENT TEA AND CACAO PROSPECTS—CARDAMOMS, PEPPER AND VANILLA—ABUNDANT LABOUR—ROADS.

WATEGAMA, 30th Oct.—I am glad to say we are not in the same position as "Eldorado" having all our cacao trees dying out, but, on the contrary, we shall all have an excellent crop this year and our trees look very healthy and fit to bear better crops as they get older.

We can safely rely on our 400 lb. per acre made tea from all estates which are properly cultivated in our district.

Cardamoms, pepper, and vanilla, are doing well. Labour abundant and cheap. Our District Engineer is giving his full attention to the roads, but the *shaving* system at present in use though good while there were lots of old metal 9 to 12 inches thick on the road will soon show the mud. There are several patches now on the road from Katugastota towards Galagedara where the cart wheels turn up the red soil. We now require a thick layer of good metal put on our roads, as the island can afford it and not wait till the last metal is shaved off. We also require better metal. Metal heaped on our roadsides (not by our present engineer) grows weeds and grass freely, thus showing the earth mixed with the stones and softness of latter.

THE CEYLON "AMERICAN" TEA COMPANY.

The following extract from a letter under date New York, Oct. 3rd, to the Hon. J. J. Grinlinton from Messrs. Wattson & Farr, gives a most encouraging account of the start made by the new Company:—

"The new Company began operations this week, and we already have had most encouraging success in obtaining a most excellent agent in Boston, and it is probable he will take the agency of the whole new England States, in return for which he will, of course, take a considerable number of shares. He is active, energetic, very well connected, and we are most fortunate in having gotten his co-operation. Several other promising agents are considering the business. We send you under separate cover copies of the first advertisements, which are quite striking, as you will see. We enclose herewith copy of the byelaws of the Company. The State Trust Company whose President, Mr. Willis Paine, you called upon, has voluntarily asked us to make them our transfer agents, which brings the Company another strong endorsement. We feel more and more that the Company is necessary to the prosperity of the planters, and we again ask your best efforts to secure for the Company the hearty co-operation of the planters in Ceylon."

THE ODOROUS EUCALYPTUS.—No worm or insect is ever found upon the eucalyptus tree, or in the earth where the roots penetrate. A row of trees planted through an orchard or vineyard will cause insects, worms, and caterpillars to vacate that region. Two branches of the eucalyptus used in the room or windows, or as decorations in dwelling rooms, will cause mosquitoes, moths, fleas and flies to leave the premises.—*Indian Agriculturist*, Oct. 11th.

A CEYLON PLANTER IN SOUTH AFRICA.—The movement of the British South Africa Company's expeditionary force should be watched with considerable interest upon country, inasmuch as the Company counts amongst its members a Ceylon planter well-known in Dikoya and Haputale—Mr. L. L. B. Dykes, who went home more than a year ago. Mr. Dykes was one who liked an adventurous life, and he seized the opportunity when at home of offering his services to the organizers of the expedition and was gratified to find them accepted.

PADDY CULTIVATION IN THE EASTERN PROVINCE.

IMPORTANT EXPERIMENTS AND PROFITS UP TO R26 PER ACRE, OR 130 PER CENT.

Colonial Secretary's Office, Colombo, 31st Oct. 1890.
The Editor of the "Ceylon Observer."

SIR,—I am desired to transmit for your information the annexed copy of a letter addressed to the Director of Public Instruction showing the results of the agricultural experiments conducted in the Batticaloa district, under the supervision of Mr. E. Elliott, the Government Agent.—I am, sir, your obedient servant,
 H. L. CRAWFORD,
 for Colonial Secretary.

EXPERIMENTAL PADDY CULTIVATION.

Batticaloa Kachcheri, 13th October 1890.

Director of Public Instruction, Colombo.

Sir,—In continuation of previous reports as to experimental paddy cultivation under the supervision of instructors furnished by you, I have the honour to state that during the past eight months I have carried on cultivation on a somewhat extensive scale, with a view of discovering what is the real cost of raising paddy with hired labour on land, the water supply of which is in ordinary years fairly assured, and working with *unborrowed* money.

2. For several reasons, I decided to work in three localities and accordingly secured 35 acres at Nintavur in Batticaloa South, 26 acres at Ampilanturai in Batticaloa centre, and 23 acres (in two parcels) at Eravur in Batticaloa North, making a total of 84 acres. The cultivation was supervised by three different instructors, who worked perfectly independent of one another. The year has been a most trying one owing to the very short rainfall of the north-east monsoon and the long subsequent drought which is almost unparalleled in the annals of the district. The consequence is our cultivations suffered in common with those of our neighbours, but even in our failures we have learnt useful practical lessons and established that the improved mode of cultivation possesses a distinct advantage even in periods of drought. At Nintavur alone was there a fair water supply and the results are satisfactory, though we should certainly have had a bigger crop of the season had been an ordinary one. At Ampilanturai the water supply ran out early and at Eravur the irrigation available for one parcel was very short, and failed almost altogether in the other case.

3. As Nintavur is the only part of the extent which has had any fair play, I give in the annexed statement full details of the expenditure and may add this has been carefully audited for me by Mr. Morphew. It is, I believe, prepared on strictly accurate principles of accounting and includes 20 per cent depreciation on the improved ploughs (iron) besides cost of new shares (which only last one cultivation it is found). The total outlay was R702.09 for the 35 acres (inclusive of Government tax and headman's fee) and the crop was 152½ avanams (or 1140 bushels) of well cleaned paddy. Half the crop was sold at public auction in my presence for R10.75 per avanam, and purchased by an outsider. (The rest was retained for agricultural purposes). The whole crop was consequently worth R16.16 or R1.42 per bushel. This is higher than paddy usually sells for in the locality, but it was excellent grain well cleaned and the actual sum realized is hardly above what the crop would have brought in an ordinary year and at ordinary prices. (We got 44 bushels per acre last year off 7 acres of this field, against under 33 this year.) So I think we are justified in taking the actual amount realized as a measure of success, not out of the usual run; the higher price only compensating for the shorter crop due to an unfavourable season.

4. The cost of production was 17½ rupees per acre or under 54 cents per bushel of crop, and Government tax &c. was 8 cents per bushel more, making a total of 62 cents per bushel in an unfavourable year when paddy is selling at R1.50 per

bushel in the same locality at *harvest time*. The net profit was R26 an acre or R914 against an expenditure of R702 in eight months or 130 per cent on that outlay. The rent agreed to with the landlord was R220 or about 11 per cent on the present selling price of the land, leaving the cultivator R694 profit on an expenditure of R702 or nearly 100 per cent. If the proprietor and cultivator were the same person his profit would be over 32 per cent on a capital of R2,800, which represents the selling price of this land plus the capital necessary to work it.

5. From enquiries made on the spot I am informed most of the lauds in the tract gave only a crop of 15 to 18 bushels per acre, but some 70 acres gave 22½ bushels and 30 acres lying lower and considered the best in the vaddai gave 26 bushels. The improved tillage can consequently be credited with 10 bushels worth R14.

6. This is really the only experiment which advances our knowledge of the subject, but that equal publicity may be given to the less favourable results due to the untowardness of the season. I give the figures for the other stations, which are as follows:—

Station.	Extent cultivated.	Total crop.	Total Expenditure.	Total Income.
	Acres.	Bushels.	R.	R.
Ampilanturai	26	187½	302	225
Eravur Munmari	16	262	306	320
Do Kalavelanmai	7	64	131	99
	49	513½	739	644
Add Nintavur	35	1,140	702	1,616
Total ...	84	1,653½	1,441	2,260

From this table it will be seen the net profit on all 4 transactions was R819 on an outlay of R1,441. The cost of production including Government tax and headman's fees is 87 cents per bushel of paddy at a time it is selling for R1.50. This is about as crucial a test as could be applied to the industry. It is said that these experiments have no value, as they are undertaken under circumstances very different from those attending the ordinary cultivation of paddy. To this I would reply that they are important in the first place in arriving at the actual cost of production, and so being a check on the fanciful estimates which appear in the public prints, and even at times in State papers such as the appendices to the recently published report of the Grain Tax Committee. Undoubtedly no private cultivator in the island expends anything like the amount the instructors have done per acre, nor I suppose do they get an equal return. I doubt if any one spends more than R10 per acre and for this he obtains in a fair land a return of 25 to 30 bushels of paddy worth generally as many rupees. In poorer lands loss is spent, but the return is as a rule in proportion in ordinary years, where irrigation is available. Of course where this is absent the industry is liable to greater fluctuations according to the rainfall and its distribution. I would in this connection call attention to the remark made in my report of last year.

7. There are some collateral points of interest brought out by these cultivations which deserve to be recorded. The advantages of transplanting were especially marked at Eravur where the water supply was very short, the transplanted portion having yielded 13½ bushels per acre against 8½ of the broadcast, while the additional cost of the process is under R1 per acre. If we had only transplanted the whole 7 acres in this portion we would have made profit! On the other land at Nintavur where the water supply was fair, the difference was very small; but the outlay on the transplanted area was slightly less than on the broads cast owing to the saving in seed paddy and the difference is only about R1 per acre in favour of transplanting.

8. At Ampilanturai though we only got 7½ bushels per acre, the adjoining land owners only got 4½ and at Eravur we got nearly 16 bushels per acre against 11 secured in the neighbouring fields.

9. At Nintavur, a small quantity of lime (40 bushels costing R4) was scattered over the land with the seed; and owing to this, the Agricultural Instructor thinks it probable the crop was exempt from the

ravages of caterpillars which infested the rest of the tract.

10. The iron ploughs used were some I got from Messrs. Massey & Co. of Madras, which cost R8 and R6 in Madras and about R1 more to bring over by native vessel. The cheaper plough (known as the Ryots) did very fair work, and is well suited for the light cattle of the country, but wants strengthening in the elbow; the shares are detachable and a new one cost 75 cents.

11. As I was on the last occasion charged with omitting to make provision for watching and fencing, I think it well to explain that at Nintavur there were five permanent labourers (i.e. one for every 7 acres) engaged for the whole cultivation, who did all the watching and fencing as well as the ploughing, ridging, irrigating and sowing, in addition to helping in the reaping at a cost of R266.50. Additional labour was taken as required for reaping, thrashing, stacking, etc., which was paid for in money. Similar arrangements were made at the other localities.

In conclusion I have to intimate that I propose again undertaking cultivation of the same extent during the coming season.—I am &c.

(Signed) E. ELLIOTT, Govt. Agent.

Actual outlay in the cultivation of 35 acres of paddy land at Nintavur in the Batticaloa district under supervision of Mr. Chelliah, Agricultural Instructor.

NUTMEG CULTIVATION.

(From a Correspondent.)

"Old Planter" is quite right—nutmegs will thrive all along Hanwella on both sides of the river's banks, and do thrive splendidly, judging by the specimens I have seen in a headman's garden in a village just opposite the 15th milepost on the Hanwella road, on the other side of the river and close to its banks. I have also seen nutmegs grow luxuriantly along the banks of the lake at Bolgoda. There is no doubt that nutmeg plants must be well shaded and tended (watered during the dry season) for at least about 3 years after planting, after which it is all right. I believe that mangosteens will also thrive in the Howagam Korale, and would suggest to the present Mudaliyar the advisability of applying to Government for 100 plants to be distributed in his korale. The

present young Mudaliyar of Siyane Korale West has with his usual generosity distributed a good many mangosteen and other valuable fruit plants throughout his district to all such landowners as he deems deserving, irrespective of caste and creed; and not only this, it is well-known that valuable breeding bulls were generously lent by this young gentleman to those in his district who needed them, and this good example may well be copied by his brother Mudaliyars. Nutmegs are said to thrive wonderfully well at Weke, where this Mudaliyar has a good many trees to show in his superb coconut estate which is the admiration of all who see it.

PLANTING IN MAURITIUS.

(From the *Merchants and Planters' Gazette*, Oct. 11th.)

SUGAR: THE WEATHER AND THE CROP.—Manipulation is being carried on with great activity on all the estates of the island. The yield is sufficiently satisfactory although inferior to that of last year in certain quarters. According to the results obtained up to this day, the total production will be inferior to that of last year.

VANILLA.—The market is entirely bare of fine qualities. The products of the new crop will not appear on the market before the end of this month. We entirely confirm our last valuation as regards the total output of the coming crop which does not exceed 14,000 kilos.

The following quotations are nominal:

	per kilog.
Vanilla 1st quality R18 to R20	
do. 2nd ,, 16 to 18	
Vanilloes 8 to 10	

ALOE FIBRE.—100 bales of good quality have been taken for Australia at R250 per ton. There would be takers at the same price for Europe but the fibre is scarce, holders ask for higher prices.

FREIGHTS.—The following are the quotations of the day:

London...27/6 to 30 and 5/0 N.

THE FINANCIAL POSITION.—It appears from a financial statement placed on the table of Council on Sept. 23rd that the receipts since the 1st January amounted up to the 30th July 1890 to R4,030,488.41, the expenditure during the same period to R3,389,378.75, leaving a balance of R641,109.66 in favour of the Treasury.

COFFEE.—Since our last, arrivals having succeeded, prices for both Good Ceylon and Réunion have decreased and are selling at R59 to R60 and R60 to R61 per 50 kilos, respectively. We quote mixed "triage" qualities from R35 to R50 per 50 kilos, according to quality.

GEMMING IN RAKWANA.—We learn that there is very considerable activity shown in sinking gem pits in the vicinity of Aberfoyle estate. In one case a shaft has been sunk for 100 feet and the "illan" has been struck so freely that profitable results are anticipated. This is a pit carried on under European auspices, Mr. Siedle being Colombo agent and Mr. W. Home, the pit manager. Close by there is an equally deep pit belonging to Mr. Fernando and another to an enterprising Moorman. The efforts of some of the practised native gemmers to mystify the Europeans as to the "illan" are described as very constant and persevering. Such native experts hope that their European superiors not finding the long-expected illan at 40, 60, 80 or 100 feet may abandon the pit and go to work elsewhere, when the abandoned shaft would be very speedily taken up and worked out by a native confederacy.—We are told that the value of £1,000 put on a week's findings of stones at Rangwellatenne is an exaggeration; at any rate that the Company would be very glad to accept that amount for the gems they have so far secured.

LIBERIAN COFFEE.

AN ADDRESS BY HEER H. J. WIGMAN TO THE BATAVIAN ASSOCIATION OF AGRICULTURE, AT A MEETING HELD AT BUTENZORG ON THE 23RD JULY 1890.

(Translated for the "Tropical Agriculturist" from Dr. H. J. Wigman's Address, by John Dent Young.)

It cannot be too strongly urged, that in colonies such as Java the prosperity of the natives and colonists depends in a great measure on the cultivation of the soil. Should the prosperity of agriculture diminish—whatever may be the cause—the evil results are immediately felt throughout the length and breadth of the land. In countries where commerce and manufacture have reached a high stage the inhabitants may have made themselves less dependent on the soil; here we have not yet attained that point. A few years ago agriculture underwent a fearful crisis, from the effects of which we have not yet quite recovered. Such circumstances are not strange in the history of agriculture in most countries; generally it emerges from them with renewed vigour. It then becomes the question whether by a better system of working, and by more rigid economy, it be possible to continue the competition with other countries, or whether it be inevitably necessary to abandon the existing kinds of cultivation and to seek for others. An example of this last we find in Central Europe, at the time when America flooded the European markets with her colossal importation of corn, causing the prices to fall to such an extent that in some countries, notwithstanding the most strenuous efforts, the corn growers found it impossible to continue the competition. Especial duties were levied on imported grain for protecting native industry, but in spite of all efforts to sustain a kind of factitious prosperity, it was only in very favorable circumstances that such cultivation could be carried on.

Many looked round in search of other products to cultivate. In lands suitable for cattle breeding, this industry was extended. England chiefly led the way in cattle breeding; elsewhere so-called *minor products* were tried. A large portion of former corn fields are now planted with beet-root for sugar making, and it is this cultivation that wages a life and death struggle with the tropical sugarcane. Another of our staple products is more directly threatened by America: the enormous quantity of coffee exported thence caused a considerable fall in price a few years back, and although at present the article has recovered a satisfactory value, still the position of the produce here is attended with anxiety, all the more on account of the leaf-disease and the "jamur upas" which persevere in their work of destruction.

It causes no wonder that agriculturists and those who are interested in cultivation use their utmost endeavours to bring about a better state of affairs. That matters are now very much better than they were a couple of years ago cannot be doubted. Of one of the branches of culture which was introduced during the disastrous epoch alluded to, which has every chance of being greatly extended, I now purpose more fully to speak, it is the Liberian coffee.

Here I must unavoidably refer to what I have already written in the "Teysmannia" under the head of "Notes on Agriculture."

As the name indicates, this kind of coffee has its origin in Liberia, a negro republic, founded by an American philanthropic society, which purchased the freedom of seventy thousand slaves, and sent them from America to the coast of Upper Guinea.

The Republic now counts 215,000 inhabitants; it does not yet go well with them, and that their condition is in a great measure the fault of the liberated slaves, appears amongst other proofs from the wasting neglect of the splendid kind of coffee which is there indigenous.

It is only in the uttermost need, so tell us travellers who have visited Liberia, that the negro goes into the forest, there gathers ripe and unripened coffee just as it comes to hand, and dries it in the most careless

manner. Such coffee used to be taken to London in small lots, and as it had (not without justice) earned a bad reputation, it was generally disposed of at very low prices. Latterly, more care has been bestowed on the preparation of the Liberian coffee, and its exported of good quality.

In a recently published work by J. Büttikofer, Conservator of the National Zoological Museum at Leiden, entitled "*Reisebilder aus Liberia*,"—Brill 1890, I find some particulars respecting the soil and climate which I now communicate. In the second volume of this work, which has not yet appeared, the cultivated plants are to be treated of, and I hope later on to furnish you with full information on them.

The soil of Liberia consist for the most part of red clay ground containing a great deal of iron.

The only months free from rain are January and February—and even towards the end of the latter month the clouds begin to gather, thunder is heard rolling in the distance, till at length a tornado bursts with storm and rain. From this time to the end of March frequent storms occur; and still more often in April, when they happen almost daily. Vegetation had been in a state of summer sleep during January and February, when many of the trees and shrubs lose their leaves, is now awakened up by the powerful influence of the superabundant rains, and again assumes its magnificent attire, with the glories peculiar to the tropics alone.

This is the most favourable season for planting and sowing the fields; during the first two months of the year the labor of felling and burning off are performed, and in the first place rice and Indian corn are sown, which quickly germinate and spring up. In May the storms and squalls subside, and the regular rainy season sets in. The sky is constantly covered with dense clouds and rain falls almost without intermission; hardly a day passes without rain. About the middle of July the weather moderates and there is an interval of fine weather, and the harvest season begins, the rice and Indian corn are got in and dried as quickly as possible, as the second half of the rainy season quickly approaches and would render such work impossible.

At too soon the few fine days, the number thereof varying much in different years, come to an end and the rains pour down with redoubled violence. Indeed it can hardly be called rain; the water streams down from the atmosphere, day and night, at times for weeks together. The rills become great streams, whole tracts of land are laid under water, and most of the roads or ways become impracticable. Day after day the negro is as it were shut up in his hut, and forced to idleness he lives on the rice and maize which he has been able to store up under cover. Thus go by the months of August and September with almost continuous rain. In October the tornadoes begin again, in November the rains become less frequent, and during December they generally take up altogether.

The thermometer shows a mean temperature of 25° Celsius at 6 a.m., 30° at noon, and 29° at 6 p.m., at nights the thermometer seldom falls below 24°, and at the warmest weather it rarely rises above 31° in 1 p.m. When the magnificent species of Liberian coffee became better known, Dr. Scheffer, the then director of the National Botanical Garden here, made strenuous efforts to introduce it into this country. The Liberian coffee was introduced somewhat earlier into Ceylon than it was into Java; the well-known firm of William Bull, in London, obtained seed from Liberia and succeeded in getting it to germinate in their hothouse, and the plants thus raised were planted in Ceylon in 1873. In July 1874, the first Liberian coffee seed was brought to the National Botanical Garden by the intermediation of the Ministry for Colonies. I well remember the surprise which was excited here on the appearance of the fine large coffee beans when they were first shown here. The largest of these seeds in the parchment measured in length not less than 22 millimetres, and 12 in breadth. This seed was packed in two cases, one in dry sand and the other in charcoal; but in spite of all the care that could be taken in bringing them over, not one of the seeds germinated to the great disappointment of all concerned. Towards

the latter part of the following year (1875), we at last received two wardian cases containing 118 plants, which were landed here in the best possible condition.

These plants had first made the voyage from Liberia via the Cape of Good Hope to Netherlands; they were unpacked at the Leyden Hortus, and when they had somewhat recovered from the effects of their voyage they were replaced in wardian cases and sent by the steamer "Conrad" of the Maatschappij Nederland to Java.

The commander of the steamship was requested by the Government in Netherlands to bestow the utmost care on his valuable freight. I was in the roads when the "Conrad" arrived, and on the same day the plants were safely placed in the National Gardens at Buitenzorg.

These were the first live Liberian coffee plants imported here, and although we cannot now declare that all the Liberian coffee at present growing in Java derive its origin from those same plants, for since that time private persons have brought over further supplies, still such is the case to a great extent. In the early part of the year 1876, these plants were put out. As we knew little of this cultivation, the distance between the plants was fixed as usual at 6 feet. It soon appeared that the plants were much too close together, and the distance apart was brought to 10 ft., and even this space was afterwards found to be insufficient. The Liberian is now generally planted 12 feet apart, and yet it is found that the entire ground is so fully taken up by the roots, that it would be better to give them more room.

In the beginning of 1877 the first blossom began to show itself; it was then feared that the new sort of coffee would produce very little, as only a single blossom showed itself at each joint of the branch. Happily it was soon found that such fear was groundless, as an abundant show of spike speedily developed itself on every joint. The first crop of any importance was gathered in the Experimental Garden between the middle of June and the middle of August 1878. It is a curious fact that when this first crop was gathered, the trees grown under shade yielded $2\frac{1}{2}$ pikuls per bouw, whilst those fully exposed to the sun produced $3\frac{1}{2}$ pikuls.

The culture of the Liberian coffee is still new to us. We have yet to a great extent to learn it; there is much that we do not know, but of one thing we may rest assured, that is, that this kind of coffee has a great future in store for many. It suits itself in a wonderful manner to all kinds of circumstances. I have seen fine plantations on abandoned coffee lands, as well as in tea plantations under cultivation. This last fact, gentlemen, is worthy of remark, for it is well known that the roots of the tea plant permeate the soil in all directions like a net-work, so that there is literally not an inch of soil left free from their interlacing. Thus only a very strong plant can flourish in such a position.

I have seen thriving plantations of Liberian coffee at an elevation of a few hundred feet above the sea-level as well as at 2,000.

In 1875 researches were instituted in Liberia at the instance of the English Government for the purpose of obtaining information from the natives regarding the various circumstances in which this kind of coffee grew best. The particulars thus obtained were as follows:—

Liberian coffee grows as well in the immediate neighbourhood of the sea as in the interior, and it is cultivated at heights above sea-level varying from 10 feet to 550 feet. The variety which produces small berries bears fruit in 18 months. The large sort is preferred because the coffee it yields is of better quality and more abundant, although the first crop is not gathered until the third year, and in the more elevated districts the fruit is less in size.

Under shade the tree does not come on well, though the ground should be well covered by planting the trees close together, or by covering the ground with dry leaves, grass, &c. This is especially necessary for young plants. The distance of the plants from each other varies from 6 to 12 feet. Full-grown trees bear from 20 to 24 pounds of (dried?) fruit.

Until we shall be in possession of the second volume of Büttikofer's work, we are unable to say how far the above information can be relied on. The writer just named passed two years in Liberia, and is in every sense of the term an observer who may be depended on.

As regards shade it is an established fact that Liberian coffee here requires shade. As I have previously stated in the "Teysinannia," the first plants were divided into two lots, one of which was put out in the open and the other under shade of the *Albizia moluccana*. They were in all other respects similarly circumstanced. Those that were exposed to the full force of the sunshine at first did better, they grew more quickly, threw out branches lower down, and when three years old yielded one pikul per bouw more than the others. Then they began to shew signs of weakness, especially after a second good crop; they deteriorated perceptibly, became sickly, and the "jamur-upas" and leaf-disease commenced their devastating, and if the necessary shade was not speedily supplied, certain decay soon followed.

Why it is that Liberian coffee succeeds so well in its original habitat without any shade, whilst here we learn from experience that shade is indispensable, has not yet been explained. For in other countries, Singapore for instance, and elsewhere in the Straits, no shade is planted on coffee estates.

Besides the experiments made in the State's Gardens at Tjikenneuh, many planters have learned from experience that shade is essential. Although it is an established fact that here we must have shade, the best kind of tree for the purpose has not yet been ascertained. As had been proved in the State's Experimental Garden shade is not necessary for the young plants, for they are stronger when grown exposed to the direct action of the sun's rays; therefore a shade tree of quick growth is made use of and the coffee and its shade can be put into the ground at the same time. The trees most in use are *Albizia moluccana* and *Erythrina* (dadap), and which of these is to be preferred depends on local circumstances. There are places where the dadap grows badly; in other localities the *Albizia* has much to suffer from strong winds. Upon a large estate in a neighbouring residency the dadap did not grow well, and it was decided to plant the *Albizia* here and there; this kept the ground cooler and the dadap was then planted with success. The latter must be lopped for the purpose of forcing it to shoot up to the required height.

Other trees besides these named are planted for the sake of the shade they afford,—the *Caesalpinia dasyrhachys*, with which good results have been obtained, amongst other places at Dramaga.

These *Caesalpinias* which were discovered by the late Mr. Teysmann during a journey through the Lampong districts, and thence introduced into the National Experimental Garden, attracted the attention of the late Heer Zeper at Aardenburg (Soekaboemie). This latter gentleman published an account of the properties of these trees in the Journal of Agriculture and Industry (*het Tijdschrift voor Landbouw en Nijverheid van N. Indië*). The publication had for result that applications were made by a great many people for seeds for the purpose of experiments. The limited quantity of seed produced by the two trees of the kind in the gardens did not furnish sufficient to satisfy all the demands.

The native name of this tree in the Lampong districts is *Petal-Petah*, *Petar* or *Pepetar*. The Resident of the Districts named supplied some of the seed. The tree affords fine shade not too dense, and is stronger than the *Alb. mol.*, but its growth is by no means so rapid.

As regards the height above sea-level at which Liberian coffee can be profitably grown, as far as we have seen, it succeeds well up to the height of two thousand feet; but we are not in a position to say whether we can safely go higher than that. There certainly are here and there trees that thrive admirably up to 3,000 feet, and likewise yield a satisfactory quantity of fruit. And a planter in the Preanger Regencies informed me that he had determined on forming a plantation at that height guided by the luxuriant

appearance of some trees on the spot. But I would not venture to recommend planting at so great a height, as I have seen Liberian coffee growing at 3,400 feet above the sea, which I must say left much to be desired in development, as well as in bearing.

Buitenzorg and its neighbourhood seem to offer a favorable climate for this kind of coffee. If you ask me, gentlemen, how Liberian coffee would fare in the often dry lower lands of East and Central Java, I must tell you that as is well known and as is stated in Büttikoter's work, the climate of Liberia is very wet, and although in this respect it resembles West Java, it is questionable whether it could hold out against a drought of six months and at times of longer duration. In the year 1877 there occurred an unusually long drought; even at Buitenzorg there was no rain for months; although the young Liberian coffee plants grew but little during that dry period, they suffered but slightly from its effects.

Great care is called for in the working of the soil. Generally speaking we are in the lower lying lands less favourably placed than in the mountain forest; lands, rich in humus, which has such a beneficial influence on coffee, and which is wanting with us. It is evident that we must supply its place by good tillage, drainage, and manuring; without these factors we shall not arrive at much. More than one Liberian coffee plantation has failed, because no sufficient allowance was made for the difference of soil.

In such matters it is impossible to lay down hard and fast rules; all depends on local circumstances. On level ground many will prefer having the whole surface dug up before planting, others content themselves with having holes dug for the plants, a method which may answer very well, provided that it be not neglected to turn over the ground well round the holes afterwards, or at least to loosen the soil to some depth, should the subsoil be inferior to that of the surface.

Drains are indispensable, and in deciding the distance between the drains the formation of the ground has to be considered, as the nature of the drainage required depends on that. Stiff soil naturally necessitates closer drains than does light soil. The manuring of the ground in like manner must be regulated by the nature and formation of the surface; above all, heavy compact soil, such as is generally met with in the lower lying lands, must be enriched with humus, for which purpose green crops, stable manure and compost are the most suitable materials.

Must Liberian coffee be pruned, and how is it to be done? These are questions often put to me. As far as my own experience goes, I must answer no. At first I was of opinion that such operation was necessary, or at least that the tree should be limited to a single stem; but I am now by no means so sure on that point. I have seen a great number of magnificent trees, growing in two, three and even four stems fully as well as those confined to a single stem. The advantage in allowing a plurality of stems to grow appears in case of any attack on one of them by the "jamur upas"; as the injured stem can be removed easily and the tree remains in good condition.

I need hardly say that every stem or branch attacked by the "jamur upas" and thus cut off should be burnt immediately; although every one must be aware of the necessity of this burning of the diseased parts, it is not sufficiently attended to.

Some of the plants have a disposition to throw out suckers; these must naturally be removed in time.

I cannot recommend the topping of this kind of coffee. The trees are of too vigorous growth; they become too high, so that it is impossible to keep them to a limited height. Should it be attempted to do so, the production of an impenetrable mass of branches would be the consequence, which would interfere with the setting of the fruit and end in injury to the plant. It is true that we have numberless trees here of between 20 and 30 feet high, loaded from top to bottom with fruit, and that ladders are indispensable for gathering the berries. There is no help for this, and it is well worth while to employ them.

How high or how old the tree can become here is not yet known; our oldest plants have reached 15

years, and some have arrived at the height of 25 feet, without showing the smallest sign of age, and go on flourishing and blossoming.

Like every cultured plant the Liberian coffee has its diseases to fight with. I have just mentioned the "jamur upas," besides which the leaf-disease attacks the Liberian coffee. As regards this latter, I need only refer to Dr. Burck's work on the coffee leaf-disease. There are other complaints which coffee here suffers from, but none of a nature to cause any doubt as to the successful future in Java of Liberian coffee under a rational system of cultivation.

And now as to the produce. I regret to say that this is not in keeping with the appearance of the plant. When we look at a tree of 25 feet high, from top to bottom laden with the fine large berries, under the weight of which the branches threaten to give way, we feel inclined to hope for a fabulous quantity of crop. But much of the substance is lost, the pulp and skin are very thick; according to trustworthy data during the East monsoon about 125 gantongs of cherry give 1 pikul of clean coffee, the proportion being 12.5 to 1 in pikuls. In the West monsoon the proportion is more favourable then; from 10.3 gantongs of cherry, 1 is attained of clean coffee, being 10.3 to 1.

Trees of 8 to 9 years old, which yield from 5½ to 8 gantongs of fruit are not unrequent. But the mean yield of a large plantation is another matter. Besides the data furnished from the Experimental Garden at Tijkeneuh, I have by the kindness of den Heer P. O. van Motman, obtained data of the produce of a plantation 8 years old with 8 bouws in extent.

The trees were planted in 1882 and gave in 1886, 50 pikuls; in 1887, 96 pikuls; in 1888, 80 pikuls; and in 1889, 88 pikuls. The harvest of 1890 is not all in yet. The harvest is thus respectively 6½, 12, 10 and 11 pikuls per bouw. The proprietor of this plantation is of opinion that the mean produce of the last three years, viz., 11 pikuls per bouw, would be too much to expect regularly from a large extent of ground.

The price of Liberian coffee is now very good, and the fact is sufficiently established that well-prepared Liberian coffee is fully worth the price of ordinary Java coffee. Two weeks ago a planter showed me accounts from which it appeared that his Liberian coffee of 1st, 2nd and 3rd sorts had averaged after reduction of all expenses for transport &c. had yielded him at the rate of 60.8 guilders per pikul.

All kinds of difficulties and vexations must be expected in the way of "new products;" the preparation was by no means the least of these difficulties in the case of Liberian coffee. On some plantations, the pulper of Walker & Co. et Colombo is in use, which answers pretty well, although it has its peculiar defects. The chief trouble is caused by the remarkable irregularity in the size of the berries of the Liberian coffee. When the pulper is adjusted to suit the large berries which are the most numerous, all below a certain size pass through unpulped, and have to be separated from the pulp and put through a more closely-set pulper in like manner should the pulper be set so as to suit the smaller-sized berries, the larger do not pass through in both cases, much time and labour are lost.

For the purpose of overcoming this defect, Messrs. Walker & Co., at the instance of Heer P. O. van Motman, have constructed a new pulper, which will soon be in use on Dramaga (Buitenzorg). The principle of this pulper is somewhat more complicated than that first mentioned, but in my opinion very practical. The cherry coffee is first brought by water to the pulper, which is set for the larger berries; the pulp falls into a gutter and is carried away by the steam of water flowing through with it, whilst the larger fruit being freed of its pulp, and the smaller unpulped fall into a sieve. The pulped beans pass through the sieve, whilst those that are not pulped fall over the sieve into a trough and are taken up by an elevator and placed in a more closely set pulper, by which the smallest berry is pulped. The whole machine is worked by water power, and is on a scale sufficiently large to prepare the produce of a large plantation. For the purpose of securing the desired yellow colour, the coffee on the abovenamed plantation is subjected to the following process. After the plucking

the fruit is allowed to lie in moderately deep layers for two days before being pulped; after pulping the coffee is kept four days in fermenting cisterns; it is then well washed and cleaned, and allowed to dry for a day; it is then heaped up, and allowed to remain four days more, for the so-called "after fermentation," after which it is perfectly dried in the sun.

Over de smaak valt niet te twisten (There is no disputing on matters of taste) has often been said, but I assure you that coffee prepared in the above-described manner, when properly roasted and made, can compete with the finest produce of Moka.

There is something peculiar in the harvest times. They generally happen in two periods: the former lasts from the beginning of December to the half of March, and occurs thus in the driest time of the year in Liberia, the second crop is gathered in the months of July, August and September. According to Buttkofer July is generally a rather dry month, but from the beginning of the latter half of August to the end of September is reckoned the wettest time of the year.

When the separate plants of Liberian coffee in a plantation are carefully examined, a considerable difference can be observed among them, as well in the leaf as in the fruit, and the due selection of plants from which to take seed for propagation is a matter of much importance. It is not sufficient to choose out the largest berries from a great quantity of fruit, but the trees the most suitable should be first selected and the largest berries of these selected trees should be chosen for sowing in the nursery. In this way alone is it possible to improve (veredelen—to enoble) the Liberian coffee here.

Besides the ordinary varieties, I saw on the plantation Tjomas (Buitenzorg) a coffee plant amongst the Liberian coffee which had much the appearance of a hybrid between the ordinary coffee and the Liberia variety. The plant had some peculiarities of both. In luxuriance it rivalled the strongest Liberian coffee, the leaves though as large as those of the lastnamed possessed a softer texture, and the form of those of Java coffee, but the most remarkable particular is that the pulp had not the coarse and disagreeable taste of the Liberian coffee, but was soft and sweet like that of Java coffee; the size of the berry being the medium size of the Liberian coffee.

At Tjikeumcuh (chikeumcuh) there are some hybrids which are the result of an artificial fructification between Liberia and Menado-coffee.

The young plants of which the mother plant Liberian coffee is fertilized with the pollen (stuifmeel) of Menado coffee, up to the present take after the latter variety, whilst with the contrary (treatment), when the Menado coffee is fertilized with the pollen of the Liberian kind, the resulting plants resemble the Liberian plant. In both cases they resemble at first the male progenitor.

Thus is the Liberian coffee cultivation prosecuted and extended throughout this country with great energy. To my knowledge there is already an extent of over 3,000 bouws of Liberian coffee planted in the subdivision of Buitenzorg, and there are vast tracts of land in the lower lying districts, now waste, that with due cultivation and manuring can be turned into flourishing coffee estates. [Note by Translator.—10 katis=1 gantong; 10 gantongs=1 pikul 133½lb.]

A MERCHANT of Campinas, S. Paulo, has been fined by the authorities for mixing roasted maize with his ground coffee. And this in the very heart of the S. Paulo coffee district! Some people have no regard for appearances and this merchant should have been hung.—*Rio News*.

COCONUTS.—It is a pity that in Bengal the planting of the coconut is not more largely followed in the Sunderbuns and on the seaboard of Cuttack, where they would probably, under proper cultivation, yield as plentifully as in Ceylon.—*Indian Agriculturist*, Oct. 11th.

CEYLON TEA IN AMERICA! GOOD NEWS FOR CEYLON PLANTERS.

GUARANTEE GIVEN FOR SALE OF PURE
CEYLON TEA ONLY.

The following is an extract from a letter of Messrs. Wattson & Farr to the Hon. W. W. Mitchell, under date New York, 26th September:—
"We are now actively at work preparing to push the interests of the new Company and feel quite confident that we shall make it a success and create a large and growing demand for your teas in this country."

We have also received a copy of the prospectus of the new Company with a capital of a million dollars. Besides the names already given as Directors in New York, we have all the Ceylon Directors on as a Board of Management while the following extracts show the object of the Company:—

The object for which this Company is formed is that pure Ceylon tea may be introduced into the United States of America and Canada, or elsewhere, as may be found desirable and that its sale may be widely extended. The present consumption of tea in America amounts to about ninety million pounds per annum, of which about eighty-two millions are from China and Japan, but it is hoped that, if once Ceylon tea get a footing in America, its excellence will create a taste for such tea, and lead to its ultimately taking the place of many of the teas of rival producing countries, in the same way as has been the case in Great Britain. The services of Mr. R. E. Pinco (formerly a planter of long experience in Ceylon) have been secured by the Company, as Manager and Secretary in America, and from his long connection with Ceylon and America, it may be reasonably hoped that the results will justify the selection of Mr. Pinco for this appointment. A Central Tea Emporium has now been in successful operation for nearly a year, at Broadway and 22nd Street, New York City, and a large amount of tea has already been sold and distributed with excellent results. It is intended, as soon as possible, to open further emporiums in all the large cities and to appoint agents throughout the country. The welfare and future prosperity of Ceylon are largely dependent on the success of this enterprise, and the cordial co-operation of all interested in the Island is confidently looked for.

All this shows how entirely honourable and above-board has been the action of Messrs. Wattson & Farr, and considering how much they have already done without a cent of remuneration, and considering also the fact that they are to bear the large expense of advertising and other preliminary expenses, out of the shares allotted to them, we think that they in every way deserve well of Ceylon Tea planters. Mr. Grimlinton's personal report will place this in a clear light.

A TIDAL SUPPLY OF ELECTRICITY.—A French engineer, M. Decœur, proposes to supply electric power to Paris. He would generate the required electricity by utilising the tides. For this purpose he intends to construct, near Havre, two large basins joined to each other, into one of which the sea at flood tide flows over a dam, while during ebb it flows out of the other into the sea again. At the inlet and outlet will be erected a number of powerful turbines for transmitting the energy of the water. The mechanical energy produced for transmission to Paris is estimated by M. Decœur at 42,000 horse-power. Perhaps the calculations have not been correctly made, as it costs something to build such works, and the result cannot be much.—*English Mechanic*.

MR. JOHN HUGHES AND ANALYSES OF
CEYLON TEA LAND—THE BARREN SOILS
OF CEYLON—MR. D. MORRIS AND
BOTANICAL STATIONS IN THE
WEST INDIES—COCONUT BUTTER.

Meeting Mr. J. Hughes this week he told me that he had received a letter from your Planters' Association asking him to mention the terms upon which he would undertake the analyses, after the system lately discussed in the *Observer*, of 80 or 100 samples of teas. Mr. Hughes said he should answer that letter by this present mail, and we hope, therefore, that his services may soon be made available in a direction in which, as it seems to us here, they may be most beneficially employed.

During the course of conversation, Mr. Hughes remarked to me that he had read with much interest your editorial in the *Tropical Agriculturist* last received here on the barren soils of Ceylon. He told me that with all that was advanced in that article he very fully agreed, and that it was in accordance with experiments made by himself upon samples of Queensland soils which had been sent home to him some years back by the late Mr. Daintree, who was—to the best of my recollection—formerly the Colonial Secretary of Queensland. These samples represented soils upon which virgin forests grew; others which had relapsed from cultivation others which produced scrub only; and some upon which no vegetation at all could be grown. Mr. Hughes did not enter upon full details, but he told me that he found that all the soils which would not produce a tree growth were singularly deficient in potash. He believed, therefore, that the last constituent is a necessity for the cultivation of timber or fruit trees, and that this can never be successful unless potash is either naturally present or is artificially supplied. He remarked further that there was great difficulty in laying down any invariable rules for the fertilization of soils, thus—he mentioned to me an instance lately under his notice in Cornwall where the farmers are in the habit of covering their fields before the cultivation season with six inches of sea-sand—obtaining the best results. Seeing such results follow the practice, farmers in other localities had tried the process, but with most unhappy effect. Inquiring into the cause of difference, Mr. Hughes said that he found the whole of the sea-sand around Bude—where the practice mostly prevailed—to be composed of finely comminuted shells. The dressing was, therefore almost of pure lime. But in the districts where the experiment failed so signally the sea-sand had an altogether different character: It was of comminuted rocks only, and this was hardly likely to possess fertilizing constituents. Mr. Hughes' deduction from this and from other instances in his experience is that no invariable rule can be laid down as to measures likely either to restore lost fertility or to increase that existent. Both soil and fertilizer must be closely examined in every case, and the combination of their several ingredients considered. Nevertheless he believed that the suggestion made in your article as to aerating long disused soils must be ever of good effect, as these, when exposed, would naturally take up from the atmosphere what their condition demanded, and would reject assimilation of those which it did not require.

We see that Mr. D. Morris of Kew is going out shortly to the West Indies to advise the authorities of the Windward and Leeward Islands with respect to botanical stations. He will take out with him several wardian cases containing

gambier plants, it being believed that this may prove to be a profitable cultivation.

My reference to Kew reminds me as to a subject treated of in the latest issue of the *Kew Bulletin*, in which you are sure to feel a great interest. This is the manufacture of butter from coconuts. I lately asked you in these letters if you had heard anything of this new substance, having seen some casual reference to it, but was not prepared to learn, as we have now done from the details published by the Kew authorities, how important a manufacture coconut butter is likely to become. Quoting the British Vice-Consul at Berlin, the *Bulletin* inform us that the process of extracting edible fat from coconut "marrow" was discovered about five years ago by a Dr. Schlink, and that it has been worked since 1888 by a firm in Mannheim. The appreciation of this butter has so extended that factories of it are now in course of erection in Pau and at Amsterdam. The Vice-Consul tells us that the substance has already an almost unlimited sale, the trade being chiefly with Germany and Switzerland. He declares it to be gradually but quickly ousting from public favour oleo-margarine and all other butter preparation from animal fats. The present factory, he further tells us, can only supply about 50 ewt. daily, while the demand is frequently up to twice that amount. The *Bulletin* informs us further that the price at which this butter is sold is from 6½d to 7½d per lb. the nuts being procured from the South Sea Islands and the African and South American coasts. The butter product consists of 60 to 70 per cent of fat and 23 to 25 per cent of organic matter, of which matter 9 to 10 per cent is albumen. The product is of a clear white colour and hardens at 66 degrees Fahr. It is said to be very suitable for cooking purposes and has no disagreeable taste or smell. Altogether we seem justified in the expectation that coconut butter will ere long become a large article of consumption in every household. No housewife, however much she may justly turn up her nose at oleo-margarine and doubt its origin of manufacture, would do so at the outcome of the pure coconut; and as we can't buy cooking butter under 1s 2d to 1s 4d per lb. here, the alternative would be sure to be welcomed, and you in Ceylon should be on the look-out for sharing in the supply of its "raw material," the demand for which will probably increase highly. I can't say, the cooking with coconut oil, however freshly this may have been expressed, was ever quite to my palate. Probably the offending cause, whatever it may be, is removed under this new process.—London Cor.

THE CEYLON AMERICAN TEA CO., LD.

The following is an extract from a London letter to the local agents:—

"The new Tea Co. seems to be making encouraging progress, and I think Wattson & Farr will be successful in getting all the agents they require; if so I consider that success is secured. Grinlinton will tell you all about the meeting of the Tea Committee of the Ceylon Association here. Mr. Davidson, who came from America primed with the accusations and charges made by an anonymous individual in New York, laid all these before the Tea Committee last week. On Mr. Grinlinton's being informed of it he expressed a wish to meet him before the Committee, and this was arranged for the 15th inst. Mr. Davidson was shut up practically by Grinlinton's first answer, and opened not his mouth again. Grinlinton's statement was well received."

From the *New York Journal of Commerce*, we quote as follows:—

"The Ceylon Planters' Tea Company has been incorporated with a capital of \$1,000,000 to take over the

business of the Ceylon Planters' American Tea Company, Limited, of Ceylon. Agents are appointed to carry on the business of the company, each of whom is financially interested in the welfare and success of the company. This is in accordance with the scheme favoured by Ex-Mayor Howitt at the meeting of the Iron and Steel Institute. He said: "It should be a matter of congratulation that the formation of trades unions contemporaneously with the rapid growth of large corporations whose stock is divided into such small shares as to admit of easy distribution clears the way for the new era when every self-respecting workman will insist upon being an owner, and every well-managed corporation will see that its workmen are directly interested in the result of the business. To effect this desirable end no compulsory legislation and no additions to the powers of corporations are needed."

And the advertisement displayed on a big scale in the paper is as follows:—

"The Ceylon Planters' Tea Company, trading under the auspices of the Planters' Association of Ceylon, want representatives everywhere on the co-operative plan. Responsibility and good standing required. Address: 4 East 22nd Street, New York."

BARK AND DRUG REPORT.

(From the *Chemist and Druggist*.)

LONDON, Oct. 9th.

CINCHONA.—The supply offered at Tuesday's auctions was somewhat in excess of the average of recent sales. It consisted of:—

	Packages	Packages	
Ceylon bark	1,561	of which	1,458 were sold
East Indian bark	403	do	865 do
Java bark	62	do	62 do
S. American bark	970	do	593 do
W. C. African bark	1	do	1 do
Total	2,997	do	2,409 do

It was believed in some quarters that the sales, in sympathy with those held in Amsterdam last week, would exhibit a dull tone with an easier tendency, but such was by no means the case. From the outset the competition was strong, and as the sales proceeded the demand improved, and the equivalent of the preceding sale's rates was willingly paid. The unit is generally placed at 1½d to 1¾d per lb., a few parcels even reacting the twopenny unit. There was a very considerable supply of *Succubra* bark from Ceylon, and a few lots of fine renewed chips and shavings realised extreme values. Ledger barks were poorly represented; but there was a very good show of *Officinalis* chips from India and Ceylon. Cultivated South American *Calisaya*, too, was unusually well represented, over 25 tons of it being sold at steady rates. Altogether the extraordinary proportion of 92 per cent of the supply offered was sold.

ESSENTIAL OILS.—For *Citronella* ¾d per oz. is required but perhaps ½d would not be refused.

LONDON, Oct. 16th.

ARECA NUTS remain very scarce and dear. Ten bags of good sound seeds were shown today, and bought in at 45s per cwt. The owner, we believe, would take 39s per cwt.

COCA LEAVES.—The recently reported arrival of 110 packages "cocoa leaves" appears to have been entered in mistake at the Customs, and does not seem to exist. At today's auctions, 20 cases Java cocoa leaves, which have been offered several times previously, were bought in at 6d per lb. nominally. An offer of 1½d per lb. was made for the whole parcel, which consisted of ordinary dark crushed leaves, but it could not be accepted. For 3 bales South American leaves, fair but rather broken palish green, good flavour, the price is 1s 1d to 1s 2d per lb.

CROTON SEEDS.—Of a parcel of 30 bags from Colombo, advertised for sale, no samples were shown.

ESSENTIAL OILS.—*Citronella* oil quiet, but steady. We call the nearest spot quotation ¾d per oz. while for arrival, fair native oil offers at 1½d per lb. c.i.f. terms. A sale of 100 cases *Lemongrass* oil is reported at 1½d c.i.f. per oz for arrival, the nearest spot price being 1½d per oz at which the article is very firm.

QUININE.—The shilling limit has again been touched this week, 20,000 oz. second-hand German bulk having changed hands at that limit, but since then 12½d and 12½d has been paid on the spot, and the market eases steadily, with buyers at the latter figure. A sale of 10,000 oz. January-March at 12½d to 13d (second hand) is also reported.

MEETING OF THE SUB-COMMITTEE OF THE C. T. ASSOCIATION.

MESSERS. GRINLINTON AND ROGIVUE GIVE ACCOUNTS OF THEIR MISSIONS.

(From Our London Correspondent.)

LONDON, Oct. 17th.

On Wednesday last a meeting of the members of the Sub-Committee on tea, and others, was held at the rooms of the Ceylon Association in London to consider further steps in regard to the weighing of tea, and to hear reports by Messrs. Grinlinton and Rogivue on their respective missions to the United States and Russia. The following were present:—Mr. J. L. Sband in the chair, and Messrs. H. K. Rutberford, O. Sband, A. Brooke, T. Dickson, J. Stretch, T. Gray, L. Davidson, A. S. Pagden, C. C. S., J. Anderson, A. Ross, J. J. Grinlinton, C. Rogivue, Esdaile, representatives of Messrs. Geo. White & Co., Messrs. Gow, Wilson and Stanton, Messrs. J. and H. Thompson & Co., Mr. J. Capper.

The Chairman reminded the members of the Tea Committee of the appointment of a Sub-Committee to confer with the members of the Indian Tea Association in reference to the recent Customs Order as to the weighing of tea, and its suspension. After conferring together, members had arrived at the conclusion that it would be more advisable to address themselves on this subject to the Lords of the Treasury than to the Customs authorities, and if this were approved by the General Committee the course would be adopted. A resolution to this effect having been carried, the Chairman said that they would now pass to the next subject before them, the pushing of Ceylon Tea in America; and, as Mr. Grinlinton was present, they would be happy to listen to what he had to tell them in regard to his proceedings whilst in the United States as the representative of the Ceylon American Tea Company.

Mr. Grinlinton then addressed the meeting on the subject of his mission to America, in terms and in substance pretty much as I have related in my previous letter. He reminded them that he had gone thither in the first place on private affairs connected with his family, and took the opportunity, whilst there, of arranging for the final settlement of the negotiations between the Ceylon American Tea Company and Messrs. Watson and Farr of New York. He was happy in being able to assure those present that his efforts to place matters between the parties on a satisfactory footing had been completely successful, and he had not the slightest doubt that the arrangement would be cordially approved by friends in Ceylon. He might mention that, before he left New York, orders for Tea had been sent by the Company, whose prospectus he laid on the table, to the Colombo Agents for an amount of £3,000, accompanied by bills for the amount, and he had since learnt that a further remittance and order had been made to the extent of £2,500, so that a substantial commencement had been made. Letters he had recently received from the Company informed him of most gratifying development of their business. In conclusion, he said he should be happy to reply to any question that might be put to him regarding this matter by those present.

Mr. Davidson, of Gikiyanakanda, who has also recently returned from the United States, enquired whether it was not a fact that, although the Company was established in New York and had its place of business there, it had nevertheless been registered in the State of New Jersey? What was the reason for this arrangement?

The reply was that the fees for registration were much lower in New Jersey than in New York, and the yearly fee payable by trading companies was also much more moderate in the former State.

In reply to a further question by Mr. Davidson, as to the Company having gone to allotment and as to the amount of capital paid up, Mr. Grinlinton said that, of course, allotment had taken place, but he had no certain information as to the capital paid up. He believed the whole had been guaranteed much in the same manner as capital is underwritten in this country by promoters.

Mr. Thos. Dickson suggested that as a matter of fact the American Company was at present no more than a Syndicate, as we term it in England, and that the actual Company was now being floated by that body. Mr. Griminton remarked that Syndicates according to the English methods were not known in America; but he fancied the first installation of the body was in reality of that nature. The extra shares to be given to the Company's Agents on their subscribing and paying for others came from the promoters' 20,000 shares, for which they had stipulated. Of course, if the shares of the Company were not eventually subscribed for, it could not be floated, and all expensos for advertising, &c., which would be considerable, would be borne by Messrs. Wattson & Farr.

A desultory conversation followed a vote of thanks to Mr. Griminton, during which a remark was made out at all complimentary to Mr. Pineo, upon which Mr. Griminton took up his defence, declaring that the gentleman in question had done everything in his power to forward the interests of Ceylon Tea, and that he deserved well of Ceylon planters.

Mons. Rogivne having been requested to state his work and views in connection with Ceylon Tea in Russia handed to the Chairman a written Report, a copy of which will, no doubt, be sent to Ceylon by this mail. He said that he had been favored by his London Agents, Messrs. Malcolm, Kearton & Co., and others, with excellent introductions and had everywhere been received with much consideration, but he had not had the advantages possessed by Mr. Griminton of addressing himself to dealers speaking his own language, and he (Mr. R.) had also to encounter far stronger prejudices than are met with in America. He had interviewed many of the best wholesale firms in Moscow, St. Petersburg, and Nijni, but one and all declared there was no demand for Ceylon Tea, and that what was now imported was obliged to be disposed of by blending. But when he came to interview retailers and consumers, he was told quite a different story—that the tea was excellent and moderate in price—and a number of persons had requested him to sell them quantities of 20 and 30 lb. for trial. It was evident that time would be required to bring it before the consuming public, and therefore money. He should consult with the Committee, after they had read and considered his report, and it would be then needful to determine what course should be pursued in the future. In Russia, as in this country, complaints as to the falling-off in the quality of China were loud and general, and he believed the present time was favourable for pushing the teas of Ceylon in that country. He had tasted the tea prepared by the Russian people and it was so utterly flavorless that he could not understand how they could be induced to drink it: while the leaves, poor as they were, had to stand four or five successive waters!

From the above statements it is evident that in Russia, as in America, it is the wholesale trade who oppose the introduction and sale of your teas on their own merits, as they can make for more money by blending than by selling them pure as they reach them.

Mr. Griminton left London this day for Brussels, proceeding *via* Metz, Venice, Florence and Rome to embark at Naples on the 25th on the P. & O. steamer "Khedive."—Local "Times." J. C.

INDIA TEA NOTES.

DEHRA DUN, Oct. 14th.—We are still making tea, but the flushes are stunted owing to the cold nights.

SELENG, Oct. 12th.—So far lots of leaf about, and the little rain just fallen may help us on to end of month. Cold weather is setting in fast.

NORTH LAKIMPORE, Oct. 6th.—The end of Sept. was very dry and hot; rain has, however, come at last—1.20 having fallen during the last three days; from the look of the sky, we may expect more, and which should give us a good start for Oct. Mosquito still out all over the district. Rainfall to date 144.18.

DOOARS, DAM DIM, Oct. 17th.—This season came in with a ruinously hot dry spring, but is finishing up with a miserably cold, wet Autumn. For the past four days and nights, it has rained incessantly, and the weather has been so cold that coolies could do little for no work.—*Indian Planters' Gazette*, Oct. 21st.

A NEW KIND OF "TEA."

We recently noticed the industry which has lately sprung up in Germany of manufacturing the leaves of the strawberry into a substitute for tea, but the people of Kent are going in for hops as a substitute. They are of opinion that as hops make such capital beer the plant will make equally excellent tea, and they are hard at work elaborating a process for converting hops into fresh tea leaves. The object of this, they state, is not merely to get a new tea, but to furnish an article which will alter both the flavour and the quality of the teas now in use. The fresh infusion obtained from the dried flowers of the hop, in which fermentation plays no part, is an excellent drink quite free from alcohol. This beverage contains all the tonic, soothing and nutritive properties of the hop without any objectionable admixture; but the flavour would not be acceptable to the palates of the unsophisticated. However they may be led to appreciate it gradually in the same way as beer or stout. The taste of the infusion could also easily be modified by the addition of sugar and cream. The hop growers of Kent also intend to use hops as a qualifier and improver of the common Indian and Chinese teas. Works have been started at Maidstone for drying and rolling the leaves so as to reduce them to the appearance of ordinary teas which are to be mixed with them. The leaves are also to be powdered and mixed with coffee or cocoa.—*Madras Mail*, Oct. 25th.

CACAO STEALING ON ASGIRIA ESTATE.

IN THE POLICE COURT OF MATALE.

No. 5,603. F. G. Jokim of the Asgiria estate, complainant, vs. Sangan of Asgiria estate, defendant.

In this case the accused who was employed as a night watcher on the Asgiria estate was charged with stealing a quantity of cacao pods by the complainant, who is the day watcher.

It transpired in evidence that when complainant went to relieve the accused early in the morning of the 26th instant he missed him, but soon after heard a noise in the cacao field saying "Don't fear, no one will come here." Complainant went in that direction with another man and seized the accused in the act of stealing cacao pods, when two others whom he was unable to identify ran away from the cacao bushes. Complainant reported the facts to Mr. Booth, the superintendent, who directed the prosecution. The evidence called for the prosecution fully supported the charge, and the accused was found guilty and sentenced to six months' rigorous imprisonment.

This same accused was a short time ago charged with causing hurt to a watchman who was ordered to watch in his stead by Rengasami kanakapulle on a certain night as the accused had failed to attend to his duty. In defence he urged that the substitute was stealing coffee for the kanakapulle and that he struck him as the former threatened to injure him. The Magistrate then considered him to be an injured innocent and let him off with a nominal fine. It is now evident that he calculated too much on the favorable impression he had made on the Magistrate in the former case.

A HOBBY FOR COUNTRY SCHOOLMASTERS.—On Saturday afternoon, 27th ult., Mr. T. W. Ogilvie, Demonstrator of Natural History, Aberdeen University, delivered a lecture to the members of the Aberdeen branch of the Educational Institute of Scotland, on "The Fertilisation of Plants." Mr. Ogilvie, in opening his lecture, said, country teachers had an excellent opportunity of working out the flora and fauna of their respective districts, but he had observed with regret the extreme infrequency with which those opportunities were embraced, and he had chosen the subject of his lecture in the hope that he might induce some to take up such an interesting study as an antidote to the *ennui* with which country teachers who and not a hobby, must be afflicted.—*Gardeners' Chronicle*.

TEA-PLANTING IN NATAL.

The *Witness* has interviewed Mr. L. H. Neall, formerly manager of the Jorehaut Tea Company of Assam. Mr. Neall said he had come to Natal with a view to promote a company for tea cultivation on the coast. He has paid a visit to all suitable lands along the coast, from the Lower Tugela to the Lower Umzimkulu. With regard to the latter district, Mr. Neall says it is eminently adapted for tea plantations, and the lands are rich in every property necessary for healthy and vigorous development of the plant. Tea-planting can be made in some cases much more successful in Natal than in India. The plants here enjoy absolute immunity from several diseases common to them elsewhere. Recent failures he ascribes to insufficient capital and want of knowledge of after-treatment and various processes of manufacture. He condemns the class of coolies at present imported, and is certain that the conduct of labour negotiations through proper sources in Calcutta, would procure efficient tea workers; £20,000 in £1 shares is the capital deemed necessary for the proper starting of a company and the initial expenditure for a year's rent of 2,000 acres, survey, buildings, stock plant, tea seed, &c., is estimated at over £1,200. Mr. Neall expresses the conviction that there is a greater opening for tea industry in this colony than many imagine, and that it only requires experienced men and careful management to render in the most paying of all colonial undertakings.—*Natal Mercury*, Sept. 17th.

PLANTING IN THE INTERIOR OF
MADAGASCAR.

The following is from a contribution to the *Madagascar News* describing the interior of the island:—

Leaving Andrangoloaka and climbing on up the hill the forest is entered. Away down in the depths of the forest are some fine trees. For three hours Mr. Jukes was journeying through the forest, then the mountains abruptly terminate and a sudden descent is made into the beautiful and fertile valley of Lohasaha. On each side of the valley rise lofty mountains over whose slopes are spread waves of verdure indescribable of tint and inconceivable in grandeur. In the valley very fine tobacco is grown, and, it is said, His Excellency the Prime Minister has a tea-plantation there. The soil is most suitable for agricultural purposes, being a rich alluvial deposit, but the valley shut in by mountains on three sides is a *cul de sac*, and, consequently "as the summer breezes cannot waft readily through, is extremely unhealthy, so much so that it is only with the utmost difficulty that the natives of Antananarivo can be induced to go down there during the fever season. The valley is very extensive and contains a great number of small hamlets, consisting of about five houses each. The tribe inhabiting the valley is the Bezanozano. This race is becoming crushed in spirit and slothful under the weight of an oppressive *fanompama* (forced service). So broken down are they under that hurtful and hateful system that they are unable to profit by the bountifulness of the soil upon which they dwell. Knowing that whatever crop they might produce would be pounced upon by some harpy of an official, the Bezanozano make no effort and pass their lives in squalor and want, living in the merest hovels. Undoubtedly! the time has come and the hour has struck for civilization to enter Madagascar, and 'to create roads into the fastnesses of cruelty and ignorance.' There are five churches and schools in the valley in charge of native evangelists and teachers who are mostly Hova. How is it that these Hova evangelists and teachers do not raise their collective voice against the oppression of officials who, despite their fervent Sunday professions and impassioned weekday prayer, are every whit as bad and intolerable as "the Arab kidnapper and man destroyer" of Africa. Is it because that honourous and solemn 1885 Notification to

the Provincial Governors was issued for the prusal of the Christian Powers rather than for that of the Provincial officials? Otherwise how is it that "people who are guilty of nothing are threatened and ruined" and the Queen's kingdom is not preserved but damaged by her provincial officials monstrously abusing the power with which they have unfortunately been entrusted, or permitted to usurp *unchecked*?

NORTH BORNEO NOTES:—GENERAL.

His Excellency the Governor accompanied by Mrs. Creagh and family left Sandakan for Labuan in the British North Borneo Cruiser "Petrel" on Saturday September 6th last. The *Serang* of the steam launch "Kimanis" was in charge of the "Petrel."

Captain R. D. Beeston visited the Suanlamba Estate on September 6th, in company with Mr. A. E. Turner of Messrs. Mansfield Bogaard and Company, and transferred the Obinese and Javanese Coolies to different estates to work out their contracts. The whole of the coolies were perfectly willing to sign their agreements and acknowledged their debts accruing from advances they had to work off. Most of the coolies have been transferred to the Batu Puteh Estate on the Kinabatangan of which Mr. Breitgag is Manager.

On Saturday September 13th, Captain Beeston visited the Segaliud Estate, managed by Mr. T. Johnston. Mr. H. St. J. Hughes as agent for the Company having asked Captain Beeston to accompany him. The estate proved well worthy of inspection the tobacco being of capital quality and likely to go some seven piculs per field. Cutting had commenced some few days before and at the date of the visit some 150,000 plants seen were hanging in the drying sheds. The tobacco plants had been cut and were very high averaging some six feet each, and in the fields it was difficult to see the coolies cutting, so high was the tobacco. A capital crop is expected from this estate as also from Mr. Kalfsterman's which is close by and is aids to contain an equally good crop.

We are sorry to have to chronicle an accident that might have had serious results, which befell Baron de Lissa on Monday evening September 8th last. On that day a heavy thunderstorm swept over Sandakan, the rain coming down in torrents, and rushing down the main street like a water course. Baron de Lissa had mounted his horse and was leaving the Court House entrance. His horse placed his fore foot on the plank of a culvert, which was rotten. The horse fell and rolled over, his rider receiving a severe strain. We regret to say that the Baron has had a very painful time of it, but thanks to the care of Doctor Walker he is now recovered.

We are happy to say that all reports from the various tobacco estates on the East Coast, namely in Darvel Bay, the Kinabatangan river, Sandakan Bay, the Sugut and Labuk rivers show a state of affairs at once most promising and flourishing. The present year so far seems determined to make amends for the unusual and phenomenal year of rain and floods of 1889. On all sides we have news of good crops of first-class tobacco. We trust to see the best of results for the planting interest when the prices of the 1890 crop are known.—*North Borneo Herald*, Oct. 1st.

"THE AMERICAN GIRL'S latest restorative (says the *L. & C. Express*) is quinine. She carries it in the form of pills in an ornamental cut-glass bottle with a gold stopper. It has quite superseded morphia and strychnine lozenges. If she is tired she takes two pills; if in a draught, one; if hungry, four or five; and if her feet get wet, ten are the correct number. Each pill contains two grains. Six are a cure for indigestion. The quinine bottle is produced on all occasions and in all sorts of place." There is great exaggeration here: 20 grains of quinine constitute a truly heroic dose.

PROSPECTS OF THE TEA INDUSTRY.

There has been a good deal of correspondence on the depressed state of the Calcutta tea market, and the impending crisis so likely to cripple the tea industry seriously. Some correspondents advocate combination amongst proprietors, &c., or suggest some artificial "propping up" of the market during the present uncertain period. But though these vague hints are thrown out, no real plan likely to meet with success has been promulgated. The Calcutta market reflects the English market pretty truly, allowing for commissions, and the profits which the middle-man *i.e.*, the Calcutta buyer, comes out here for the purpose of making. I cannot see that the local market is affecting the price of our produce this season more than it has done in any previous year. We are suffering from the rise in exchange, and that only; and so, as to carry on our business we spend the majority of our rupees in this country, where they have the same purchasing power as before the alteration in exchange, we are in a way double sufferers by the inflation of silver.

Prices in London are entirely governed by supply and demand, and "cornering," or artificial interference with supplies, will and can only have the temporary effect it has had in the case of so many other products, with a probable eventual collapse, putting producers in a far worse position than they are in at present.

As far as planters are concerned, they can only do as your correspondent "Spectator" suggested; reduce the price of production; that locally is now cut down as low as it safely can be, with the exception of freight charges, which possibly though improbably, the Associations, by representation, might induce the United Steam Companies to lower. This is hardly the place to discuss the rival merits of high and low cultivations, but retrogression in these days seldom pays and high cultivation carefully adopted and superintended doubtless repays itself many times over. The cost of labour is a question on which there can be no two opinions, and the remedy lies with the proprietor, shareholders, and agents, more than with the planter. Agents' charges would also bear careful scrutiny at a time when all others interested in the enterprise are sufferers. But all these remedies and suggestions amount to little as long as prices remain at the present rate.

Combination amongst owners, shareholders, and debenture-holders, could secure the abolition of the Calcutta weekly auctions. What a saving that in itself would be—the buying and selling commissions, brokerage, &c.! And it would obtain for the producer the profit the Calcutta buyer does—must, secure. Did he not—and he invariably states it is a losing game—how could he afford to come to India annually, live at the best hotels, enjoy himself, return to England at the end of the season? On the face of it, this profit would go into the proprietor's pocket.

Should the local demand for India be sufficient and the financial condition of certain concerns necessitate quick realisation of proceeds, a monthly Calcutta sale would quite satisfactorily supply the requirement.

Again, overproduction, or rather, say, too rapid increase in production, has been the chief cause of the low prices prevalent the last few years. If those financially interested would combine for one year, and agree not to open out any new extensions during season 1891, but create a strong Syndicate and spend, say, 50 per cent. of what they would have spent in extending the area of the plant, to its own detriment, in opening out new markets in the Australian and Cape Colonies, Canada, and the United States of America, hitherto practically undeveloped—I believe the real solution of the present difficulty is found.

By push resolution, and the purity and superiority of our produce, we have outdone China tea from its first place in the London market. With capital, the same resolution, and continued superiority of our article, without too rapid production, we can, and will have, to do the same elsewhere.—H, in the *Englishman*.

THE CEYLON PLANTERS' AMERICAN TEA COMPANY LTD.

REPORT OF THE DIRECTORS WITH STATEMENT OF ACCOUNTS FOR HALF-YEAR ENDING 30TH JUNE, 1890.

The Statement of Accounts to June 30th, 1890, shews a debit balance of R29,096-95.

The profit on Salos has amounted R2,521-34, but the heavy initial expenditure, together with the cost of pushing the business in America, have absorbed a large amount of the limited capital of the Company. In May, proposals were made by Messrs. Watson and Farr, New York, for the taking over by a new Company there of the business of the Company formed in Ceylon, under which, each Shareholder in the latter would receive for each of his paid-up shares, two shares in the new Company.

An Extraordinary General Meeting of Shareholders was held on July 11th, at which the terms were accepted, and the Hon'ble J. J. Grinlinton, who proceeded to New York with powers to ratify the arrangement, has telegraphed that it has been given effect to, and that the necessary documents have been signed.

The limited number of shares taken in the local Company rendered it improbable that its operations could have been carried on very much longer, and it is hoped that the ample amount of capital necessary, and which will be provided under the new scheme that has been inaugurated, will ensure the carrying out effectually of the objects for the Ceylon Planters' American Tea Company was formed.

By Order of the Board of Directors,

For the Ceylon Planters' American Tea Co., Ltd.,
DARLEY, BUTLER & Co.,
Agents and Secretaries.

Colombo, 22nd October 1890.

HIGH PRICES FOR CEYLON AND INDIAN TEAS.

“Peripatetic Planter” writing to the *Indian Planters' Gazette* refers to the sale of the Hethersett golden tips at 30s 6d as follows:—

Query, how many hundred pounds of decent Broken Orange Pekoe were reduced in appearance several pence per lb. by the abstraction of these 15 lb of their “glory?” Hethersett is a garden of 232 acres under Tea, near Kandapola, in Ceylon, managed by Mr. H. Macandrew, for Mr. J. Macandrew, the Agents being Messrs. Whittall & Co., Colombo. This price is the highest by far, which has been known in recent years, and personally I have no recollection of its ever having been approached by any British Grown Tea. Of course such Tea can only be made at a very great sacrifice; and is probably really only beneficial as an advertisement to get an estate's name talked about and known; which is no small advantage; especially when original estate-packed packets are on sale in England, as in the case of many Ceylon estates now-a-days.

The next feature for comment is the extraordinary invoice from the Panitola Estate of the Jokai (Assam) Tea Company, Limited, items from which invoice appear above. Four lines above 2s per lb is good enough in these times; but to be able to decline a bid of 2s 7½d is an additional feature in Mr. Madden's cap—and to realize 1s 4d per lb for his Pekoe Souchong! when some are getting 8½d to 10d a lb for their Broken Pekoe and even Broken Orange Pekoe, after such prices too, for his better qualities which prove that he is not “under marking,” is phenomenal, simply. The Chairman of the Company told me with glee yesterday, that he had not seen such an array of prices for five years! It

s worth adding, in accordance with what I said last week, that Panitola has Blackman Fans; not that I wish to imply for one moment, that these prices are due to that fact—but this much is safe to infer, they haven't injured Mr. Madden's splendid Tea. This invoice, unlike the Hethersett bid for “glory,” is *Business with Honour*, to paraphrase B. D. Earl of B. As regards the market of the week, the above prices are all the more remarkable, in that the market has shown a down grade tendency in some respects, and is decidedly weaker in the case of ordinary and inferior Pekoe Souchongs, which have declined ½d to ½d per lb and sell from 7½d to 8½d. There was a decent ordinary demand, which would have done justice to more limited offerings, but the market was flooded, and there was also an excessive number of Breaks which rather exceeded the physical powers of the Brokers to sample properly thereby, leading to irregularity in prices.—*Indian Planters' Gazette*, Oct. 21st.

PLANTING SCIENTIFIC NOTES.

The urns of all these plants enclose, before the opening of the operculum or cover, a limpid liquid slightly acid. When the operculum opens the liquid seems to putrefy, and the vestiges of insects are found in it. M. Dubois found that if the liquid was drawn from the still closed urn by means of a sterilised pipette, it continued limpid for several months and when first drawn had no effect on coagulated albumen, even if heated to a temperature of 35deg. or 40deg. C. When filtered at the end of several hours it contained no peptones. Nor were any micro-organisms found in the pure liquid of the closed urns, or any trace of putrefaction. Only a *Torula*, similar to the yeast of beer, was noticed at times, but its presence and purpose there has not yet been fully examined.

On the other hand, when the liquid was drawn from urns which had been open some little time, and was still clear, it rapidly attacked the albumen (little tubes of white of egg) which became transparent and gelatinous, and lost its angles. In some cases the liquid became putrefied. It was found to swarm with diverse micro-organisms, and after filtration gave some of the reactions of the peptones. Many of the open urns contained insects, but in process of putrefaction, not of digestion. Fresh fibrine was not used in these experiments because it dissolves in certain liquids without there being a true digestion, and because it would have been cooked during the sterilisation. Nor was cartilage used, because it would have been partially transformed into gelatine.

M. Dubois concludes from his researches that the liquid of the *Nepenthes* does not contain a digestive ingredient like pepsine, and that they are not carnivorous plants. The phenomenon of false digestion observed by Hooker was, without doubt, caused by micro-organisms which had entered the urn from without, and were not secreted by the plant.

Vegetation appears to be retreating on the high Alps. Mr. David Marin, a geological surveyor, has observed that the rhododendron is not found above a height of 2,000 metres, whereas 20 years ago it flourished at 2,350 metres. Birch, pines, &c., disappear at an altitude of 1,800 metres, except in certain parts exposed to the moist winds of the north, where they reach 2,300 metres. Lower down, the vine, which formerly grew at Valgourdemar, an altitude of 1,050 metres, is only seen to-day at a height of 850 metres. Poplars are nearly all dead upon the crest of the hills.

This retrogression of vegetation has also been observed in Siberia, and, among other places in Savoy and at the Grande Chartreuse. Mr. Martin thinks that owing to the disappearance of glaciers the trees suffer from drought in summer, and extreme cold in winter, against which they are not sufficiently protected by the snow.

The new explosive “carbonite” is giving satisfaction to coal miners. At a recent meeting of the South Wales Institute of Engineers, Mr. W. Stewart

stated that within his experience a ton of the material had been used without a sign of flame or sparking. It is a stable compound, and can be stored without deterioration for any length of time. It is rendered comparatively safe by the fact that a detonator is required to explode it. If struck with a hammer or stone no danger need to be apprehended.

Cardonite is lighter than dynamite, is of a brownish colour, and contains 28 per cent. of nitroglycerine. Certain sulphuretted hydrocarbons are added to moderate the susceptibility of the nitroglycerine.

Some years ago the late Sir William Siemens obtained some interesting results by growing vegetables and fruit under the continued influence of the electric light. In the botanic department at Cornell University some further experiments have been made in the same direction. The rays of powerful electric lamps were allowed to fall on the plants day and night, and the seedlings fairly shot up. In a few weeks they were several times taller than others growing in the natural way. So far as foliage went there seemed a decided advantage in the luminous forcing but in the matter of fruit, the plants which had grown as usual were more prolific than those which had been forced.

PROSPECTS OF CINCHONA.

It will be remembered that some time ago an Amsterdam cinchona broker alleged in our columns that the cause of the depression in the price of quinine was the action of some of the manufacturers who had made contracts with the Java planters direct to buy their bark upon the basis of the cinchona unit upon its arrival. This same broker now returns to the charge in the *Indian Mercury*, with special reference to the last bark sales in Amsterdam. The sales of October 2nd he says, were exceedingly disappointing. Some of the large buyers only brought very moderately, and the Brunswick works took practically nothing at all. He alleges that the decline thus caused was due directly to the action of some of these buyers. Shortly before the auctions, he writes, the quinine market was firm although quiet, but on October 1st the Brunswick works suddenly offered quinine at a considerable decline. The steamer which recently arrived in Holland from Java, and others now on the way have brought considerable quantities of bark, all consigned directly to the works by the planters. The planters will be paid for that bark upon the basis of the cinchona unit prevailing when it arrives at the works; consequently the buyers have a direct interest in depressing the quinine market, apart from the fact that they may simultaneously use the occasion to buy cheaply in the market in order to fill previous contracts made by them. Until this state of affairs is altered, the broker declares, it will be impossible to look for any improvement in quinine or in cinchona.—*Chemist and Druggist*, Oct. 16th.

THE AMSTERDAM CINCHONA AUCTIONS.

AMSTERDAM, Oct. 22nd.

CINCHONA.—The sales in Amsterdam on Nov. 6th, will consist of 4,699 bales and 450 cases, or about 392 tons, viz.:—Java bark from Government plant, 418 bales 47 cases, about 39.5 tons; from private plant, 4,281 bales 403 cases, about 352.5 tons; British Indian bark, 45 bales, about 3.5 tons. These are divided as follows:—*Druggist's bark*: *Succirubra* quills, 428 cases; broken quills and chips, 351 bales; root, 89 bales, *Officinalis* quills, 13 cases; broken quills and chips 114 bales; root, 58 bales. *Ledgeriana* broken quills, 3,169 bales; root, 744 bales. *Hybrides* quills, 69 bales; broken quills and chips, 85 bales; root, 20 bales. *C. Schukrafft* quills, 8 cases; broken quills and chips 1 case. Total, 4,699 bales 450 cases. All the analyses are not yet published.—*Chemist and Druggist*,

THE LINNEAN.—A meeting of this Society was held on June 19th, Prof. Charles Stewart, President, in the chair. Messrs. W. H. Beeby and Mr. H. E. Milner were admitted, and Messrs. W. Cross and S. Schouland were elected Fellows of the Society. Mr. W. H. Beeby exhibited a specimen of *Rumex pro-pinquus*, new to Britain, and procured in Shetland. Mr. Thomas Christy exhibited, and made remarks upon a specimen of *Callistemon rigidum*. Mr. E. M. Holmes exhibited some marine Algae new to Britain, including *Ascoocyclus reptans*, *Halothrix lumbicalis*, *Harveyella mirabilis*, *Sorocarpus uveformis*, and *Vaucheria litorea*; also specimens of *Rhodymenia palmata* with atheridia, and *Punctaria tenuissima* in fructification; the last two not having been previously recorded to occur in this state in Great Britain. The following papers were then read:—"Observations on the Protection of Buds in the Tropics," by M. C. Potter; "On the Distribution of the South American Bell-birds belonging to the genus *Chasmorhynchus*," by J. E. Hartney; "On the Vertical Distribution of Plants in the Caucasus," by Dr. Gustav Radde; and "Notes on the Forficulidae, with descriptions of new genera and species," by W. F. Kirby. This meeting terminated the session of 1889-90.—*Gardeners' Chronicle*.

PISCICULTURE IN CEYLON.—There arrived at Colombo by the B. I. S. S. "Goorkha" yesterday morning, consigned by Dr. Thurston at Madras by Mr. O. J. R. LeMesurier, four young specimens of the fish Gourami which were first brought from Mauritius, but are now to be found at both Calcutta and Madras, and grow to 12 lb. or 15 lb. One of the four was found to be newly dead and justified the reputation of its kind shortly after by making a savoury dish; and the others were alive and well. A fifth had died a day or two before. Those to hand are intended for the ponds at Kandy, viz; one at Lady Horton's walk and two in the Pavilion grounds which Mr. LeMesurier is staking and also using for breeding grounds. When he returned from Madras at the beginning of the year he brought some Gouramis and also specimens of the *Tribco* and both are believed to be doing well. Fishes of several other kinds too, arrived in July last, and have all been placed in the Kandy ponds. Mr. LeMesurier has only carp and trout in the Nuwara Eliya streams. In the budget now before Council there is a vote for R2,000 for this good work, which in time we hope will realise the plan of the principal promoter, which is to supply many villages with their little fish ponds and stocks of edible fish.—Local "Independent."

THE "ONE-COCONUT-PER-TREE-PER-ANNUM" TAX.—We forgot to refer to the actual incidence of this tax. The usual number of palm trees to the acre is about 75 and the incidence of the single-unit tax would therefore be on an average, we suppose, about R2 per acre per annum. Now, we have in our possession a letter from the late Dr. Sordain who knew as much about coconuts as anyone of his day, most seriously alleging that a direct tax of 2s 6d (old currency) or R1.25 per acre on coconuts would suffice to ensure the abandonment of a large extent of cultivation under the auspices of foreign capital. He alleged that the margin of return was so narrow beyond actual outlay year by year, that there could be no other result. We suppose Dr. Sordain had then in view a coconut land-tax in addition to the grain levies. How he would view the matter if both grain taxes were simultaneously abolished, we are not prepared to say; but his opinion is of value as showing that of the "milk in the coconut," very little often falls to the absent proprietor—in other words that while coconut properties in some cases—in the Western and North-Western Provinces undoubtedly—are very often valuable; in other instances, they scarcely pay their way. Nevertheless, that coconuts, with every other form of cultivation in the island, pay their share of existing taxation—both through grain and salt,—is undoubted,

CEYLON TEA IN RUSSIA.

We call attention to the interesting, not to say piquant, Report furnished by M. Rogivue to the Ceylon Tea Fund Committee of his operations and their results in Russia. Returning as M. Rogivue is to that country with a fresh supply of "the sinews of war" we may fully expect a large amount of actual business in Ceylon teas through his agency; while the recent official recognition of our product and the well-known active interest of the Russian Consul (M. de Frisch) at this port afford a further guarantee that we are on the eve of a regular tea business with Russia. Curiously enough, last evening we received a letter direct from St. Petersburg, from the gentleman to whom M. Rogivue refers, whom we first met at Vichy in France three years ago, Mr. W. Barnes-Stevani who is the correspondent of an influential English journal in Russia. Before we met him, he had interested himself in the mission of Sir G. H. D. Elphinstone to St. Petersburg and Moscow, when "Logie" went over to introduce our teas into Russia. Our friend has special influence it will be observed, and although he supposed that he, if any one had a special claim on the Ceylon Tea Agency, he very cheerfully accepts the situation and promises his cordial support to M. Rogivue in his attempt to convert the Russian people to a full appreciation of the merits of Ceylon tea. For this assurance of co-operation, Mr. Barnes-Stevani will deserve a cordial vote of thanks from the tea planters of Ceylon. We quote as follows from his letter:—

St. Petersburg, Sept. 30th (Oct. 12th).

I received your very welcome letter a few days ago on my return from a long journey in the Caucasus on the confines of Asia.

I travelled in the State train of the Minister of Finance with one of the minister's old friends, so you can understand I had a grand time of it. Now I am again here in the capital of the frozen north, thousands of miles away from the sun, the wind and the beautiful scenery of the Caucasus.

AND NOW ABOUT CEYLON TEA,—

I was sorry to hear that the planters had already appointed an agent, especially as I had made such sacrifices in Moscow to introduce the tea in that centre of conservatism and superstition and was the first Englishman here who foresaw the great future this tea has in Russia. It is now about 5 years ago since I first found the tea at Mr. Henikey's in London and resolved to introduce it in this country. It has, however, been reserved for another to take my work and reap where I have sown. I not only believe that Ceylon tea will make its way into the Russian markets; but that this tea and tea grown on the Himalayan mountains might be transported into Russia direct through Afghanistan at a great saving of time and money, if we could only come to some agreement with Russia about the Eastern Question. I have friends, Russian engineers, who have built thousands of miles of railway, who would build a railway through Afghanistan "like a shot," if the Governments could only come to a "modus vivendi." I am pretty convinced that Russia does not want India. She has in Central Asia, Siberia and the Caucasus more wealth and more land than she can develop in the next hundred years. She is however, wishing to get to the sea either through Constantinople or Persia. The Russian Empire is entirely self-supporting. It has everything within itself, and all that she requires to do for the next 50 years is to plough, dig and build. If her statesmen are all as sensible as M. Vishnigradsky and the Tsar, they will do it; but should they die we know not what may happen. In my last journey I travelled day and night for five days without coming to the end of Russia. Another friend who has just returned from a journey of 10,000 miles in Russia and Turkestan states that he is simply astounded at the wealth, power and resources of this country, still in its first youth.

I shall be very glad to assist Mr. Rogivue in this work as far as my duties as Correspondent will permit. He seems to be still very unused to the ways of the Seythians or in Shakespearean English, a little "green." For all that, I believe the planters have hit upon a first-rate man, energetic and honest. One cannot know Russia in a day and what knowledge I possess of the country I shall be glad to place at his disposal if he requires assistance. I believe I can help him in many ways, but principally in getting the Russian press to direct public opinion to the new tea and to write favorably about it. This I can do, being personally acquainted with the press men on most of the papers in Petersburg and Moscow. This is very important. The "Press" in the country can make or mar this business if they choose. I know more than one business they have ruined by their attacks at its very commencement.

CEYLON TEA IN RUSSIA.

Kandy, Nov. 5th.

To the Editor, *Ceylon Observer*.

Sir,—I beg to enclose letter received from Mr. Wm. Martin Leake, Secretary, the Ceylon Association in London, transmitting Mr. M. Rogivue's Report on the subject of making known and pushing the sale of Ceylon Tea in Russia. I also enclose copy letter from Mr. Rogivue.—Yours faithfully,

A. PHILIP, Secretary.

London, Oct. 16th.

A. Philip, Esq., Secretary of the Ceylon Planters' Association, Kandy.

Dear Sir,—This is to inform you that Mr. Wm. Martin Leake, the Secretary of the London Association is posting by today's mail to your care my general report upon my mission in Russia on behalf of the Ceylon Tea Fund which I trust will meet with the approval of your Committee.

At a well-attended meeting of this Association held yesterday, I gave the gentlemen present an illustration of the work done by me in Russia during the past two months and of what remains to be done in order to introduce Ceylon tea into the country.

I came to London with the intention of making arrangements with some friends to open depôts and retail places in Moscow and St. Petersburg for the sale of Ceylon tea and I am very hopeful to be successful in my undertakings, so to enable me to return to Russia with the shortest delay.

Thanking your Committee for the grant of funds voted recently to be placed at my disposition for the continuation of my mission, I remain, dear sir, yours faithfully,

(Signed) M. Rogivue.

Ceylon Association in London, 4 Mincing Lane,

E. C. London, 17th Oct. 1890,

A. Philip, Esq., Ceylon Planters' Association, Kandy.

Dear Sir,—Since I wrote to you on the 26th ultimo I have had the pleasure of receiving your letter of 15th ultimo forwarding copy of resolution of the Standing Committee of the Tea Fund under which Rs. 5,000* are placed at the disposal of Mr. M. Rogivue for further prosecuting the sale of Ceylon tea in Russia.

This liberal vote has given very general satisfaction here and to no one more than to Mr. Rogivue, who has just arrived in London in excellent health and spirits.

He has handed me a very interesting report of his proceedings of which I enclose a copy for publication in Ceylon.

He is doing his best to make all possible arrangements for strengthening his position for renewing the campaign. And he proposes to return to Russia very shortly.

On Wednesday last both he and Mr. Grinlinton attended a meeting of our Tea Committee here and told us, each the tale of his travels.—I am, yours faithfully, (Signed) WM. MARTIN LEAKE.

* Sic; but M. Rogivue speaks of £150?—ED. T. A.

HOW TO INTRODUCE CEYLON TEA IN RUSSIA?

GENERAL REPORT ON M. ROGIVUE'S MISSION TO RUSSIA.

The Ceylon Planters' Association "Tea Fund" having, in several of their meetings, discussed the very important question of finding the best mode, to be adopted for introducing Ceylon tea in Russia in view of the securing new markets for their ever-increasing production, had once contemplated to send a Commissioner to China with the idea of his interviewing there the Russian buyers' agents by way of showing them samples of pure Ceylon tea and persuading them to devote more attention, when passing through Colombo, upon this interesting product, which offers so great advantages over the tea grown in the dominion of the Celestial Empire, viz. of being pure, of greater aroma, stronger and therefore more economical and cheaper. This idea, although perhaps good in principle, was however soon abandoned for some reason or other, but chiefly on account of the great criticism started against the scheme by the Colombo press, the *Ceylon Observer* especially. Seeing this, and at the eye of my departure for a holiday trip to Europe, I offered the Ceylon Planters' Association to take the "bull by the horns" and to go to Russia—the great tea-drinking country—there to advertise and push pure Ceylon tea, by trying to persuade her inhabitants to drink it and to appreciate it for its own merits.

My offer was accepted and a grant of £100 cash for my expenditure and £30 for value of tea samples to be taken to Russia for distribution, was voted by the Committee of the Ceylon "Tea Fund."

I left Colombo on the 13th of May 1890, via Italy and Switzerland, and arrived in London on the 22nd June, where I spent about a fortnight in collecting information about Russia, visiting merchants and brokers connected with the tea trade, tasting teas likely to suit the Russian market and making myself ready for the campaign, well-provided with numerous letters of introduction for Russia.

Very little indeed seems to be known in London about Russia, her tea trade and the way of making and drinking tea there. I was told that the sorts most likely preferred to suit best the taste of the people in general would be teas of a *light mild liquor* and *very light-coloured infusion* and therefore, with the aid of the London brokers, selected my samples accordingly and, as near as possible, to represent this description, taking with me 4 chests and 6 half-chests of the following teas:—

Labukello	Broken Pekoe
Do	
Aberdeen	
Mahousa	
Patiagamma	Pekoe
Ferudale	
Gleugariffe	
Rahatungoda	
Labukello	Pekoe Souchong
Kuruwitte	

In all 671 pounds nett of tea, and well-equipped as above-mentioned, I arrived in St. Petersburg on the 23rd July and lost no time in visiting the people for which I had letters of introduction. I may here mention that I have been very well received by all, the class of men to which these friends belong being indeed very civil, courteous and obliging, and not speaking of the dangers and bothers of all sorts shown to me in expectation by many, before leaving England, I found my way very easily everywhere and without the slightest trouble. Mr. D. Haverlands, the agent in St. Petersburg of a large London Export-house, to whom I was also introduced by a kind friend in London, after having heard me, for more than two hours, on the subject of Ceylon tea, told me that, previous to my visit, he very often received samples of Ceylon teas, with offers from Firms abroad for inducement of business; which samples, on account of his being always quite unable to interest anyone in the article, so very little known in Russia, he had to lay aside as an unsaleable produce, but, since he had heard from me more about its qualities,

the way it is manufactured, its purity, flavour, cheapness, &c., he now believed it to be the article of the future, called to supplant Chinese tea against the quality of which so many complaints have been raised lately, and he was very pleased to accept my proposal to act as my general agent in St. Petersburg.

It took me some long time—fully six days—before I could clear, at the Custom-house, my samples landed per S. S. "Viatica," the Custom authorities in Russia being very slow in their work and great *paper-wasters*, not speaking of Government recognized holidays so numerous in the country and as inconvenient to a business man.

Duty on tea in Russia is 21 gold roubles per pound of 40 Russian pounds, of which 124 equal to 112 English pounds, or one hundredweight.

Exchange on gold varies from 30 to 40 per cent at present and is regulated by the value of the "Demi-impériale" which at par is worth "five" silver roubles (100 gold roubles equal now about 136 silver roubles.) Exchange on English money has fluctuated during the last two months

from roubles 8.40 kop = about 6.90 gold per demand £ to " 7.90 " = " 6.50 "

The present mode of passing a tea invoice at a Russian customhouse is to produce the invoice which may be passed as it is, or verified by the Customs authorities taking about 10 cases out of 100 to verify the tares of which the weight is accepted as the average for the whole invoice. Duty is paid on this average nett weight without any addition of 3 per cent as it was done formerly; it is therefore most important that the very exact weights are given in the invoices and that the packages, cases or chests, are, as much as possible, of a uniform weight for the tare.

After having cleared my samples, I stored them in a local rented by me for the purpose, got them packed as per pattern herewith, in $\frac{3}{4}$, $\frac{1}{2}$ and $\frac{1}{4}$ lb. packets, and, with Mr. Haverlands, began my work of excursion around the place, visiting all the principal wholesale tea-houses, such as A. W. Rothermandt & Co., Eliasajeff Brothers, Berchard Gruening, Otto Dittborn, Raftal Brothers, Wm. Strauss, Schlaisser & Co., and others. My samples were tasted by all and, generally speaking declared good, wanting however more colour but everyone told me that, although there was no doubt that these teas were of very good quality and pure, it would be very difficult, if not impossible, to introduce them in the country; their taste being quite different to that of Chinese teas would never be appreciated by the Russian public; some pretended that their very peculiar "raspberry" taste was caused by the sweetness of the Neva's water (I was told that a well-known St. Petersburg tea dealer, when going to Moscow and/or Nijni to purchase teas always takes with him a supply of the Neva water in order to taste teas with it); many called Ceylon tea "flower" or "medicinal" tea and some others upheld the opinion that its aroma and flavour are given artificially. I found out that about 1000 chests of the best Ceylon Pekoe are yearly finding their way into St. Petersburg for mixing purposes with inferior Chinese teas wanting strength, aroma and flavour, quite unsaleable as they are. A Firm (Dittborn & Co.) has promised me an order of some importance but, after further consideration, for some reason or other expressed their regret of not being able to do so at present. However, for all this, I did not lose courage I had only heard the opinion of the wholesale trade, I wanted to be quite convinced about the matter and knowing that the small traders, retailers and the Russian public had never had before the opportunity of seeing, selling, buying or drinking pure Ceylon tea, never offered before as such on any Russian market, I decided to see them and to have their direct opinion regarding the genuine article. I therefore, with samples and circulars about me and accompanied by an interpreter, started on a regular expedition—a crusade—visiting daily, in almost every quarter and street of the town, small tea dealers, retailers, shops, hotels, "Tractires" (Russian tea drinking places), restaurants, public bars, &c.

To the dealers I said,—“Give me for my mouey a pouod of pure Ceylonsky Tsohai”; the reply was of course “Sorry nono” everywhere. I then handed them samples asking them to get the same article for tho next time I would call, and sent afterwards some friends to ask them the same thing.

In the Restaurants, *Tractires* and public bars I asked for a glass of tea which, on being served and after having tasted it, I rejected indignantly complaining of its bad taste and asking for the only good and genuine “Pure Ceylon Tea” of which a sample packet was most graciously presented to the owner of the establishment. A well-patronized and largely frequented “Tractire” has served, for more than a week, to its clients the pure Ceylon tea without anyone knowing it and anyone complaining about the quality!

Hotels, friends and new acquaintances were also presented with a $\frac{1}{8}$ or $\frac{1}{4}$ lb. packet, and very numerous are those who told me, the next time we met, “Your tea is very good, excellent, economical and cheap, where can I buy it, givo me another small packet for my friend so-and-so.” I did this for about a month in St. Petersburg, which place I left for Moscow on the 24th of August, well convinced that Ceylon tea will, before long, be drunk *pure* and largely by many people there, and leaving samples to some friends with the task to continue, in the above manner, the work commenced by me; more was for me impossible to do, the wholesale trade refusing peremptorily to bite at business.

With about 200 lb. samples of tea, I arrived on the 25th August in Moscow which is no doubt the large central place in Russia for tea business, but there I met with the same objections from the part of the wholesale trade, viz. that Ceylon tea do not suit the taste of Russians and can only be used for mixing with inferior Chinese teas—about 3,000 chests of Ceylon tea are now used yearly in Moscow for this purpose, and this in the best qualities of pekoe and pekoe souchong, such marks as Labukelle, Chapelton, Rabatungoda, Bogawantalawa, etc.—My best eloquence was useless and could not convince them, and when I suggested to some of them that they would certainly find it a plying business to introduce Ceylon Tea by way of *retail*, in order to give the Russian public the opportunity to buy it and drink it pure, their unanimous reply and argument was: “The taste is against it and moreover why should we now help the introduction of this Tea to prejudice the sale of other marks and qualities we have taken the trouble to introduce and which are now selling well and readily on this market; it would be against our own interest, we would simply spoil our business and stand the risk to keep in stock perhaps for some long time and at a loss for us an unsaleable article.” One firm, however, well-known in Loudon, who has, quite recently, started in Moscow a semi-retail Chinese Tea business, on hearing that it was my intention to open such a business for Ceylon Teas, mentioned to me their willingness to take up the matter in hand and to order through me, *direct from Ceylon*, a yearly unlimited quantity of tea, provided they were alone to import these teas, have a sort of monopoly for the article, and that I would bind myself towards them, not to do any business with any other firm in Moscow and not to open myself any store or shop of any kind for the sale in *retail* or otherwise of these teas. Such a thing, I was of course unable to guarantee, as it is quite impossible to prevent other Firms to import Ceylon teas and being myself unwilling to be cut of some scheme which I am contemplating to arrange. Seeing all this, I began in Moscow the same campaign that I had done in St. Petersburg, distributing samples and circulars to almost all hotels, tractires, restaurants and public bars of the town, also to the numerous friends and acquaintances I made there. The result were the same as above, and after a four days visit in Nijni Novgorod where I was at about the end of the fair and my samples were also tasted by many people—Russians, Tartars, Siberians, Armenians, etc., I feel now sincerely convinced that Ceylon tea can be and will be drunk *pure* in Moscow

as well as in St. Petersburg, or any other place in Russia, as soon as it is placed within *direct* reach of the public—the consumers. A few months time and some “réclame” are only wanted to establish there a good and profitable business, and here I will take reference to Mr. Wm. Barnes Stevani’s—St. Petersburg correspondent for the *Daily Chronicle*—letter, published in the *Overland Ceylon Observer* of the 21st August last when he writes:—“And that Russians will drink Ceylon tea I am convinced,” etc., and further of his advocating the opening of a shop or shops, as being the best plan to be adopted for its introduction in Russia; this would soon compel the wholesale merchants to come to the front with their orders. The idea has long been mine, and having, for the present, no need to remain any longer in Russia—leaving the remainder of my samples to the care of a trustworthy and competent man who, during my absence, will continue my work of “réclame” and advertising, I left Moscow on the 29th Sept., via St. Petersburg on my way to London where, upon the suggestion of some friends, I intend trying to interest some capitalists in a scheme of this kind.

When passing St. Petersburg, the other day, I was agreeably surprised to be asked by many: When and where Ceylon tea would be sold in retail; and I am sure that there and in Moscow had I had a stock at my disposal, I would have been able to sell more than a thousand pounds without any trouble at all to friends and acquaintances only.

In Moscow, I had the pleasure of the visit of Mr. Geo. Seton, an Assam tea planter, who, introduced to me by Mr. Martin Leake, was visiting Russia on behalf of *Indian* teas; we visited together most of the largest wholesale tea houses and after having heard all that they they had to say *pro* and *con* Ceylon and Indian teas, we both agree to the same conclusion, viz.:—That their introduction into the country was only feasible by way of depôts and retail shops aided at the beginning with some well-conducted and judicious réclame by pamphlets, circulars and advertisements or articles in the press. Mr. Seton went so far in suggesting the opening of Ceylon Tea-drinking places on the tractires style, and a friend of mine suggested the “automatic” machines. An exhibition for French products is to be held in Moscow about June next, and although other nations’ products will not be allowed to be exhibited I have ascertained that a space, outside the exhibition, could be obtained for the building of a Kiosk and the sale in cups and in packets of Ceylon tea.

I may mention that Indian teas have very little chance of success in Russia, they are found too strong with an indifferent flavour and aroma reminding the smell of fermented hay and so different to Ceylon and China teas. Chinese teas are sold in Russia from Rouble one to Roubles 3.50 per Russian pound, as to quality, those below Roubles 1.50 being very bad—samples herewith—and with better qualities and cheaper prices Ceylon teas are bound to have preference. The qualities I would recommend as being most likely to suit the markets and sell well, are the following:—*Finest*, even made, leafy Orange and Brok-n Pekoe, *without tips*, of superior *rich* but *smooth* liquor, fine Moning flavour, mild taste, not too strong, not pungent or bitter, dark-red infusion, to sell, duty paid at about Roubles 3 per Russian lb.

Finest Pekoe	} of above { description	Roubles 2.50 per Russian lb.
Fine Do		do 2 do.
Good Do		do 1.75 do.
Good ordinary	} Pekoes and/or Pekoe Souchongs, leafy, to sell about, smooth flavour and good liquor, rather strong but not pungent, Moning taste, dark liquor.	
and common		
to sell about, duty paid,		
Roubles 1.50, 1.35, and 1.20 per lb. respectively		

Also *common Pekoe Souchong* of a dark colour infusion, rather strong but not pungent, to sell duty paid at about Roubles 1, 1.5, 1.10 and 1.15 per lb. or lower if possible. I have seen in St. Petersburg whole leaf China tea costing in London 4d a pound (English) f. o. b., and sold in

retail at 90 kopecks per Russian pound. Tippy teas are to be avoided, not being at all appreciated in Russia, but leaf, colour of infusion, and smoothness of liquor are the most important points to be taken into consideration.

Mr. Vladimiroff, of the large firm of Alex. Joubkin, heritiers A. Kansuatzoff & Co. the largest teahouse (wholesale) in Moscow, whom I have seen in Nijui-Novgorod, in giving me the accompanying complete collection of Chinese "Monings," told me that if Ceylon planters could only give to their tea the appearance, taste, flavour and perfume of these teas—which qualities and character are, I suppose, due to the difference of soil—he would be prepared to guarantee that before long time had elapsed, no other tea would be drunk in Russia; he is already of opinion that Ceylon teas, which he himself declared to be of very good quality, have a great and near future in the country on account of the evermore decreasing quality of Chinese teas in general of which everybody is bitterly complaining at present.

I have been showed some awfully bad qualities of a stuff that I certainly cannot call tea—"caravan or Overland Tea"—sample produced—sold at one rouble per pound, and I was astonished to hear that such drug was allowed to be sold and not stopped by the Police authorities as being infectious, and I really cannot understand the nonsense of the Russians as regards their so-called *taste* for tea, when they can drink such a filth, and drink it as they do, so weak and almost tasteless by dozens of glasses in a day, very seldom with sugar or a slice of lemon and almost never with milk or cream.

Caravan teas have greatly fallen off in importance for the last five years and the import into Russia by Overland route has been considerably reduced; good teas arrive now all by steamers direct to Odesa by Volunteer Fleet steamers, or with transshipment at Port Said by other steamers, and from London to Odessa, Riga, Revel and St. Petersburg.

Green Ceylon or Indian teas will never do for Russia, their colour and taste being not suitable for the market.

The Russian "Samovar" or "Selfboiler" is a capital invention, it resembles the old-fashioned English tea urn still in use in some English country households. It is heated by a charcoal fire let into a tube in its centre, just in the same way in which the urn used to be heated by means of a red-hot bar, the charcoal fire keeps smouldering for hours, and the water in the urn is thus kept at boiling-point for the whole of tea-time. The mechanism of the Samovar is extremely simple. A cover, to which is adapted a safety steam-valve to prevent the bursting of the machine, recovers the urn which is filled up with water from the top, another small cover on the top of the tube serves in regulating the fire, the hot water is let out by a tap fixed at the bottom of the urn and two handles—one at each side of the Samovar—serve to carry the whole apparatus, which is considered an indispensable adjunct to the Russian tea or breakfast table.

Tea is made in the following manner:—the required quantity of tea (leaf) is placed in a beforehand heated tea-pot which is filled up slowly and gradually at intervals, with boiling water from the Samovar, and then placed on the top of the tube for about five minutes when it is supposed that the tea is ready and fit to be drunk, glasses are then filled half-full with it, with an addition of hot water, the tea-pot is again refilled on the same leaf for a second infusion and this goes on for three to even four times without addition of any new leaf. This explains how the Russians drink so weak tea and why they require it of a strong colour, to keep up as dark as possible, up to the third or fourth infusion.

Regarding the packing of Ceylon tea, I have already written on the subject to the Secretary of the Ceylon Planters' Association, and I think, in view of further and larger business with Russia, some steps ought to be adopted for the adoption of better packages, better made, with a nicer appearance, and of even sizes, containing about 60 to 65 pounds nett of tea. The weight of the packages for *tare* should be *uniform*, so near as possible, in order to facilitate the Customs

entries, and these very exactly given in the weight notes and or invoices.

Living and travelling, etc., in Russia is rather expensive. I have spent during these three months travelling—on account of my tea mission only—and up to the day of my return in London (on the 14th Oct.) the sum £190—inclusive duty and charges on tea samples—against which I have received £145 only from the Ceylon "Tea Fund," for which expenditures I am prepared to furnish detailed account. I am very thankful to the Committee of the "Tea Fund" for their further grant of £150 advised to me by Mr. Leake and in conclusion of this report, I again strongly advocate the opening in Moscow and or St. Petersburg of Ceylon Tea Depôts and retail shops for the establishment of which I am prepared to subject all the necessary information, and I sincerely trust that men with capital, members of the Ceylon and London Associations, will kindly help me for the realization of my scheme, which I can guarantee as being a good one, not only financially speaking, but also in the interest of the Ceylon tea industry.

I am ready to return to Russia within the shortest time.

(Signed) M. ROGIVUE.

London, the 15th October 1890.

CEYLON TEA FOR THE CONTINENT OF EUROPE:

THE NEED OF SUPPORTING THE COLOMBO MARKET.

(From a Colombo Tea Buyer.)

Our Continental correspondents write as follows:—
"If there were only a larger selection on your market we might probably have done a larger business together by this time." In another part of the same letter they say: "We must have a little to go on with, as we have introduced this class of tea into some parts."

FRUIT FROM JAMAICA.—In this article on the awakening of Jamaica, in the latest *Nineteenth Century*, Sir Henry Blake mentions that within the past ten years the value of fruit annually exported from that island has increased from £40,000 to £337,000. The fruit is principally bananas, and the demand is likely to continue. "The value of the banana as food for working men has been recognised in the United States, and it is found peculiarly sustaining for those engaged in heavy labour in warm situations, such as blacksmiths and iron-founders. The operatives in cotton factories also use it largely. In England it is but little known, but Jamaica bananas are now being exported to Hamburg *via* New York." Sir Henry thinks this fruit trade is only in its infancy, and no doubt he is right.

THE WORD SUGAR.—Webster defines "sugar" as "a sweet, crystalline substance." In ordinary use the word refers more to cane sugar than to any other kind. The oldest form of the word is found in the Sanskrit, *çarkara*, candied sugar. In Persian it is *shakar*, and in the Arabic *ookkar*. It is not a little curious to find this word in the Old Testament under the form of *Issachar*, meaning wages, sweetness. "Leah said, God hath given me my hire, and she called his name *Issachar*," sweetness. Though known and used in Asiatic countries from time immemorial, it was little known or used in England, except as an apothecary's drug, until within a few centuries past. There is no modern word that takes the place of that of the early ages. In Chinese the word is *che*, and as the character expressing it is original, it is claimed that sugar cane is indigenous in China.—*Sugar-Bowl and Farm Journal*,

PROGRESS IN OLD KADUGANNAWA:
COFFEE AND TEA.

We hear very favourable reports of the young tea plantations in the old Kadugannawa districts. Mr. Akbar's 200 acres in tea at "The Farm" are described by a competent authority as very fine. On the other side, the young estates of Messrs. Thomas and Shelton Agar are promising; also one belonging to Mrs. Burt; while close by a spirited native gentleman is opening land with Arabian coffee as well as tea. May success crown his enterprise in both products.

CACAO PODS DISAPPEARING!

(The Enemies of a Cacao Planter.)

Nov. 6th.

I have been smothered with work lately; uneasy lies the head that thinks of cacao pods, as there is now a regular industry in stolen cacao. Which of the Colombo firms are the final 'receivers'?

The Census Commissioner might, while revelling in figures, add a column to his lists for the cacao districts for the headmen to fill up, showing the number of villages owning no property and doing no work! This would help to explain why half of our crop never reaches the drying-house.

DR. VOELCKER.

SIMLA, Oct. 28th.—Dr. Voelcker leaves Simla about the 21st of Nov. and proceeds to Poona, and sails from Calcutta en route for London on the 18th of Dec.—Thursday's "Observer."

Dr. Voelcker, we learn, is due in Colombo on the 23rd Dec. and will be the guest of Mr. T. Watson Hall for three or four weeks, during which time he intends taking a trip through the planting districts. We are very pleased to have this intelligence. The Planters' Association should arrange to show some special attention to this great agricultural and chemical authority.

PADDY CULTIVATION IN THE EASTERN PROVINCE.—We call attention to the very important Report furnished by Mr. Elliott on the careful experiments carried on under his direction by Agricultural Schoolmen with paddy culture in the Batticaloa district. The full details given are most interesting and certainly give us a new idea of the scope that exists for improvement in local grain cultivation by the people and of the really handsome profits per acre that may be realized. Of course no one will say that careful experiments on selected fields can be equalled over a wide area; but Mr. Elliott shows that the land taken up was only of an average description and that the bad season affected his experiments very considerably. So that we are forced to the conclusion that over the extensive paddy-growing fields of such exceptionally favoured districts as Batticaloa and Matara and no doubt over a great part of the Colombo and Negombo districts of the Western Province, not to speak of Madampe, Chilaw, and some other divisions of the island,—a clear profit of from R15 to R25 per acre in paddy-growing would not be difficult of realization if attention were given to such means of improved cultivation as are well within the cultivators' reach. It would be well if other Government Agents followed Mr. Elliott's example in carrying on careful experiments after the pattern he has set.

CEYLON UPCONTRY PLANTING REPORT.

PEPPER CULTIVATION—CACAO PODS AS FOOD FOR CATTLE
—CACAO PROSPECTS AND PRICES—COFFEE AND COOLIES—DECLINE OF THE CINCHONA MARKET—WEATHER
—LABOUR.

Nov. 6th.

The *Pepper* spurt, which about a year ago was very much in evidence, seems to have exhausted itself. You never hear anything of this spice by any chance, and when you do see it, and ask as to its ways and doings, the record is not an encouraging one. I begin to fancy that to grow it successfully a very rich soil is necessary; and when it has not got this it struggles along in a half-marked kind of way, vigorous enough just to keep hope alive but not to contribute anything reasonable to the exchequer. Now and then you fall on a vine that does gladden, with an exuberance of fruit; but this is the exception not the rule. I wonder how many who have gone in for it in Ceylon are satisfied with the present or the future outlook? Precious few, I fancy. We would all, however, willingly see an extension of its cultivation, as there would be a chance of making something off cuttings! With a flow of coin and a hopeful spirit abroad it is wonderful how bright life can become and how the potentialities of even *Pepper* culture would swell out.

Has anyone ever tried Feeding Cattle on cacao pods? Cattle take to it very kindly, and as far as I have seen without any evil effects, and it may be that what really is a valuable cattle food is allowed to run to waste at present for lack of knowledge. In a matter of this kind, however, the natural feeling is, that you would prefer another fellow to try in case of accidents! The piles of broken pods which accumulate in every cacao garden, need not be wholly wasted, as they can be and are returned to the soil as manure; but if it were proved that they were a good fodder, those gardens which had a cattle establishment would score.

The *Cacao* crop is coming in fast now, and it would seem as if in some places at least it will be quite as good, if not better than last year. This, however, is not to be the rule everywhere, as I understand that Dumbara is not going to do so well owing to the drought in the early part of the year. The grand prices ruling at home are very encouraging, and make up for a lot of former disappointment and worrying work in bringing the gardens into bearing.

The little *Coffee* we have on this side is looking fairly well for coffee, but it is very little. It, too, is ripening, but there will be no great rush over the gathering of it. It is strange how so many keep in touch with the old king; for there are few estates which have not got some trees about. A clump under a jak, or by the lines, or in the bungalow garden, is evidence of the past universal order. Then the coolie is not willing to let the memory of coffee die out wholly, for you find them referring to tea, as coffee; and they will speak of a line of tea as a "coffee nirrē." I have noticed them even using the word coffee to cacao. I suppose this is language in the act of being made; and that by-and-bye the Tamil people in the hill districts of Ceylon will use the word coffee as a general instead of a particular term. It may puzzle some future philologist to account for this, but if he digs but deep enough he will discover what other students have often noted, that a single word may contain the compressed history of a great crisis.

What is to be made of this wretched *Cinchona* market? I don't know how many years ago it is now, since we all confidently looked for a

recovery of prices, and the rate is as poor as ever. The whole thing is simply disgraceful, and I am convinced that even Job himself, if he had been growing cinchona, or had held any for a rise, would long ere this have cursed and died rather than go on with it. When the price of the unit advances an eighth, there is consternation among the manufacturers, and the sellers of bark grow jubilant. I suppose it is the most sensitive market in the world, and that is why it makes so much fuss over so little. Anyhow an industry whose hopes have been bounded for years by about 1½d on the one side and 1¼d in the other, leaves precious little room for a fortune to the growers of the article, or for speculation either.

The Weather is very favourable for tea flushing, and the leaf comes on in a cheery way.

Coolies are plentiful, and are preparing for a lavish outlay at the "Tivali." The quantity of coin drawn from the banks about this time to pay wages on the estates must amount almost to a run on them. He will be a fortunate man who can afford a day to his labourers for holiday-making and stand the strain of the absentees later on. Few object to the holiday,—it is of the after effects, and the time it takes some of our coolies to work it off. PEPPERCOBN.

THE RUBY MINES OF BURMA.

As a gem-producing country Ceylon is interested in the following not very encouraging notice of the Burma ruby mines, evidently by Sir Lepel Griffin from the unworthy but perfectly characteristic attack he makes, in a part we do not quote, on the American missionaries and their Karen converts:—

The country leased to the Ruby Mines Company begins in the neighbourhood of Kyatpyin, but it is of great extent some 800 square miles in area, and is unsurveyed or very imperfectly surveyed. It includes the whole country in which precious stones are known to be found, except one or two outlying mines like Saygin on the Irrawaddy not now worked. The operations of the company have been delayed by the great difficulties of transport and labour and the impossibility of conveying heavy machinery across mountain roads in any but the finest weather. A large amount however, has now reached the headquarters, and is being put up; the stream running through the valley is being diverted, and mining operations on an extended scale are being begun. The labour question however, is one of difficulty. The best labourers are the Mainthas, who come from Chinese territory, and who are strong men and desperate gamblers, so much so that if any attempt is made to stop their unceasing gambling out of work hours they threw up their engagements and leave the place. These men hardly arrive in Mogok before January, and in April they are anxious to return to their homes to sow their fields before the rainy season. The labour procured from Mandalay or Lower Burma is unsatisfactory and very expensive. Another difficulty the English Company has to face is the jungle fever, which is very trying to new comers, but it may be hoped that with better food and better conditions of living, and as the *employés* become acclimatized, this inconvenience will each year be less severely felt. Kyatpyin is the machinery headquarters of the company, its principal settlement being 12 miles further on, at Mogok, a large and flourishing town in a wide and beautiful valley, through which runs a stream of abundant water. The town is picturesque in the extreme, with groups of temples and pagodas. The houses, all constructed of wood and built on stilts in the fashion of the country, are substantial and commodious, and the inhabitants, all of whom live by the ruby trade, appear to be a most flourishing community, the women being covered with jewels, some of great size and beauty. We visited the weekly fair at Mogok, in company with Sir Charles Crosthwaite and his staff, and the sight was a striking and picturesque one, for men and women

from distant villages in the Shan and Chinese hills, strange in appearance, especially the Kachyens flocked in from all directions, and their curiosity and astonishment at the sight of an English lady, who was followed by great crowds through the bazaar, was most amusing. Mogok is fast becoming an English settlement of some importance; it is the headquarters of the district, with a resident magistrate, and of the divisional military police, who are mostly Sikhs from the Punjab, while the offices and numerous wooden chalets of the officers of the Ruby Mines Company dot the hills surrounding the town. The great alluvial plain through which the river runs is excavated in many places by the shafts of the native miners, who have been allowed to work for rubies through many generations, and that they have found the occupation a profitable one is evident in their appearance and manner of living, but their system of digging shallow holes from which the water and mud is painfully taken out by baskets and buckets is not one which would be profitable to a scientifically working company, whose method would be more elaborate and more in accordance with the principles adopted in diamond mining in South Africa. It has not been found politic to oust the miners in the alluvial soil of the valley from their holdings, although, under the native Government, they held these as tenants at will for until Upper Burma is permanently tranquil, it is unwise to take any action which would render hostile to the company these whose co-operation might be to its advantage. They have consequently been allowed to continue mining, paying for each person employed a poll-tax of 20 rupees. As about 600 miners are engaged in the work this brings in an annual revenue, of about a lakh and a quarter of rupees, while a useless embargo on smuggling having been removed, the miners more readily bring to the company's officers for purchase such of the good rubies as they find. This plan, which has been experimentally adopted, will be modified if its results are not satisfactory. In the hills about Mogok and Kyatpyin native miners with much larger rights of occupancy work open cuttings in the sides of the ravines, and it is to this work by hydraulic power that the company's operations will be chiefly directed. What may be the ultimate result of the company's labours it is impossible to pronounce, but much activity is now being shown, and, with the arrival of sufficient and effective machinery, the real operations of the company, too long delayed, will practically begin.

Two thousand feet above Mogok, by an exceedingly difficult mountain path, is the military station of Bernerdmyo, some eight miles distant, and ordinarily reached by a military road joining the main line above Kyatpyin. It was hoped that the elevation of this cantonment above the sea, quite as great as those in the Himalayas, would have insured the troops against jungle fever: but this was not the case, and the great sickness almost caused the abandonment of the place. The health of the troops stationed there has, however, much improved of late, and, like all Burmese stations, the peculiar climatic conditions require a European resident to be somewhat acclimatized before he finds them healthy.—*Times Weekly Edition.*

It will be observed that the chief difficulties specified in the case of the Burma Company—scarcity of labour and difficulties of transport—do not in the least apply to the gemming country of Ceylon. Clearly British capital should have come here before it went to Burma.

ARTIFICIAL MUSK.—The comparative scarcity of musk, and its considerable use in pharmacy make the discovery of a substitute of some importance. Mr. A. Bour has succeeded in preparing a substance which, though not identical in composition with natural musk, yet is possessed of its peculiar smell. It is formed by nitrating isobutyltoluene with a mixture of the strongest nitric acid and fuming sulphuric acid. It is not poisonous, and is now being produced on a manufacturing scale in Germany.—*Industries.*

COCONUT BUTTER :

A NEW FIELD FOR EXPORT FROM CEYLON.

For some little time past we have been hearing rumours as to the successful extraction from coconuts of a butter which it has been asserted might eventually take the place to a very great extent, of the genuine article. Information, however, respecting this new process has hitherto been of a very limited character, and from all that could be learned on the subject the experiments made seemed to have been of a tentative character only. It is, therefore, with considerable surprise that we have read the account given in the latest *Kew Bulletin* and which was summarized in our London Letter by last mail. To judge from what we have thus learned, the process has not only passed out of the region of bare experiment, but its success commercially has already been established, and a very great demand, far beyond the present means of meeting it, has sprung up.

To an island like Ceylon, which not only now produces an enormous yield of coconuts, but in which the cultivation of the palm bearing it is possible of still farther extension, the news now reaching us is of very material importance. But we deem it to be probable that local interest in the matter must to a considerable extent await the fuller development of the methods employed. Unless it be found impracticable hereafter to work the manufacture locally and with profit, the probability is that our own interest in it must be dependent upon the discovery of a method by which the extract may be obtained from the copra, the name by which the dried kernel of the nut is known. So long as the power of extracting the butter is limited to the fresh nuts, it is scarcely possible, we should say, that Ceylon, despite all its capacity for production, can compete in the supply of them to European countries, with sources which lie nearer home. For, after all, the question of the cost of transportation is a serious one in regard to the nut itself. The unbroken nut, even when stripped of its husky covering, occupies much space relatively to the weight of kernel it contains, and this fact must, of course, increase the freightage greatly. Two courses, therefore, await experiment before this island can hope to share very largely in the supply for the actively increased demand which this new discovery is likely to cause. The most important of these would be the discovery of a method whereby the butter may be extracted from the dried kernels, while the second one would be the adoption of the process of manufacture locally.

The method of the latter process is unknown to us, nor does the *Kew Bulletin* afford us any intelligence with reference to it. The probability is, we should say, that it is—for the present at all events—a trade secret, and there can be little doubt that if it be so, the endeavour will be made to preserve to it that character as long as may be possible. The local prospect, therefore, of sharing in the advantages to be expected from this new invention must, it would seem, be dependent on means being found for the substitution of the dried for the fresh kernel. As to this, everything must depend as regards ourselves upon whether the drying which converts the juicy nut into a hard substance is inimical to the preservation of the constituents from which the butter is derived. This is, of course, a point upon which we are unable to express an opinion, but it is one which may well engage the attention of scientific chemists, and would even be of importance enough to our island interest to warrant our Government in seeking information from home. According to the

Kew Bulletin, the new extract has a fair prospect of largely superseding the butterines, such as oleomargarine, &c., which are extractions from animal fats. Indeed we are told that it has already largely done so, and that the present demand ranges as high as 100 hundredweights *per diem*, while the existing means of production limit the outturn to 50 hundredweights only.

We may be sure that the official organ of the Great British Botanical Gardens would not have committed itself to the reproduction of these figures, had not its directors been possessed of good warranty for so doing, and we may therefore accept them as fully reliable. It is not difficult of belief that people would prefer a pure and healthy vegetable extract to one, the sources of which are open to taint and much suspicion. As regards these last we have even heard it hinted at that the soapy scum which rises to the surface of the Thames at the points of sewage discharge into them is collected partly with the object of the manufacture from it of oleomargarine! Although we greatly doubt this, it is quite certain that many very base and disagreeable substances may be, and probably are, the foundation of much of the oleo-margarine sold. We have never practised the experiment ourselves of tasting this compound, but there is ample evidence of its very extensive manufacture and of its large and legally-practised sale. There is every likelihood that this substance will be largely displaced by the pure extract from the coconut if all that we have been told about the latter be correct. In that case we shall do wisely to keep "our eyes about us" in the hope that our native industries may largely benefit by this new departure.

BIG RETURN OF TEA.

Ruwanwella division of the Kelani Valley is in a fair way to take the palm with a return of tea per acre last month that beats anything yet recorded—300 lb. made tea per acre over about 30 acres flat, with the prospect of being repeated in the current month, are the figures given to us. Has this been beaten?

JAVA BEATING JAVA IN THE RICHNESS OF ITS CINCHONA BARK.

Our Java friends are fond of boasting of the superiority of their cinchona bark to any grown in Ceylon; but we should like to know of any single shipment from Batavia equal in weight, exceeding the analysis of the one we have just got particulars about. Last week a parcel of cinchona bark from the Messrs. Macfarlane's Canavarella estate, Badulla, of 28,000 lb. analysed in Colombo 5.10 per cent sulphate of quinine—so it will be seen that the Java people—as our informant says—have not yet got the matter entirely in their own hands. This is the highest analysis for a large quantity of bark ever obtained in Ceylon we think.

CEYLON TEA PLANTATION COMPANY, LD.—A GOOD DIVIDEND.—We have come to regard this Company at the premier Tea Company of Ceylon, being the largest and one of the most prosperous. When, therefore, it does well, having interests in many districts of the island, and at both high and low altitudes it certainly is hopeful for the Ceylon Tea enterprise generally. We are, therefore, pleased to be able to state that the last mail brought news to the Colony that the Directors of the above Company had decided to declare an *interim* dividend for the past half-year at the rate of 7 per cent per annum, which, considering the enormous rise in exchange which has occurred during the last five months, is a most satisfactory result, and one of which no one should be more proud than Mr. G. A. Talbot, the Manager of the Company, and the superintendents.

BOOK NOTICE.

SAP: DOES IT RISE FROM THE ROOTS?

By J. A. Reeves. (London: George Kenning.)

The purpose of the author, he tells us, in the beginning of his book, is to describe certain known facts, to lay before the reader an outline of the theories hitherto advocated, and to show that there is no evidence to prove "that the sap in trees rises at any time; that inorganic matter rises from the soil; that the soil is exhausted by the growth of vegetation; that sap is elaborated in the leaves; that suckers from the roots are injurious." The physiologist and the cultivator will at once see that the author has a hard task before him. It is quite true that contradictory opinions and conflicting statements have been and are held upon several of the points raised by the author, that very little is known for certain, and that very much remains to be done before all the questions relating to the movements of the juices in plants can be solved. It will be understood that the problem is partly physical, partly physiological—physical in so far as concerns the mechanism of the plant, and the forces which set the machinery in motion; physiological in what concerns the plant in action. Some knowledge therefore, of physics, of chemistry, of vegetable anatomy are essential, and the capacity of applying the principles derived from them to the explanation of the observed phenomena is no less a necessary condition. The author of the work before us attacks, with perfect impartiality, the views of his predecessors; so far as he knows them; he demolishes their arguments to his own satisfaction, and concludes by the assertion that, "instead of water ascending and gases descending, the facts ... go to prove that the water descends to the roots, and the gases ascend to the leaves, both actions being in strict conformity with the laws of gravitation."

Oppressed, as every physiologist and teacher must be with the unsatisfactory state of our knowledge on the subject, we should gladly hail our author as a guide, if he were able to show satisfactory credentials, and then to substantiate his statements. If we turn to his credentials, we find they are two-fold, consisting of "extracts from the best authorities;" and amongst these, while we find a few whose names carry weight, we find some who at best would only pretend to be compilers; and many others of a very miscellaneous character, whose opinions in such a matter, however honest, are of no value whatever as evidence. The author's references to the literature of the subject are ludicrous, as much for what he has omitted, as for what he has requisitioned.

In addition to these extracts from "the best authorities" and others, from writers who would certainly not claim any authority for themselves, the author lays before the reader a brief record of his own observations and experiments. We fear the physiologist will hesitate as much to accept them in their entirety, as he would to accept the author's literary evidence. In this department we naturally look for evidence of the author's personal knowledge and competence to deal with his subject. We find a great deal of assertion, much adverse criticism, some of which is, no doubt, legitimate; but some of which will fail in its effect from the inability of the author to prove that he is competent to deal with his subject. Take for instance, a passage on p. 48, and consider whether the physiologists would be likely to attach importance to the theories of a writer who can say, "The roots (formed from a *Pelargonium* cutting) being a hardened or solidified exudation of the sap [!], of course, grow from between the rind and the wood."

It is no wonder that a writer who can thus describe a root, should arrive at a very different conclusion as to root-action from other people. His question of root-action is the one in which cultivators will naturally take the most interest, and the reader poring the pages of Mr. Reeves' volume, will naturally inquire—What is the use of the roots? So far as we can see from Mr. Reeves' pages, they can be of no use except as supports. If what he tells us be true, there is

no need for root-watering at all. Manures are superfluous; root-pruning never needed; the care exercised in transplanting or in potting is so much waste labour.

Leaf-action, again, in the writer's views is reduced to little more than the absorption of water. Ignoring the teachings of physiologists, and the experiments of botanists, the author says boldly, "The elaborative function so constantly attributed to the leaves of trees appears to be nothing more than elaborated idea (*sic*) unsupported by the least evidence." Clearly the author has not read his Sachs, nor his Vines, nor has he observed to any purpose what happens when Celery is branched.

Speaking of "suckers," the author's notion of what they rely on seems rather vague, while his statement that a healthy tree has no suckers, may be contradicted by the first white Poplar or Elm he may come across.

In fine, whatever the deficiencies in our knowledge of the circulation of juices in plants, and they are great, we do not think that Mr. Reeves' book at all helps us to supply them. His teaching will not commend themselves to the practical horticulturist, while they will most certainly be repudiated by the botanists.—*Gardeners' Chronicle*.

SCOTTISH TRUST AND LOAN COMPANY OF CEYLON.

Report of the Directors to be laid before the Thirtieth Ordinary General Meeting of Shareholders, held on Friday, the 24th day of October 1890.

The Directors present their Thirtieth Report, being for year to 31st of August 1890:—

ESTATES IN COMPANY'S POSSESSION.—The cultivation of the estates in the Company's possessions continues to receive careful attention, and the sales of tea and coffee during the year have commanded satisfactory prices in the London market. The sales of cinchona were restricted owing to the state of the market, and part of the Company's produce has been retained in the hope of better prices. The whole cost of tea cultivation has, as formerly, been charged to revenue. Acting on the advice of the Company's Ceylon agents, the Directors authorized the erection of a tea factory at Kaipogala, from which remunerative returns are anticipated. The outlay on Tea Factories and machinery amounted during the year to £655 10s, and the Directors have written off the sum of £745, 4s 6d, being one-fifth of the total expenditure on this account during the past two years.

PRODUCE ON HAND.—The valuations have, as formerly, been carefully made by the London Agent, and are largely based on the result of actual sales made subsequent to the date of the closing of the books.

MORTGAGES HELD IN CEYLON BY THE COMPANY.—Sundry payments have been received during the year in reduction of mortgages, and interest has been punctually paid, with the exception of the amount shown in the accounts, which, however, has been reduced since the books closed. Early in the year the Directors found themselves compelled to take active measures in connection with two Rupee Bonds standing in the Company's books at the old rate of exchange, at the *cumulo* sum of £11,000. The estates were known to be much deteriorated in consequence of the failure of the coffee, and tea cultivation had barely been commenced. The Directors were most averse to take over these estates, and judged it in the best interests of the Company to accept an offer of £8,000 payable by instalments in sterling money, which was made to them by a neighbouring proprietor. The loss of £3,000 arises in about equal proportions from the fall in Exchange, and the depreciation of the estates, and the amount falls to be written off. The Company now retains only one Rupee Loan, of about £1,000.

DEBENTURE DEBT.—The amount borrowed and the rates of interest have again been reduced.

The Balance at the Credit of Profit and Loss Accounts is £5,925 9 0 and the Directors propose—

To write off the above loss	£3,000 0 0
To pay a Dividend of 6 per cent, free of Income Tax	2,250 0 0
	£5,250 0 0
Leaving	£675 9 0

to be carried forward to next Account.

The Dividend will be payable, as before, on the 11th of November.

Under the rotation fixed by the Directors, Mr. Dickson retires from office at this Meeting; but he is eligible for re-election in terms of Section 14 of the Articles of Association.

During the year Mr. J. Campbell Penney, who has acted as Secretary of the Company since its formation in 1878, tendered his resignation on his appointment as Accountant of Court. The Director appointed Mr. Francis A. Bringloe, c.a., in his place.

The Auditor for the current year falls to be appointed. FRANCIS A. BRINGLOE, Secretary.

NOTES ON PRODUCE AND FINANCE:

THE CUSTOMS AND DUTY-PAID ARTICLES.—Instructions have been given to the Customs officials to furnish, for the information of a Committee of the House of Commons, a return of the quantity of duty-paid articles, including tea, coffee, wine, beer, spirits, manufactured tobacco and snuff, &c., consumed in England, Wales, Scotland, and Ireland respectively. The return asked for is to be rendered quarterly, commencing from the period ending Dec. 31st next, and all shipping and carrying companies are requested to furnish the Customs with an account of all such articles conveyed by their routes between each of the three divisions of the United Kingdom.

THE PRICE OF CHEAP TEA.—Tea was never so cheap as it is today, and never so dear, says a grocer's paper. It can be bought at any price from 1s per lb. A good deal was made of a parcel of Ceylon tea which fetched 30s 6d per lb. in London the other day. However, it appears that Sheffield can beat that, for we are informed that Mr. Tuckwood has in his Fargate stores a parcel of Ceylon tea for which he gave 55s per lb. in London, and the broker would buy it back at 60s.—*H. and C. Mail*, Oct. 24th.

ADULTERATION AS A FINE ART.—According to statistics produced in an American paper the average quantity of genuine coffee actually imported averages only 130,000,000 lb. per annum, but with roasted beans, peas, and rye and other coffee substitutes, an annual consumption of at least 216,000,000 lb. is provided for, some estimates indeed placing the yearly consumption of bogus coffee in the United States at 120,000,000 lb. We learn that the "bean" is still the most difficult to produce, but a good "specimen," composed of rye flour, glucose, and water, is now manufactured in Philadelphia and Trenton. It is further stated that "taking even the lowest estimate, the cute Yankee engaged in this particular field of 'commerce' makes 25,000,000 dols. a year out of his fellow-countrymen, the manufacturers taking six millions of this, and the retailers nineteen millions."

A NEW COFFEE COMPANY IN BRAZIL.—A Brazilian paper refers to the formation of an important company "with a capital of 50,000,000 dols. already subscribed, and 'which does not contemplate a monopoly nor a struggle with the intermediate exporter, seeking merely to direct the market towards stability, subject only to the natural fluctuations caused by consumption, limiting the bases upon which it proposes to operate, incurring none of the risks of exporting—it being forbidden to it to work in this direction—and making of itself only a great buyer which may resist for the moment artificial declines, at the same time facilitating transactions in the article." Occupying itself in all the industries accessory to the proposed business, the coffee-bagging company will establish the necessary workshops, will acquire ware-

houses and stores, will provide for means of carriage and shipment, and will establish agencies in the markets of New York, Havre, Hamburg, and London. At the head of this enterprise, of which the president is Visconde Cruzeiro, are as directors and auditors, Conde de S. Clemente, Conde de Figueiredo, Barão de Andarahy, Barão de Ipanema, Dr. João Baptista de Castro, and Comandadores Urbano Faria, Manoel de Araujo Guimaraes, and Joaquim de Castro de Silva.—*H. and C. Mail*, Oct. 24th.

THE JAVA BUDGET.—The Amsterdam correspondent of the *London and China Express* writes in the issue of Sept. 26th:—

The Java Budget was introduced in the Second Chamber on the 22nd inst. The service of 1890 promises a more favourable result than in 1889, as there will be a profit balance of f.4,500,000 instead of a deficit of f.7,500,000. The expenditure for 1891 is estimated at f.136,840,616 and the revenue at f.116,414,315. There is thus a deficit of f.20,426,331 or f.12,916,926 more than estimated for 1890. The quantity of coffee to be offered at auction at 1891 will be about 190,000 piculs, against 520,000 piculs for 1890, and in the quantity of 190,000 piculs there are included 60,000 piculs reserved for the sale of 1890. In consequence of this the proceeds of the coffee is estimated at about f.15,500,000 less. * * * The average sale price of the coffee is estimated at 52 cents, against 43 cents last year.

In commenting on the budget our contemporary says:—

Almost the whole of the estimated deficit for 1891 is caused by the reduction in the quantity of coffee, which it is anticipated will fall short by 15,500,000 guilders of even the lesser income received in 1890. The quantity, according to latest advices, is only expected to total 190,000 piculs, against 520,000 in the present year, which itself was only one of a constantly descending sequence. It is not necessary to remind our readers that in past years the amount netted by the Government of Holland has been immense from coffee, and the falling off of millions of guilders shows how large they are. When some three years ago the receipts had fallen off to a large extent the Government appointed a commission to inquire into the whole subject, and though the members made a number of suggestions on the matter, all were not put in force, and the continued ravages of leaf disease have more than counterbalanced any modifications that were introduced into the method of culture. The *scorch*, or leaf disease, is a matter which may or may not be successfully combated in time. It is sincerely to be hoped that science may devise some means, but seeing that about one-third of the world's production of coffee is estimated to come from Netherlands India any other means that can be devised to again reinstate the production should be energetically applied. One great means would be to give the natives a greater interest in growing the bean. The abandonment of the compulsory growth enforced by the Government might be relinquished, or an increased price given to the native for the coffee he produces. This would give him a zest which is only supplied at the present time by the periodical visits of the inspector to see that the minimum number of trees is kept up. Perhaps, viewing other circumstances in Netherlands India, it would be better to increase the purchase price rather than abandon the compulsory growth. There are many places in the Padang Highlands of Sumatra which would prove suitable to its extension provided the remuneration was greater. The natives here have always been more antagonistic to the present system than have their *confères* in Java, and the Government should seriously consider the question whether it would not ultimately conduce much to their own gain if they allowed to the native cultivators a reasonably fair share of the profits of the industry.

ESSAYS ON THE FERMENTATION OF COCOA.

(From the Trinidad "Agricultural Record.")

FIRST PRIZE ESSAY.

The fermentation of cocoa, or sweating as it is often termed, is very properly considered as an essential part of its preparation for the manufacturer's use. The principal objects to be obtained may be set down as the development of flavour, the suppression of the bitter principle, so marked in the Trinidad varieties, and a certain allotropic modification of its substance (i.e., the Cottedons) not easily recognised by chemical analysis.

Fermentation properly consists of decomposition or slow combustion (oxidisation) accompanied by the formation of new products; in the case of cocoa this is spontaneous, and must by no means be confounded with the scientific methods known to malsters, distillers, &c., in the process here described, the object being not to deal with the products, but to affect the cocoa bean by long continued heat, moisture, &c., and, furthermore, to remove the adherent pulp. This sweating must not be regarded either as a simple process; on the contrary, it includes, more or less, the secondary fermentations, such as the lactic, butyric, mucous and putrefactive or eremacausis.

The cocoa pulp to be fermented is a viscons gummy mass not unlike the substance of the custard apple or soursop, and contains an abundance of fruit sugar, cellulose and carbo-hydrates necessary to support combustion or fermentation; it also possesses, as many other fruits do, within itself a natural diastase and yeast ferment; having, therefore, been in contact with atmospheric air and then closed up in a chamber, packed with plantain leaves, &c., the alcoholic fermentation is readily established, the self-contained natural ferments, as already described, being soon supplemented by countless bacteria from the air.

If the mode of proceeding in sweating or fermenting cocoa was the same throughout, it might be easily described. Such is, however, very far from being the case. The great difficulty is that the Trinidad varieties (termed on the Spanish Main "Trinitario") are so very different in character, "each sub-variety or hybrid requiring a different period of fermentation," that the planter is at his wit's end to make his batch turn out all alike, and nearly every one has, therefore, "a way of his own."

On the best estates in Venezuela the Criolo alone is planted, but as it was found not to bear so well as the "Trinitario," our seed some time ago was extensively planted along the Guiría Coast, but after a short experience they concluded that the choicer and higher priced cocoa paid best, and I have myself seen planters in that district rooting out our cocoa trees from their plantations.

The Criolo is much better flavoured than any other, and requires but three days' fermentation. This choice kind has been extensively planted in Trinidad, but surrounded with inferior plants (and perhaps on inferior soil) it has become hybridised and assimilated to the native sorts, and has not maintained its supremacy, so we must ever look to the mixture of Criolo, Forestero and Calabacillo, &c., with which we are blessed, only taking especial care in picking to exclude pasi or flat beans and unripe pods. If our varieties were well marked and we determined the exact temperature and the precise number of days that each kind wanted, then, as many persons advocate, it would be well to separate them in the field, but practical men know better than to attempt this, or, at least, on any large scale, and they are contented to deal with them as a whole.

The general practice in fermentation varies from that of the small *conuquero*, whose object is to realise quickly and to get the utmost weight possible, to the elaborate plan of Mr. F. Strickland extending over fifteen days. The *conuquero* puts up his beans to drain and forthwith exposes them to the sun for, say, five or six hours, then heaped and packed up, they sweat afresh until the following day, when they get five or six hours more sun and so on. He turns out a fair

looking bean sometimes, and pays especial attention to its red appearance, inasmuch as he knows that the light red will always bring another dollar per fanega in the local market; this is true, and is probably owing to the fact of its weighing lighter and being cleaner, due to the more careful rubbing and removal of the gummy coating. In America this red cocoa is especially approved, and quite regardless of the interior condition of the bean; this may be of a very dark brickdust colour varying, according to the quality, to purple or yellow. Another contrivance of the small grower is that of bagging the cocoa at end of day, whilst still hot from exposure to sun, and so to sweat it during the night; this little scheme was learned from the Venezuelans, and is often practiced in Port-of-Spain by cocoa dealers to improve unfermented cocoa.

Next we trace the system of the more pretensions planter who boasts of elaborate sweating and drying houses; their fermentation varies from five to eight days, the process, however, is carried on "without the least reference to the thermometer" in close chambers, and it is certain that in many cases they heat the cocoa up to a stage at which alcoholic fermentation could not go on, say 160°. What follows then is destruction of the diastase and other ferments, and a lower type of fermentation or eremacausis (as in nature) the cocoa becoming eventually fusty and sour. The planter working on such a scale should "break bank," as the tobacco planters term it, when it reaches 140° or earlier.

Treat it as you may, however, fermentation at high temperatures cannot go on beyond eight days, for the reason that the fuel, i.e., the Sugar, is all exhausted, if not the ferments, and although it may be possible to start it afresh by adding some invert and a little dried yeast, in the same way as tobacco curers often ferment fusty tobacco, yet, most men will say "*cui bono.*" At the best it will contain a large proportion of unsatisfactory beans which on section will show their inferiority, and, "nota bene," section is the test employed by all brokers now in examining samples of high class cocoa. At this stage of our inquiry it will be proper to consider the bearing of the state of the weather on fermentation as just described, a very important matter, where the cocoa has to be dried during persistent rains, and this very often happens when the crop comes in early. The small proprietor then is not so very unreasonable, according to his light, in making the fermenting and drying process go hand in hand as it were, for the partially fermented cocoa stands damp weather and absence of sun longer than that which has been thoroughly treated. Un-sweated cocoa, moreover, gives the same results on analysis as any other, and although it is not aromatic, and fetches a smaller price, the poor man argues that it is better than a dead loss. A much better remedy for these troubles will, however, be found further on.

It would be a mere waste of time to dwell longer upon the unsatisfactory short and un-scientific method in common use, so we will pass on to the plan introduced by Mr. Strickland and for which he deserves full credit. His system has been adopted with various modifications in both Grenada and Trinidad, but to understand its importance we must study the composition of the bean first, and see how it is affected by the fermenting process according to the different varieties.

Reviewing twelve separate analyses by such eminent authorities as Professor Parkes, Hassall, Playfair and others, one is surprised to see that their estimation of fat or cocoa butter should vary from 36 to 56 per cent. The late Professor McCarthy found from 18 to 28 per cent. (from unferred cocoa probably). Is this a slur upon chemical science, or does it not rather prove the wide diversity of our cocoas in respect to that particular constituent and, thereby, explain the different requirements with regard to fermentation? The average of these analyses is follows:—

Cocoa butter ...	50
Albumenoid substances ...	20
Starch ...	13
Salts ...	4

Theobromine	2
Other substances (including in one observer humic acid 7)	11
Total	100

This relative composition of the different varieties of cocoa is maintained whether in the green state, fermented, or roasted. Are we not then justified in deciding that no chemical changes are brought about in the bean by fermentation, or at any rate none that can be formulated?

The ingredient ulmic or humic acid is a curious discovery, and one would fancy straight away that it was derived from Sugar! But that cannot be, for the starch granules within the bean are not changed into Sugar. Mr. Prestoe thought that the sweating of cocoa was a malting process (vide Annual Report of Botanic Gardens for 1880, para. 337), and many planters still think that germination has something to do with it; if so, it can be but in the very earliest stage, inasmuch as the radicle is always *in situ*: it may influence the swelling out of the bean which always takes place in the sweating house, and that is about all. When the vinous fermentation sets in, germination is arrested. At this stage, if fermentation has been properly established, the cotyledons are found separated and the vinous liquor of the pulp, which passes through the membranous covering, occupies this space, as well as the lacunæ between the convolutions, the cocoa bean being distinguished as *foliaceous*. This it is which has so marked a physiological influence and affects its flavour, the bean being, as may be said, *cuite dans son jus*.

This phenomenon is described chemically as "osmosis," and may be shown in a very simple manner by placing the fermenting beans in a solution of fuchsin, which passes inside at once.

When the cocoa is eventually dried—in the sun or otherwise—the fluid, of course, disappears, but the lacunæ remain, and are the cause of the elastic feeling on pressure which some buyers hold by so much. *It is the sign of fermented cocoa*. If the following axioms are admitted, viz.:

1. The different requirements of our cocoa with regard to fermentation are mainly regulated by the amount of fat they contain.

2. It is not possible to separate the varieties in the field for practical purposes, we may proceed to consider Mr. Strickland's method. He has a series of vats or tanks (3) in a row, built of concrete. They are 11 feet wide, 5 feet deep, and about 22 feet long, (the row of three); they are covered by a galvanised iron roof, but the shed is not boarded up from the level of the tanks to the roof (about 5 feet), there is a vent, of course, below for the escape of liquor, and the cocoa is covered carefully on top with plantain leaves; there is no other cover.

The drainage from these tanks runs away to a little pond and stinks quite as had as the lees from a sugar battery. One cannot help thinking this is a foolish waste of good material, for if the pleasant tasting vinous liquor cannot be used as a beverage, why not convert it into vinegar?

The cocoa remains in the first vat five days, and the temperature is not allowed, under any circumstances, to rise beyond 115° or 120° (by thermometer); this is regulated by the admission of cold air through bamboo tubes, with many openings (5 bamboos in each tank), with their ends protruding through holes in the concrete wall at each end of the tank; the ends of the tubes are plugged with clay when required to modify the current of cold air—a rough and ready plan, but quite effectual. In this tank the evolution of carbonic acid gas is very marked, and may be easily demonstrated by connecting the ends of the bamboos with a glass filled with lime water. There is also a delicious odour from the fermenting mass, as of apples or cider. The vinous fermentation in this vat induced by "saccharomyces cervicæ" (?) is accompanied before removal probably by a commencing lactous fermentation, the ferment of which is "penicillium glaucum."

The cocoa is next turned over to vat No. 2, and about this time a marked acid reaction is shown by the reddening of litmus paper. The lactous fermentation may then go on alone at a somewhat lower temperature, and after another five days the cocoa is turned into vat No. 3. Here, some very complex changes take place, such as the conversion of lactic into butyric acid,

The pleasant cider-like smell of the vinous ether has vanished, and it is curious that it should be replaced by its isomer (Butyric Acid). The latter is familiar as the sour smelling substances met with in rancid butter. The presence of butyrates in this vat is very easily shown. One must be careful that at this stage the temperature does not fall below 95°, and even then, some of the secondary fermentations must take place, (which some people think might be left out, for fear of spoiling the flavour of the bean) such as the mucous and putrefactive, with vibrio and the formation of nitrous and nitric acid, and at times the evolution of offensive gas, the beans becoming discoloured and covered with algæ. After five days in this vat the cocoa is removed to the drying house, where three days' exposure to the sun suffices to dry and finish its preparation. The cocoa has then decidedly not an inviting appearance, it is dark, somewhat shrivelled, not too elastic on pressure, and even sour smelling, but this sour smell is certainly not the *common sour smell* which is condemned in inferior cocoa. It is by section only that the advantage of this process can be seen, and then you will find a characteristic light cinnamon colour, an agreeable odour, and every bean *uniform*—not a purple or yellow bean, even amongst the flattest and most unpromising. This is what the manufacturers want, and it is the only way known at present to get over the difficulties of sweating the many varieties of our cocoas. It may, however, be suggested that the outward appearance of this cocoa is susceptible of improvement; and with this view washing might be tried, and the cocoa afterwards sprinkled with a solution of boric acid to prevent mildew. If treated with this or some similar *antiseptic* such as sulphurous acid (fuming sulphur) "as suggested by Mr. Prestoe," it might be dried in a current of air without any exposure to sun at all and would resist damp for many days, but if dried by artificial heat such as that of Mr. Ross of Grenada, (dry heat) or hot water apparatus, the risk would be still less. This plan would be applicable to all cocoas, of course, without respect to the period of fermentation, and in wet weather it would be found a very great advantage to remove the mass of *sour gummy substance*, although this may act as a preservative coating when the cocoa is sun-dried. The husk is certainly much more brittle in washed cocoa, and does not therefore protect the bean as it should; it weighs also considerably lighter, but this might be made up by *re-coating* the bean with a mixture of starch, gum tragacanth, and boric acid. This would be preservative, and improve the look of the cocoa very much; colour might be added if desired. If so, it should be *red earth* and not common colouring material, because earth coating is recognised as legitimate. Some might prefer the fresh cocoa pulp; if so, boric acid should still be an ingredient, and the proper way would be to sprinkle during the drying process, and not wash on in quantity. One favourable point in the removal of the fusty products of fermentation before drying would be the saving of infinite *labour* in treating and hand rubbing the cocoa as usually practised. The boric acid might be added in the proportion of 1 per cent.

"REM ACU TETIGISTI."

SECOND PRIZE ESSAY.

* * * * *

After picking the pods are gathered into heaps, this heaping being a first step in the process, and one requiring special attention.

The time fermentation in the pod is allowed to take place varies according to the state of the weather, for

instance, during warm and sunny days from twelve to thirty-six hours, but during the rainy season or other showery days when the development of fermentation in the pod is slow, the duration may extend to as much as six or seven days; the exercise of some judgment is required here so as to give the operator a fair start to enable him ultimately to achieve success. The next is heaping, being easier to hand for the breaking process, the pod is taken in the left hand and split on both sides longitudinally and opened in a somewhat similar manner to the shell of an oyster; the gelatinous contents are then scooped out and thrown upon plantain or fig leaves, which must be closely spread upon the ground, previously, for the purpose of placing the pulpy mass thereon. In case of rain meanwhile, an impromptu covering of leaves forms an ample protection from wet, which, if not prevented as much as possible at this stage, will result in rotting within a very short period of time.

The principal method of transport of the green cocoa from the fields to the fermenting cells is in baskets (expressly manufactured for the purpose), carried upon the backs of donkeys. Before entering into further details of the processes of the fermentation of cocoa, I shall describe the manner in which a fermenting house should be built; an oblong square framework of any size as may be required and of about ten feet high, roofed over with galvanized tiles, the sides of which should be concreted up not higher than three feet, four inches, sectioned off into three equal compartments; a size of eight feet, six inches by four feet, six inches each cell will be found very handy for working purposes; about six holes each side of, say, three inches diameter should be pierced through each compartment, the lowest three being placed about six inches above the floor, while the upper ones should be placed about eighteen inches up and equally distant from the ends of the compartment (to secure uniformity of ventilation when required). Through and through the holes, should be fixed in bamboos, which have been previously bored around and about at three inches apart with $\frac{3}{8}$ ths of an inch auger holes. The floor should be double, a lower one being made of concrete, four inches space left, and then an upper one made of creole wood pierced with auger holes forming three-inch squares throughout; both floors being dished in from the sides to the centre at an angle of about thirty degrees: holes being left through the partition and end walls in the bottom centre to allow the watery matter thrown off by the fermenting cocoa to escape. The tops of the fermenting cells should be provided with tight wooden covers hermetically fitted and the framework above left open.

To prevent acidity in the cocoa, which is often caused by the chill resulting from its contact with the cold sides of the concrete cells, I recommend that short lengths of board be fitted in on every side, the horizontal holes being cut through so as to allow the free passage of the perforated tubes before mentioned. Well, our fermenting (or sweating house, as it is sometimes called) being finished, we proceed to fix in our perforated tubes, which are then well plugged at each end with wooden or clay plugs, to prevent during fermentation an inrush of atmospheric air exceeding the regulated amount required; the lower escape holes are also closed and then cell No. 1 is filled up nearly to the top with green cocoa.

Covering over the mass with plantain or fig leaves aids slightly in hastening the process of fermentation, but this is not an absolute necessity if the wooden covers are well and closely fitted on and covered over with a tarpaulin held in its place by any loose pieces of wood at hand. At the end of four and twenty hours during warm weather and somewhat longer during wet weather, one of the upper and another of the lower ventilating tubes should be unplugged to prevent a sudden chill, another of the causes of sourness in cocoa; the unplugging should be done on the side away from the direction in which the wind happens to be blowing at the time, both to allow the escape of carbonic acid gas and also the introduction of a thermometer so as thereby to be enabled to regulate the mean temperature of the fermenting

cocoa which should not exceed 110 degrees Fahrenheit. At the end of seventy-two hours all liquid is let off from one of the plug holes at bottom, the covers being unshifted, the operation of an interchange of cells takes place.

Two or more experienced hands armed with wooden scoop shovels get inside on top of the now steaming cocoa and partly by trampling and rubbing with hands, feet and shovels, the whole mass is rubbed together and disintegrated, shovelled up and over into cell No. 2, which had been previously prepared to receive it. No. 1 being properly cleaned and refilled with green cocoa, the same precautionary measures, now as before, being strictly adhered to, the fermentation continues; in cell No. 2 the temperature may be allowed to rise as high as 118 degrees Fahrenheit, but should not exceed this as otherwise an excess of heat may stew, or ultimately result in shrivelling up a large number of the beans; this can always be avoided by a uniformity of regulation in the mean temperature of the fermenting cells.

After the cocoa taken from cell No. 1 remains in cell No. 2 for another seventy-two hours, this cell is then opened and here the handling and management of the scoop is of prime importance, every portion, every grain of the cocoa must be turned over and over, while being also handled to sort, or separate such as may yet be sticking together during its transference over into cell No. 3. No. 2 is cleaned and well ventilated, where into the contents of No. 1 is transferred, and No. 1, after being also cleaned and aired, is filled up again with green cocoa and so on to the finishing of the picking on hand. After the expiration of a further ninety-six hours or about ten days in all (being sufficient to complete the process of fermentation), and also to render complete the metamorphosis of suppressed germination, the cocoa is now ready, the weather being favourable for transference to the curing house.

Permitting cocoa to remain so long as from fifteen to twenty days undergoing the process of fermentation, especially during the latter stage, is merely making a choice between fermenting a few days longer and drying a few days less and *vice versa*.

The above variety of processes to be carried out as they are here laid down requires a nearly continuous succession of sunshiny days, for according to atmospheric changes from warm and dry, to moist or wet, so has also the fermentation of the various qualities of cocoa to be regulated; so that an extension of the fermentation process to nearly three weeks is justifiable only during the rainy season, or otherwise during a continuous succession of rainy days, but great care and experience are required to prevent the cocoa from being rendered sour, mildewed or irretrievably rotten.

The above processes of fermentation of cocoa, as followed out in the Island of Trinidad in some instances and adapted to the Criolo and all other qualities indigenous to our soils (with slight variation) to the thin-skinned red and yellow kinds, the duration of fermentation, when such is found necessary to be done apart from the thick-skinned red and yellow kinds also, should be shortened by at least six hours at each stage; but here again we have to depend much upon atmospheric conditions besides a mixed cocoa cultivation.

Cocoa prepared as above, when sectioned, will be found to have developed a rich cinnamon colour, the grains will be mealy, plump and fair to look upon, the smell pleasant, while not a vestige of mildew nor sourness will be present.

The advantage of washing cocoa in Trinidad is a matter of opinion; this question lies principally within the domain of the experimentalist; opinions are divided as to its local adoption; much general gain would result in case experiments in this line should prove commercially successful for the improvement of the quality of cocoa grown here; but to have a cocoa-house filled with washed and wet cocoa, and then to be hemmed in by a succession of rainy days extending over weeks together, the consequences following therefrom can better be imagined than described. Washing does not recommend itself either at any one

of the stages of fermentation, as the chill then caused may rather be productive of harm than good.

Colouring or painting over the bean with pigments should not be countenanced for one moment, as resorting to such measures is both retrogressive and deceptive; retrogressive because it prevents an expansion of experimental ideas to seek out the means whereby to develop natural first-class colours, and deceptive because when the subterfuge is most depended upon it will of necessity fail signally. The production of the first-rate article can and must be realized,—that which the frequenters of Shove's and others so well love to base quotations upon in the markets of England, Europe and America, there realizing paying prices and here returning a harvest of gold to the thoughtful and industrious, whereas on the other hand subterfuges are sure to be found out in the long run, and but bring in train disappointment to individuals and ultimate loss to entire communities.

In conclusion, having in the course of this essay touched upon all the principal circumstances connected with the fermentation of cocoa, a brief summary of the means whereby a first-class marketable article can be turned out will not be out of place. They are as follows:—

- (1st.) Warm sun-shiny days.
- (2nd.) Great attention to the cleanliness and proper airing of the c. lls. (Fermenting tanks.—Ed.)
- (3rd.) A proper and uniform regulation of the mean temperature of the cells during fermentation.
- (4th.) The fermenting cocoa should never be allowed to remain in its lees.
- (5th.) The handling, interchange of cells and sorting process being deftly done and the curing being gradually and regularly preceded with curing the first forty-eight hours, these taken in the aggregate may be accepted as the *summum bonum* of the fermentation of various qualities of cocoa and also the turning out of a first-class staple.

To produce aromatic and well-developed beans in the cocoa pod is the *ultima thule* earnestly aimed at by our really pushing and enterprising planters.

Sot.

THIRD PRIZE ESSAY.

When we ask ourselves the question, "How to ferment Cocoa," we set ourselves the task of resolving a problem that presents a multiplicity of side issues, each bearing directly on the main question, and each vital to it. It would be erroneous, indeed, to start with the cocoa already broken and boxed in the sweating compartments, for a uniform fermentation, and that it is we aim at, necessarily depends on the uniformity of the fermentable matters. The first step, therefore, must be a proper selection in the field, and a judicious classing of the cocoa we intend fermenting. The best criterion for this selection, the surest principle for this classification, is undoubtedly the degree of maturity of the cocoa. As cocoa ripens its saccharine parts increase proportionately to its maturity, and since, as we will further on demonstrate, this saccharine principle plays a most important part in the fermentation process, it is but logical to set up as a basis for our selection the amount of contained saccharine matter; in other words, the amount of maturity. And this selection is of vital importance; for the less mature cocoa, less rich also in saccharine, will ferment much slower than the riper beans, and if these two be "sweated," as the term goes, together, we will find the latter oversweated when the former has but just reached the proper point.

Having therefore properly classified our cocoa, according to its degree of maturity, our next step is to place it in sweating boxes where it can ferment. We now come to the question: "What kind of boxes will best ensure the result we are aiming at;" viz., a uniform fermentation.

The fermentation of cocoa is essentially alcoholic; the sugar of the pulp becoming converted into alcohol and carbonic acid; so that, as Lavoisier says: "If we could re-combine alcohol and carbonic acid gas, we would reconstruct Levulose," (fruit sugar.)

Now, basing our arguments on the firmly established dictum of Pasteur "that alcoholic fermentation is the function of the life of certain cellular vegetable organisms, Zymogenic Microphytes, which are *a priori* the leaven, and the production of alcohol is simply the result of the absorption, at the expense of the sugar, of the oxygen necessary for their vitality," we feel no hesitation in laying down this rule for the disposition of the sweating boxes. These boxes should be not more than fifteen inches high, and the cocoa in them should be uniformly laid. This maximum of height will obviate the mutual pressure of the beans, preventing the amount of atmospheric circulation required for conveying, to the mass, the organisms on which fermentation depends; and it would, besides, economize the labour now utilized in transferring the cocoa from one box to the other, to ensure the contact of the lowest beans with that air, which they would never receive in the sweating compartment of the depth in vogue.

A point, which will fitly find its place in the present paragraph, refers to cocoa which though mature has been weathered or rained on in the field. Part of its saccharine principle has been washed away, and being now, but a poor medium for the development of the microphytes, it is apt to "postpone" a great deal, often undergoes putrid changes, and becomes fit only for the manure heap. Under-matured cocoa, from a similar cause, a deficiency of levulose is also retarded. A great deal of cocoa was lost last November and December, especially among the smaller proprietors who ignore the remedy requisite to save the cocos. And this remedy is so simple that I am indeed surprised it has not been more generally employed by cocoa planters. It is rational enough to suppose that if we can replace the deficient material, levulose, we will ensure a healthy and uninterrupted fermentation. The best substitute is sugar, and that of the commonest kind, that is to say, sugar containing the most glucose. Cocoa treated in this way and raised to the same composition as matured cocoa will ferment as readily, as quickly, and as thoroughly as the latter.

During the process of fermentation a great amount of heat is generated, and this acting on the bean both through the pores of the pellicule and through the opening at the top, known as the "Hile," vaporizes the aqueous elements and develops the fatty substance which absorbs and retains the essential aroma of the cocoa. Still the heat generated is not sufficient to vaporize all the aqueous portion of cocoa, and it is in our drying houses that the residual moisture is finally expelled. For this reason, thoroughly fermented cocoa, containing a minimum quantity of moisture, must be dried gradually so as not to blister the bean, especially if the remaining pulp or "bava" has been washed off as is done in Ceylon. On the other hand, cocoa indifferently fermented, or surrounded by an undue proportion of moist bava, is very liable to be attacked by fungi, and to mildew, if, as is often the case, heavy rains retard the drying process. The repeated hand and foot rubbing, practised to remove the mildew, often breaks the bean; and the fungi spread to the interior of the cocoa, which, if not rendered altogether unmarketable, is, at all events, much depreciated in value. No artificial means of drying cocoa has yet given satisfactory results; but in rainy weather the following process has been found to minimize the risks of mildew. It consists in heating pulverized red earth, and mixing it intimately with the cocoa. This pulverized earth acts both by absorbing the moisture from the cocoa and by vaporizing that moisture. By taking advantage of a sunny day the cocoa may be freed from its earthy coating by slight washing and immediate drying.

But before concluding, one point is deserving of notice in this matter of cocoa fermentation. It is the specific wants of the various markets. Nothing is better known to the cocoa planter, when his cocoa is sold abroad, than the fact that, however scientific the preparation of his cocoa, by fermentation, the special wants of a particular market, may require an imperfectly fermented cocoa with certain external characteristics rather than a perfectly fermented cocoa.

But this feature is not gaining ground from the obvious superiority of the perfect over the imperfect cocoa.

QUOD SCIAM.

ESSAY BY "TALISMAN."

* * * * *

Various qualities of cocoa are grown promiscuously in cocoa plantations, therefore they have to be picked and fermented altogether. There is no remedy for this evil except where a new cocoa estate is to be formed, when the planter can choose the best quality of cocoa to plant, known as the Creole Cocoa and almost universally grown in Venezuela.

2. Fermentation process.—Begin picking cocoa, say on a Monday, and continue picking up to Friday, each day heaping up the cocoa pods so as to cause a certain amount of fermentation; on the Saturday cut open the cocoa pods and put the beans in large sweating boxes covered up well. On the following Saturday take the cocoa from the boxes and place it in the drying houses, clean and open it out, then immediately before the gum of the cocoa gets dry sprinkle on fine sifted red earth and hand-rub occasionally until the cocoa is dry, then it can be sacked ready for shipment, but care must be taken not to bag it before the cocoa is perfectly cool. This is the process adopted on the *San Antonio* estate which realizes the first market price.

3. Another process.—Ferment the cocoa as described in paragraph 2 for three days, then take it out of the boxes, stir thoroughly, and put it back covered up well, giving it further fermentation for three days; then take it from the boxes and open it out in the drying houses, rub it occasionally until dry, but do not sprinkle on any red earth as mentioned in paragraph 2. This second process is commonly carried out on all the large estates, and obtains the second best price in the London markets.

4. Another process.—Pick the cocoa and ferment it in boxes or simply cover it up in a large heap for four days and open it out for drying; hand-rub each morning, then sack it. This mode is practised by the small cocoa proprietors.

5. Another process.—Each day you pick; in the evening open the pods and take the beans to the sweating house, cover up well, adding each subsequent day's picking to the first. Do this for three days successively, every evening mixing up the cocoa and covering up well. On the morning of the fourth day put the cocoa in the drying-house; clean and rub. In the evening gather up the cocoa in a large heap, then cover it so as to exclude air. Continue this process alternately drying and fermenting for three days and nights—that is, three days' drying and three nights' sweating. On the morning of the fourth day take about forty pods of cocoa and open out in about three buckets of water, wash out all the juice and take that water and throw over the cocoa in the drying-house, slice up the pods and put them to soak in water. On the fifth morning after the cocoa has had another night's sweating, open out for drying, skim off the gum from the pods that were put to soak, take the gum, apply to the cocoa and rub well; but before the gum is dry sprinkle on sifted red earth or red ochre and hand-rub occasionally until the cocoa is dry. On the morning of the sixth day get some good quality of butter, wash out all the salt thoroughly and rub the cocoa with it. About three cents worth of butter is sufficient to each bag; the butter will give the cocoa an agreeable perfume without destroying the chocolate aroma, and will prevent mildew, one of the greatest enemies that cocoa planters and shippers have to contend against.

6. To generate fermentation in hard, green, unfermented cocoa, take about three to five bags according to the quantity in hand, wash and dry it; get about forty pods of cocoa and follow the process explained in paragraph five, but with this difference: put the cocoa in a sweating box, saturate with cocoa juice and cover up well to cause fermentation. The next morning repeat the process, mix up the cocoa and again cover to cause fermentation. In the morning of the fourth day put it out to dry and continue the process explained in paragraph five in regard to alternate drying and sweating, adding in this case a very small quantity of

good molasses to the cocoa gum skimmed from the cocoa pods by process described in paragraph five.

7. Artificial Process by Steaming.—Take the beans of the cocoa fresh from the field with the pulp on and put them into large coppers, first taking care to line the interiors of the coppers with plaintain leaves in order that the cocoa should not touch the metal; throw in one or two buckets of juice from the pulp of the cocoa with a little water as described in paragraph five. To generate steam add a few bay leaves, if at hand, cover the cocoa to exclude air and put fire under the coppers, heating slowly and examining the cocoa now and then to see that the fire is not too hot and cracking the shells of the beans. At the expiration of from two to three hours it will be found that the cocoa beans have become round and full, with a good red colour externally. Withdraw the fire and cool down, then put into the drying-house, employing the alternate drying and fermenting process explained in paragraph 5. This artificial steaming and fermenting is certainly the most expeditious, taking a few hours only, instead of days, and it can be accomplished with a few cheap appliances, and the fire can be connected without much ingenuity to a drying apparatus if required in wet weather.

APPENDIX.

(A.) Properly fermented cocoa by the processes described in paragraphs 2, 3 and 5 has a sweet chocolate taste, nice aroma and a pretty cinnamon colour when the bean is broken. It has more fatty matter than inferior cocoa.

(B.) If planters were to apply to our well-known and energetic Botanist, Mr. J. H. Hart, I am certain that they would get assistance from him by advice as to the best quality of cocoa to be planted, and in a few years the new plantations would yield the best quality of cocoa, and fermentation would become easier.

(C.) The mode of fermenting cocoa as described in paragraph 5 is from my experience the best way of curing cocoa, the alternate drying and sweating causing every bean to be of the same quality, the interior having a fine cinnamon colour with an aromatic smell, and the exterior an uniform red colour and is heavier than when fermented by the other processes.

(D.) As an example that the renovated cocoa may take a price equal to good fermented cocoa, I may mention that in the year 1881 I shipped fifteen bags of cocoa of the same estate brand for trial—five of the process described in paragraph 3 and five of that described in paragraph 4, and also five of the renovated cocoa described in paragraph 6, putting a private mark on each lot of five bags and writing to ask my agent in London to sell them separately. I was astonished to find that the renovated cocoa realized the highest price, viz: 80 shillings per cwt., the other two processes realizing one or two shillings less.

(E.) The application of butter to cocoa for the prevention of mildew as described in paragraph 5 may excite the risibility of some persons, but I have tested it well; and cocoa that has had butter judiciously rubbed on can be shipped without fear of mildew to any cold or damp climate. The milk of the cow must have some latent virtues antagonistic to the little germs or microbes which infest damp cocoa. This mildew is called grey cocoa in the London markets, and is rated at the lowest price.

(F.) One of the evils prevalent on cocoa plantations is the picking of unripe cocoa; the beans are hard, flat and green and cannot be properly fermented. If these beans are not carefully separated from the good, as is done on the *San Antonio* estate, there is a certainty of deterioration in the market value. The cheapest method is to separate the unripe fruits from the ripe in the field; heap and cover the unripe fruit whilst in the pod and break open after eight days; bag and sell to the chocolate manufacturers in the island. Cocoa planters are generally penny wise and pound foolish in engaging inexperienced men at low rates of wages to pick cocoa. These undisciplined hands not only pick a great quantity of unripe cocoa, but do a great deal of damage to the cocoa trees.

Ten experienced men will do as much work per diem (without doing the damage as described) as fifteen inexperienced labourers.

(G.) An evil that ought to be remedied by Government is the clause in the Cocoa Ordinance which prevents the cocoa dealers from buying less than ten pounds of cocoa. This prohibition induces the small holders of cocoa (when they have not got the sufficient legal quantity of cocoa of their own to sell) to raid on their neighbours' cocoa for the purpose of making up the required 10 lb.; and whilst engaged in these nocturnal excursions it is only natural to suppose that they should make a great addition to the 10 lb. at their neighbours' expense. This pilfered cocoa is generally sold green and unfermented to the shopkeepers or dealers in the country. The planters who heap up the pods in the fields as stated in paragraphs 2 and 3 suffer greatly from these thieves, but by taking in the cocoa every evening as mentioned in paragraph 5, the robbers have less chance of stealing; and this is another reason, and a paying one, that the mode prescribed in paragraph 5 is the best way to ferment cocoa.

(H.) A good sugar planter knows well that to make good sugar and to get a good return in the boiling-house, he must commence operations in the earlier piece from the first agricultural stage. So it ought to be with a good cocoa planter. The first care should be to cultivate the cocoa trees in a manner that would make them bear healthy fruit abundantly. The result of this would be a large return of cocoa yielding well and the process of fermentation made easy.

(I.) There are small stinging ants which build an earthly nest round stems of the young cocoa pods, and there are large black ants that nip the young pods; these predators destroy at least three-fourths of the cocoa crops, and the pods all turn black on the trees. There are many of the pods injured by the ants which are unhealthy when they arrive at maturity, making fermentation difficult. A little white lime sprinkled round the roots of the trees will make these destructive little insects migrate to more congenial quarters.

(J.) It would be a boon to the Colony if His Excellency the Governor, who has hitherto been the great promoter of the major and minor industries, would unite with the Chamber of Commerce and endeavour to prevail upon the English Government to reduce the duty on chocolate from 2d. to 1d. per pound, thus equalizing it with the raw material. Capitalists would then be induced to invest in chocolate manufactories, and I may venture to say that unfermented cocoa would never be purchased by them which in a great measure would compel the small planters to ferment their cocoa properly. The Botanist, Mr. Cruger, and many others who followed after him in trying to establish chocolate factories in Trinidad failed, as the extra duty on chocolate imposed on arrival in England did not allow them to compete with the Home factories, and our chocolate industry consequently has had to succumb to the adulterated chocolate made in England, some of which is actually imported here where the cocoa trees flourish and where the manufacturing of chocolate ought to be one of the major industries.

TALISMAN.

[The prize essays are published by direction of His Excellency the President of the Central Agricultural Board. The essay of "Talisman" is added because in our opinion it is of interest, as illustrating the "old and time-honoured" system of procedure.

They cannot be taken as they now stand for the purpose of comparison "as prize essays," because in the case of the second essay certain portions have been excised as not bearing directly on the subject of fermentation, and being unsuitable for publication in this journal.

In the second essay the statement "that fermentation begins in the pod" is in our opinion erroneous (the same thing is stated by "Talisman"); possibly the author meant to say a certain degree of softening, or losing of tissue rather than fermentation (?) We

all know that the juice of the grape does not ferment unless the skin is pricked, and in the same way with the contents of a cocoa pod, it must be broken before atmospheric air can gain access to it and fermentation take place.

Mr. Hart, as judge of the competitive essays at the San Fernando Exhibition, has promised a Notice in the next issue, and he will probably touch on some interesting points in the unsuccessful essays at the same time.—EDITOR.]

THE COCOA PRIZE ESSAYS.

At the meeting of the Trinidad Central Agricultural Board,

Mr. Hart announced that the essays on the fermentation of cocoa had been opened, and that the first prize was awarded to Dr. J. F. Chittenden—(His Excellency): I guessed you would have got it—(applause)—The second prize had been awarded to Joseph Augustus Crichlow, of Arima. The third prize had been awarded to Mr. Eugène Lange (senior). His Excellency had been kind enough to add second and third prizes to the prize of \$25 originally offered. There were nine essays received, and one was disqualified by coming in too late. With the consent of the authors the successful essays would be published in the *Agricultural Record*.

Mr. Adrien de Verteuil gave notice of the following motion: "That, with the object of meeting the difficulties which too often arise from continuous rainy weather, it is advisable to adopt some process for drying cocoa by hot air, or any other artificial means, and to appoint a Committee who will inquire and report on the best method to be recommended."

DRYING COCOA BY HOT AIR.

Waltham, St. Mark's, Grenada,

March, 1890.

DEAR SIR,—In reply to your letter asking me for some information of the working of my cocoa-drying house, I have pleasure in enclosing a rough plan, by which you will see that the idea is most simple, but it answers its purpose splendidly. The pipes are of iron, and are one foot in diameter and half an inch in thickness. The drawers, or trays, are 7 feet by 2½ feet, the bottoms of which are of thick wire netting. The oven, which is placed outside the house with a shed over it to keep off the rain and to store fuel, should I think be built of bricks.

In my house I can thoroughly dry cocoa straight from the sweater in 48 hours.

Col. Duncan had an American fruit-dryer, but it was found useless for drying cocoa.

I may mention that I was the first in this Island who dried cocoa by hot air, and now many of the planters here are erecting similar houses.

I hope you will be able to understand the plan of the house. I am not good at draughting.

Yours, &c.,

CHARLES H. A. ROSS.

To Dr. Chittenden,

Secretary, Central Agricultural Board.

[The plan Mr. Ross has been kind enough to send is hardly suitable for the purpose of a lithograph, but it can be seen by any interested in the subject, on application.—EDITOR.]

THE GREEN ONYX which is being quarried in the west of Grant County, New Mexico, is found in a fissure vein about 50 feet wide and over a mile in length. The stone is becoming fashionable in the United States for interior decoration. It shows a variety of colours—green, white, pink, and salmon—is both striped and mottled, and susceptible of a high polish, while it is the only kind of onyx which can be carved like marble. Blocks of it have been offered by the proprietor of the mines for use in the construction of the exhibition buildings of the World's Fair.—Globe,

THE NEW WATCH COMPASS.

(Communicated.)

A paragraph is going the round of the home papers to the effect that the watch in anyone's pocket may serve to indicate the points of the compass, at any hour of the day. It was pointed out by a Yankee, that you have only to direct the hour-hand of a going watch to the sun, and midway between such hour and XII will be due south. For instance, the hour-hand at IV o'clock directed to the sun, II will mark south. This is new to me, and seems to be taking the world by surprise—even Stanley, the explorer and American, never having heard of it.

Pending the arrival of an "authoritative" explanation, I submit the following:—The earth's surface presents everywhere, to us diminutive crawlers upon it, an "offing," as at sea—that is, a perfectly circular patch of a few miles in diameter. This patch of surface, however, is the same, for all celestial phenomena, as if it were the plain parallel to it of the full diameter through the earth's centre. Neglecting this fact, and the variation in the sun's north and south declination, we arrive at the approximate rule that 'the sun rises in the East and sets in the West,' occupying at the equinoxes twelve hours, from VI to VI, in doing so. But whether the days are short or long, the sun is always due south at XII o'clock. This is true for all countries north of the Mediterranean, but not always the case in Ceylon, where in June, at XII noon, the sun is due north; but this *en passant*.

Now if you will imagine this "offing,"—which as the same on land as at sea (only the hills, houses and trees prevent our noticing it),—to be divided round its southern semi-circumference (*i.e.*, the southern horizon from E. to W.) into 12 equal parts, (as a watch whose face is marked for 24 hours is divided) the reason of the rule becomes sufficient obvious,—bearing in mind that the watch in your hand however much you move it, or walk about with it, is practically, and actually as on a pivot, in the very centre of your "offing." At VI the hour-hand points to the rising sun, XII is due west, and IX must necessarily be due south. As the sun advances in his course, the hour-hand—of a watch marked for 24 hours—would follow him, hour by hour (XII always being south); but as the corresponding semi-circumference of the ordinary watch is divided into 6 hours only, one hour of the watch covers two hours of the sun. Hence the result that, by keeping the hour-hand to the sun, the "XI" of an ordinary watch moves east at precisely the same rate as the hour hand moves west, till they meet at noon, both there indicating due astronomical south. They then pass on, receding from each other as they had advanced, midway between them necessarily being at any instant of time due south.—Q. E. D.

The true compass indicates the magnetic north, while the watch can only indicate the cardinal points astronomically and approximately. Bearing this in mind, it is a pretty use to which to put our watches, and may not unfrequently be found useful.

ASTRO.

COFFEE PEST.

In the correspondence on the above subject, which we publish in another column, it is rather amusing to find Miss Ormerod referring Mr. Thomas Dickson to such well-known local authorities on coffee pests as Nietner, Morris and Green. Miss Ormerod, although one of the greatest living authorities on insect pests, admits that fungi are out of her line. Had Mr. Dickson consulted Mr. D. Morris, that gentleman would have affirmed, and with truth, that he had discovered a remedy for *Hemiteia vastatrix* in sulphurous acid, the product of a mixture of lime and sulphur, applied to the coffee bushes, in dewy or drizzly weather. This acid proved fatal to all the fungi it reached; and not only bushes but whole estates were cleared of the pest. But all in vain

while millions of spores existed all around and were ready to enter the stomata and suck the life-blood of every fresh coat of foliage put on by the unhappy trees. It was found that unless the whole of the coffee in Ceylon could be simultaneously relieved by the entire destruction of every spore of the deadly fungus, there was no use in fighting a losing battle. The general principle, too, that the best way of fighting a plant pest is to strengthen the plant by means of manure, failed in this case, because it was found that manuring merely provided food, in the shape of rootlets, for white grubs underground, as well as for the fungus aboveground in the shape of fresh leaves. Finally, as if to lead the unhappy coffee planter to take up the patriarch's cry, "All these things are against me," green bug made its appearance, attacking the juices of the coffee bush with a virulence far exceeding that of the old pest, the brown or black bug. Phenyle, which Miss Ormerod recommends, is not a new remedy in Ceylon, although we do not recollect hearing of it as an application to the roots of the bushes. Those who have coffee still yielding any crop might try this radical application. There is true philosophy in Miss Ormerod's recommendation that any mixture applied for the destruction of green bug should be of a viscid nature so as to adhere until not only the parent scale insects were killed, but the thousands of their progeny hidden beneath them were smothered. All kinds of spraying applications have been tried in the United States, including fine sand. The danger in all such cases, as Miss Ormerod points out, is, that what destroys the pest may fatally injure the plant by entirely destroying its foliage and harming the bark. Those interested ought certainly to purchase and study the new edition of Miss Ormerod's valuable book. They will there find directions for preparing and applying the mixtures most likely to prove effectual in ridding coffee bushes and fruit trees of insect pests. We are rather surprised that Mr. Dickson's correspondent did not say anything of insects which are the natural enemies of scale bugs and prey upon them. We observe from our exchanges that such insects are being introduced and largely bred in California, and it is stated with good effect in ridding orange, peach and other trees of scale insects. It is possible, though hardly probable, that the coffee fungus may, with effluxion of time, disappear from Ceylon, and coffee be again amongst our staple and profitable cultures. Let us cherish the hope, while we cultivate our new staple, tea.

MAKING FARMING PROFITABLE.—Now, in order that farming may be profitable, we must make the consumption of a cheap food produce a thing that will sell for a high price. Wheat, barely, oats, are costly food; on the contrary, barn, clover-hay, linseed, and cottonseed, are cheap foods. It pays, therefore, to sell grain and buy these cheap foods. Manufacturers only answers on the condition of buying raw materials cheap, which we subsequently convert into articles of high value. Farmers, like manufacturers, must buy cheap and sell dear. Part of the food the beast eats is converted into heat. The animal heat must be kept up at any cost in every part of the body, else it will lose weight. The system must be maintained at 98 deg. Fahr. The production of milk is in a great measure determined by the quality of the food. The best food, in my opinion, is clover-hay and mixed grasses, clover is good; you cannot sow too much of it. Bran is another good food. Bran contains phosphates and other elements entering into the formation of the bones and muscles. Cottonseed, in the form of cake or meal is a good food for milk making. It contains an excess of albuminoids, and is one of the best things to mix with straw, hay, ensilage, &c.—Facts and Conjectures.

COORG AND ITS COFFEE.

(From a Correspondent.)

The Commissioner of Coorg, in a recent Statement of the past season's crop of plantation coffee, showed that 1,746 tons were exported from the district, via the West Coast, against 1,093 tons—and 700 tons Eastward, against 596 tons—in 1888-89, making a total of 2,446 tons against 1,684 tons in 1888-89. The returns are prepared from data furnished by the various curing firms through whose hands the produce passes. The Commissioner also gives the quantities passing through the toll gates where accounts are kept. The figures for the past season are 3,353 tons against 2,760 tons in 1888-89. These quantities are understood to represent all the coffee that leaves the province, native grown as well as plantation; but in connection with them the Commissioner remarks that "no dependence can be placed upon the toll gate returns as showing accurately all the coffee which passes out of the province," making allowance for quantities exported through channels not included in Colonel Clarke's returns the following will probably be found a close approximation to the actual exports for the past season:—

Plantation Coffee	tons	2,700
Native Coffee	"	1,500
Total Crop of the season				...
				tons 4,200

A forecast of the crop in the early part of the season had been made by the Commissioner from figures supplied by the principal owners of estates. The estimate was 6,715 tons, so the shortfall is quite 2,500 tons. The forecast was framed no doubt on the belief that the crop would be a good one, judging from what the blossom promised; and a good crop was due, for the previous season's had been miserably small. Some time before it ripened, however, the planters had made up their minds for figures much below estimates, and in most cases disappointment increased with the gathering of the crop. It is seldom too such small yields have followed each other; not only so, but it is feared the one about to be picked will be little better than the last, making three small crops in succession, a thing almost unknown in the annals of Coorg coffee planting. The same remarks, however, apply to the neighbouring districts of Mysore. The question now is, is this simply the result of unfavourable seasons, or does it indicate a more serious condition of affairs, actual deterioration and impaired fertility in the plant? There are pessimists who take the latter view, and who point to the poor returns which young estates give, even in good seasons, in these days compared with what the same sort of places gave in former times. They point to properties on the ghauts which, in spite of all that was done for them, went steadily, rapidly, and irretrievably to the bad. Open new land in the ghaut and you cannot make it yield as the old land did. Travancore, North and South Wynaad, they say, have had a shorter life, only because shade in Coorg and the Mysore districts have helped to baffle for a while that fell destroyer, leaf disease. But every plant and sapling has felt its fatal touch. Its germs have entered the sap, and the deep green and glossy leaf, with sturdy stem and lithe branch, must ere long wither and die under the baneful blight. This is certainly a gloomy picture, begotten perhaps of a despondent and morbid state of mind. Still it is so sufficiently true to nature that it would be foolish not to keep it in view, although the more hopeful need not allow themselves to be too seriously impressed by it. It cannot, of course, be gainsaid that he is surrounded by evidences of the extensive and destructive effects of leaf disease, for it has caused all but the total extinction of coffee in Ceylon, while in Java, which showed a yield second only to Brazil some years ago, things are little better. Travancore and Wynaad have gone the same way. Those who take a hopeful view point to the healthful appearance of estates that are properly cultivated and attribute the short yields of late years solely to unpropitious

seasons. As to shortage of yield on young estates they say that the land, where such is the case, is only second class, all the best land having been taken up years ago. To what extent shade will neutralise the effect of leaf disease time alone will show whether it will save it entirely, or only delay the fatal period. A year or two will probably show whether the pessimist or optimist is right, and the next crop or two will doubtless be watched with nervous anxiety. There is, of course, in Coorg a good deal of coffee which may now be considered old, having been planted 25 to 30 years ago—at these ages it is considered that the plant has passed its prime and its yielding powers begin to fail; and there is no doubt this is only too evident on several estates.

The failure of the old Mnozerabad plant or "chick" was fraught with useful lessons. It was understood to have originated from seed brought by the Arabs from Arabia and planted in the Bababoodin Hills. It had always been grown under the original forest shade and it produced a berry second only in quality to Mocha itself. But 15 or 20 years ago a general failing of its fertile powers became apparent. Crop in any quantity was only obtained once in two years, and it was difficult to get seedlings when planted as supplies to come on at all. It became worse and worse, but meantime some planter—was it Mr. Jupp of Igoor?—happened to bring some Coorg seed from Mercera, where he had been on a visit. He tried it on land he had several times planted up with local supplies unsuccessfully. The result was most satisfactory. It was found that the Coorg sprang up and flourished as if on fresh virgin soil, producing a plant much more vigorous and fertile than the old Muzzarabad. Some time, however, elapsed before its superiority became generally known, and longer before the fact was generally admitted. But it was only a matter of time. At length nothing was planted but "Coorgs." The old plant seemed quite used up, its bearing power becoming less and less though this might appear all the greater by contrast with the heavy yield of the Coorg tree. It had not suffered much if at all from leaf disease, being always well protected by shade, and it would hardly be said that the soil on which it drew was exhausted. The heavy deposits of leaf from the original forest trees, with which they were shaded, along with the moderate amount of manuring which was generally done, maintained the integrity of the soil. On the same soil at least the new plant grew splendidly. This seems to point to the advantage of the timely introduction of a new variety of plant, and the Coorg planters would do well to return their attention to the subject. Seed from Arabia, or better still perhaps from the indigenous coffee found growing in our new African possessions on the shores of the Victoria Nyanza and other parts, might be obtained. The Government would no doubt willingly help the planter in procuring it. Planters in Wynaad are going in for Liberian, but I think most men would probably prefer the Arabian species. It is to be hoped that everything will be done to avert such ruin as has overtaken the coffee enterprise in Ceylon and elsewhere, for although the fears of those who think the Coorg plantations likely to meet the same fate may not be realised, the planter should do all he can to provide against such a serious contingency. The Government, too, should be alive to the importance of the matter.—*Madras Mail*, Oct. 28th.

SNAKES of the Boidæ family are sometimes found very tightly coiled within the clusters of bananas imported into the United States from the West Indies and tropical America. Not long ago a specimen, which proved to be the *Epicrates augulifer* of Cuba, was captured in Savannah, and is now in the United States National Museum. Another was taken in the same way at Chicago, and found to be the *boa imperator* of Central America. They are generally young ones, as the adults could not be so easily concealed there.—*Globe*.

Correspondence.

To the Editor.

THE CEYLON TEA INDUSTRY FROM THE POINT OF VIEW OF AN EXPERIENCED LONDON BROKER.

12, Great Tower Street, London, E C., Sept. 26th, 1890.

SIR,—May I trespass again on a space in your paper respecting the tea industry of Ceylon. It appears to me that the fears of the planters have again been disturbed by what appears to me an unnecessary alarm, chiefly caused by the great rise in exchange. The enhanced rate of exchange is certainly an important item in the increased cost of the tea in the selling market, and to compensate for this, the planter or shipper requires an equivalent increase in price. But I would ask the question whether this does not also affect the price of tea from India and China; therefore, on that point Ceylon is no worse off than the other two places of production. Indeed a rise in the exchange is more detrimental to the low-priced China teas than to the better grades which India and Ceylon produce, and therefore it is not likely that China will materially increase its supplies to this country.

Again, in looking at the effect which the increased cost will have upon consumption, it must be borne in mind that the reduction in the duty here, will up to the present time fully meet the difference of exchange, so that practically the consumer is now paying no more than he did before the duty was reduced, and it is a very doubtful question whether the reduction alone of 2d per lb would have led to any marked increased consumption. Further it must not be forgotten that there has of late been a great increase of wages in this country, and increased wages mean increased spending power in the hands of the masses, who exercise that power to a considerable extent, and purchase the better descriptions of consumable articles, than when wages are low; and this is the case notably in sugar and tea.

As Ceylon tea continues to gain favour throughout the country, the consumption under these circumstances necessarily increases; therefore I fail to see how Ceylon tea especially can in any way be injuriously affected. On the contrary, there is now more hopefulness for a full maintenance of present values which already show an improvement, nearly, if not quite, equivalent to the difference in exchange; and any temporary depression in the market can scarcely be considered as sufficient ground for dependency.

The following figures will show the deliveries of tea in London for eight months, by which it will be seen that the percentage in the increase this year of Ceylon tea over the deliveries of last year is more than double of the percentage in the increase of Indian tea for the corresponding periods.

Deliveries of Tea in London for each month from January to August in 1890 and 1889:—

	CHINA.		INDIAN.	
	1890. lb.	1889. lb.	1890. lb.	1889. lb.
January	7,136,443...	8,837,000	8,831,223...	8,932,000
February	6,898,311...	7,399,000	8,187,293...	8,007,000
March	6,519,761...	7,939,000	7,141,953...	8,143,000

GREEN TEAS IN TRAVANCORE.

October 9th.

DEAR SIR,—As you kindly inserted a letter a few months ago from Travancore regarding Mr. Robt. S. Imray's first experiment and samples in green tea when so favourably reported on by Mr. F. F. Street, it may interest your readers to know what further advances he has made in the manufacture of it. The enclosed is an article which appeared in the Madras Times of the 6th. I may mention that Mr. Imray's first break of green tea fetched a very fair price in the London market so that there is every reason to expect that his second break from which the present sample I believe was taken and sent to Mr. F. F. Street, will fetch a much higher price still, judging from Mr. F. F. Street's report and valuation of it.—
Yours faithfully, TRAVANCORE.

INDIAN TEA EXPORTS.

Indian Tea Association, Calcutta, Oct. 11th.

DEAR SIR,—The General Committee have the pleasure to hand you their usual Monthly Return of shipments of tea from Calcutta, and also a Return of Exports of Ceylon Tea for four years up to the 18th September 1890.

EXPORTS OF INDIAN TEA FROM CALCUTTA.

	1890 lb.	1889 lb.	1888 lb.
Exports to Great Britain in Sept. ...	14,263,059	16,253,978	12,188,328
Exports to Great Britain from 1st May to 30th Sept. ...	40,415,251	40,761,931	40,025,482
Exports to Australia and New Zealand in Sept. ...	712,200	806,863	495,061
Exports to Australia and New Zealand from 1st May to 30th Sept. ...	2,293,446	1,807,392	1,344,564
Exports to America in Sept. ...	25,837	23,566	19,990
Exports to America from 1st May to 30th Sept. ...	62,072	90,847	63,119
Exports to other places in Sept. ...	195,095	154,311	158,867
Exports to other places from 1st May to 30th Sept. ...	526,277	1,061,604	464,217
Total Exports from 1st May to 30th Sept. ...	43,297,016	43,721,777	41,897,382

—Yours faithfully, S. E. J. CLARKE, Secretary.

A COLLECTION OF SEEDS OF INDIAN AQUATIC PLANTS, such as the Sinhara nuts and others, are to be sent from India to New South Wales for experimental cultivation there under the local Agricultural Department.—Pioneer, Nov. 6th.

MR. ROBERTS ON FACTORY-BULKED TEAS
AND ON SILVER AND EXCHANGE.

October 17th.

SIR,—In reply to "Inquirer's" letter which appears in the *Overland Observer* of 20th Sept. last, page 976, about "factory-bulked" teas and exchange, I hope the following explanations will supply the information required.

If packages of tea are marked "factory-bulked," and on examination after arrival here the teas in those packages are found to "run evenly," and provided also the tares of the packages are of uniform weight—they are passed as "factory-bulked" and sold accordingly; but if found otherwise, although marked "factory-bulked," they are re-bulked here.

In the case of packages *not* being marked "factory-bulked," the teas are bulked here as it is presumed they have not been bulked at the "factory."

If parcels marked "factory-bulked" could always be relied on as being of even quality and even tares, the trade generally prefer these, so as to avoid the necessity of turning out for hulking in the warehouses here which is done to ensure uniformity.

With regard to the other enquiry as to the relation between the prices of Bar Silver and Exchange, it invariably follows that as the price of Bar Silver fluctuates, so the rate of Exchange rises or falls in the same ratio, though there is no fixed standard of an *exact* proportionate difference, as other circumstances occasionally intervene to cause variations. Bar Silver in the early part of July last was at about 48d to 49d per ounce and Exchange was then about 1s 6½d; when the price of Bar Silver in the beginning of Sept. rose to 54½d, Exchange rose to 1s 8½d; and recently again, with Bar Silver at 50d, Exchange is 1s 6¾d;—the percentage of rise and fall being in both instances about equivalent, and which, for all practical purposes, may be taken as a safe basis for calculation.

—Yours faithfully,
J. HENRY ROBERTS,
S. Rucker & Co., 12, Great Tower Street,
London, E. C.

COFFEE PESTS.

London, October 17th.

DEAR SIR,—To leave no stone unturned to try and find out some remedy or palliative for green bug and fungus on what remains of our once fine coffee fields in the Uva district, I applied to the foremost authority in England on insect and other pests which devastate our fruit trees, viz., Miss Ormerod. In case it interests you I enclose her correspondence, but I had to wind up by stating that in my 43 years' experience of Ceylon I had made the acquaintance of all the Ceylon authorities she quotes, viz., Mr. Nietner, Mr. Green, and lastly Mr. Morris to whom she refers me, and that in the case of the latter he had, like Balaam of old, been called to curse and lo! he found himself powerless before *Hemilea vastatrix* and had to go home even like the son of Beor.

I am now sending to Ceylon a keg of sulphate of copper such as has been found so useful in the vine disease and we will try it on a few rows of coffee after I have acquired the knowledge as to application, and this I hope to receive in a day or two.—I am, yours faithfully,

THOMAS DICKSON.

St. Albans, Sept. 26th, 1890.

Thomas Dickson, Esq.

Dear Sir,—I am always glad to be of use so far as the intensely heavy amount of work sent to hand permits, and though I am not acquainted by *personal*

observation with the coffee attacks I will try to offer some suggestions.

You mention "An insect called 'Green Bug' (Aphis) forms its scales in our coffee tree branches," &c., &c.

From the mention of "scales," I conjecture the pest to be the "Green Bug Scale" insect—the *Lecanium viride* scientifically—on which it so happens that I have a very careful and as far as I can judge good practical paper.

But first with regard to your enquiries. I have never used sulphate of copper as an insecticide; therefore am unable to offer any advice on the subject. As I rarely work on extra-British attacks, perhaps you are very much better informed than myself as to what answers—but as in the case of this insect it is presumably expected to kill by contact,—and if your attack is a scale, so very much of the infestation would, for a while, be sheltered under the parent insect that I should not expect it to be of much use; and so far as I know I should expect it would be likely to do a deal of harm to foliage.

The very best reply that I could give to your enquiries would be to lend you my pamphlet, and I would do so with pleasure if you would distinctly promise me to return it within a fortnight. I am so greatly inconvenienced and injured by books not being returned that I now hesitate to lend any.

But in this pamphlet is reference to Phenyle being used as a watering at the root, and I have myself found such excellent effects brought about by the application of this in the form sold as "Soluble Phenyle" that I think it might be well worth trial.

But with regard to washes, I should think that soft soap and kerosine (or mineral oil) washes would be far more likely to do good than sulphate of copper.

You want something *tenacious* which will stick to all the little "buglets" before they have settled down into full development with the sheltering scale, and also something which will so coat the mothers scale that the eggs beneath her, or young hatching larvæ (popularly "buglets") may be killed before they escape.

What is known in South Australia as Burford's "Soap and Sulphur Compound" is easily mixed and I should conjecture would be serviceable.

You have to remember in dealing with attacks of insects of the kind you name, *i.e.* bug or scale (or Aphis) that it is probably of no use to attempt to poison them. They feed by inserting their suckers into the tissues whence they draw their supplies; therefore however poisonous the wash it is more likely than not that unless it is so caustic that it kills by contact, (and also damages the vegetable tissues) it will do no harm to the insects.

What you need is a *sticky* wash such, for instance, in general nature as is used for hop wash in England. This settles on the insects and clogs up their breathing pores, or in the case of the eggs, prevents them hatching. With regard to formation of these washes (or "emulsions") you would find endless good recipes in the publications of the U. S. A. Government.

If you care to study recipes taken by myself from almost world-wide (authorized) sources you would find many very good working ones in my own Manual just published, of which I enclose a circular. Under the head "Soft Soap Washes in India" you will find reference to mixtures found serviceable for scale, aphis, &c., &c.

I do not like to suggest purchase of a book of my own; but I cannot give you the recipes at full length in a letter and I know no other work where you would find at any moderate price similar details.

Trusting that this may be of some service, I am, yours truly,
ELEANOR A. ORMEROD.

St. Albans, Oct. 7th.

Dear Sir,—Enclosed is the paper on the "Green Scale-Bug," in which I hope you may find something useful.

I know that in the case of the attack known as "rust" in carrot I have found much good result from the use of a preparation sold by Messrs. Morris & Little, Doncaster, called "Soluble Phenyle." This is to

some slight degree absorbed into the plant as shown by analysis, and also the preparation contains stimulants to growth (what I do not know), so that the mixture acts well in more ways than one. It is a fertilizer and an insect deterrent, so far as carrots are concerned, but I do not know whether it would answer on the large scale of coffee growing.

Do you know "The Coffee Tree and its Enemies" by the late J. Nietner, Ceylon, 1880? There is a deal of information in it both on *Hemiteia* and Coffee insects?

When you return me the enclosed I would lend this to you if you like, but I believe it has long been out of print; so I should have to ask you to be sure to return it to me.

Hemiteia being a fungus is not in my line of work—my Department at the Royal Agricultural Society is British Agricultural Insect Pests—but I am only thankful if I can be of service, and I should think that if you were to write to Dr. D. Morris, Sub-Director, Royal Botanic Gardens, Kew, Surrey, that he would be able to give you the names of the most approved publications on the subject.

If you were able to run down to Kew yourself this would probably greatly facilitate. You could consult the chiefs at the Herbarium and see publications.

It is not in the regular work of Mr. Jackson, the Curator of the Museums, but he is a very old and valued friend of mine, and if you could see him I am sure (in case that is if you wish for an introduction) that if you mention my name he will do all he can to put you on the right path to obtain information. His address is, J. R. Jackson, Esq., Royal Botanic Gardens, Kew, Surrey. And he would tell you when he was likely to be at the Lake Museum where his offices are more especially.

As you say it seems hopeless to wash at the rate of 1,200 trees per acre, but yet we are obliged even in England to wash and greaseband on a great scale. At Toddington we have 120,000 trees thus to attend to.

Did I enclose a circular of my new Manual? I think that most kinds of available wash must surely be named.—Yours truly,
ELEANOR A. ORMEROD.

THE NEW WEIGHING AND TARING REGULATIONS.

October 17th.

DEAR SIR,—Can you explain the new weighing and taring regulations for tea at the London Customs?

I do not understand what is wanted to insure the minimum loss of weight: it appears more important to have the tare correct than the net weight, but perhaps some correspondent of yours will be able to give us an example.

Supposing a break of 40 chests tared from 23 lb. 8 oz to 23 lb. 14 oz. for the whole 40 chests and it was desired to pack 90 lb. net with minimum loss in weight, how would one set about packing it and the next break say also 40 chests taring from 24 lb., to 24 lb. 7 oz, also to contain 90 lb. net?

What I wish to arrive at is the necessity or otherwise of taring within half-a-pound. Under the old system if your packages tared say 23 lb. 14 oz. it was called 24 lb., and to get in 90 lb. certain one would add 90 lb. 2 oz., making 114 lb. 2 oz. gross = 114 lb. If one's package on the other hand tared 23 lb. 2 oz. it was called also 24 lb., and to make the total 114 lb., one had to add 16 oz. tea; it was obviously important to have one's tare as nearly under a full number of lb. as feasible when the loss in weight (*i.e.* extra tea put in chest) was reduced to a minimum.—Yours faithfully,
dear sir, INQUIRER.

EXAMPLE. (Gross 114 lb. 2 oz. = 114 lb.)

Pekoe.	lb. oz.	lb. oz.
5 chests tare say	.. 23 8	(90 10)
6 " "	... 23 10	(90 8)
14 " "	... 23 13	(90 5)
15 " "	... 23 14	(90 4)
4 chests		

Pekoe Souchong.	(Gross 115 lb. 2 oz = 115 lb.)
	lb. oz. lb. oz.
14 chests tare say	... 24 2 (90 16)
10 " "	... 24 3 (90 15)
5 " "	... 24 6 (90 12)
11 " "	... 24 7 (90 11)

40 chests.

With regard to above tares it is desired to pack so as to get credit for 90 lb. net tea.

The figures in brackets represent the tea which would have had to be packed under old system.

[We trust some public-spirited Broker or Tea Buyer will give planters the benefit of their opinion on the above.—Ed. T. A.]

CEYLON TEA IN RUSSIA.

Kandy, Oct. 22nd.

SIR,—This is certainly most gratifying intelligence about Russia going into the market for our tea, but where is sufficient of the article to come from to supply Australia, America and Russia as well as England? That I fear will be the rule! If agents for the customers named come here and find they cannot satisfy their orders, is it not to be feared their clients will go elsewhere? Producers should therefore do their utmost to keep the local market well supplied.

I look with confidence to 75 cents per lb. being the average before another twelvemonths are over our heads. 'Maun it be so!' Then look out for a "boom." ONE INTERESTED.

"CHERTSEY" TEA AT THE TEA SALES.

Chertsey, Yatiyantota, Oct. 30th.

DEAR SIR,—I regret to find that a mistake has occurred in your paper: I would therefore thank you to be good enough to rectify same.

The actual prices realized by Chertsey at the local sales lately, were as follows:—

100 lb. Bro. Pekoe out at	.. 55 cents
270 " Pekoe Sold at	.. 41 "
200 " Pekoe sou. out at	.. 38 "
80 " Souchongs out at	.. 34 "
180 " Pekoe Fannings sold at	.. 33 "

In the local papers my broken pekoe, I find, has been put down as "out at 51c": this is misleading, and may have an influence of an unfavourable shape on the bids at future sales.

Hoping you will place this matter to rights I am, dear sir, yours faithfully,
F. J. DICKSON.

TEA EXPORTS.

The Strathellie Tea Co., Ltd.,

Nawalapitiya, Nov. 3rd.

DEAR SIR,—Now that the Commercial Season has been altered from the fiscal to the calendar year I intended postponing until next month my computation of probable export of tea. At your request, however, I now give my figures for the fiscal year. You will observe that they are made up on the same basis as regards acreages which I have on previous occasions taken, adding however 20,000 acres as giving their first returns at say 100 lb. per acre, and that I have allowed for a slight decrease on the maximum acreage rate, with the increased area (70,000 acres). My approximations again run out

somewhat in excess of yours ;		
70,000 acres at 340 lb. per acre	=	23,800,000 lb.
45,000 " 300 "	=	13,500,000 "
35,000 " 250 "	=	8,750,000 "
30,000 " 150 "	=	4,500,000 "
20,000 " 100 "	=	2,000,000 "
		Total say 52,550,000 "
Deducting the odd 550,000 lb. for local consumption	550,000 "
		We get probable exports at say ... 52,000,000 "

Uva will make a distinct mark on tea exports this season and if no serious labour difficulties intervene, I fancy my estimate of 52 millions will be overtaken.—Yours very truly,

ARTHUR E. SCOVELL.

PADDY OR RICE CULTIVATION IN CEYLON.

Nov. 6th.

Sir,—A controversy has been for long carried on and still continues as to whether the cultivation of rice is a remunerative or an unremunerative industry. In a recent issue of your paper was printed a contribution thereto by a public servant who claims to have proved by an account of four experiments, over three of which he lost money, that the cultivation is a profitable one; while other persons have on other occasions published accounts of experiments by which they have purported to show that the cultivation of rice is the shortest and easiest road to ruin, or, as the case may be, the readiest route to the heaven of Mr. Andrew Carnegie.

The present writer, who has never sown a grain of rice or turned a watercourse or cheated a renter, ventures very respectfully to submit to the parties to this controversy that they are shooting wide of the mark if what they wish to find out is not what the returns should be, but what to the ordinary unlearned agriculturist they actually are. In so far as the question is of other than academic interest, it is interesting only as the results will enable us to gauge and estimate the condition of the ordinary native inhabitant of the country. The question is interesting not as an agricultural but as a political problem, and as such it is solved by demonstrations which employ factors that are outside the lines of native usage. The Government Agent of the Eastern Province has tried his experiment with an English plough in his hand and an agricultural primer in his pocket; other experiments and experiences of which accounts have been published, though lacking these advantages and differing among themselves in other respects, all agree in this that the system on which the labour has been employed and paid is different to that used in the ordinary course of native cultivation. If then what we want to find out is how the native agriculturist gets on in his native simplicity, and personally that is what we desire; then and in that case our experimentalists throw no light on the question.

It has occurred to your correspondent, who has been pondering over the little results of so much misapplied ingenuity, and he is not a little vain of being the first person to make public so recondite a suggestion that the proper way to ascertain whether a native industry is remunerative is to enquire what classes of workers are engaged upon it, and to ascertain first the outgoings and then the distribution of the

net proceeds, and he has thought that these particulars, if correctly ascertained and reported are likely to go further to throw light on the matter than the experiments of a whole college of agricultural instructors.

But before going further it would be well to define—it would have been of no small advantage to the parties concerned to have done so earlier in the dispute—what precisely the question at issue is. Is or is not the cultivation of paddy a remunerative industry? Remunerative to whom? The answer which is bound to come—"the goyiya"—is not sufficient, for Mr. Elliott clearly is answering the question as if it referred to a capitalist landowner, and most of the other contributors to the discussion have done the same; some appear by the "goyiya" to mean the day-labourer to the exclusion of the landowner, and yet others, (among them the editor of the "Independent,") take him in his double capacity as landowner and labourer, and do not hesitate to state that he makes nothing in either capacity.

Let us appeal for a moment to Political Economy. It is a maxim of that science, undisputed even in Ireland and probably unsuspected by the parties to this argument, that the three elements and the only three elements of production are land, labour and capital, the returns for their services received by the three cooperative elements being respectively rent, wages and interest. Our goyiya in his native simplicity may represent one, or two, or all three of the elements at once, and the returns he draws from the cultivation may be either wages only, or wages and rent if he is the landowner as well as the cultivator, or wages, rent and interest if he supplies from his own resources his seed paddy, and the other needful if scanty capital. The industry will be unremunerative if it returns to the landowner less rent than he would have obtained had he devoted his land to some other cultivation: unremunerative to the labourer if he draws less wages in it than he would have gained if he had devoted an equal quantum of industry to other pursuits: unremunerative to the capitalist if he draws from the capital advanced for employment in it a lower return than he would have obtained if it had been used in some other way.

It is then apparent that the question resolves itself into three; and an endeavour will now be made, by a statement of the native practice in the employment of labour and the distribution of crop, to show how answers must be sought to those three questions. It is to be premised that by the native agriculturist nothing whatever is paid for, neither the labourer's wage, nor the capitalist's interest, nor the landowner's rent, until the harvest is reaped, and that the wisdom of immemorial antiquity going before the wisdom of the Education Department ordained that the labourer in the rice field like the modern schoolmaster should be paid by results. The system is this: All those persons who have had any share in producing the harvest being present, and the crop having been reaped, threshed and cleaned, the whole as it lies is divided as follows:—

(a) 1-10th gross crop to the landowner to meet his liability for the Government tithe.

(b) 1-7th gross crop, for the cost of reaping and threshing.

(c) $1\frac{1}{2}$ times the amount sown to the person who provided seed paddy—the supply of seed paddy being a privilege of the owner.

(d) Sundry small payments, for services rendered: huwandiram, measuring, the soothsayer, &c., &c.

After the above deductions have been made, the balance is divided into three equal parts, of which the owner takes one (e), the person who supplied

cattle (usually the owner) a second (*f*) and the cultivator the remainder (*g*).

Clearly (*a*) and (*c*) are rent, (*e*) and (*f*) the profits on capital, (*b*), (*d*) and (*g*) are wages.

If the crop fails wholly, no one gets anything but (*a*) and (*c*) remain a debt to be discharged out of the next harvest. If in part, the deductions are made in the order (*b*) (*c*) (*a*) and the balance, if any, distributed by the rule. It must be remembered that this distribution is not the same for all fields, or for all parts of the country. The systems of distribution are many, but they are all on the same plan; the one above described is for a field yielding 10 fold: a common class of fields. Richer fields yield a larger and less fertile fields a lower rent, the balance being divided in different ways. The less fertile the field the better the *apparent* though not the real wages: this being, of course, to meet extra labour in cultivation and increased risk of loss.

It follows that among native cultivators, pursuing their cultivation in accordance with their own customs, the landowner gets a rent in kind exactly proportioned to the productive capacity of his land; the capitalist gets a certain and liberal interest on his loan, and a proportionate return, if successful, on that portion of his enterprise which he has entered on as a speculation; and the labourer a return in proportion to the success of his labours. But does the landowner thus get a less rent for his land than he would if he cultivated it with some other product, that is, is the industry unremunerative to him? In Colombo the native paddy-landowner has turned his paddy-land into grass fields; outlying corners of fields, unfertile or incapable of irrigation, are in the Western and Southern Provinces sometimes planted with coconuts: very rarely in old days the Kandyan planted coffee in his disused rice field, but on the whole, once a paddy-field always a paddy field is the rule in Ceylon. Even the Jaffna Tamil who grows everything keeps his paddy-field for its accustomed use in its turn. Surely it is probable—the writer is not a philanthropist and will therefore not venture to dogmatise,—that this is so because it is to the owner's interest; in other words because paddy land owning is remunerative. For what is the alternative? That a very large body of persons, and no inconsiderable number of whom are wealthy, intelligent and speculative commence or continue to grow rice on land which could be more profitably employed otherwise, because (*a*) it is the custom or (*b*) because they are oppressed by unpaid headmen or (*c*) because they think the cultivation of rice a more honourable pursuit than others. These are the only reasons that are ever offered us on the other side and it is not for a seeker after truth to deny that they may have weight, but do they account for *all* the facts? A large body of persons, Sinhalese, Tamil and Malay have migrated from Hambantota and its neighbourhood to Tihawa to cultivate rice. Was it under the influence of custom, or at the instigation of unpaid headmen, or in the pursuit of reputation, or did they hope to make and—for they are constantly being followed by others—do they make money?

Is that wealthy speculator Mr. de Mel seeking the bubble reputation at Maturajawela, or is he terrorized by a village arachchi?

Under the new Walawe irrigation work in the S. P. not yet working 1,000 acres of Government land have already been purchased by private buyers: are they seekers of honour, slaves of custom, or victims of the Great Unpaid?

Are the rich Moormen who poured their money into the Government coffers in return for irrigable laud in Batticaloa content with the mere name of landowner, or do they hope for a profit?

The local philanthropist tells us that they have engaged in the least remunerative of native industries. Have they, and if so why have they, or do they by any chance understand their own business better than the local philanthropist?

And, now comes the turn of the capitalist. He need not keep us long; nobody ever wastes a tear on him. On his advance of seed paddy he gets 50 per cent interest certain, and he may be trusted to be making a good thing over any other advance he makes. Let us leave him and turn to the labourer. Does the labourer in the rice-field get more or less than a similar amount of work would earn for him in other occupations? No one can certainly tell; for though it is possible to measure his receipts, no one can measure the amount of his work, for the fact is this, that 2 or 3 days of arduous labour at the beginning once over, the rest consists of a hand's turn done at odd times and is by no means incompatible with the contemporaneous pursuit of other industries.

It is constantly stated in this connexion that Sir C. P. Layard, a very high authority, expressed his opinion that labour in the rice-field was the worst paid of all labour. It is usual for the philanthropist and sometimes for less positive and better informed persons to quote as nearly as he can remember them Sir Charles's words and to apply them to both branches of the industry—but this is because he has never had them with their context in the original. The statement is, if the writer—who is far from books of reference—is not mistaken, contained in one of the earliest printed Administration Reports of the Government Agent W. P.* in the course of which an account is given of the improvement in the position of the peasantry following on the extension of the coffee enterprise. Mr. Layard, as he then was, spoke of the wages to be earned by Sinhalese as carpenters, cart drivers, fellers of jungle, &c., and he added, (the quotation is from memory): "Paddy cultivation is about the least remunerative industry in which a villager can engage." Too much has been made of this very moderate statement of an opinion, which went in fact no further than that, at a time when speculation was brisk and the coffee industry in the height of its prosperity on the borders of W. P., the stay-at-home agricultural labourer could make less wages by following his ancestral pursuits in his native village than he could earn by migrating to a place where business was brisker and by their plying such trades as he was fit for. It has no sort of application to the employment of the agricultural labour in ordinary times and at a distance from European centres of trade and speculation, and it does not refer to the landowner at all. But, that being so, the opinion so expressed, probably a correct one so far as it then went and in the place for which Sir Charles intended it, is not to shut out all further argument concerning consideration of the point? Let us try the question by such other tests as are at disposal.

What are the best known or least disputed points in connexion with Sinhalese labour? They are these. That during the periods when paddy farming operations are in full swing it is impossible by the offer of any reasonable wages to induce the Sinhalese to engage in any other works and that no field in a fairly populous district ever lies uncultivated for want of labour. If these two undisputed facts are not to be accounted for by the remunerative nature of the work, what

* The statement was made in answer to our personal enquiry and embodied in a "Summary of Informations" some thirty years ago, but "A." 's argument is all the same very strong.—Ed. T. A.

is the explanation? Why is it that, though the planter may want labour for his estate, the Government for the roads and the native employer for his plumbago pit, the owner of a paddy-field never looks an *andakaraya*? Is it due, as we are told, to the tyranny of custom, the oppression of the unpaid headman, or the keenness of the villager in the pursuit of honour?

Or is it—it seems possible—that the villager likes best the work at which he can make most wages in the easiest and most congenial way? At least he himself never complains of the work but only that there is not enough of it.

Are we all quite sure that we know the villager's business, as we know that of the native capitalist, better than he knows it himself?—Your obedient servant, A.

SUNFLOWER AS FUEL.

DEAR SIR,—With reference to your article on the *fuel question* I enclose an extract which appeared some years ago in the *Observer* in case you may think it worth while to reproduce. I know how the sunflower grows in the lowcountry, and I believe it must thrive better higher up. It appears to me that an experiment on a small scale might easily be made just to ventilate the matter—from sowing to reaping would only take about four months, the question of rich soil would be no great obstacle, as no large area would be required, and if systematically grown the resulting potash could be reapplied to after crops—with any other available manure.—Yours &c., —

(Extract referred to.)

SUNFLOWERS AS FUEL.—A correspondent of the *Dakota Farmer*, after having tried "turk" Coalwood and Sunflowers, has settled upon the lastnamed as the cheapest and best for treeless Dakota. He says: "I grow one acre of them every year and have plenty of fuel for one stove the whole year round, and use some in another stove besides. I plant (? sow) them in hills the same as corn (only these seeds to the hill), and cultivate same as corn. I cut them when the leader or top flower is ripe, and let them lay on the ground two or three days; in that time I cut off all the seed heads, which are put into an open shed with a flow in it, the same as a corn crib; the stalks are then hauled home and packed in a common shed with a good roof on. When cut in the right time the stalks when dry are as hard as oak, and make a good hot fire, while the seed heads with seeds in, make a better fire than the best hard coal. The seed being very rich in oil it will warm better and burn longer bushel for bushel, than hard coal. The Sunflower is very hard on land. The piece of ground selected to plant on should be highly enriched with manures. In the great steppes (prairie region in the interior of Russia and in Tartary) where the winters are more severe than here in Dakota, the Sunflowers are, and have been for centuries past, the only kind of fuel used."

SUNFLOWER CULTIVATION: PRACTICAL EXPERIENCE.

Storm Lodge, Colombo, Nov. 10th.

DEAR SIR,—In your issue of Saturday is a letter on sunflower as fuel. Having experimented on the plant I give you results. For the many uses to which flowers, seeds, and stems may be put, consult, "Beeton's Dictionary of Daily Wants," which gives full information with directions for cultivation. When living in Maskeliya (1876-1880) I grew sunflowers in a part of my garden for feeding poultry. There was a rose hedge near, with the usual accompaniment of small beetle. These visited the flowers in thousands feeding on the stamens, but, so far from doing harm, by their agony the seeds were fertilized and every head was full of good seeds.

In 1885 I got out two bushels of seed from Sutton's, "Giant Russian" variety, to see if it would

pay to cultivate in the lowcountry for oil. Mr. S. C. Obeyesekere very kindly cleared two acres of virgin forest for me on his estate at Rambukkana. We planted the seed 18 inches apart in rows three feet from each other, the result being a very large crop of flowers, some of which measured over a foot across; but nearly all the seeds were *deaf*, a few only at the lower border of each being fertile. This was probably due to the absence of insects; the seeds that were fertile having become so by pollen dropping down on them from above.

In addition to this clearing Mr. Jameson and I rented ten acres at the Model Farm, which we planted in a similar manner. Unfortunately, just as the plants were coming up, Capt. Cleland, although warned by the man in charge, marched the R. D. F., followed by a large crowd of natives over the ground, the result being that all except a few growing round trees were trampled out.

Those that remained being amongst roots and under shade grew up small, their flowers also being small and, like those at Rambukkana, partially fertilized, probably from a similar cause.

In all we got a few bushels of seed which Mr. ——— very kindly crushed in one of his ponac mills, the result being five bottles of oil, smelling strongly of coconut oil; this from the mill. I sent this to a friend in London who submitted it to a firm of oil merchants. They reported it as worth about the same as coconut oil, but that perfectly pure oil would be worth as much as olive. You will see that Beeton says "sunflower affords good pasture for bees." I am sure that with their assistance, or that of other insects, it can be very profitably grown in many parts of Ceylon.

I forgot to mention that the stems of those grown in Maskeliya burnt in a stove (They were pithy and not a bit like oak, as you mention,) gave a very large percentage of potash, some pieces, especially roots, coming out like coral—only much more brittle and friable.—Yours faithfully,

T. H. F. TOTHILL.

TEA-GROWING IN RATNAPURA.

Ratnapura, Airy Hill, Nov. 11th.

DEAR SIR,—I have this day posted to your address a sample packet of tea grown on a land in the town of Ratnapura and prepared at my own residence. I shall thank you to try the tea sent and afford me your opinion.—Yours faithfully,

J. P. JAYEWARDENE, Head Clerk, P. R. C.

[The tea seems very well made, but the flavour is peculiar and an expert says this is owing to over-firing. This can readily be avoided again.—We are not at all afraid of the result should the Sinhalese gardenholders turn their attention to tea, for before they produce their million lb. or so, we may expect one if not two millions of the population of Ceylon to become regular drinkers of the new beverage.—ED. T. A.]

JUTE MESH FOR TEA.

Yatiantota, Nov. 13th.

SIR,—I send you, as promised, samples of jute mesh made in Calcutta. I have been expecting another sample of a better make of the single yarn mesh (both warp and weft should be hard spun), but it has not come to hand. The prices of these will be about 18s. and 15s. per yard.—Yours truly,

E. F. DAVIS.

[The samples referred to can be seen by anyone interested at our office. They seem substantial enough.—ED. T. A.]

EXPERIMENTS AT THE SCHOOL OF AGRICULTURE.

Mr. S. Davis, Travelling Agent for an American firm of implement makers, accompanied by Mr. W. H. Davies, visited the School of Agriculture this morning by arrangement, and spent about two hours in demonstrating the use of some new inventions. Two hand implements were first tried, with attachments for hoeing, raking, moulding, &c., which worked most admirably in the Indian corn and turmeric plots. They are well adapted for all manner of crops sown in rows, and are the most perfect implements of their kind. The amount of labour and time they save are incalculable, while the prices of the machines are comparatively cheap. Next an experiment was made with the horse hoe which was attached to two buffaloes. This implement was also made to do the work of ploughing, skimming, moulding, trenching, &c., and is said to be largely used in tobacco and sugar-cane plantations. The exhibition of the working of these machines was much appreciated by the students. The horse-hoe is perhaps too heavy for the cattle of the country, and there is probably not much scope for the use of the implement, which may also be too expensive for the Ceylon Agriculturist, but the hand machines, which can no doubt be seen at Messrs. W. H. Davies & Co's, ought to have a good sale in the island, as they are simply invaluable for garden cultivation of every kind, Indian corn (which by the way is being very successfully raised at the School of Agriculture) and such crops.

NOTES ON POPULAR SCIENCE.

By DR. J. E. TAYLOR, F.L.S., F.G.S., &c.,

EDITOR OF "SCIENCE GOSSIP."

Dr. Beyerinck has just described before the Royal Academy of Sciences at Amsterdam some highly interesting and important experiments relating to the infection of the common bean (*Vicia faba*) with a species of bacillus (*Bradicola*). He filled twelve pots with sterilised river sand, which had been rendered very poor in nitrogen by washing with distilled water. These pots he divided into four sets of three each. On April 25 a well-sterilised seed of the bean was planted in each pot. The dust of the air was wholly excluded from the pots, and arrangements were made so that the watering was carried on under dust exclusion. The first set of pots was watered with 0.1 of phosphate of potash, 0.03 chlorate of lime, 0.06 sulphate of magnesia, dissolved in one litre of distilled water. The second set with the same mixture; the third set ditto, to which was added 0.2 grammes of nitrate of lime; and the fourth set ditto, to which was added 0.2 grammes of sulphate of ammonia. When the plants had developed their second leaf, the three pots of the first set and one single pot of each of the other three sets were infected with a gelatinous culture of bacillus, cultivated in 1889 from the tubercles of the common bean, and since that time kept in successive cultures. The bacteria used to infect the beans with were mixed with sterilised common water. On June 20, on one old cotyledon of a bean, a fungus (*p. nicilium*) was found. The experiments were, therefore, not continued further. All the plants were taken from the pots, and their roots were well washed and examined. Every one of the six infected plants bore many tubercles, whilst not one of the six remaining non-infected plants showed the least sign of tubercles. Dr. Beyerinck showed that the presence or absence of nitrogen, as nitrate or as ammonia, is indifferent with regard to the practicability of the infection.

That nitrifying organisms exist in the soil has been known for some years past. A French scientist, however, has communicated to the Academy his discovery that not only are nitrifying microscopic organisms univer-

sally distributed, even on the bare rocks of mountain peaks, but that to them may be attributed a considerable share in the important work of breaking down rock-masses into soils.—*Australasian*.

BARK AND DRUG REPORT.

(From the *Chemist and Druggist*.)

LONDON, Oct. 23rd.

CINCHONA.—At Tuesday's auctions a fair average supply of bark was offered for sale, the catalogues including:—

	...	Packages	Packages
Ceylon bark	...	1,658	of which 1,251 were sold
East Indian bark	...	735	do 484 do
South American bark	...	1,129	do 431 do
Total	...	3,522	do 2,166 do

The assortment was a fairly good one so far as the Ceylon cinchona was concerned, while East Indian barks also included some very good lots, particularly in *Succirubras* and *Officinalis*, a large proportion being of somewhat old import. South American *Calisayas* were strongly represented, and met a fairly steady sale, up to 1s 1d per lb being paid for the richest lots, though it is doubtful whether the average price now realised by these barks is a remunerative one for the growers. No Java bark was offered at all. The sales opened with a fairly good competition, but this ceased after the first two or three catalogues, and prices gradually ceased off, a large proportion being bought in. The average unit may be placed at about 1½d per lb, or, say, about 8 per cent lower than at the previous auctions. Druggists' barks, however, were in very steady request, and realised full values generally. One of the German manufacturers did not compete at all until near the end of the auctions.

The following are the approximate quantities purchased by the principal buyers:—

	Lb.
Agents for the Mannheim and Amsterdam works	107,231
Agents for the American and Italian works	73,520
Agents for the Frankfurt o/M and Stuttgart works	52,121
Agents for the Brunswick factory	49,547
Agents for the Pelletier works	48, 33
Messrs. Howards & Sons	...
Agents for the Auerbach factory	...
Mr. Thomas Whiffeu	...
Sundry druggists	...

KOLA.—A small bag (41 lb.) of good bold well-dried West Indian seeds sold by auction last Friday at the extraordinary price of 2s 8d per lb. For fair dry nuts 2s 6d to 2s 7d per lb, has been paid privately this week. The report that sales have been made at 1s 9d in Liverpool is discredited here unless the quality of the kolas is exceptionally poor.

COCONUT OIL: rather lower, good to fine Cochon, on the spot, 3s to 3s 6d; for distant shipment, 3s 6d c. i. f. is quoted; fine Ceylon may be had at 3s on the spot or at 2s 8 c. i. f. for distant shipment.

THEFT OF CARDAMOMS AND CACAO

FROM THE YATAWATTE ESTATE.

IN THE POLICE COURT OF MATALE.

November 8th.

Jas. R. Martin, complainant v. Kandi Carpen, Defendant.

In this case the complainant, who is a gentleman known as being "loath to come to Court," charged the accused with the theft and unlawful possession of a quantity of cardamoms partially cured, property of Lanka Company, valued at R3. It appears that for some time past the outturn of the cardamom crop when cured ran short in small quantities, and the complainant had reason to believe that some light-fingered person or persons had something to do with it.

In evidence it transpired today that the defendant was employed by Mr. Martin on both Ross and Yatawatte estates, and owing to his having been suspected of misconduct was paid off.

The accused engaged a house in the Yatawatte village about half-a-mile from the estate and was keeping a "kada" there dealing in dry fish, arecanuts, etc.

On the evening of the 6th instant he was coming along the village path and when he got on to the main road, met the clerk of the estate and a sawyer. The former questioned the accused as to the contents

of the bundle under the arm when he said it was accanot and as things would have it, the saywer said that he wanted a chew of betel badly and both felt the bundle when the accused dropped it in the hands of the latter and ran away. The evidence for the complaint proved conclusively the possession and the charge having been read and explained the defendant said he had cause to shew and wanted time to get his witnesses which was allowed, the accused in the meantime being remanded till Friday next.

The next case was that in which one Podia was charged with the possession of some Cacao partly cured. The accused in his statement said that he had purchased the Cacao from Kandi Carpeu (accused in the previous case) and had paid him R5. This boy used to go about in the Yatawatte vilage from house to house trading in dry fish, salt and other sundries, at the same time purchasing whatever he gets from the villagers and from what could have been gathered. Podia was a ready purchaser from Kandi Carpen; this case is also fixed for Friday next, Podia being remanded.

It is an admitted fact that cardamoms of the Malabar variety are not grown within a radius of six miles from the Yatawatte estate with the exception of a few bushes on Nawagala which does not give a crop worth curing, neither are there any bushes of this variety in the vilage.

As regards Cacao there are but very few trees scattered about the vilage and not a single vilager could have the quantity taken up and none of them know the process of curing as this quantity had been.

PEARL FISHING is still carried on—says a home journal of Oct. 31st—on the Tay, though by no means to the extent that it used to be. Last week a brooch was presented to a lady of the neighbourhood in which were forty Tay pearls, six of them being large and valuable.

TEA AND PROGRESS.—Another sign of social progress is the new Tec-to-tum cafés in the East-end. A quiet elegant and almost artistic one may be found in the Commercial-road, and a less pretentious but very pleasant one exists in the Whitechapel-road. These cafés are founded and managed by Mr. Buchanan, a wealthy tea-merchant, who is quite an enthusiast for social reform. He does not desire to make money out of the enterprise, but to provide an attractive place which shall be at the same time restaurant and club for the East-end masses.—*L. & C. Express*, Oct. 31st.

TELEGRAPH LINES are subject to a great variety of pests. In the neighbourhood of Rio Janeiro, says the *London Globe*, there is an orchid that flourishes on the excrement of birds which encrusts the wire and the "earth contacts," resulting in leakage of the current to the ground, which is a fruitful source of trouble. Again, in Japan, where the lines run along roads bordered by cryptomeria trees, the large webs of a spider, dripping with rain or dew, frequently interrupt the traffic. In Norway the poles are often perforated by a large woodpecker, which is supposed to mistake the humming of the wire for a nest of insects in the wood; and we now learn from Arizona, U. S., that the green woodpecker of California, *Melanerpes formicivorus*, is in the habit of digging cavities in the red cedar poles. In these it builds its nest or stores the larvæ upon which it feeds. Of course, the poles are snapped across by the high gales. In Ceylon, branches of cocoonut palms falling on the wires sometimes drag them down, and on the Wilson's Bungalow road, a vegetable growth has been pointed out to us on the wire, arising doubtless from bird droppings, which interferes with insulation.

PARIS GREEN AND LONDON PURPLE.—The *Gardeners' Chronicle* hears of much recklessness in America in the use of this poisonous tree dressing, and others deleterious to human beings and grazing animals. The requisite quantity is often greatly exceeded, thereby adding to the cost and labour of its application. One farmer used it over a crop of cabbages, and caused serious illness to those who partook of them. Too much caution can scarcely be taken in the employment of these preparations of arsenic. Sulphate of copper is somewhat less poisonous, and it is almost equally efficacious when used against the Codlin-moth and mildew. This is what has been recommended in a mixture for green bug on coffee.

SEA-WATER AS THE SOURCE OF GOLD.—We were aware that silver in quite appreciable quantity was diffused in the ocean, but now we learn from a paper read before the British Association that to the same source we must look for the origin of gold. Mr. J. Logan Lolley, F.G.S., stated

—that while geological evidence is against its igneous origin, all the gold of all the rocks may have been derived from aqueous deposition; that, in fact, all this gold may have been deposited by marine action in the same way as the materials of the aqueous rocks themselves have been. And, moreover, our unaltered sedimentary rocks, even of tertiary age, may contain an equal amount of gold in proportion to their bulk with that of those altered or metamorphosed Cambrian and Silurian rocks, which have hitherto been regarded as the earth's great treasures of the precious metal. The knowledge now possessed of secondary and tertiary auriferous veins in California controverts the Plutonic as well as the palæozoic hypothesis, and the discovery of gold in sea-water and of its precipitation by organic matter alters the position of the question from that it occupied in the days of Murchison and Forbes. Since silica may combine with gold under heated conditions, and the silicate of gold so formed besoluble in hot water, as is also silica, gold in the form of silicate could be carried by water, heated by deep-seated conditions or by the neighbouring uprise of fused matter, from its original position, and be deposited in veins with silica itself when subsequent segregation would separate the silica of the silicate of gold and leave it as free gold imbedded in quartz as it is now found. The discovery by Sonstadt of nearly a grain of gold to the ton of sea-water shows that the sea has always held in solution an ample store to give to its sediments the amount of gold they are now found to contain, and Daintree's discovery of the power of organic matter is precipitate gold from a solution of the perchloride explains the deposition of gold from sea-water, since on the sea-bottoms there has always been a large amount of organic matter. Though the gold so deposited would be in infinitesimal proportion to the mass of the marine mineral sediments, it would be aggregated by nuclei of metallic sulphides by which it would be retained until thermal conditions favoured its conversion to a soluble silicate. The sulphide of iron, or pyrites, is known to nearly always contain gold, and hence it is to be concluded that the gold of the sedimentary rocks which have not been subjected to the favourable conditions for its separation and preservation in quartz veins is now in the metallic sulphides these rocks contain. In such rocks as the chalk and the London clay, the amount of pyrites is very great, and the author concluded by giving a rough estimate of what may be the amount of the gold now in the surface-rocks of the south-east of England, from which it appears that these deposits may contain gold to the value of £100,000,000 sterling.

The Chairman said that the prospect held out by Mr. Lolley was very encouraging, and he hoped that some one would be able to suggest how so much wealth could be rendered available. There was good ground for believing that gold deposits were gradually growing, and therefore for the present this enormous amount of gold might be left until it had aggregated into convenient nuggets. (Laughter.)

HILLCOUNTRY PLANTING REPORT.

THE DWARF MOUNTAIN BAMBOO AND ITS FLOWER—THE PATANA SWAMP BAMBOO—OTHER BAMBOOS—FLOWERING TREES—BO-TREES AND PLANTAINS AT HIGH ALTITUDES—TRAVELLING BY ROAD VS. RAILWAY—THE WEATHER.

The dwarf mountain bamboo, which forms so large a proportion of the undergrowth of the Ceylon forests, at and over 4,500 feet altitude, is in flower and seed here at present; and in reply to a letter from me Dr. Trimen states:—

"Your small mountain Bamboo is *Arundinaria debilis*. I think it flowers yearly as do many of the small species, whereas most of the larger kinds blossom and seed only at long intervals. The patana swamp one is *Arundinaria densifolia*. It is flowering and seeding profusely this year for the first time in my experience, and I cannot find that anyone has ever seen it in that state before."

It is not in accordance with my observation that the dwarf bamboo flowers annually: on the contrary, I remember the late Mr. Wm. Ferguson being interested in the flowering and seeding of this species some years ago, as to him a novel circumstance and as enabling him to distinguish this bamboo from the other prevalent in our jungles, and of the long supple stems of which baskets, sieves, &c., are woven. Then as to the patana swamp or aquatic bamboo, I wrote very fully about its abundance and extreme beauty, as also its probable utility as a substitute for osiers, after a visit to Horton Plains in March 1888. Specimens brought away on that occasion are near me as I write, as perfect in tall elegance and fine foliage (though altered from green to yellow in colour) as when they were cut from the banks of the Belihuloya, at an altitude of 7,000 feet, on the occasion mentioned. I again visited the Plain in Nov. 1889 with a companion to whom I had descanted on the attraction which this bamboo added to the Maha Eliya expanses. In proportion was my mortification to find that the swamp bamboo had flowered and fruited, and that most of the tall, slim, beautiful stems had withered and were lying prostrate. This state of things I also fully described in a letter "from the Hills." The scene of desolation, although on a smaller scale in relation to space but especially as to size of plants, reminded me of my experience in South Wynaad in 1876, when I saw hundreds of thousands of large and tall stems of *Bambusa arundinacea*, which had flowered, seeded and died down, and of which I procured a large quantity of seed. Plants from that seed grew only too well at low altitudes, but here they have made but poor progress, except in sheltered ravines.

I should think Dr. Trimen will find that many of his correspondents in all parts of the world will be glad to have seeds of the specially elegant *Arundinaria densifolia*.

About two other plants which Dr. Trimen has been good enough to identify for me, he writes:—

"There is nothing to say of any general interest about the two mountain trees of which you send me specimens.

"A is the montane form of *Turpinia pomifera*, a common inhabitant of the hill forests. I did not know its young foliage was so brilliant; I suppose I do not happen to have seen it just at the right time.

"B is *Pygeum Wightianum* (not a 'Weralu' but) called 'Ununu' by the Sinhalese, a name which enters into the composition of several place-names.

"Many trees 'flush' (as the tea-men say) with the first rains of each monsoon, and many also blossom twice in the year at the same times."

I wrote to Dr. Trimen respecting *T. pomifera*, because up here it vies with the iron-wood in splendour of colouring, the tints of the flush

shading from pink to scarlet and orange. From the *damba* and *kina* this tree differs, inasmuch as the whole of the foliage does not become coloured, but only masses of flush at the ends of twigs, which at a little distance assume the appearance of rich clusters of flowers, contrasted beautifully with the green of the glabrous leaves. On a portion of Lorne estate which was not burnt, some of these trees were left to grow separately, and having plenty of room and light, they are truly beautiful objects handsome in form and rich in contrasted colouring. Many ravines and dells in Nuwara Eliya are at present brightened with the warm red of the young foliage of this tree, the more welcome as the rhododendron trees at present scarcely show a flower.—*P. wightianum*, which I fancied might be a *symplocos* or a *weralu*, has been recently enriching the forests with an abundant wealth of spikes of white and fragrant flowers. It is quite worthy of being associated with the name of the great South India botanist, as famous in the south as Wallich was in the north, more than half-a-century ago, when the former was publishing his *Icones*, and the latter, having admitted that the Assam plant which he had ranked as a *camellia* was a true tea, was teaching botany to the students of the Calcutta Medical College, amongst them Loos and Dickman and Anthonisz and Wambeck from Ceylon.—Of course the well-known Ooonoogalla estate in Madulkele has derived its name from the prevalence of this tree in the forests which so long ago were felled to make room for such cultured plants as coffee, cinchona and tea. A young bo-tree has just been planted opposite the Nenuoya station. In looking at it, I doubted if it would grow at the altitude, but I now recollect that one of the first estates opened in the Dimbula District was Bogahawatte. The estate of Kehelwatte, close by, was, I suppose so named in consequence of the prevalence on its forest site of the wild plantains? How the opening of the railway has thrown once well-known places and familiar names into the shade! How many of the present generation of Europeans in Ceylon know anything of the once frequently traversed Colombo-Kandy road? But much of the country can best be seen in the course of leisurely road drives.

This day, which opened so brightly, continued sunny and hot until clouds gathered at eventide and we heard a distant rumble of thunder; but no rain fell, and there is every prospect of a fine day for our projected visit to Mr. Nock's mountain paradise under the hoary and precipitous brow of the lofty Hakgala,—the three peaks of which look towards the Central, Uva and Sabaragamuwa Provinces with loving regards.

COLD MORNINGS AND HOT DAYS—A TRIP TO HAKGALA—THE FERNERY—FLOWERS—POTATOES—A FINE VIEW OF UVA—FUTURE IMPROVEMENTS FURTHERED BY THE RAILWAY—RAIN WANTED.

NANUOYA, Nov. 12th.

"Hotter and hotter every day," with mornings cold in proportion, must be the meteorological record. Yesterday was a "blazing hot" day in Nuwara Eliya and Hakgala: a day which rendered the cooling effect of a drive through the atmosphere grateful, and doubly so the dense shade and coolness of the beautiful "Fernery" at Hakgala. We cannot wonder at this being the favourite resort of visitors to the mountain Gardens; for, besides the wonderful collection of ferns, which Mr. Nock is engaged in classifying and naming, there is a great variety of allied plants, or plants which habitually indicate a preference for the shade into which we were glad to retire on this occasion, although we had been

charmed with the many beautiful or new vegetable and floral treasures arrayed on the parterres and in the borders of the open and prettily turfed expanses. To children a visit to these Gardens affords great enjoyment, and those who accompanied us had "such fun" in running round and round and hither and thither over the maze of narrow walks, on the sides of the ravine in which the Fernery is situated, and were so delighted with all the interesting and beautiful objects they saw, that they gave voice to the feeling of us "children of a larger growth," when they expressed reluctance to leave Hakgala. Mr. Nock, as usual, had many plants, new or newly in flower, ornamental and useful, to which to direct our attention; and not the least interesting "exhibit" was a plot of potatoes, wonderfully prolific and healthy, although the fourth successive crop was being grown in the same ground. I could speak of our admiration of roses, camellias, begonias, tree daisies and other things of beauty, but the place must be visited to get an idea of its beauty, and on a day such as we enjoyed, to realize the grandeur of the view of the vast spreading valley of Uva, with its rice fields, its patana hills and forested mountains and the majesty of the precipitous face of sheer rock which rises over the Gardens. We saw interesting photographs of the views from some points, but not of a size to do justice to the massiveness of the mountain or the extent of the prospects. The sight of the enormous proportion of grassy prairies in Uva cannot but raise questions as to the possibility of improving the pasturage in some cases, of culture of useful food or fibrous products in others, and of considerable afforestation in suitable situations. We cannot doubt that much of this is in the future, progress—material, intellectual and spiritual—being indefinitely furthered by the railway over which trains laden with passengers and the exchanges of a profitable commerce will soon be entering the ancient Principality of Uva and awakening its echoes to the sounds of a new dispensation.

This morning here is no exception to the sunny brightness and perfect calm of the openings of previous days, and but for a mass of moist looking haze up towards the table-land between Totapala and Pidurutalagala, we should feel inclined to predict a continuance of the present brilliant weather. Mr. Nock on the Uva side, like others on this side who are putting out plants, would be glad of a little rain. Our thermometer went down to 52° in the very early hours of this morning, but all the signs point to a sun heat today represented by not far from three times that figure.

SUPPLY BASKETS AND THEIR VALUE IN TRANSPORTING—
SUCCESS OF EUCALYPTS & C.—PEPPER IN CEYLON—
THE WEATHER.

NANUOYA, Nov. 12th.

Yesterday, when *en route* to Nuwara Eliya, we came upon a gang of coolies, eight in number, carrying loads, each made up of several hundreds of funnel-shaped supply baskets, packed one into the other in long rolls. The baskets had probably come from Kalutara to Nanuoya by train, and we naturally speculated on their destination. With a good deal of probability, considering the extensive failure in planting after the ordinary fashion in the partially cleared forests below Nuwara Eliya, we credited the consignment to the local forest officers. In any case it would seem that it would be better for foresters and planters to incur the cost of such baskets, where sections of bamboo, or other substitutes, are not available, than to lose, as is so frequently the case, plants put out, which have cost so much in the shape of purchase of seed and labour expended on nurseries. Plants differ very much in sensitiveness to the effect of transplanting.

Tea does well when put out at an early stage of growth and I believe better when of an age which renders "stumping" necessary. Frenelas, on the other hand, succeed as seedlings, but "insidious defunction" is the rule with plants above half a foot in height. Many of the Australian eucalypts, too, die from the effects of transplanting. No wonder though the grevilleas are such favourites: not only are they amongst the most free-growing and beautiful of trees, but the plants put out in anything like decent weather practically all succeed. That is in the hill and mountain regions, for of white toons and grevilleas recently sent to a low-country estate the report is that fully 80 per cent of the toons have succeeded, while 95 per cent of the grevilleas perished. The fact is probably significant of the zones in which each will best flourish, although I have seen some fine specimens of grevillea and also of Norfolk Island pine at Colombo.

The mention of the lowcountry estate in which I am interested reminds me of "Peppercorn's" recent allusion to the comparative failure of the plant from the fruit of which that clever writer has derived his *nom de plume*. Our climate in the south-west of Ceylon bears so much of general resemblance to that of Malabar, where some of the best pepper in the world is grown, that many of us thought that the vine ought to grow well and be fruitful of its special spice with us. In my own case I had encouragement in the shape of groves of jak trees in native gardens near my land, which were certainly not grown merely as ornamental creepers. I have, therefore, grown the vines to some extent on trees and on rocks, and in both cases, there has been no failure in luxuriant growth. But fruit has not been in proportion, and of the small quantities of peppercorns yielded, my native neighbours have for two successive years helped themselves pretty liberally. The effect of turning the tops of the plants downwards, of pruning and of watching will be tried before the experiment is abandoned; but I have a considerable degree of fear that pepper must be added to Liberian coffee, cacao, indiarubber trees and manioca as cultivation of a non-paying nature, in the locality where tea and coconuts flourish.

November 13th.

The fine weather remains unbroken, although the sky clouded over and there was an attempt to rain yesterday. The light, cool breeze we get is steadily from the north-east; and this clear, cold but sunny morning does not certainly indicate the proximity of rain. All we knew of your great rain-storm up here was the appearance of a mass of darkness far in the west and far below us, which led to the exclamation, "They are having heavy rain at Colombo." This being the last working day before the Tivali, extra pluckers have been crowded on to save the abundant tea flush. Another will be well on before steady work is resumed, we fear.

AFFORESTATION—AUSTRALIAN TIMBER TREES—USEFUL
JAPAN TIMBERS—RICE CULTIVATION IN CEYLON.

NANUOYA, Nov. 12th.

In writing this morning about our yesterday's delightful trip to Hakgala and of the vast expanses of patana visible in Uva I mentioned the afforestation of portions of those patanas as desirable. Amongst the most barren portions of our patanas are those the soil of which consists mainly of ironstone. Now it is in soil of this nature in Western Australia that two of the best of the eucalypts flourish and bear timber of the best quality. I refer to the JARRAH (*E. marginata*) and the KARRI (*E. diversicolor*). Those trees and others ought, therefore, to be tried on such soils,

good-sized holes being of course dug for the reception of the plants or seed, and time for thorough aeration being allowed before the seedlings or the seeds are deposited. The fact I have mentioned of specially fine timber trees growing best on hard ironstone soil has been stated by Baron Von Mueller and other writers on Australian trees, and has been repeated by the author of a paper on some of the leading Australian timbers written for the Institution of Civil Engineers in 1887, and to which Mr. Walter Tringham has been good enough to draw my attention. Mr. Chamier, M. I. C. E., the writer in question, gives a fair account of the conflicting testimony as to the power of jarrah to resist the attacks of the white-ant and *teredo navalis*. It seems to be certain that jarrah is one of the best wood for jetties and for many other purposes. Those purposes do not include its use as firewood, however; for Baron Von Mueller dwells on its non-inflammability as its great merit for roof shingles. The cost of working some of the best Australian timbers is great, on account of their weight and extreme hardness. But such qualities add to their value as sources of hard wood sleepers for railways. In this purpose, however, karri and red gum (*E. rostrata*) timber seems superior to that of jarrah. It is interesting to learn from Mr. Chamier that he accompanied the late Mr. W. T. Doyne (the first Chief Engineer of the Colombo-Kandy railway) on an official visit to Western Australia for the purpose of reporting on harbour improvements when the magnificent jarrah forests and their utilization were reported on by Mr. Doyne. But the Government contented itself by according liberal encouragement to private enterprise. The export is considerable, and the demand in advance of supply. On the estate whence I write, as I lately mentioned, we have found this fine tree by no means a slow grower, and specimens of this eucalypt and of *E. robusta* are amongst our finest trees. The timber of the jarrah, like all others, would be more valuable and appreciated, if it were well seasoned. Karri, which grows to the size of 300 to 400 feet, resembles jarrah, but is not so red in colour. Its transverse strength is superior and it can be obtained in pieces of enormous size. Red gum (*E. rostrata*) differs from jarrah and karri, in preferring moist situations and yet its timber is of the very best quality, and is a special favourite for railway sleepers. This is the tree to grow beside streams or in swamps. Next to red gum Mr. Chamier classes the various iron barks, *E. siderophloia*, found mainly in New South Wales and Queensland. Its timber is one of the hardest and strongest in existence. But it is of such slow growth that it may not be so suitable as many of its congeners for cultivation in Ceylon. The next tree mentioned by the writer is the world-famous blue gum (*E. globulus*), which grows rapidly enough in Ceylon and can be coppiced for firewood, but it seems to flourish in many other countries, the Cape, Algeria and even Italy, better than in many parts of our island. The timber is good, but, unless well seasoned, is apt to warp and shrink. Mr. Chamier's list closes with stringy bark (*E. obliqua*). This, with *E. gigantea* and *E. capitellata*, yields the bulk of the "hard wood" used in Australia, useful for a large number of purposes, although not equal to those trees previously noticed.

In the same volume of the Proceedings of the Institution of Civil Engineers is a paper on useful Japan timbers, by Mr. J. H. T. Turner, Assoc. M. I. C. E. The writer states:—"Of the 120 kinds of Japanese timber catalogued by the late Dr. Gesto, in the transactions of the Asiatic Society of Japan, the six following have been selected for notice, as those which chiefly concern the builder, namely

Shira, Kashi, Keyaki, Aku Matsu, Kuro Matsu, Hinoki, and Sugi." The last-named is the so-called cedar, *Cryptomeria japonica*, of the timber of which most of the tea boxes used in Ceylon are made. Of "Momi," which is advertised as preferable, in being destitute of odour, I find no mention. The shooks we get here are composed entirely of Sugi wood, which is just a superior kind of deal, occasionally prettily marked with wavy shadings, so that I cannot doubt its looking well as furniture or wainscoting, if polished and varnished. But neither when I have stood close to the carpenters when they were planing and fitting the pieces have I observed any marked odour, nor have we ever had complaint of its affecting the tea through the lead lining. The tree, *C. japonica*, is very largely and successfully grown in and around Nuwara Eliya and personally I have readily invested in a pound of the seed advertised by Messrs. Mackwood at so moderate a price. Apart from our own experience of this handsome, araucaria-like tree, the sight of some fine specimens, well-grown at an early age, in the Hakgala Gardens yesterday quite reassured us of this being a good tree to grow. So, we should think must be the very handsome *Pinus sinensis*, resembling considerably in foliage that king of pines, the *Pinus longifolia* of the Himalayas, with its copious bunches of foliage consisting of spines so long and elastic as to look like masses of green hair. Mr. Nock is growing some other pines, including *Pinus conariensis*. The Sugi, or *Cryptomeria japonica*, may not yield a first-class timber; but it is useful and easily wrought, and, although last on Mr. Turner's list, it stands well with us for readiness of growth and beauty of form. Specimens of a little over four years old in Nuwara Eliya are over 20 feet high, although they have put on abundance of lateral branches from the root upwards. The timber is useful for house work as well as for tea boxes and like purposes, Mr. Turner describes Keyaki as the most important of his group. Its scientific name is *Zelkova Keaki*. The wood is light brown, strong and durable, handsomely marked and takes a fine polish, so that it is valued for furniture. This tree ought, if possible, to be introduced into Ceylon. The Shira Kashi is an oak, (*Quercus glauca*), and, therefore, not likely to be successful here. The *Aka Matsu* or *Me Matsu* or Red Pine (*Pinus densiflora*) seems a very useful tree equally good for house building and all kinds of carpentry. This tree ought, also, to be tried in Ceylon. So also, ought the Kuro Matsu or O-Matsu (*Pinus Thunbergii*), the common timber of the Japan hill forests. Still more valuable, apparently, is the Hinoki (*Chacycypario obtusa*), good for house construction, railway sleepers and cabinet work.—In Japan, as in many other countries, the trees are cut at too early an age and the timber is very imperfectly seasoned. The proper cutting age of the trees named varies from 30 to 50 years, but there can be little doubt that in our climate maturity will be attained at half the periods required in Japan. Many of the trees good for timber at an advanced age must be useful for fuel at much early periods of their existence, a good proportion coppicing freely. *Cryptomeria japonica*, we cannot doubt, will coppice well, seeing that it can be easily propagated from cuttings. This we know from experience as well as from books. Mr. Turner mentions that in Japan "neglect of seasoning is seldom aggravated by the use of paint of any kind, but it is not unusual to stain wood with shibu (the juice of persimmon) darkened with lamp black or ashes. Shibu is a powerful astringent, and does not hinder the sap from leaving the green timber, whilst it affords some protection from the weather." We suppose most of our readers are aware that lime in moderate

quantity is useful, placed in water where logs of timber are seasoned; and that, applied in quantity and directly, it gives a dark hue to the lightest coloured wood.

I have read with interest and pleasure the very able letter, signed "A.," on Rice Culture in Ceylon, proving that whatever the force of the sentiment of regard for "patrimonial inheritance" may be, it cannot possibly account for thousands of persons, year after year, being willing, or, even if they were willing, being able to continue an unremunerative pursuit. Rice-growing must certainly be remunerative, according to the native standard of profit, or it would not be persevered in. As the writer points out, if the returns are not such as might be obtained by superior modes of cultivation, the pursuit suits native idiosyncrasy, because, if the results are moderate, so is the amount of physical labour necessary to obtain them: a few weeks of exceptional work and then mouths of the dearly loved *dolce far niente*. The late Mr. James de Alwis went the length of saying that Europeans often did injustice to native cultivators from ignorance of their habits. "Ye are idle! ye are idle!" has been said of them when observed sleeping during the day hours, by persons who knew not that the preceding night had been spent in labour on the fields. And it is a fact that I have personally seen the Jaffna cultivators busy raising water from wells and irrigating their fields on moonlight nights. The natives can work hard and continuously, occasionally, so as by the results of such labour spurt to secure the luxury of absolute idleness for lengthened periods. This, in a pursuit which is ordinarily remunerative, or it would be abandoned. But there can be no question that with steady industry applied to improved modes of culture, the pursuit would be far more remunerative and the condition of the cultivators far better and happier than is at present the case. That is, if to steady industry in improved cultivation, provident habits were added. The object of the School of Agriculture and its *alumni*, the "Agricultural Instructors," scattered over the country, and of gentlemen like Mr. Elliott, is to teach the people to increase the produce of their lands by improved methods of agriculture and by steady instead of spasmodic work, and also to inculcate such provident habits as saving seed-paddy from the proceeds of harvest, instead of paying, as many of them do, 50 per cent per crop season for its supply. If the landlord supplies the seed and receives it back with 50 per cent added, it will be acknowledged that this is unjust to the labourer, whose share is in proportion lessened. But in most cases the seed-paddy is supplied by outsiders, who also lend money for exorbitant interest on the mortgage of lands. This it is, the going into debt to usurious money-lenders, which weighs down the cultivators here as in India, and which in the latter country has induced Government to pass exceptional laws, providing that in no case can the land be alienated, and arranging a system of money advances by Government to the cultivators at moderate interest, a system which our Government might well imitate. For the rates of interest charged by ordinary moneylenders are generally excessive and ruinous. In a large number of the cases of experimental land settlement by Mr. J. H. de Saram, the lands were mortgaged, in most instances to members of the "great unpaid" class, for sums on which 16½ per cent interest (why the odd fraction?) had to be paid. How can any ordinary enterprise bear such a rate, or the much higher rates which I believe are in many cases exacted! While, therefore, it is certain that paddy cultivation pays

fair returns, or it would be abandoned, it has to bear burdens compared to which the Government's rent of less than 10 per cent is as nothing. The efforts of those who are labouring in a legitimate manner to improve the condition and lighten the self-imposed burdens of the *goyiyas* are, therefore, worthy of all encouragement and praise.

MOISTURE ON PLANTS MISTAKEN FOR DEW—FROST AND TEMPERATURE AT NUWARA ELIYA—THE DEPOSITION OF DEW—MIST EQUIVALENT TO RAIN—EFFECT OF DUST IN THE ATMOSPHERE—THE MIST LINE AND COFFEE—MIST AND HEALTH—FIGS—FINE WEATHER.
NANUOYA, Nov. 14th.

Now that the season is approaching, has indeed arrived, when, according to the popular conundrum, the moisture which ascended from the earth for *sun-dry* reasons will descend in *dew* (due) time, Dr. Macpherson's article in *Longman's Magazine*, embodying the results of the very interesting experiments by Mr. Aitken, F. R. S., of Falkirk, possesses special interest. It seems that moisture on plants, which for centuries has been mistaken for dew, is really exuded from the leaves by an amount of reserve energy in the roots, which in the case of healthy vegetation acts with a force quite remarkable. That the leaves of plants exuded moisture, especially when exposed to sunlight, has been long known, and the process was described by Bousingault in the case of mint. What Mr. Aitken has established, besides measuring the force with which the roots act, is that the moisture excreted from the leaves of grass and other plants in a healthy condition takes invariably the form of a drop (what in Scotland we call a blob) resting on the extremity of the leaf, and that such false dew exists when true dew, for which it has constantly been mistaken, is entirely absent. We have all been in the habit of crediting the atmosphere with depositing condensed moisture, when in reality, the moisture has come from the earth and has been forced up the stems of plants and out through the pores of healthy leaves by a species of energy even more remarkable than that which enables some forms of mushrooms to upheave not only superincumbent earth but even heavy masses of stone. Dead or withered leaves never show this excreted moisture, but they can be "wet with the dews of the night;" with moisture diffused over their whole surface. So with healthy leaves: in addition to the *drops* of excreted moisture at their points, their whole surface, and specially their lower surfaces, can be rendered diffusively moist by true dew, which is *always* evaporated from the earth, that earth being ever warmer than the air in contact with it. If plants or stones or any substance on the earth's surface have been rendered cold, or rather have been deprived of their warmth by the radiation of heat into space, the moisture coming warm from the earth is condensed on such cold objects, especially on their undersides; the dew, in a very low temperature, taking the beautiful form of rime or hoar-frost. This is the explanation of the snow-white appearance so frequently assumed on cold, clear nights and mornings by the grassy plains of Nuwara Eliya, in the winter months of November, December, January, February, and March,—the cold, or rather the abstraction of heat, being there intensified by the evaporation of swamp moisture as well as the radiation of heat. In February and March the mean nocturnal temperature at our Sanatorium is 7 deg. below the mean shade temperature: that is the mean nightly temperatures for those months is 50 deg. and 51 deg., against

57 deg. and 58 deg. mean shade temperature. But on exceptional nights the temperature goes down to freezing point. For instance, in January and December 1889, the minimum nocturnal temperature went so low as 32 deg.; in February 33 deg.; in November 33 deg. 3; and in March 34 deg. Coffee trees growing in swamps, at elevations far below that of Nuwara Eliya, were sometimes blighted ("killed by frost" was the popular idea) in very clear cold weather. Of course the injury arose from air near the ground chilled by the combined effects of evaporation of moisture and radiation of heat into space. There can be cold at night and in the early mornings, intense enough to injure vegetation, without the presence of actual frost. But to return to Mr. Aitken's conclusions regarding dew. It will be obvious that dew, owing its origin always to the earth, as he has proved, is not always condensed by plants or other objects near the surface. Much of it occasionally ascends into the atmosphere, until it meets with strata cold enough to condense its minute particles. It then falls back to the earth whence it arose, if there is a breeze blowing it may be carried hard and

of India and Ceylon is less satisfactory in dealing with haze and fog, than in any other department of the work. He does not seem to have studied the phenomenon of mist in mountain regions, such as that whence I write, and where for days together sometimes the sky is darkened by dense vapour at and above 5,000 feet altitude, while brilliant sunlight prevails below the limit mentioned. While dew is condensed by cold, it would seem as if heat were the agent required to dissipate fog or mist. And yet there is a haze which owes its origin to heat. I always feel that above 5,000 feet here the prevalence of mists should count a good deal in qualification of our comparatively limited annual rainfall of 90 inches. That quantity must be equivalent to over 100 inches where mist does not prevail? Why does it prevail, and why is it occasionally so unpleasantly persistent, and why is mist-moisture not rapidly condensed and precipitated by the cold of the atmosphere, as dew vapour is? For above the mist line the temperature is appreciably colder than at the lower altitude, where, if mist does form, it soon "lifts" or is dissipated. But for dust in the atmosphere, we are told, rain will not resolve itself into drops, but would be every material thing including the interiors of buildings as much as their exteriors. In that case does the absence of dust at high altitudes account for the frequent prevalence of the pervasiveness of moisture known as fog or mist? It would not help me with answers to such questions, except as answers may be found in terms of belief as the following, under the heading "Fog":— "It is a well known physical fact that two masses of air at different temperatures, and both completely saturated with invisible vapour, when intermingled, no longer hold the whole quantity in suspension; the excess must therefore be deposited as fog." But what of the diffused particles of moisture which constitute mists? Are they surely not deposited? They sometimes remain suspended in the atmosphere for days. The Rev. Joseph Burnet, a very careful observer, mentioned to me the curious fact that the line of prevalent mist and of connected success in coffee culture in the Matale districts of our hill region was found to be 4,500 feet. Here the line is about 5,000 feet, and on the eastern side of the mountain system it is higher still, coffee having flourished at 5,500 in Haputale. Except in cases of bronchial affections, misty weather does not seem to be insalubrious, but on the contrary healthier than hot, bright, dry weather. It is a popular belief that, as mountains are denuded of forest, mist will disappear, but my experience does not confirm this belief. It seems mainly a question of altitude and, no doubt, of temperature of the air as the result of altitude. In cold, north-east monsoon weather, however, we often look down from our clear heights on lower ranges and valleys enveloped in a sea of white mist, I have no meteorological work at hand to refer to, except Blanford's, and the Penny Cyclopaedia is now somewhat ancient. Still the following seems worthy of quotation:—"Mist. The vapour of water, when mixed with air of the same or a higher temperature, is invisible; but when the temperature of the air is reduced below that of the vapour, the vapour becomes visible and forms a mist. * * It has been found that the quantity of vapour in the air diminishes nearly uniformly with the temperature, from the equator to the poles. But as the quantity of vapour which the air will hold at any given temperature is limited, whenever that quantity is at or near the point of saturation, a very small reduction of temperature renders the air misty, and a further reduction converts the vapour into rain."

ERRATA.—On page 452, 2nd column, last line of subheadings, "FIGS" should be "FOGS." On page 453, 1st column, line 25, for "added" read "eddied," and in line 34, "subjects" should be "objects."

has been condensed or in one of "the fields of upper air." I have correctly represented the main results of Mr. Aitken's interesting experiments as embodied in Dr. Macpherson's paper; but the paper is so interesting and in some aspects so important, that I trust you may be able to reproduce it in its entirety. In any case I cannot deny myself the pleasure of quoting the concluding paragraph, in which the scientific facts are clothed with the language of poetry, thus:—

These two facts, then, have now been established: that what was long considered to be dew is merely the exudation of vigorous plants, and that true dew rises from the ground. Brilliant globules are produced by the vital action of the plant—the liquid being the *elixir vitae* of vegetation—showing life in one of the most charming forms in the phenomena of nature, especially when the deep-red setting sun makes them glisten all a-tremble with gold light; while an infinite number of minute but glistening particles of moisture bedeck the blade-surfaces in the form of gentle dew, which has risen in water-vapour from the warm bosom of Mother Earth, to refresh the thirsty plants and diffuse fragrance all around.

I wish I knew as much about one of the earliest meteorological phenomena mentioned in the sacred record,—the "mist" which "arises out of the ground" in a moist state of the earth, as, by means of the paper referred to, I now do about the dew, which is peculiar to weather in which the atmosphere contains the minimum of moisture. In Nuwara Eliya, for instance, rain and mist prevail in June, when the average mean relative humidity is represented by so high a figure as 95 deg.; dew, in its frozen state, giving hoar-frost in Feb.; the average humidity of which month is so low as 73 deg. Mr. Blanford in his valuable work on the weather and climates

quantity is useful, placed in water where logs of timber are seasoned; and that, applied in quantity and directly, it gives a dark hue to the lightest coloured wood.

I have read with interest and pleasure the very able letter, signed "A.," on Rice Culture in Ceylon, proving that whatever the force of the sentiment of regard for "patrimonial inheritance" may be, it cannot possibly account for thousands of persons, year after year, being willing, or, even if they were willing, being able to continue an unremunerative pursuit. Rice-growing must certainly be remunerative, according to the native standard of profit, or it would not be persevered in. As the writer points out, if the returns are not such as might be obtained by superior modes of cultivation, the pursuit suits native idiosyncrasy, because, if the results are moderate, so is the amount of physical labour necessary to obtain them: a few weeks of exceptional work and then months of the dearly loved *dolce far niente*. The late Mr. James de Alwis went the length of saying that Europeans often did injustice to native cultivators from ignorance of their habits. "Ye are idle! ye are idle!" has been said of them when observed sleeping during the day hours, by persons who knew not that the preceding night had been spent in labour on the fields. And it is a fact that I have personally seen the Jaffna cultivators busy raising water from wells and irrigating their fields on moonlight nights. 57 deg. and 58 deg. mean shade temperature. But on exceptional nights the temperature goes down to freezing point. For instance, in January and December 1859, the minimum nocturnal temperature went so low as 32 deg.; in February 33 deg.; in November 33 deg. 3; and in March 34 deg. Coffee trees growing in swamps, at elevations far below that of Nuwara Eliya, were sometimes blighted ("killed by frost" was the popular idea) in very clear cold weather. Of course the injury arose from air near the ground chilled by the combined effects of evaporation of moisture and radiation of heat into space. There can be cold at night and in the early mornings, intense enough to injure vegetation, without the presence of actual frost. But to return to Mr. Aitken's conclusions regarding dew. It will be obvious that dew, owing its origin always to the earth, as he has proved, is not always condensed by plants or other objects near the surface. Much of it occasionally ascends into the atmosphere, until it meets with strata cold enough to condense its minute particles. It then falls back to the earth whence it arose, if there is a calm; but if wind is blowing it may be carried and added so as to fall on surfaces so hard and dry, that obviously from them no moisture could be derived. This is the explanation of dew on arid ground and on rocks which possess no moisture or none near their surface. It follows from all that has been stated, that, unless we carefully observe and distinguish, we may be deceived by leaf-excreted moisture into assuming the presence of dew when it is absent. But I submit that when we see such subjects as spiders' webs of the most beautiful and elaborate geometrical forms made conspicuous in every detail by means of diamond-like reflections of sunlight from copious moisture on every filmy thread, we cannot be mistaken as to the existence of genuine dew which has been condensed near the surface of the earth or in one of "the fields of upper air." I believe I have correctly represented the main results of Mr. Aitken's interesting experiments as embodied in Dr. Macpherson's paper; but the paper is so interesting and in some aspects so important, that I trust you may be able to reproduce it in its entirety. In any case I cannot deny myself the pleasure of quoting the concluding paragraph, in which the scientific facts are clothed with the language of poetry, thus:—

These two facts, then, have now been established: that what was long considered to be dew is merely the exudation of vigorous plants, and that true dew rises from the ground. Brilliant globules are produced by the vital action of the plant—the liquid being the *elixir vite* of vegetation—showing life in one of the most charming forms in the phenomena of nature, especially when the deep-red setting sun makes them glisten all a-tremble with gold light; while an infinite number of minute but glistening particles of moisture bedeck the blade-surfaces in the form of gentle dew, which has risen in water-vapour from the warm bosom of Mother Earth, to refresh the thirsty plants and diffuse fragrance all around.

I wish I knew as much about one of the earliest meteorological phenomena mentioned in the sacred record,—the "mist" which "arises out of the ground" in a moist state of the earth, as, by means of the paper referred to, I now do about the dew, which is peculiar to weather in which the atmosphere contains the minimum of moisture. I always feel that above 5,000 feet here the prevalence of mists should count a good deal in qualification of our comparatively limited annual rainfall of 90 inches. That quantity must be equivalent to over 100 inches where mist does not prevail? Why does it prevail, and why is it occasionally so unpleasantly persistent, and why is mist-moisture not rapidly condensed and precipitated by the cold of the atmosphere, as dew vapour is? For above the mist line the temperature is appreciably colder than at the lower altitude, where, if mist does form, it soon "lifts" or is dissipated. But for dust in the atmosphere, we are told, rain would not resolve itself into drops, but would saturate every material thing including the interiors of dwellings as much as their exteriors. In that case does the absence of dust at high altitudes account for the frequent prevalence of the pervasive form of moisture known as fog or mist? Blanford does not help me with answers to such questions, except as answers may be found in terms so brief as the following, under the heading "Fog":—"It is a well known physical fact that two masses of air at different temperatures, and both completely charged with invisible vapour, when intermingled, can no longer hold the whole quantity in suspension; the excess must therefore be deposited as fog." But the diffused particles of moisture which constitute fog are surely not deposited? They sometimes remain suspended in the atmosphere for days. The Rev. Joseph Burnet, a very careful observer, mentioned to me the curious fact that the line of prevalent mist and of connected success in coffee culture in the Matale districts of our hill region was found to be 4,500 feet. Here the line is about 5,000 feet, and on the eastern side of the mountain system it is higher still, coffee having flourished at 5,500 in Haputale. Except in cases of bronchial affections, misty weather does not seem to be insalubrious, but on the contrary healthier than hot, bright, dry weather. It is a popular belief that, as mountains are denuded of forest, mist will disappear, but my experience does not confirm this belief. It seems mainly a question of altitude and, no doubt, of temperature of the air as the result of altitude. In cold, north-east monsoon weather, however, we often look down from our clear heights on lower ranges and valleys enveloped in a sea of white mist, I have no meteorological work at hand to refer to, except Blanford's, and the Penny Cyclopaedia is now somewhat ancient. Still the following seems worthy of quotation:—"Mist. The vapour of water, when mixed with air of the same or a higher temperature, is invisible; but when the temperature of the air is reduced below that of the vapour, the vapour becomes visible and forms a mist. * * It has been found that the quantity of vapour in the air diminishes nearly uniformly with the temperature, from the equator to the poles. But as the quantity of vapour which the air will hold at any given temperature is limited, whenever that quantity is at or near the point of saturation, a very small reduction of temperature renders the air misty, and a further reduction converts the vapour into rain."

According to my observation the mists to which we are subject up here are not often condensed into rain *in situ*. They are generally raised into the higher atmosphere, to be there, no doubt, brought into contact with strata of cold air or frozen moisture, by which they are condensed and sent earthwards again in the shape of rain-drops?

Fogs have their own merits. Some of these are noticed by Hartwig in "The Aerial World," thus:—"By preventing nocturnal radiation into space, they prevent many a tender plant from being nipped" by cold. Misty weather is also, no doubt, favourable to success of transplanting operations. On the other hand, the change to such weather as we are now enjoying is delightful, not only for its cheerful influences generally, but for the impulse it gives to flowering as well as flushing. The wealth of blossom now out is wonderful, the rose bushes being especially glorious in abundance of buds and flowers, in richness of colour and in many cases in exquisite odour. "Now is the winter of our discontent made glorious summer."

Your goodnature must have been in the ascendant, when you admitted so much controversy about a matter so plain as that a man pursuing a squirrel which he never overtakes cannot possibly go round the animal. Someone will next ask if two parallel lines cannot meet! Whatever possessed Vantovsky Renten, the philological and poetical, to father the proposition of a (pseudo) "scientific friend" that a man who goes in a circle always with his face one way and who never gyrates "turns on his axis"? I feel inclined to join the Bengalee Baboo, who execrated Sir George Campbell's *cui bono*! That for the mock scientist. As for the true poet, to him, even in his association with a strange bedfellow, I say:—

"While terra firma on its axis,
Diurnal turns,
Believe me, both in faith and practice,
Yours, —."

The propounder of the self-solving riddle has the merit of having done justice to the agility of the squirrel, however. There is one beside me as I write. Not Miss Jewsbury's "little mime and thief" of the Colombo coconut topos, which he makes musical with his metallic notes; but a grey mountain squirrel, with a long-spotted tail. To this appendage he evidently attaches much importance, dressing it carefully when he so funnily and with such care performs his toilet. He is such a dear affectionate little pet: a greatly improved edition of a monkey, with his pretty hands and his flesh-coloured nose. When awake he is incessantly in motion, and when inclined to sleep he curls himself up and wraps his tail around him. A bit of a Huntley & Palmer's biscuit gains his heart, and in an empty biscuit tin in his cage he frequently indulges his nest building instinct, packing it full of straw and then attempting to pack himself into it. When a finger is presented to him, he nibbles at it and pretends to bite, but he never does so. The case is very different with his neighbour, an Australian parrot of brilliant plumage. *He* likes to have his neck scratched and his head stroked, but in the midst of a purring noise by which he expresses his pleasure he gets tired, and then he makes no pretence of biting, but uses his nutcracker beak with emphasis. When the squirrel first came and received attention, the parrot rushed between with jealousy and anger, and now he often clings to the bars of the cage and attempts to catch the squirrel, vain attempts which the animal seems to enjoy. Indeed I think the parrot himself is actuated by the sense of fun, for, although in our quadrangle he plays amicably with the Australian magpie, he posts him-

self at the door of this bird's cage to prevent access, biting at the long legs of the "maggie." The latter, instead of using his sharp bill, takes the parrot's action all in good part.

To pass from birds to snakes, it would be very interesting to know if the snake mentioned by Mr. M. H. Thomas, which projected its venom into the Madras officer's eye, was able to do so by voluntary muscular effort, or whether, in the effort to strike, its head did not come in contact with some object which led to the spurting away of the poison? My inclination is still to doubt the power of projection. That the deadly reptiles should be provided with apparatus most efficient for the purpose of injecting a deadly fluid, seems mystery enough.

"TEA-PLANTING IN CEYLON."

TWELVE VIEWS "WITH THE SEASON'S GREETING FROM CEYLON."

Messrs. H. W. Cave & Co.'s Christmas booklet is an extremely neat production, the cover with its coloured picture of Lanka's coast, fishing-boats and palm trees which has been engraved and printed here, being fully worthy of the twelve Views (from photographs of the late Mr. M. H. Clerke of Effindale estate,) reproduced at home. The price being so low as two rupees a copy, there is sure to be a great run upon this most attractive Christmas gift. The Views include:—"General View of Estate, Bungalow and Factory, Tea Nursery, Pruning, Plucking, Weighing-in, Withering, Firing, Sorting, Sifting, Packing, Shipping." A nicer X'mas gift from Ceylon to friends at home there could not be; and if accompanied with a few lb. of good Ceylon tea, all the better. Happy thought: let our tea dealers buy up the edition from Messrs. H. W. Cave & Co. to distribute with their packets!

SCOTTISH TRUST AND LOAN CO. OF CEYLON.

The thirteenth annual meeting of the Scottish Trust and Loan Company of Ceylon was held yesterday in Edinburgh—Mr. Henry Johnston, advocate, presiding. The report showed a credit balance of £5,925, of which the directors proposed to write off a loss of £3,000 on estates. A dividend of 5 per cent was recommended. The report was approved. Mr. F. A. Bringlee, C.A., was appointed secretary in place of Mr. J. C. Penney retired, —*Glasgow Herald*, Oct. 25th.

NOTES ON PRODUCE AND FINANCE.

CONTROLLING THE SUPPLIES.—As a result of the action lately taken by the Brokers' Association, it is satisfactory to note that the supplies of Indian tea, although pretty heavy are not in excess of the quantity the dealers are able to cope with. It is to be hoped that importers, in their own interests as well as those of the whole trade, will use every endeavour to support, as far as is practicable, the efforts of their representatives in the "Lane."

TESTIMONIAL TO MR. JAMES TAYLOR.—Acting in accord with The Ceylon Planters' Association, the Executive Committee of the Ceylon Association in London has appointed Messrs. J. Whittall, H. K. Rutherford, J. L. Shand, and Wm. Martin Leako as a sub-committee to collect funds at home for a proposed testimonial to Mr. James Taylor, of Loolecondura Estate, who has played so important a part in the introduction and cultivation of tea in Ceylon. In 1862 the first considerable experiment in the

practical cultivation of cinchona in Ceylon was entrusted to Mr. Taylor. And so successfully was it conducted that in the year 1885-86 upwards of 15,000,000 lb. of bark were exported from Ceylon. In 1866 Mr. Taylor began making experiments in the manufacture of tea with leaves growing on bushes in the gardens of Loolecondura and Waloya bungalows. During the same year tea was first planted out on the former estate, the seed being obtained from plants of China tea growing in the Royal Botanical Gardens at Peradeniya. Early in 1868 Mr. Taylor received from Calcutta the first consignment of Assam Hybrid tea seed. Unfortunately these seeds failed. A second consignment arrived at Loolecondura on the first day of 1869 and with plants raised from these a field of twenty acres that had been cleared for tea in 1867 was planted before the end of the year. While these bushes were coming into bearing, Mr. Taylor was unremitting in his endeavours to perfect himself in the preparation of the leaf. And to such good purpose did he work that in 1872 he was able at once to produce a tea of such quality as not only to ensure the ready sale in Ceylon of all his produce, but also to secure the approbation of the leading London brokers. The following sums have already been subscribed:—The Right Hon. Sir W. H. Gregory, K.C.M.G., £5; Sir Alfred Dent, K.C.M.G., £5; J. Whittall, Esq., £5; H.K. Rutherford, Esq., £5; J. J. Sband, Esq., £5; Messrs. Matheson and Co., £10; Messrs. Baring Bros. and Co., £10; G. D. B. Harrison and W. M. Leake, £5; John Hamilton, Esq., £5; Messrs. Anderson Bros., £5; Norman W. Grieve, Esq., £5.

INDIAN TEA IN RUSSIA.—According to a telegram from Vienna, the Russian Finance Minister, M. Vishnegradski has proposed to the Council of State to sanction a considerable increase of the duties on tea imported from British India. The new tariff will greatly affect the British tea trade, which is carried on through Turkestan.—*Il. & C. Mail.*

CINCHONA DUTCH MARKET :

AVERAGE 392 PER CENT SULPHATE OF QUININE.

Amsterdam, October 29th.

All the analyses for the cinchona bark sales to be held in Amsterdam on November 6th have been published now, and the manufacturing bark contains about 13½ tons sulphate of quinine, or 392 per cent on the average. About 27 tons contain 1.2 per cent; 59, 2.3; 80, 3.4; 123, 4.5; 31, 5.6; 15, 6.7; 7, 7.8; 1, 8.9 sulphate of quinine.—*Chemist and Druggist.*

A GARDEN OF PAMPAS GRASS.—We read in *Garden and Florist* of a garden of Pampas-grass of 10 acres in extent, which is one of the objects of interest to tourists who visit Anaheim, California. This year about 40,000 plumes will be harvested, and the yield after the plants have become well established, will average 100,000 plumes. These plumes are worth about 5 cents apiece.—*Gardeners' Chronicle.*

PROFESSOR VAUGHAN-STEPHENS who returned from Pahang by the last trip of the S. S. "Glanggi," has covered a considerable stretch of country in the course of his recent ethnological explorations among the Sakei and other wild tribes, chiefly between the Sungai Bubau and the Kemaman river. He has brought back a large quantity of the famous ipoh poison used to tip blowpipe arrows, and also a quantity of various other barks and saps for analysis. Thirty-eight living ipoh plants have been brought down by Professor Vaughan-Stephens and have been handed over to Mr. Ridley at the Botanical Gardens. The Professor has also brought down a large number of cases of Sakei curios of sorts. In the course of his tour he has received much kindly assistance from various European officers and other residents in Pahang including Messrs. Mitchell and Wall, Mr. J. A. Bell, and Mr. McEwen (Kabang).—*S. F. Press*, Oct. 31st.

NOTES ON POPULAR SCIENCE.

BY DR. J. E. TAYLOR, F.L.S., F.R.S., &c.,
EDITOR OF "SCIENCE GOSSIP."

Dr. Cunningham's paper on the fertilisation of *Ficus Roxburghii* is creating much interest amongst botanists, inasmuch as it reveals the possibility of certain flowers having the female parts fertilised without pollen. Dr. Cunningham shows that in the above species of fig the process of ordinary pollination is impossible, and he believes that the embryo arises as an outgrowth of the cellular tissue of the body of the ovule outside the embryo sac, and not as the result of any development within it such as happens after ordinary pollination. Minute insects gain access to the interior of the fig, and these set up irritation and overgrowth, so that both male and female flowers are possibly matured by the overgrowth of the receptacle caused by insect irritation, and the embryos of the female flowers may be due to the same agency.

It is interesting to notice that your Moreton Bay pine (*Arucaria Cunninghamii*) which forms such dense forests in Queensland, and is such well-known ornamental tree in and near all Australian cities and towns, has been discovered on the recently explored mountains of New Guinea at the height of 10,000 ft. What adds to the interest of this remarkable tree is the geological fact that during the early tertiary period it was a native of England, for its leaves, fruits, &c., have been found at Bunnemouth and elsewhere, and have been described in the volumes of the Palaeontographical Society by Mr. J. Starkie Gardiner.

The phylloxera is very much abroad in France this year, and you will be all sorry to hear, in the Champagne district, it has hitherto avoided. An inspector of vine disease has been sent down to investigate and report, so you may imagine how hopeless the case is. The district between Vincelles and Treloip is that most affected.

Mr. A. W. Badger read an important paper last week before the Royal Horticultural Society on drying fruit by evaporation. Specimens were produced, and subjected to much criticism. The process, however, is an accomplished fact, but the worst remains behind. At present, drying necessarily destroys the flavour. Mr. Badger's aim was to introduce the American fruit evaporators to the notice of British fruit-growers. He claimed that evaporated fruit keeps better, and is more digestible and nutritious than when sun-dried or kiln-dried. In one district in the western portion of New York State, within a radius of 40 miles round the city of Rochester, no less than 37½ millions of pounds of evaporated fruit was produced the last season but one, realising the value of £297,000. The greater part of these crops consisted of apples. One pound of evaporated apples, he said, contained all the constituents of six pounds of fresh fruit. Only water, he declares, is lost, and this is replaced by soaking. But it was contended, in the discussion which followed, that the evaporation volatilises the aroma.

Mr. E. H. Acton has recently shown that, notwithstanding the prevalent opinion to the contrary, some green plants can assimilate carbon from certain organic compounds in the absence of carbonic acid from the atmosphere. He prepared what he calls a normal "culture solution" for the purpose, and he concludes that green plants cannot normally obtain carbon for assimilation from any substances except carbo-hydrates, but that a compound may be a source of carbon to the leaves although not to the roots.—*Australasian.*

SUNFLOWER CULTURE IN CEYLON.—We have to thank Dr. Tothill for his letter giving the results of his several experiments in sunflower cultivation in Ceylon. These are not very encouraging, although it is evident that a trial under the immediate care of a resident planter might turn out much better, and to secure an oil equal in value to olive oil is a result not to be despised, apart from the other advantages mentioned.

CROPS IN INDIA :

SEASON TELEGRAM TO THE GOVERNMENT OF INDIA.

Week ending Nov. 1st.—North-east monsoon, though late, has fairly set in and good rain has fallen in all the southern districts and in Ganjam and Nellore. Standing crops generally good, and reviving after recent rains in several districts. Want of rain and of water still felt in parts of Vizagapatam, Kistna, Nellore, Cuddapah, North Arcot, Chingleput, Salem and Malabar. Paddy in Godavari and oil-seeds in parts of Cuddapah blighted; sugarcane damaged by heavy rains in parts of Coimbatore. Locusts appeared in parts of Ganjam, Cuddapah and North Arcot. Out-turn of grains generally middling. Prices, rice and cholam rising, other grains falling. General prospects improving.

MALARIAL TROUBLES.

It is not every one who has a proper conception of what malaria means and really is. Malaria really means bad air, but for some reason, difficult to define, it has been restricted to the emanations from swampy districts. For example, a man who has fever and ague, or, as it is known among professional men, intermittent fever, is said to be suffering from malaria; whereas a man suffering from the noisome effects of sewer-gas in his house is assuredly the victim of malaria, though not suffering from intermittent fever. The fevers then, and the ailments following in their wake, that are produced in districts where there are warmth and decaying vegetable matter, are said to be malarial.

Malaria is a hydra-headed disease. Even that one form of it, "fever and ague," presents itself in various forms. It occurs most frequently in newly-populated districts; and in lands from which it has been supposed to have vanished it has been reproduced when their soil was turned. A man who has suffered once may suffer again, after a score of years, by simply running down in health. It may appear first as a chill, followed by intense fever, which, in its train, is followed by a sweating stage. It may appear simply as an intense neuralgia, and it may be noted that the most frequent form of malarial neuralgia appears over the brow, and is known as "brow ague." As if there was some similarity, distant no doubt, between paludal fevers and sewer-gas poisoning, it may be noted that neuralgic symptoms characterize both, and quinine certainly seems beneficial to both.

Formerly, quinine, and indeed all the cinchona preparations, were more appreciated than they are at present. In the whole range of medical treatment nothing ever is encountered which is more wonderful than the action of quinine in malarial fevers. With its administration, the disease disappears, and that quickly. No doubt the dwellers in old countries and the residents of old towns would derive great benefit from a far freer use of quinine, and here we should take occasion to point out that the ordinary sulphate of quinine, the form usually used, is objectionable; it irritates the stomach, is quite insoluble, and is frequently not all absorbed.

The soluble Quinine Tablets are the best preparation, inasmuch as one of them dissolves in a little water the minute it touches it. They do not irritate the stomach, can be taken without the taste being perceived, and none of the drug is lost in the system. Those suffering from enervated health, whether from sewer-gas, or marsh emanations, overwork, worry, sleeplessness, or any of the thousand ills that go hand in hand with civilization, will find quinine useful—more useful as a tonic than any of the myriad drugs that glut the market.

Under ordinary circumstances a two-grain Tablet is sufficient. In malarial troubles as much as twenty grains should be taken in a day.—"Health" London.

THE ENEMIES OF COTTON:

IN THE HAPITIGAM KORALE, CEN

No. 1. Rats dig out and eat the seeds before they germinate.

2. A fly cuts holes in the leaves.

3. A grub rolls up the leaves and lives on them.

4. A grub enters the pods shortly after they form, and eats the seeds.

5. Rats break up the pods as they approach maturity, eat the seeds, and scatter the fibre mixed with the seed husks on the ground.

Result of all those encouragements: one sound pod in fifty.

A very prolific species of ladybird swarms on the bushes, but seems harmless, living probably on some excretion of the plant.

We will be good boys and never do it again;

WIREWORM AND LIME.—A correspondent of the *American Florist*, October 1st, asserts that 3 or 4 lb. of unslaked lime to every bushel of soil to be used, will act so perniciously on the wireworms contained in the soil that they will give it a wide berth. The best way to use the lime is to spread the soil in a flat heap, say 10 or 12 inches high, and place the required quantity of lime on the surface, and when the latter is slaked, it should be pulverised and mixed thoroughly with the soil.—*Gardeners' Chronicle*.

ARTESIAN WELLS AT MADRAS.—A bore at Negapatam has been sunk to a depth of only 200 feet which in the country of Artois itself would have been considered extremely moderate and far below the average. With a bore of this depth the water rose to within one foot of the ground surface, thus practically demonstrating that an artesian spring had been struck. In the Madras Presidency at least wells have not been bored to any great depth and great advantages might accrue if the Negapatam Councillors persevered in their efforts to sink the bore deeper, even though it may not be clear to them that better results would be achieved. The Government order on Dr. King's Report promises help from Provincial funds as an inducement to the Councillors to continue work. As it now stands the well is a success in as far as the two essential requisites of a water-supply, namely, quality and quantity, have been secured.—*Pioneer*.

"CLEARING THE AIR" OF DISEASE GERMS.—We referred the other day to thunder "clearing the air" in connection with our first thunderstorm of the North-East Monsoon season. But we are reminded by a scientific writer that heavy falls of rain also "clear the air" especially when accompanying a thunderstorm. A Home writer says:—

Copious thunder-"plouts" level to the earth the millions of disease-germs that impregnate the atmosphere. It has now been acknowledged that near a large town the average number of bacterial micro-organisms is in summer about 500 per cubic yard. Of course, in a town the number is about sevenfold. Now the heavy rains carry these germs to the ground. After very dry weather, a cubic yard of rain has been found to contain 150,000 organic dust-germs, besides an enormous quantity of inorganic dust-particles. In a filthy town, no less than thirty millions of bacteria in a year will be deposited by the rain upon every square yard of surface. No wonder, then, that scientific men welcome the thunderstorm, which by the heavy showers removes from man and beast the terrible floating nuclei of disease and death. During the twenty-four hours before a thunders'orm, a man will require to breathe 37,500 bacteria, more or less active agents of sickness, besides millions upon millions of dead organic and inorganic dust-particles—a fact which makes one really marvel how he can possibly escape; yet, after the deposit of these germs by the joint action of tumelic current and copious rains, the air is far more wholesome.

ARTIFICIAL GEMS.

Mr. Charles Bryant writes to the *Standard*:— I notice that in a recent issue Mr. Greville Williams, of the Gas Light Company, has manufactured a perfect emerald from the refuse of a gas retort, and that he could in like manner produce other precious stones; but fortunately, as you state, the cost of producing them would be prohibitory, and this is one reason why those who possess jewels need not entertain the least fear that their gems are about to become diminished in value, if not absolutely worthless, by the artificial production of precious stones, because there is virtually nothing new in Mr. Williams's discovery—precious stones having been artificially produced more than sixty years ago, and with all the experiments that have since been made by eminent chemists, the results have been very far from successful in a commercial sense.

It may be interesting to many of your numerous readers to know that several kinds of precious stones have been actually produced by artificial methods, endowed with all the chemical and physical characters of Nature. In 1837 Gaudin produced rubies by heating ammonia, alum, and potash by means of the oxyhydrogen blow-pipe, the intense heat developed by this apparatus volatilising the potash and the alumina, then crystallising in rhombohedral forms identical with those of the natural stone, and having the same specific gravity and hardness. Ten years before Gaudin's experiments Berthier produced a great number of minerals, such as peridot, pyroxene, &c.

The spinel has been produced so perfectly as to be indistinguishable from the natural gem, by subjecting a compound consisting of proper proportions of alumina, magnesia, chromium, and boric acid to a high temperature for several days, and later experiments founded on the principle of Dabree and Durocher have resulted in the production of crystals of white, blue and red corundum, *i.e.*, colourless sapphires, blue sapphires, and rubies. Crystals of chrysoberyl I have produced by subjecting the fluorides of aluminium and glucinum to a very high temperature.

Attempts have been made to produce the diamond artificially, but the specimens obtained have been so extremely small as to be of no use, and the results obtained do not differ much, so far as success goes, from those of the alchemists who sought for that imaginary substance, the philosopher's stone, in the hope that they could make gold out of the baser metals, and although the attempts at reproducing many of the precious stones have been met with a certain amount of success experimentally, no one is likely to take upon himself the trouble and expense of so unprofitable a business, commercially, as producing artificial precious stones.

Ten years have now elapsed since Mr. Hannay, of Glasgow, succeeded in producing, at much cost and great danger, artificial diamonds, by enclosing a mixture of paraffin spirit and bone oil distillate with metallic lithium in a strong wrought iron tube, and exposing it to a prolonged heat in a reverberating furnace. The success which followed was undeniable. The result was diamonds, but they were of such small size as to be practically worthless, even could they have been generated by a cheaper process especially as it was found that when placed on the cutting wheel they immediately crumbled. At the same time, if anything is certain, it is that eventually by means too simple even to be foreseen, noble crystals of a gem still precious in spite of South Africa will be manufactured in the laboratory, as a price so low that they and the prismatic pendants of the chandelier may be

rated at much the same value. But the diamonds and the other precious stones came into different categories. The one is a pure substance, the others are mixtures of various mineral matters. The moment that Smithson Tennant proved, nearly one hundred years ago, that the diamond was merely carbon, the crystallisation of this element, which is one of the most widely distributed in nature, was simply a question of chemical manipulation. And the processes of the arts have of late years undergone such vast improvements that it is impossible not to believe in the eventual solution of the problem which in Mr. Hannay's hand was only a *succès d'estime*. But we may be well assured that the fortunate man who first sees the gems glittering in his crucible will not be in any hurry to take the Royal—or any other—society into his confidence. Unless differently constituted from the rest of his species, he will utilise the victory at which he has arrived for his own enrichment.

Most of the precious stones are, however, complicated mixtures of ingredients of which the mechanical disposition, as in mossagates and other pebbles, cannot always be exactly ascertained, while the precise percentages of the substance to which they owe their varied hues have often defied the chemist's analysis. Thus the gem which Mr. Williams has modified from the refuse of the Gas Light Company's retorts is composed of about sixty-seven to sixty-eight per cent of silica, fifteen to eighteen of alumina, twelve to fourteen of glucina, minute proportions of magnesia, carbon and carbonate of lime, while the intensely green colour for which the jewel is valued is believed to be due to a slight dash of sesquioxide of chromium, though this tint has by some chemists been attributed to vegetable matter, the analyst having to proceed warily when dealing with such costly stuffs as diamonds and emeralds. We may, therefore, presume that Mr. Williams has turned out his artificial emerald by skilful fusing and crystallisation of these ingredients. It is also permissible for us to imagine that in time he will simplify his process, until the Gas Company's "superior six carat" stones set in fourteen carat gold will be recommended to thirty dandies at a price which will defy competition, even though the profits from this branch of the business do not add materially to the dividends of the shareholders. Still as Mr. Bryant says, Mr. Williams's experiments, if interesting, are not in themselves unprecedented, except that they have resulted in the concoction of a gem not hitherto produced by the same means. For crystals of chrysoberyl have been turned out by subjecting the fluorides of aluminium and glucinum to a very high temperature, and early in this country Berthier fabricated a great many minerals, including peridot (chrysolite), pyroxene (augite), and others not of any economic importance. Colourless sapphires and blue sapphires are among the triumphs of the laboratory. But most remarkable of all, rubies of excellent hardness and hue have been produced by a process of synthesis under the action of fire, though it is doubtful whether this was the means by which they were originally crystallised in the earth's crust. As far back as 1837 Gaudin produced the ruby on a small scale, by exposing ammonium-alum to the heat of the oxyhydrogen blowpipe. By the intense heat, thus generated he obtained fused alumina which is readily coloured by the addition of oxides of chromium, the crystals appearing in the rhombohedrals and characteristic of the mineral, and having the same specific gravity and hardness. At a later date, Ebelmen arrived at much the same results by a different method. He dissolved alumina in boric acid at a high temperature, and on the cooling of the mass

obtained the alumina in a crystallised form, and if chromate of ammonium was present the crystals were to all intents and purposes rubies. Again, Sainte-Claire, Deville, and Caron heated fluoride of aluminium, fluoride of chromium, and boric acid, and in this way obtained fluorids of boron, which escaping in a volatile condition left a residue of solid alumina coloured by the chrome.

These results, it may rightly enough be urged, were mere laboratory experiments. But the manufacturer of precious stones has gone a great deal further than this stage, and it is certain will proceed far beyond the milestone at which it is at present resting. For in 1878 Frey and Feil reproduced the ruby and sapphire on a large scale, by heating in a fire clay crucible a mixture of alumina and red lead. The result of this fusion was a vitreous silicate of lead (the silica being derived from the crucible) and crystallised alumina. When to this bichromate of potassium was added, the alumina assumed the desired tint of the ruby. By this process spinels have been produced quite undistinguishable from the natural gems, even when the most minute tests were applied to them. It cannot, perhaps, be claimed as yet that such laboratory jewels will satisfy all the requirements of the cutter and polisher, but when this point has been once attained, it is certain that they will soon run the real, or rather the old fashioned, article very closely. The most pessimist of seepies cannot carry his prying so far as to apply the test of the knife-point for hardness of the acid for composition of the dichroscope for "pleiochromism," or ask the wearers to allow their jewels to be weighed for specific gravity in Sonstadt's solution. And if not, who need trouble themselves further? Family diamonds are costly articles to keep simply for the gratification of the owner's knowledge that they were dug out of the mines of Golconda or of Minas Geraes, and they would soon be locked up in safety if a set externally identical could be bought at a twentieth of the price. Already, in fact if only a portion of the tales told are true, prudent people are growing loth to keep in their jewels cases exposed to the risk of robbers, convertible securities representing an income of four or five hundred a year, when the ingenious artists of the Palais Royal can supply something undistinguishable from them for a very moderate number of francs. These jewels, which are mere imitations, not chemical reproductions like the gems mentioned, far surpass the old paste mimeries, their only fault being that if anything they sparkle rather too brilliantly. Some of them of which the basis is glass, are rather coarse. But there are others of such amazing perfection that an amateur runs serious risk in buying from unknown dealers on his own unassisted judgment. Amethysts in an especial degree have been made so fine that they have deceived connoisseurs, and numbers of them are regularly exported to Ceylon, where they are duly disposed of to the unsuspecting passengers of steamers halting at Colombo. Since the decrease in price of the real stones the danger of imposition is less, yet a case occurred not long ago in which a jeweller declined to pronounce on the value of a "stone," until he had submitted it to an expert, when it was pronounced one of the Parisian sort.—*Indian Agriculturist*.

THE AUSTRALIAN "SHE-OAK" (*CASUARINA*) is prospering in Aberdeenshire. "Old Colonist" who considers it the very best firewood the world produces, reports that from seed gathered by him in Tasmania, trees are now flourishing on Deeside and their growth is equal to 18 inches in the twelve months.

PADDY (RICE) CULTIVATION IN CEYLON.

We call attention to the able letter on page 462, in which Mr. Elliott—in his own name—justifies his position in reference to the recent experiments and discussion connected with Paddy Cultivation. There can be little doubt that Mr. Elliott has a more intimate and practical acquaintance with his subject than any of his critics—whether official or unofficial—and we may say than any other public servant in Ceylon. He has been consistent too in, for many years, upholding the view he has adopted and while our own inclination has been to limit the profitable cultivation of paddy to select divisions of the country—a limitation in which to a great extent no doubt, Mr. Elliott agrees—yet, we are bound to confess that he has given us reason to believe that rice cultivation is far more widely profitable in Ceylon than we had at all believed before Mr. Elliott engaged in experiments or wrote expressly on the subject.

WESTERN AUSTRALIA is certainly the coming Colony if, as a telegraphic report has it, an expert values its forests alone at a hundred millions sterling, as their present marketable value. We in Ceylon should be greatly interested in our nearest neighbour; for as its population leaps up by thousands and perhaps hundreds of thousands, we ought to do a good trade in supplying them with all the tea, cocoa &c., they require.

ELECTRIC LIGHT EFFECTS ON CANE GROWTH.—As it is a well known fact that the growth of cane or any other vegetation depends perhaps as much upon light as on heat, and that a large amount of sunshine is very desirable to secure the rapid growth of cane, the thought has been suggested that electric lights may yet be used to advantage to promote the growth of sugar in this latitude, where forcing is desirable if not absolutely necessary. At first thought, almost any one would be inclined to ridicule the idea. Still, we notice that our tropical exchanges consider that when they have storms that electricity plays an important part in the growth of cane. Is it not possible that where many electric lights are used, that the air to a certain extent becomes charged with that powerful element? If not, certainly light has great influence on vegetation, as science has proven; and this brings the thought that the "moon philosophers" may be partly right in their planting theories—or, that the light of the moon may produce that effect on vegetable growth that they attribute to something else.—Our attention was recently called to this subject by a friend, who said he thought he saw a greater leaf development on trees and shrubs on the side adjacent to electric lights. Later, he made the following clipping from a technical journal, which shows that it is a fact—and possibly a most important one for cane growers—that electric light has great influence on vegetable growth:—"A beautiful illustration of electric light on plants was recently given by Dr. Siemens before the Royal Society of England. He placed a pot of budding tufts in the full glare of the electric light in the meeting room, and in about 40 minutes the buds had expanded into full bloom. In giving a statement of some of his experiments, Dr. Siemens said that he had planted a number of quick growing seeds in pots, and divided the pots into four groups; one group he had kept entirely in the dark, another he had exposed to the influence of the electric light only, another to the influence of daylight only, and another to electric light and daylight in succession. Death soon resulted to those plants which were kept entirely in the dark; those exposed to the electric light only, and those exposed to the daylight only, thrived about equally; and those exposed to both day and electric light thrived much better than either."—*Sugar Bowl and Farm Journal*.

MANURE FOR THE GARDEN.

A capital little essay on the use of nitrate of soda for manure, and the best mode of its employment, has just issued from the able pen of Mr. Joseph Harris, M.S., of New York, of which we will give some extracts, specially written for gardeners.

Farmers and gardeners sometimes express surprise that agricultural chemists talk so much about nitrogen. When it is known, however, that of all the organic matter of plants and manures—in other words, all the matter which is driven off by burning—the only element of any direct value as plant-food is nitrogen, it will be readily seen that nitrogen is entitled to even greater attention than it at present receives.

Gardeners and fruit-growers fully recognise the value of stable and farmyard manure. In a ton of ordinary manure, containing 75 per cent. of water, there is 1275 lb. of organic matter and 225 lb. of ash. Except for its mechanical and indirect benefit to the soil, all the manurial value of this quantity of organic matter is due to the nitrogen which it contains. Is it any wonder, therefore, that we hear so much about nitrogen?

NITRATE OF SODA FOR ONIONS.

An average crop of Onions removes from the soil about the same amount of nitrogen as an average crop of Turnips; but a crop of Onions will often sell for three, or four, or five times as much as the latter.

On Mr. Harris' farm, Onions are extensively grown, and he finds it necessary to make the land exceedingly rich, especially in nitrogen and phosphates. And of all manures for producing a large crop of Onions, nothing equals nitrate of soda.

When this manure was first used, 250 lb. per acre were sown early in the spring, before drilling-in the Onion seed, with 500 lb. per acre of superphosphates. As soon as the young plants appeared, it was the custom to go through them with the hoe to break the crust and kill the weeds, and then sow 250 lb. more of nitrate. In two or three weeks, another 250 lb. per acre was sown. The effects were found to be astonishing; no amount of ordinary manure that could be worked into the soil the first season would produce so great a growth. Latterly it has been thought quite as well to sow the nitrate broadcast all at once, about the time the seed is sown.

WHY IS IT FOUND NECESSARY TO USE SO MUCH MANURE IN THE GARDEN?

Reference has been made to the great benefit derived from the use of nitrate of soda on Onions. There is a common opinion that the longer Onions are grown year after year, on the same land, in market gardening, the better will be the crop. Enormous quantities of dung are applied every year. This supplies nitrogen, phosphoric acid, potash, and other ingredients of plant-food far in excess of the amount removed with the crop. And yet it is found necessary to furnish a heavy dressing of manure every year; and if this be not done the crop is poor and unprofitable.

The same is true of early Cabbages and early Cauliflowers. It is found necessary to use enormous quantities of manure for these crops—far in excess of the plant-food removed in the crop. Gardeners who make a specialty of growing large areas of early Cabbage, find it almost impossible to make the land rich enough the first year; they find that the second or third crop, grown and manured every year on the same land, is better and earlier than the first crop.

An experienced American gardener recommends the application every year of 75 to 80 tons of stable-manure per acre for early Cabbage, and 10 tons per acre for late Cabbage. This 75 tons of manure contains 820 lb. of nitrogen, or as much nitrogen as 5,100 lb. of commercial nitrate of soda probably contains.

Ten thousand early Cabbage per acre, weighing 5 lb. each is a good crop.

These Cabbage (25 tons per acre), contains 120 lb. of nitrogen, equal to 750 lb. of nitrate of soda. In other words, gardeners use nearly 7 lb. of nitrogen in the form of manure to get back 1 lb. of nitrogen in the crop.

It is now known that the nitrogen in the organic matters of the soil or manure is slowly converted into nitric acid by the growth of a minute organism, apparently a micro-coccus. This micro-coccus cannot grow if the soil be too cold, or too wet, or too dry, or in the absence of lime or an alkali.

As a general rule, there is no lack of lime in the soil, and the other conditions necessary for the conversion of the nitrogen into nitric acid, are warm weather, and a moist porous soil.

In the early spring the soil is too wet and too cold for the change to take place; we must wait for warm weather. But the gardener, who grows for sale, does not want to wait; he makes his profits largely from his "yearly" crops. Guided only by experience and tradition, he fills his land with manure, and even then he gets only a moderate crop the first year. He puts on 75 tons more manure the next year, and gets a better crop; and another 75 tons the next year, and gets a still better crop. The nitrogen of the soil, or of roots and plants, or dung, is retained in the soil in a comparatively inert condition. As it is slowly converted into nitric acid during warm weather, the plants take it up and grow rapidly. Unfortunately, however, if we have no plants growing in the autumn, and there is much nitric acid left unused in the soil, the rains of winter and early spring wash out a large proportion of it, and it sinks into the subsoil.

How, then, is the market gardener to get the nitric acid absolutely necessary for the growth of his early plants? He gets it, as before stated, from an excessive and continuous use of stable manure, and even then he fails to get it in sufficient quantity. One thousand pounds of nitrate of soda will furnish more nitrogen to the plants early in the spring than the gardener can get from 75 or 100 tons of well-rotted stable-manure. The stable manure will furnish nitric acid for his later crops; but for his early crops, the gardener who fails to use nitrate of soda, is said to be blind to his own interests.

The same remarks apply with equal force to Celery plants. For several years, the writer has grown over a million Celery plants a year. By the use of an enormous amount of rich manure, he was able to grow good outdoor Celery plants.

Eight years ago, he used nitrate of soda cautiously as a top-dressing, and the effect was most satisfactory. The next year, having more confidence, the nitrate was sown with the seed, another dressing was given after the plants came up, and twice afterwards an application was made during rain. Instead of finding it difficult as before to get the plants early enough for the Celery growers, who set them out, they were ready three weeks before the usual time of transplanting.

At the four applications, about 1,600 lb. of nitrate of soda per acre was used, and this would probably furnish more nitrate acid to the plants than they could get from 500 tons of stable-manure, provided it had been possible to have worked such a quantity into the soil. It was said that never were finer plants grown; and compared with the increased value of the plants, the cost of the nitrate is stated not to be worth taking into consideration.

The next year the same treatment afforded equally good results, though it was noticed that on part of the land where Celery plants had been grown the previous year, and followed afterwards by a crop of late Cucumbers for pickles, and the land again sown to Celery in the spring without manure, the plants were not so good as when dung, as well as nitrate, was used.

It is now the aim to dung the land in the autumn, and use nitrate of soda in the spring. In other words, nitrate of soda is not used as a substitute for dung, but as a highly prized and invaluable addition.

NITRATE OF SODA AND DROUGHT.

Celery is a semi-aquatic plant. It delights in an abundant supply of water. But it is found that nitrate of soda is in part a substitute for water, and the same is true of many other plants. In the dry climate of America, Pansies are supposed to require a damp soil or large supplies of water. But it has been found that

nitrate of soda, even on dry, sandy soil will produce a luxuriant growth of plant, and a profusion of the largest and most brilliant flowers. The effect of this manure on the growth of the *Convolvulus* bine, and the colour of the leaves, and the size and beauty of the flowers, is said to be most remarkable. The effect on *Asters* is equally satisfactory.

NITRATE OF SODA FOR STRAWBERRIES, CURRANTS, AND RASPBERRIES.

The Strawberry grower knows the value of water. If he will try nitrate of soda he will find it wonderfully efficacious.

The effect of this fertiliser on Strawberries in the dry climate of the United States is very beneficial. It not only doubles or triples the yield, but the berries are larger and handsomer, and consequently command a much higher price in the market.

No ordinary amount of manure will produce so great an effect, for the reason that the plants grow and form their fruit early in the season. The nitrate furnishes the plants with nitric acid before the nitrogen of ordinary dung can be converted into this essential ingredient of plant food.

A few years ago, Mr. Harris, published a statement in regard to the astonishing effect of a large dressing of nitrate of soda on an old Strawberry bed. The bed had been neglected, and was full of grass and weeds. At that time nitrate of soda had not been tried on Strawberries, and it was not known but that might injure them. But this particular bed was so run out and worthless, that no anxiety was felt whether the nitrate killed the plants or not.

Two or three heavy dressings were sown broad-cast, early in the spring and a few weeks later. Instead of killing the plants, the nitrate made them grow so vigorously that with a little assistance from a sharp hoe, and by pulling out the large weeds, the Strawberries overpowered nearly all the grass, and remarkably fine crop of fruit was obtained.

Since that date nitrate of soda and superphosphate has been used on all Strawberry plantations, and this dressing is found far more effective and economical than stable dung.

Another instance is given of an old Strawberry bed, in its fifth year of bearing, which was in an exhausted condition and foul with weeds. This was dressed in the spring of 1888 with 300 lb. of nitrate of soda per acre. The effect was amazing, for this bed of $1\frac{1}{2}$ acre, from which hardly anything was expected, gave fully 7000 quarts of Strawberries. The description was variety Crescent, with fertilising rows of Wilson, Sharpless, and others. The crop was nearly as large as the best the plot had made. This was on moist bottom-land, naturally fertile. Nitrate of soda is, at least, equally as good for Raspberries as for Strawberries. On Currants, with clean cultivation, large crops of fine fruit have been raised for several years, with a top-dressing of nitrate of soda alone, applied on each side of the rows early in the spring.

On poor land it is recommended to apply superphosphate and potash in the autumn, and plough or cultivate them in; and the following spring—and, in fact, every spring—give a top-dressing of nitrate.

NITRATE OF SODA AND WEEDS.

From what has been said about the effect of nitrate on the old grassy Strawberry-bed, it must not be inferred that this substance will kill weeds and nourish wholesome plants. Nitrate of soda, properly used, makes "rich land;" and it is known that weeds, if they have the chance, will grow luxuriantly in rich soil. It is also well known that a light, thin crop, favours the growth of weeds, while a heavy, "smothering crop," will hold them in check. Much depends on whether the crop or the weeds get the start. Hence, it is of vast importance to make the land as clean as possible before sowing the crop, and to keep down the weeds by the frequent use of the cultivator and hoe. If this is done, nitrate of soda will make the crop grow so rapidly that it will smother or check the weeds. On the other, if this is not done, the weeds will prove better fighters than the crop we want to raise, and

they will secure the lion's share of the nitrate, and with the nitrate they will also appropriate other plant food and moisture, and thus the nitrate, instead of helping the crop, may actually injure it. There will be a large total growth of vegetation, but it is vegetation of the wrong kind.

NITRATE OF SODA FOR TOMATOS.

Professor Voorhees, of the New Jersey experiment station, made experiments with different fertilisers on Tomatos in 1889. The trials were made on the farm of Mr. C. M. Housell, an intelligent practical gardener, who attended to all the details. The results were as follows:—

Manures used per acre.	Cost of Manures		Value of the crop per acre.
	Dols.	Dols.	
Without manure...	271-88*
20 tons stable dung	30	291-75
8 tons stable dung and 400 lb. complete fertilizer...	15	317-63
160 lb. nitrate soda alone...	4	361-13

The above manures were all applied May 7. On an adjoining plot, 160 lb. of nitrate of soda was sown May 7, and again on June 12, when the Tomatos were beginning to set; another dressing of 160 lb. was sown on the surface around the plants. This plot produced a crop which sold for 369 dols. per acre.

The first dressing of 160 lb. of nitrate yielded a profit of 85-25 dollars per acre; the second dressing of 320 lb. produced a profit of only 3-87 dollars per acre.

It is evident, therefore, that 160 lb. of nitrate of soda per acre was all that the plants needed, or could make use of without a greater supply of phosphoric acid and potash than the soil afforded.

In addition to the above experiments, Professor Voorhees made others that are worthy of consideration. The results may be tabulated as below:—

	Manures per acre and date of sowing.	Cost of Manure.		Value of crop per acre.
		Dols.	Dols.	
A.	Without Manure	271-88
B.	160 lb. Muriate of Potash	284-25
C.	300 lb. Superphosphate	7-2		
	Same as B. with 600 lb. Nitrate Soda, May 7	11-2		356-63
D.	Same as C. with 160 lb. additional Nitrate, June 12	15-2		429-38
E.	Same as B. with 320 lb of Nitrate, May 7	15-2		395-25

It will be seen that the addition of phosphates and potash to the 160 lb. of nitrate soda had no effect. The reason for this is, that the soil could furnish enough phosphoric acid and potash for all that the crop produced by the 160 lb. of nitrate required. But when an additional 160 lb. of nitrate was used, then the phosphoric acid and potash came into play, and the crop brought 429-38 dollars per acre.

It will be seen further, that the 320 lb. of nitrate applied May 7 on Plot E., did not have as great an effect as the same amount of nitrate of soda applied at two dressings, on Plot D.

It may surprise many gardeners that 20 tons of good stable manure did not produce as large a crop of Tomatos as 160 lb. of nitrate of soda. The 20 tons of dung contained not less than 160 lb. of nitrogen, while the nitrate of soda contained only 25 lb. And that the great effect produced by the nitrate of soda was due to the nitrogen, there is abundant evidence.

Why then, did not the 160 lb. of nitrogen in the dung do as much good as the 25 lb. in the nitrate? Simply because the nitrogen in the dung has to be converted into nitric acid before the plants can use it. —J. J. WILLIS, Harpenden.—*Gardeners' Chronicle.*

Correspondence.

To the Editor.

ENEMIES OF COFFEE AND REMEDIES.

London, Oct. 24th.

DEAR SIR,—Following my letter to you of last mail on the subject of the application of solution of sulphate of copper to our coffee trees for extermination of the pests by which trees are beset, I now write to enclose copy of a letter I have received from Messrs. W. and A. Gilbey, the large wine merchants here, giving interesting and valuable information concerning the subject in question, and I am yours faithfully,

for THOMAS DICKSON,
W. G. SMITH.

Oxford Street, London, W., Oct. 20th.

Thomas Dickson, Esq., Managing-Director, The Scottish Trust and Loan Co. of Ceylon.

Dear Sir,—In reply to your letter of 16th inst. on our estate in the Medoc we use a solution of sulphate of copper for the purpose of destroying the mildew or white fungus which forms on the underside of the leaves of the vines. It is not applied to the roots but solely to the leaves. Other preparations are applied to the roots for the purpose of combating the Phylloxera, which however is an entirely different pest. The method of applying the solution of sulphate of copper was formerly to sprinkle it over the vines by means of a broom, but a more effective way is to use a force pump fitted with a fine rose. A shower of solution is allowed to fall on the upper surface of the leaves which gradually spreads over the whole surface of the plant. The solution is prepared in the following manner:—Dissolve 4 lb. sulphate of copper in 3 gallons of warm water. Slake 2 lb. of quick lime, and when cold put the lime into the solution of copper. Add to the whole 20 gallons of water and stir up well. (Pass the lime through sieve to separate gravel, etc., which might choke the syringe used for distributing.) This mixture is called Bouille Bordelaise and is prepared sometimes with cold water, and recently we learn that the addition of 1 lb. of molasses has been found to be an improvement. For vines about 30 gallons per acre are used for the first treatment say, in June, and 40 to 50 gallons for the second treatment 4 or 5 weeks later. Before distributing the liquid should always be well stirred. Sulphate of copper is dangerous to human life and consequently all experiments must be made with care. Applied to the vine in the manner indicated we find that the wine is not affected, but it is quite possible that the coffee berry might retain a percentage of the copper if strong solutions are used. A weak solution only is always applied when the leaves are young and tender. No solution should be applied for two or three weeks before the crop is gathered. If we can give you any further information on the subject we shall be happy to do so on hearing from you, or our friend Mons. Skawinski of Lesparre would no doubt give you full details as to prices of materials, syringes, etc., if you communicate with him. His full address is:—

Mons. Theo. Skawinski,
(Société Medocain)
72, Rue Jean Jacques Rousseau,
Lesparre, France.

—We are, dear sir, yours faithfully,
(Signed) W. & A. GILBEY.

INDIAN TEA EXPORTS.

Indian Tea Association, Calcutta, Nov. 15th.

DEAR SIRS,—The General Committee have the pleasure to hand you their usual Monthly Return of shipments of tea from Calcutta, and also a Return of Exports of Ceylon Tea for four years up to the 23rd October 1890.

EXPORTS OF INDIAN TEA FROM CALCUTTA.

	1890 lb.	1889 lb.	1888 lb.
Exports to Great Britain in Oct. ...	15,544,159	14,854,553	12,967,076
Exports to Great Britain from 1st May to 31st Oct. ...	55,959,410	55,669,073	52,992,558
Exports to Australia and New Zealand in Oct. ...	409,972	149,143	446,731
Exports to Australia and New Zealand from 1st May to 31st Oct. ...	2,703,418	1,956,540	1,791,298
Exports to America in Oct. ...	10,810	13,200	906
Exports to America from 1st May to 31st Oct. ...	72,882	104,017	61,025
Exports to other places in Oct. ...	145,456	54,544	40,157
Exports to other places from 1st May to 31st Oct. ...	671,733	1,116,143	538,587
Total Exports from 1st May to 31st Oct. ...	59,407,442	58,845,803	55,386,463

—Yours faithfully, S. E. J. CLARKE, Secretary.

MR. JOHN HUGHES AND CEYLON TEA

ANALYSES.

London, E. C., Nov. 7th.

GENTLEMEN,—Just a few lines to direct your attention to an interesting lecture on tea by Mr. Richard Bannister published in the Journal of the Society of Arts of October 31st which I believe you regularly receive.

After a review of the rise and progress of the tea industry generally in China, India and Ceylon, there are some practical remarks on tea-making, and tea analyses.

Only two complete analyses however are given, which is a matter of regret, inasmuch as these show considerable difference in the proportions of Tannin and Cellulose (Woody Fibre). Thus a sample of Congou gave 16.40 per cent of Tannin as against 27.14 in a sample of young Hyson—while the Cellulose was 34.00 in the former and only 25.90 per cent in the latter.

There are some 19 samples of Ceylon Tea reported upon by Dr. Paul, who however only examined them as regards the amount of moisture and Theine which they contained, and in which the variation was very small and therefore of little practical importance. The highest Theine was 4.54 per cent in a sample from Nahalma estate, and the lowest 3.22 in some Calsay Pekoe Souchong.

When we consider that Theine is an alooid which has very little flavour, though possessing powerful medicinal properties, it will be at once understood that a difference of 1 per cent cannot possibly influence the tea taster in his valuation of different samples for market purposes, and that any attempt to estimate the probable commercial value from the percentage of Theine found by analysis would be quite useless. From the two complete analyses mentioned above, however, there does appear to be a great variation in the proportion of Tannin which from my new experience, I am inclined to regard as the constituent which influences the strength of tea infusions more than any other, while we may regard the quality and

TEA EXPORTS from Japan have this year been very large, amounting (according to native papers), up to the 15th ult., from Kobe and Yokohama to, 6,700,000 cattie—the largest total reported in the history of the ports. From Yokohama alone the export exceeded 5,383,000 cattie.—*China Mail*.

quantity of the volatile oil as the chief factors in producing a difference in the flavour and bouquet.

It is in reference to these two constituents I submit that more extended information is still required, and with these few remarks I commend the lecture to the careful perusal of the readers of the *Tropical Agriculturist*.—Yours faithfully,
JOHN HUGHES.

PADDY (RICE) CULTIVATION IN CEYLON

MR. ELLIOTT IN REPLY.

Batticaloa, Nov. 18th.

DEAR SIR,—I have read "A." 's letter on paddy cultivation with pleasure; he is evidently a worker in the same field as I am and a professor of the same belief as I hold, viz., that "paddy does pay" and no mistake. He has most opportunely published a very able resumé of what may be called the circumstantial evidence on the subject. The facts he sets out seem to my mind to be consistent with the conclusion he draws and inconsistent with any other rational conclusion. He thus fulfils the requirements legally required of such evidence, but forgets "there are people who are not ready to lend an academic faith to a narration of facts which do not strictly accord with preconceived opinions, mistaken for knowledge. In all ranks and conditions of life, persons of this stamp abound and the errors to which their habits of distrust expose them are at times ridiculous."

So says an eminent authority, and it is because I have found the circumstantial evidence not generally accepted that I have endeavoured to go a step further and see what direct evidence on the point could be brought forward. But "A." (and others) have misunderstood the scope of my subsequent action and the object I have in view in securing the publication of the results of the experimental cultivation I have had opportunities of undertaking. I therefore address you in my own name to set myself right with the public and, I trust, show that my experiences have a more important bearing on the subject than is recognized by your correspondent.

For years the dictum of Sir Charles Layard had been accepted as almost settling the question that paddy did not pay, and this view was supported by the particulars of the cost of production published in a book by the late Mr. Leopold Ludovici and adopted (if my memory serves me right) by "Speculum" who now in another sphere emphasizes the erroneous views he early adopted on an imperfect investigation of the matter. Over twenty years ago, I had reason to arrive at a very opposite conclusion, and as my enquiries showed the data heretofore made public were defective and misleading I ventured to work up the information I had gradually gathered into the paper I read before the Ceylon Branch of the Asiatic Society in 1885. I have every reason for believing that my paper was the first intimation a large number of the community had received that there was something to be said on the other side and that Paddy Cultivation was not the miserable speculation it had been so long represented.

The results then published were founded on enquiries made from native sources and based on estimates of working expenses. Since that I have had opportunities of actually cultivating paddy and have published the results of my experience. I do not say that these are on all fours with native modes of cultivation: on the contrary I have always admitted that *ceteris paribus* the "dry ploughing" system introduced by Mr. Green gives a larger crop than the best ordinary native mode of working, and

of course the primary object of the experiments has been to "show the way" to our native cultivators. Here and there we have succeeded in influencing a few, and by hammering away we may induce more imitation in time; at present the excuse is "Oh! we cannot afford to work so expensively as you do," and when we point to the larger return as compensating for the additional outlay, the reply still is "Oh! it will not pay us."

The first fact, therefore, established by my experiments is that I am working far more expensively than does any native in the country including all the so-called extortionate rates of interest (which are not so heavy as they appear on paper I may add). The next point I have established is that working on a ready money basis and paying for all services, an outlay of R16 to R17 is the outside limit of the actual expenses of cultivation of an acre of land.

With these two points established, we are able to absolutely deny the correctness of the estimates of the expenses in excess of these figures we see put forward continually: such, for instance, as that given by Mr. Panabokka to the Grain Committee when the cost of cultivating two acres of land at Ratnapura is given at R107.96. Another point on which our experiments throw light is that it is possible with the expenditure stated to secure in irrigated land a profit over working expenses of about R20 an acre, to cover interest on the capital outlay, superior supervision and other expenses attendant on extended cultivation. There is no room to doubt that it is quite possible to cultivate the same land twice a year if the water supply is assured.

Such are the facts which I think the experience I have gained actually establishes; and they are I think useful factors in the discussion of the question whether paddy pays. I am also not without hopes that the information I have given may not be without its influence in encouraging capitalists to seriously undertake the extended cultivation of paddy on a money payment basis. I regret I cannot for their sake add from personal experience the cost of converting jungle land into paddy fields, but I may state that my enquiries go to show that a capital outlay of R40 would be sufficient including the purchase from Government at ordinary upset price.

I could write much more as to my views on Paddy Cultivation, but this lies outside the intention of this letter, and so I shall add no more at present.—
Yours faithfully,
E. ELLIOTT.

IS FORKING OR DIGGING ABOUT TEA ADVISABLE?

THE RESULTS OF PRACTICAL EXPERIENCE ASKED FOR.

Central Province, Nov. 25th.

SIR,—As perhaps you are aware, there is very great diversity of opinion on the benefit or otherwise of forking or digging tea. It could not but prove very valuable information, if some of the many planters who have forked fields of tea would communicate the results.

My own experience has proved (1) that it is a sure way of checking flush for a good three months, if resorted to when the tea is six to eight months from pruning (*e.g.* in full flush); (2) that there has been no marked improvement at any subsequent period.

Theoretically, forking is a permanent improvement to the soil; but from my own experience of the result, I shall not again have recourse to it except in every other line, say three weeks before pruning (given favourable weather).

Trusting the ventilation of this subject may prove more profitable than my experiments in the ventilation of the soil, I am, sir, your obedient servant,
 PERVERT.

[We shall look for an expression of opinion by other practical men who have had experience in "forking."—Ed. T. A.]

THE WATCH COMPASS.

DEAR SIR,—I think the Yankee who taught us the use of the watch as a compass was a genuine son of his country, and wise as well as 'cute. To dwellers in northern latitudes the sun is always south at noon, hence his selection of the south point. The one thing to be guarded against is—not to hold the watch horizontal, but so that the hour-hand points directly at the sun. In northern countries the sun is never vertical, and therefore there the watch could never be "made to point upwards directly towards the sun, and made to revolve round the hand &c., &c." In sub-tropical countries, however, this is possible and renders the watch of little value as a compass in March and April, and in September and October or until the sun attains a sufficient north or south declination to throw a shadow of the hour-hand on to the watch face. It is this shadow which guides the observer in holding his watch, and enables him to find approximately all the points of the compass. The watch will thus adjust itself to the plane of the sun's daily path. In Ceylon from April to August the hour-hand should be made to point directly away from the sun as indicated by its shadow. At least it is but approximate and does not show mean noon, but so far as it goes it is an interesting fact, and may often be useful. The rim of the watch face, when held as directed, is a small circle concentric to the plane of the sun's daily path; or, when laid flat, concentric to the horizon. Hence, when seeking an "explanation," I imagined the offing reduced to the size of the watch, or the watch face enlarged to the size of the offing. But by keeping the hour hand pointing to the sun (as it must be for correct results in all latitudes above 25°N) the sun's motion is seen to be quite regular.

ASTRO.

COFFEE IN THE NEILGHERIES.—The *Madras Mail* article on coffee planting in these hills remarks that the consumption by the natives of India is increasing, and if it becomes general the local price of coffee must rise considerably. It will appear that the prospects of coffee cultivation in India on good soil are encouraging. The only country in which it seems possible to cultivate coffee more economically than in India is Africa, but competition from that quarter must take time.—*Pioneer*.

AGRICULTURE A "MERCANTILE UNDERTAKING."—In connection with the question of a loan under the Agriculturists' Loans Act, which the Collector of the Nilgiris had granted to a coffee planter, the Board of Revenue recently made the astounding statement that the loan had been illegally granted under the Act because "the land on which coffee is planted does not fall within the designation of arable. Coffee-planting is rather a mercantile undertaking than an agricultural operation, and it is obvious that any measure which would tend to make Government a sleeping partner in such a mercantile undertaking is undesirable." It is satisfactory to note that Government does not share this extraordinary view, and is of the opinion that land on which coffee is planted comes within the designation of arable land contained in the Act in question.—*Madras Mail*, Nov. 20th.

SALE OF TEA COMPANY'S SHARES.—We hear today of the sale of 50 shares in the Yaterioria Tea Company for R140—a very fine price considering that this Company is quite a young one and has not yet paid a dividend. The shares are R100 fully paid up, and the price paid shows how confident investors are that the position of the company is a strong one. The first dividend is shortly expected, and it will be a good one we believe.—Local "Times."

STARTLING FIBRE STATISTICS.—The American people are no less profuse in clothing than in food. The country is a favored land in fibre production. More than \$300,000,000 is the comfortable sum which represents the present fibre product, in the form of cotton, wool, hemp and flax. There is also experimental production of silk, ramie, sisal, jute and many others suited to the climate, some of which will ultimately become the foundation of industries. More than half of the material for the cotton factories of the world is grown here, and a third of that is manufactured and mostly consumed at home. If 65,000,000 people require one-sixth of the cotton manufactured in Europe and America for the use of nearly 450,000,000 inhabitants of these continents, and of the millions in India, China, Japan and other countries obtaining supplies from the factories of Christendom, the disparity in consumption between this and other countries must be great indeed.—*Agricultural Journal*.

THE TROPICAL AGRICULTURIST MONTHLY.

Vol. X.

COLOMBO, JANUARY 1ST, 1891.

[No 7.

THE CEYLON AND ORIENTAL INVESTMENT CORPORATION, LIMITED.

WE have now received from the Managing Director, Mr. J. Huntley Thring of Alford, Castle Cary, Somerset, and Dimbula, Ceylon, a copy of the prospectus of this newly-formed Association. Mr.

Huntley Thring is associated with men of high commercial standing in the City in Mr. Arbuthnot of Messrs. P. Macfadyen & Co., Mr. Hancock of Messrs. Hancock Brothers & Co., Mincing Lane, Mr. Reiss of Messrs. L. Reiss Brothers & Co., and Mr. Cyril E. Johnston who was of Messrs. Edward Johnston, Son & Co., the largest exporters of coffee from Rio and who has one brother Deputy Chairman of the London Westminster and another brother Director of the Joint Stock Bank. The capital of the Company is fixed at so large an amount as £250,000 divided into 49,950 ordinary shares of £5 each and 250 Founders' shares of £1 each. The first issue of 9,950 ordinary, and 250 founders' shares, has, we learn, been already taken up. Five hundred shares are reserved for Ceylon and Mr. Huntley Thring, who will arrive here before Christmas, will represent the interests of the Company, along with Mr. E. G. Harding who will probably have the Colombo agency, and Mr. A. J. Denison. The New Oriental Bank will be Bankers. That such a Company should be organised and floated in the face of the commercial crisis London has just passed through, speaks well for the high credit of Ceylon and especially of her tea industry. It is in connection with the latter, of course, that the Corporation will be most concerned, establishing probably an extensive estate agency business; but very large powers are taken by the Directors which would enable them, if advisable, to take up any profitable

Ceylon investments, such as Tramways or a short line of Railway, &c. There is at present, no Trust Association on a large scale operating in Ceylon and seeing how our tea industry is really still in its infancy, there should be plenty of scope for the Corporation, in the hands of Directors so sagacious and influential, doing a large and profitable business. That such is the anticipation may be judged from the following extract from the rule laid down for the guidance of the Directors:—

“The Founders' Shares will receive no dividend in any year until the Ordinary Shares have received 8 per cent. dividend for that year. After provision for a Reserve Fund and payment of 8 per cent. dividend on the Ordinary Shares, the Founders' Shares will (subject to the Memorandum and Articles of Association) be entitled to one moiety of the remaining net profits and the Ordinary Shares to the other moiety. Every allottee of 50 Ordinary Shares will be entitled to subscribe for and have allotted to him one Founders' Shares at a premium of £5; such premium to be applied in payment of all the preliminary expenses incidental to the formation of the Corporation.”

The Prospectus—which will shortly be advertised in full in our columns—begins by stating that the “Corporation is established to deal mainly with Ceylon and Indian properties and Securities in the same manner and on the same lines as other Financial Companies have successfully dealt with General Securities.” It then proceeds to refer to the rapid development of the Tea Industry, quoting Statistics from our “Ceylon Handbook and Directory” which stand out in bold relief, namely,—

Export of Tea.

1879..	..	95,969 lb.
1889..	..	34,345,852 „

[And who will venture to deny the probability of 1899—recording even more than 80,000,000 lb.]
We next read in the prospectus:—

The Tea Gardens of Ceylon being for the most part young, and not yet having reached maturity, are daily increasing in value and productiveness. The evenly distributed rainfall combined with the tropical climate causes the Tea bushes to “flush” almost continuously throughout the year, thereby bringing the average cost of production to even less than that of India while owing to the preference given to Ceylon Tea throughout Eugand and the Colonies, the average price obtained is higher. It is not proposed to purchase properties except under special circumstances but to grant loans on the security

of Mortgages of Tea and other Estates and so to secure the consignment of the crops to the Corporation for sale, and it is anticipated that the mortgage interest and the commission on the sale of the produce will enable the Corporation to earn substantial dividends. As evidence of the profitable nature of Tea Growing in Ceylon, it may be mentioned that the Ceylon Tea Plantations Company, Limited, which was incorporated in December, 1886, has, for each of the three years since its formation, declared dividends amounting to 15 per cent. per annum.

There is then reference made to Mr. Huntley Thring's local experience and high character as affording a valuable guarantee for the success of the Corporation, and in every word of praise of the Managing Director we most fully concur; for no one is esteemed more highly among the Ceylon planting community, while he will have experienced and shrewd coadjutors in Messrs. E. G. Harding, A. J. Denison, and C. Murray Robertson. We wish the new Corporation all success.

HILL-COUNTRY PLANTING REPORT.

A VISIT TO THE KOTAGALOYA VALLEY—TEA A SUCCESS TO THE ABANDONED COFFEE ESTATES—HEDGES OF TEA.

NANUOYA, Nov. 19th.

With reference to my visit to the Kotagaloya valley (the name is derived from the resemblance of the "Duke's Nose" mountain, seen in profile, to a leopard couchant), I cannot help repeating my conviction that tea will be here as great a success as coffee was generally a failure. Passing through "Chrystler's Farm" en route to the station, we were struck with the splendid jāt (indigenous, or as near it as possible) of young tea and its luxuriant growth. A really great work in the shape of a watercourse tapping the distant river was also remarkable. Factories are being erected in all directions, and the larger proportion of abandoned coffee estates are being redeemed. On an estate nearer the station, fine hedges of tea, topped at over 4 feet, which lined both sides of the road, formed striking features in the landscape. I thoroughly believe in the system. The bushes on the lower side of the path got the benefit of the heaped soil, while those on the upper side catch and are benefited by all debris of earth, leaves and prunings from above. Yesterday I went up the railway line to the third mile, and found that Mr. Wijenayeke had made considerable progress in blasting away the remarkable bed of rock at that point. He had obtained miners from the plumbago pits of the Kurunegala district, and had sixty at work boring holes and blasting. Ten of these, for the sake of extra pay, which they receive each day in ready cash, do a second task in the evenings of each day. The day-task, averaging 7 feet (one exceptional miner accomplishes 15 feet) is completed about 3 p.m., After refreshment, the evening task, averaging about 5 feet, is performed between 4 and 7 to 8 p.m. The work here takes more time and more dynamite and blasting powder, and is therefore more expensive than would be the case were the rock more granitic than it is. But it is true gneiss, in laminae of about 2 feet thick, so that the holes bored in each stratum affect only the thickness of that particular layer. Some more or less decomposed matter intervenes between the hard strata. This rock obstacle to progress has its advantages. An enormous deposit of broken stone has been here formed, which, when tractors or trucks are able to run, can be conveyed along the line to where metal for ballasting is scarce. The feeling amongst the contractors is

that delay at the lower end of the line is more likely to occur from paucity of metal for ballast than from any other cause. A gentleman who has a contract of two miles of rocky precipices near the Haputale end was much impressed with the almost exclusively earth formations at our end, especially in Mr. A. H. Thomas's great cutting on Abbotsford, which is now fast advancing to completion. The only rock here is in the shape of isolated boulders embedded in the earth. We were present at the undermining and loosening of one of those boulders from a position halfway up the 80 feet slope of $\frac{3}{4}$ in 1, and we felt real alarm at the recklessness of the coolies. One man would stand on the mass (about 3 tons in weight), while several would go under it, to undermine it with their alavangus. It was held in position by a sharp neck which went well into the bank, and which at length broke and released the boulder, enabling it to crash down harmlessly. The only accident on this big work, although operations have gone on in the night hours as well as by day, has been the fracture of the leg of a man who would stand on a mass of moving earth and got carried down with it. But of people aggregated in numbers some will die from disease, and one grave after another appears as time advances along the service road. Yesterday morning I saw a newly formed mound near Mr. Wijenayeke's contract, on which a bit of tin with pieces of charcoal had been placed, while marigolds had been planted around it. Such little attentions (although I fear the charcoal meant the conciliation of some god or demon,) shew the best side of human nature. But its weak side is shown by the grave of a little child close to our great cutting. The child died six miles up the line, but the body was brought down for burial by the parents avowedly for the purpose of being placed "where passengers by the railway might see the grave"! It is a curious fact that, no matter what the religious profession of the people, they very generally place a cross over the graves of their dead.

USEFUL TREES—BIRDS IN NUWARA ELIYA.

NANUOYA NOV. 21st.

Populnea Bucklandia (a grand relative of the Suriya tree) promises to be a great acquisition with us. We measured a couple of thick leathery leaves from young specimens which were a foot each way. The point projects from an almost perfect circle. The behaviour of different *Eucalypti* in our climate is curious. Most of our young plants have grown luxuriantly and did not seem to feel the recent south-west monsoon, while others have now practically to renew the whole of their foliage. Those trees grow under such different circumstances of climate in their native habitats, that it is only surprising how well most of them do here.

It would seem as if teal had not found their way up to Nuwara Eliya, after all. The specimen I received at Nuwara Eliya I saw only as a plucked bird, and all who spoke to me about the birds which had been so ruthlessly shot, called them teal. But last evening I received the following note from Mr. W. Tringham:—

"I hope the Local Board Ordinance will contain a clause giving the Boards power to pass bylaws for the protection of wild birds. The teal or widgeon are breeding on the lake. A little one was caught last evening the size of a frog, and I have sent it to Mr. LeMesurier this morning. Another nest was discovered, but the eggs were riddled with shot as the bird was killed as it rose from the nest. It is a great pity, but the report that a couple of teal were seen near the lake brings down the sportsmen in flocks." Enclosed came a note from Mr. Le Mesurier to the following effect:—

"This is not a teal or widgeon, but a dabchick or little grebe. I caught one myself on the lake not long ago, while in company with its mother, but let it go again. Teal would breed here, I have no doubt, if let alone."

On turning to Legge's book, I find that the little grebe had found its way up to Nuwara Eliya a good many years ago. He writes:—"The dabchick is widely distributed throughout the lowcountry of Ceylon, besides which it has, I am informed, recently found its way up to the Nuwara Eliya Lake, which has an altitude of 6,200 feet. It is nowhere seen in larger numbers than on the Colombo Lake, where it is a permanent resident; on some occasions I have seen a flock of more than thirty on the larger sheet of water, and, as a general rule, there are a dozen or more in this locality. It is not uncommon in the tank districts from Kurunegala northwards, and I have met with it in small village tanks near Trincomalee. Its having ascended the highest mountains in the island and discovered the newly constructed Lake at Nuwara Eliya is very remarkable, as there is a rise to the plateau, both on its eastern and western side, of more than 2,000 feet, both streams flowing down precipitous and forest-clad gorges; but I am credibly informed by several people, and among them by Mr. Thwaites, of Hakgala, who pays particular attention to the birds of the district, that it has been seen there during the cool season." Legge adds that the bird is a most expert diver and that its note is a not unmusical whistle. From the testimony of Messrs. Le Mesurier and Tringham, it appears to have bred in Nuwara Eliya, so that, if properly protected, the Lake would have the attraction of flocks of the little grebe, with other aquatic birds, no doubt, on its bosom. It would be a thousand pities if the unregulated action of sportsmen should exterminate or frighten away these pretty and interesting birds. The amount of meat they yield cannot be a great temptation.

FINE SPECIMENS OF ALBIZZIA MOLUCCANA—THE MERITS AND DEFECTS OF THE ALBIZZIA—JAPANESE TIMBERS FOR TEA CHESTS—AN EXPERIMENTAL GROVE IN UDAPUSSELLAWA—THE "TALLOW WOOD" TREE AND THE KUMBUK FOR RAILWAY SLEEPERS—GUMS, GREVILLEAS, &c.—AFFORESTATION AT AND IMPROVEMENT OF NUWARA ELIYA.

NANUOYA, Nov. 25th.

I recently mentioned the truly noble growth of some specimens of *Albizzia moluccana* here, which are only nine years old. Those in Mr. Neate's garden at Nawalapitiya, which that gentleman kindly asked me, some time ago, to inspect, are, I believe, one, or perhaps two years older? Mr. Neate obtained the seed, probably, through the late Colonel Money. Not having been able to accept Mr. Neate's invitation to see his grand trees near at hand, I was glad to obtain the measurements taken by Mr. Alexander of the Forest Department. There are five trees which vary in girth from 64 to 71 inches, or practically 6 feet in the latter case! The height of the trees is from 90 to 100 feet. Mr. Munton, I am told, has similar trees in the Matale district; and I remember seeing a fine specimen in flower on Rosencath estate near Kandy. The foliage of these trees so closely resembles that of the Madagascan tree, *Poinciana regia*, that the two trees are frequently confounded. But the blossoms differ exceedingly: those of the *poinciana* being grand in size and colouring while the flowers of the *albizzia* are smaller and beautifully snow-white. Although the spreading roots of this tree often vie in size with its immense trunk and large branches, it seems to do little or no harm to tea when growing amongst fields of that plant. Its

great merits as a shade and shelter plant, are qualified by its brittleness, big branches being broken by the wind or falling down occasionally by their own weight. Many specimens, however, either grow unbragously or shoot up tall and straight and are perfect specimens of grand trees. The timber is, evidently, not suitable for building purposes or fuel, but it would, no doubt, be excellent for tea boxes.

And this reminds me, that, after all, it was of "momi" I wrote recently as giving out no odour, when being planed by the carpenter. It resembles fine spruce deal, some of the pieces showing very beautiful markings, in parallel lines and wavings. I took it to be the wood of *Cryptomeria japonica*, from its close resemblance to that of the specimen of this so-called "cedar," which Mr. Nook recently cut down at Hakgala. That did not strike me as showing any dark heart-wood, but probably it was not old enough to develop a characteristic which is attributed to the mature cryptomeria. Of "Sugi" or the Japanese cedar, I have full details in Von Mueller and Gamble, but nowhere have I been able to find "Momi." From the appearance of the wood, it must be either a cupressus or pine, most probably the latter?

Mr. Alexander had, when he came to have a look at our older trees and our flourishing young plantings, just returned from visiting a Government plantation of Grevilleas, Eucalypts, &c., in Udapussellawa. All the trees in this experimental grove were doing well, but the tree which had grown beyond all compare was *E. microcorys*, one of the "stringy barks" of New South Wales and Queensland, and known by the colonists as "tallow wood." A specimen only 8 years old measured by Mr. Alexander was 6½ inches (5 feet 4 inches) in girth and tall in proportion. The Forest Department have, in consequence of such growth and the known qualities of the timber, ordered a large supply of the seed of this tree. Von Mueller describes it as attaining to a great size; barrel up to 100 feet in length and to 7 feet in diameter! The wood is yellowish, free from kino particles, easily worked by saw or plane; it is of a very greasy nature, so much so as to be quite slippery when fresh cut. (Hence no doubt its popular name of "tallow wood.") The oily substance prevents the wood from splitting or twisting, though not from shrinking. The timber is hard and durable underground, and is employed for railway sleepers, wheelwrights' work, for knees and breast-hooks in ship-building; the young trees serve for telegraph poles. [This points to planting pretty closely, thinning for telegraph poles and like purposes, and leaving the finest trees wide apart to grow until suitable for conversion into railway sleepers.] The foliage is remarkably rich in volatile oil. In some parts of India this tree has grown 30 feet in two years, or at the rate of 15 feet per annum, 1½ foot per mensem, or ½ inch per diem. In British Guiana the growth was still more rapid, up to 18 inches in one year! This tree is likely to be a great acquisition in Ceylon, especially if the railway department accept the timber for sleepers. At present the only hard wood grown in Ceylon which finds ready acceptance for use on the railway is the product of a tree peculiar to Ceylon, the *doon*—the red variety being preferred. *Kumbuk*, which grows to such an enormous size on the banks of streams, is also to be tried in considerable quantity. I will be much surprised if the timber of this grand tree is not favourably reported on, but many of our rivers will suffer in picturesqueness by the denudation which will follow the extended use of the timber. In some of the very aged specimens on the banks of the Arivi-arū in the North-Central Province, there are cavos in which human

beings as well as whole families of wild animals might find lodgement. The mode in which fresh bark forms continually on the edges of hollows in the trees is most remarkable. The blossom of these fine, water-loving trees, with their thick bark, rich in lime, is beautiful and sweet-scented.

I remember well the time, not more than 15 or 16 years ago, when poor George Smith planted *Eucalypts*, *Grevilleas*, *Araucarias* and *Cupressus torulosa* around the then newly-built bungalow of Dessford. Last evening I was able to compare, or rather to contrast, the gigantic height and the corresponding girth of the trees with their size when planted. Some of the tall, straight, clean, columnar "gums" are over 100 feet high and stout of stem in proportion. Others are magnificently umbrageous. The *Grevilleas* are only second to the *Eucalypts* (one of which seems to be *E. amagdalina*, the tallest tree in the world) in upward growth. The soil on the comparative flat is good, the elevation under 5,000 feet, and the position is largely sheltered, so that all the conditions are favourable. Mr. Rosling's experience of blue gum timber (unseasoned) was similar to our own: it warped. It ought not, really, to be used for buildings, until six months after felling. But we were greatly interested in a large stable door, composed of fine plants of a *Grevillea* tree, certainly not more than 16 years old (if that), which had been cut down and converted into timber. Made into the door, when freshly sawn, this valuable wood had subsequently seasoned without in the least warping. Such being his experience, we were not surprised to learn that Mr. Rosling intended to cut down some of the older *Grevilleas* which can be spared from the large number on Lorne, to be converted into floor boards. *Grevillea robusta* is certainly, for beauty of foliage, for tenacity of vitality (it scarcely ever fails in planting), for fair rapidity of growth and value of timber at a comparatively early age, one of the most valuable gifts which Australia has bestowed on Ceylon. It flourishes from sea-level to 6,000 feet, and we do not wonder at its great popularity and wide diffusion. If a *casuarina* or a *frenela* is allowed to grow somewhat big in the nursery, it almost infallibly dies when planted out, while the *Grevillea* flourishes equally as a seedling, a well-grown plant, or as a "stump." Prizing as we do our beautiful Norfolk Island pines, with their whorls of horizontal branches surmounted by a cross (one of them has here attained over 40 feet in 10 years), we were sorry to hear from the forest officer, that they were dying in several places. By the way, my surmise was correct that the planting baskets we saw being carried from Nanuoya to Nuwara Eliya, were intended for the use of the Forest Department.

Of the attempts at afforestation near the Sanatorium, Mr. P. C. MacMahon, in a letter to a contemporary of yours, does not speak so favourably as he does of a large scheme of improvement for our Mountain Health Resort, which he thus formulates:—

For the purpose of taxation and the working of rules relating to thatched buildings, etc., "Abram Saibo's bridge" is taken as the centre of Nuwara Eliya. All properties—including forest land from there to the top of the Rambodde Pass, Black Pool bridge, Mrs. Baker's gate, and the New Eliya bazaars—have to pay assessment, all these points being, in a straight line, over two miles from the bridge. Now, on the North side, Government have conveniently for themselves drawn the Local Board boundary immediately below the whole of their forest, the nearest point of which is not more than a $\frac{1}{2}$ mile from the bridge, while fully 500 acres are within the radius of $1\frac{1}{2}$ miles; consequently, they get off without paying tax, though one of the principal public duties of the town Aratchi and the Nuwara Eliya police is its protection! What I propose is that Government hand over to the town the whole of the forest from the

top of the Rambodde Pass to Pedru, and from there to the Lover's Leap falls as their forest reserve and future park, and that the Board gradually improve it by cutting new roads, planting suitable trees, foreign ferns, orchards, &c. In this way Pedru would become, as it should be "part and parcel" of the town, and its noble stretch of forest saved from the systems of "forestry" which one sees along the Nanuoya road, and which is much more calculated than the planting of the tea bush to diminish the attractions of Nuwara Eliya. The road, too, to Pedru could be widened and kept in proper repair—which cannot be done now by the Board as it runs for the greater part of the way through Government forest—and seats placed along it at the principal points of vista where the weary climber may rest here or his tired limbs and admire the scenery round. Lastly, close to the top of Peiru, a Kandyan pavilion should be built where ladies could hold picnics and shelter be found from the sun and rain. I do not agree with that part of the Report which states that the attractions of Nuwara Eliya are diminishing. Ten years ago the old Resthouse was sufficient to accommodate all the visitors and planters coming to the place; now we have two large Hotels and a Club—all doing fairly well; and, if returns were collected from these, I have no doubt that the flow of visitors is increasing 10 per cent yearly at least. As regards the block which Government failed to get at their price, I think I may state that the "attractions" of Nuwara Eliya will lose nothing by their failing to secure it, and that in the march of progress of the place it will keep pace with those which they have lately purchased—not a very difficult matter, judging by what has been done to and around of Government bungalows here for the last ten years.

In propounding his large scheme of extending the boundaries of the Local Board of Nuwara Eliya so as to include the forested slope and cloud-piercing summit of the loftiest mountain in Ceylon, the Celtic "son-of-a-bear" (for such is the translation of his patronymic) might have been magnanimous enough to have acknowledged that Mr. Armitage's success at the base of Pidurutalagala has been as conspicuous as his failures towards Nanuoya have been regrettably great. But we can all of us imitate Beau Brummel, when speaking of his cravats, in saying, "These are our failures." Let us hope that the dredging operations and water supply works at Nuwara Eliya may be unqualified successes.

Nov. 26th.

I wrote yesterday of an atmosphere surcharged with moisture and of the north-east wind blowing strongly. The result was the commencement of a rain-storm about 1 o'clock, which continued until nightfall. The rain-gauge record is 1.47 inch. This morning rises fine, but with masses of cloud on the eastern horizon.

NO SUCH THING AS WATER POWER—VARIOUS METHODS OF UTILIZING WATER—TURBINES—MOISTURE IN THE AIR—DIFFERENCES OF RAINFALL—WELLS—WATER SUPPLY—A CHANGE TO FINE WEATHER—THE LOFTIEST MOUNTAINS IN CEYLON—MR. NOCK'S EXPERIMENTS WITH POTATOES—GRUB—REMEDY FOR GREEN BUG.

NANUOYA, Nov. 26th.

With reference to possible aid in regard to the Nuwara Eliya Water Supply Works, Mr. W. Tringham has asked me to return a book he was good enough to lend me, and which I have read with very great interest. It is a special volume of the proceedings of the Institute of Civil Engineers, containing papers on the Theory and Practice of Hydro-Mechanics, and dealing with Physiography, Water Supply, Water Motors, Inland Navigation in Europe, Tide and Coast Works, and Forms of Ships. What struck me specially was the proposition, so startling to the popular mind, by the author of the paper on water-motors, that there is, strictly speaking, no such thing as water-power. What we are in the habit of attributing to the impact and weight of descending fluid on waterwheels is due entirely to gravity! However startling such a statement may seem, I suppose the scientific principle is beyond doubt. But less

I should have misapprehended or misstated its effect, I quote the paragraph from Professor Unwin's paper:—"The term water-power is convenient but inaccurate. Strictly speaking there is no such thing as water-power. Whether the water descends on a water-wheel, or actuates a pressure engine in connection with Mr. Ellington's pressure mains, the water is a mere agent of transmission. In the one case the water-wheel is driven by the energy of gravitation, in the other by the energy developed in a steam engine; the water merely transmits the pull of gravity, or the push of the steam engine. In neither case is the water itself the source of the power utilized. As we speak of a steam engine as a heat-motor, so we might speak of most water-motors as gravity-motors." Another principle is thus stated:—"The ordinary source of water-power is a supply of water raised by the sun's heat to a convenient elevation, and falling through natural channels back to the sea," and then follow mathematical proofs. It is fortunate for us in Ceylon, that, in the absence of coal and the increasing scarcity of wood fuel in convenient situations, water thus returning to the sea is so generally present in a form easy of utilization, especially in our hill regions. Professor Unwin states even of Britain, that "No great increase of the price of coal is needed to make water power of much more value than at present. On the other hand if the electrical engineer will make the transmission of energy easier, the importance of water-power would also increase, for one of its greatest defects is that it exists in the localities where nature has placed it, and not in the places where it can be most conveniently used." The author believes that the electrical transmission of water-power would be common, if a diminution of the cost of electrical apparatus took place. On the Continent of Europe and especially in America, water-power is very largely utilized, and at Holyoke, below the rapids of the Connecticut river, water power is supplied to mills at the rate of 20 shillings per horse-power, per annum,—the cheapest manufacturing power in the world. While I believe in good turbines where considerable power is required, and skill and intelligence are readily available, we have always had much faith in the common and simple overshot-wheel for ordinary purposes. Two such wheels, equal to 8 or 9 horse-power are sufficient for most tea factories. I again quote Professor Unwin:—"By a bucket water-wheel we can recover the energy corresponding to an unexpended part of the fall; by a pressure engine we can get the energy due to the pressure, and by a turbine we can get the energy due to the velocity. First then there are bucket or ocell wheels, in which the water fills the buckets near the top of the fall and descends in contact with the wheel without acceleration. About this class of motors I have time to say very little. They are simple in principle and have a fairly high efficiency. But they are somewhat cumbrous and antiquated machines. On falls above 70 feet they cannot be used. On falls of 20 to 60 feet a turbine is cheaper, and yields an equal efficiency. [Does the world 'cheaper' apply in Ceylon?] On a low fall, if a turbine costs as much, it has, *if well constructed*, a higher efficiency. Still, in one respect a good overshot or high breast wheel is superior to most modern water motors. *Its efficiency is nearly the same with a reduced supply of water as with the full supply.* In this respect many turbines, otherwise excellent, compare very unfavourably with the water-wheel." Compared with steam, water is 500 times heavier, and its incompressibility and inertia are disadvantages. Of an undershot wheel it is remarked, that apart from the

losses by the friction and leakage, it utilized less than half the energy of the fall. The Professor does not believe in more than 80 per cent efficiency in turbines and does not regard the American turbines as better than the British. The description of the various classes of turbines sounds like scientific gibberish:—"There are, therefore, cutward flow, inward flow, and axial or parallel flow turbines." But Professor Unwin looks on the hope of turbines with greater normal efficiency than 80 per cent as equivalent to the search for the philosopher's stone.—I have noticed Professor Unwin's paper first because of the impression made on me by his denial of the existence of innate power in water, but the first of the series is a very able paper, by Mr. John Evans on Physiography, in which the laws of our atmosphere are analyzed in the spirit of that wonderful passage in the sacred record:—"All the rivers run into the sea, yet the sea is not full; unto the place whence the rivers come, thither they return again." Beyond this alternative movement of moisture from the sea via the atmosphere to the hills and thence back to the sea science has not progressed. Practically the atmosphere is never free of moisture, but neither diffused moisture nor steam is visible until condensed by cold into small particles of water. "The quantity of moisture present in the air varies considerably in different countries and at different seasons. Here in England it is said that the average proportion of water present in the air is about 1½ per cent. When the air at an ordinary temperature is nearly saturated, a slight reduction of heat suffices to make the moisture visible. How often do we not see a mist rising, as it is called, towards sunset, after a bright warm day; and how often have we not seen the morning's mist, and even the clouds at a higher level, gradually disappear under the genial influence of the sun's rays." Evaporation is often almost equivalent to rainfall. At Madras it has amounted to 90 per cent annually; and the hot winds of the equatorial regions get surcharged with moisture, which they deposit mainly at 4,500 feet altitude on mountain sides in India, and Ceylon, the level of greatest deposit in England being at 1,500 feet. "Mountain ranges indeed are the great condensers of atmospheric moisture, and the amount of rainfall in any country is in the main dependent on the position of these ranges, and the prevailing direction of the winds." Whatever local effects forests may have, in modifying climate and preventing floods, my experience is that it neither increases nor diminishes rain, where warm clouds come laden with moisture and there are mountains, no matter how bare, to condense the moisture. "At Sethwaite in Cumberland, the average rainfall is 140 inches.*" At Hunstanton in Norfolk and elsewhere it is little more than 20 inches; so that on an average there is seven times as much rain in one part of England as there is in another. In India the disparity is still greater, between 500 to 600 inches at Cherapunji and 4 or less in places in Sind. Some of your readers may be interested to learn that 1 foot of undrifted snow is the rough equivalent of one inch of rain. There is much of interest about the capacity of different soils to absorb and retain moisture and about subterranean water and its temperature, rising 1 deg. with every 50 feet or so of depth. "It cannot be too often insisted that, in the case of water supply derived from porous soils, it is in the highest degree illusive to depend on averages. The minimum, or, at the best, the lowest average of three

* At Stye, in Cumberland, in 1883, no less than 190 inches fell

successive years, is the utmost on which we can rely." Mr. Evans also denounced the idea that the supply of water in wells was illimitable; it depends on the amount of rainfall absorbed by the soil in which wells are dug. These are only a few points in an elaborate paper. Still more elaborate is that of Dr. Pole, F.R.S., on "Water Supply," in regard to which his experience was extensive. He reminded his brother civil engineers that they owed their origin and also their name, as contradistinguished from architects, to hydraulics,—in the shape of measures to improve the condition of the rivers of North Italy. He characterized water as the most important natural substance known, and the most indispensable for maintaining the present order of things in organic life. He recollected in his boyhood water sold in cans as milk is now. He referred to the Roman aqueduct, and to the first house supply in London in 1582. The New River supply came in 1613, so that the two systems of pumping and gravitation were in force. Then came filtration in 1829. The effects of filtration and oxidizing were described. Moderately hard water like that of London was good, but for washing and manufacturing purposes soft water was required. The lime in hard water can be precipitated by adding more lime, which, seizing the free carbonic acid, forms a carbonate. For ordinary purposes 10 gallons per head water supply ought to suffice, and 5 to 10 more for extraordinary purposes, such as watering gardens &c., would be ample if there were no waste, but say, to meet all demands, 25 gallons per head per diem. *And provision ought always to be made for increased population.* Ordinary reservoirs and irrigation tanks are fully described. The responsibility of engineers was illustrated by the terribly fatal consequences of the bursting of the Dale Dyke reservoir above Sheffield in 1864, when the water rushing with a noise like "hissing thunder" drowned 250 persons. "Gathering grounds" and their yield of water and occasional failure in years of drought were described. All the rain that falls cannot be stored. "Part of the water will be restored to the heavens by evaporation; another portion will be absorbed by the vegetation growing on the land; and another portion will percolate through pores and fissures of the earth." Out of a fall of 44 inches, only 30 will be available. Interesting accounts are given of the utilization of Loch Katrine and other lakes as suppliers of water to great cities in Britain. The writer, while dwelling on the oxygenizing power of the air on contaminated rivers, pleads powerfully for the direct application of town sewage to the land: as both sanitary and profitable. In some cases, as at Oxford, the water of a river is taken from its saturated bed and not direct from the stream. These notes give but an imperfect idea of the scope and value of Dr. Pole's most able paper.—Those on the Inland Navigation of Europe, by Sir Chas. A. Hartley; on Tides and Coast Works, by T. Stevenson, and on Forms of Ships, by Sir E. J. Reid, although all very interesting, I must, in view of the length of this communication, refrain from noticing. The volume is well worthy of being read and studied by others than professional men.

NANUOYA, Nov. 27th

The rainstorm of the 25th seems, for the time, to have emptied the lower atmosphere of suspended moisture, for yesterday remained fine, and today commences crisply cold and beautifully bright, with only the ghost of a breeze. Kabaragala which lies over Nawalapitiya shows its characteristic spots distinctly through the Kotualo Gap; and but for

masses of haze in the north-east the whole circumference of the horizon would be clear. Of course the north-east monsoon would say:

"Ye have not seen the last of my rainstorms, or me,"

but the dry intervals, which are quite appreciable, are very enjoyable.

Our position here, midway between the valleys of the Nanu and Dimbulanda oyas, on a spur of the Katupillamana range, the head of which faces Hakgala,

"Like cliffs which have been rent asunder," we are as nearly as possible in the centre of a circle formed by the loftiest mountain peaks and ranges of Ceylon. Nearly due north of us is Pidurutalagala, 8,296 feet above sea-level. But for the "trig point" on its summit, the observer would find it difficult to realize that it was higher than its flanking ranges. But there can be no mistake about Kirigalpotta, the second mountain in Ceylon, 7,831 feet altitude, which faces the monarch almost due south. Its white rock face renders Kirigalpotta ever conspicuous; but yesterday, in the clear but not glaring sunlight, after the rain, we saw the sheet rock in a new aspect, reminding us all of one of the minor glaciers we had seen from the summit of the Rigi in Switzerland. The rock was no doubt saturated with moisture, from the heavy rainfall of the previous day, and it positively glittered as it reflected the concentrated rays of the midday sun. Those who have ascended the mountain have stated that the white colour of the rock is due to lichen which covers the surface of the gneiss. But seen with a good glass, which brought out its every precipice and jutting point and ravine, it looked to us like brilliantly white, crystalline quartz scored vertically with strips of dark colour, apparently due to earthy matter carried down by the torrential rains. In any case we are not likely soon to forget the grandeur of this rock glacier, as the sun looked on it so lovingly and with such brilliantly reflected effect, yesterday. Most markedly different in aspect is the mass of Totapalakanda (7,746 feet) which guards the entrance to the great tableland of Horton Plains, and the sharp point, like a bird's beak, of Kuduhugala (7,607 feet) which stands midway between the two. The pyramidal top of Adam's Peak (7,352 feet) rises, from our point of view, over the keel of the upturned-ship mountain Talankanda (6,137 feet), while our own special mountain, Great Western (7,264 feet), rises close to us, from the Dimbula Valley, over which it presides in massive grandeur. Our circle includes also the Bopatalawa mountains and patanas, Elbedda, Kotagala, Rilagala; and beyond and through gaps, in these we see the more distant ranges of Bogavantalawa, Dikoya, Maskeliya, Dolosbage and the Kelani Valley. In Scotland we are proud of the altitude of Ben Nevis, over 4,400 feet above sea-level. But the bungalow in which I write and look out on no fewer than fifty mountains 5,000 feet to over 8,000 is itself situated 1,400 feet higher up in "the lift" than Scotland's (and Britain's) loftiest mountain.

To descend to Potatoes: Mr. Nock's account of his experiment is most interesting, but he seems to have been exceptionally lucky in not being troubled with black (or brown) grubs. Here they caused us to abandon attempts to grow the prince of edible tubers.—As to getting rid of green bug on coffee, I believe the effectual remedy with all scale insects is an application which will smother mother and offspring; say any coarse flour and any coarse gum or viscid substance mixed with water and laid on so as to cover the insects and stick. But I will write fully the result of large roading on this subject.

SOIL INGREDIENTS.

Iron.—I know of no soil whose contents of ferric oxide would not be more than ample to supply all the needs of vegetation, so far as direct absorption is concerned. Its ascertained percentage rarely falls below 1 per cent. and more commonly ranges from 2 to 5 per cent. A curious fact amply illustrated by analysis is that soils of high ferruginous color do not always contain unusual amounts of the ferric hydrate, the color apparently depending more upon the mode of distribution than on the quantity. This is obvious enough in soil, containing bog ore in visible grains; but in many cases it appears to be a semi-crystalline aggregation of the substance around particles of soil and sand that hides the tint. The almost universal preference accorded to "red" soils as against gray or whitish lands in the same soil region, has given rise to the proposition to render the latter classes equal to the first by the addition of iron in some form, even to the use of magnetite sand and iron scraps. It need hardly be said that the true cause of the preference given to red lands is chiefly that the presence of this color indicates good drainage, whereas in the corresponding "white" lands the iron as usually accumulated in the subsoil in the form of bog ore in consequence of stagnation of water, forming a subsoil in which the process of reduction may recur at any time, and in which (as analysis has shown and as might have been anticipated) a large proportion of the phosphoric acid of the soil has been accumulated and locked up. A red soil is a "safe" one and is usually freed from the need of artificial under-drainage. That the color imparted by ferric hydrate favors the absorption of heat is another recommendation of red soils; they are "earlier" than those of white or gray tints. Moreover, as direct determinations show, well-diffused ferric hydrate is powerfully hygroscopic, and adds materially to the retentiveness of soils for moisture; hence crops on such soils are less liable to suffer from extreme heat than those on less retentive land. My former determinations of this factor in the soils of Mississippi amply illustrate this point, and California as well as Hawaiian soils [some of the latter contain as much as 39.2 per cent of ferric hydrate, corresponding to 27.4 per cent of metallic iron] confirm the conclusion. A point of practical importance is that doubtless in consequence of reductive processes, soils very rich in ferric hydrate suffer more promptly and severely from lack of drainage than similar soils of low iron percentage.

Phosphoric Acid.—The conviction that has gradually established itself that the practical values of the several calcic phosphates are not nearly as different as was at first assumed, has materially increased the interest of phosphoric acid determination in soils, particularly when these are strongly calcareous, and, therefore, according to the well-known play of affinities, most of the phosphoric acid present will be in the form of a tri-calcic phosphate. There is a good reason why less phosphoric acid in a soil will suffice in soils rich in lime, than in those in which there is no base ready to dispute the possession as the acid with ferric oxide and alumina which render it relatively insoluble and inert. The very minute amount of phosphates present in the best of soils will render the search of the roots for them very laborious, unless it can be conveyed to them in solution, independently of the acids the roots may exclude. From the discussion of the upland loam soils of the South-western States, I have been led to consider .05 per cent of P₂O₅ as the least amount that can be considered adequate for profitable production in their case, and that the percentage should rise to .10 per cent to be satisfactory. But in calcareous, and also in very sandy soils of great depth, less seems a good supply even there, and in California (where nearly all soils are calcareous) the percentage does not very often exceed 10 per cent, even in soils of great present productiveness and durability.

Humus.—The determination of humus by Grandcau's method is of the highest interest, as against the extraction with potassic or sodic hydrates, still sometimes recommended. As the latter solvents do not

discriminate between the crude, unhumified vegetable matter and the active humus, it misses the main point of interest. What degree of uniformity can be predicted of the composition of humus in virgin soils, I have not had time to determine. Even the physical properties of the ammoniacal solution obtained vary greatly yet, as in any case humus must be considered the repository and store-house of the soils, nitrogen supply, its proportion is of high interest. In the loam (oak) uplands of the cotton States the percentage of humus seems to range usually between .70 and .80 per cent in the poorer sandy pine soils, .40 to .50 per cent in the black calcareous prairie soils from 1.20 to 2.80 per cent. The determinations made there are not, perhaps, sufficiently numerous to give fair averages. In California and in the arid region generally the humus percentages as might be foreseen average somewhat lower; lowest in light loam soils of the high mesas of Southern California, where .30 per cent and even less has been found; yet these soils produce well at first, when irrigated. Percentages of .45 to .60 of humus are common in good upland loam soils that are neither very calcareous nor highly ferruginous. The "prairie," or black adobe soils usually range from 1.20 to 1.80 per cent, a very few as high as 3.00. On the whole, the highly ferruginous soils are remarkable for large amounts of humus; as in the red soils of foot hills and of the Coast Range. In these latter cases, however, the ammoniacal solution is usually quite light-colored, and only becomes dark on evaporation, doubtless by oxidation. It is pointedly claimed in some of the fruit-growing regions of this State that a too clean cultivation, entirely suppressing the growth of weeds, and thus affording no annual addition of vegetable matter save from the fall of the leaves, tends to injure the production of the orchards. It is readily conceivable that the long, dry and hot season would tend to cause a very rapid oxidation of the humus in the soil well tilled amounting to deprivation when only a very little is originally present. From experience had in green-manuring, it seems that half of 1 per cent (.50) is the minimum of humus desirable in California, and that when less is originally present an increase should be brought about as soon possible. In Western Oregon and on Puget Sound, where the summer rainfall is very heavy, humus percentages ranging from 3 to 6 per cent are quite common.—*Farmer's Review.*

CEYLON COCOA.

BY DR. A. J. H. CRESPI.

One of the most curious features of modern commercial activity is that Nature is, as it were, compelled to improve on her own earlier efforts. Supposing that some much-prized plant is found to do well in a particular region with a climate of given warmth and under certain recognised conditions; the next thing is to find out a region where these conditions are still better, and to introduce the plant there. This seems to have been done with the cacao tree in Ceylon, and cocoa of superlative excellence has for many years been manufactured from cacao beans imported from that beautiful island. Some brands of Ceylon cocoa have been recently commanding very high prices; this shows what a magnificent field exists in Ceylon for cocoa culture, and that the quality of the cocoa from that island is far above the average of West Indian varieties. The principal peculiarity of the Ceylon brand is its delicate flavour and rich aroma; although when prepared for use its price is not very high, and quite within reach of most incomes. We confidently predict that as it becomes more generally known it will be sold in still larger quantities, and so open up a fresh and most important branch of trade to British enterprise.

Messrs. J. S. Fry and sons, the well-known makers, whose house was founded in 1728, were not slow to recognise the peculiarly delicious flavour of Ceylon cocoa, and they have accordingly added another luxury to our household beverages in the form of Ceylon chocolate, a speciality that is being much appreciated by connoisseurs.

While on the subject of Ceylon cocoa, we have just been favoured with some of the most recent statistics relating to the consumption of cocoa in England. Although a great authority gives the average consumption as five ounces, per head, it is now ascertained to amount to eight, or, to be more precise, in 1889 it reached 18,464,164 pounds. This is not a large total after all, but marks progress. In 1820, duty was only paid on 267,000 pounds; in 1875, on 2,900,000 pounds. In other words, the consumption has doubled in fourteen years, and should the present rate of progress continue another fourteen or fifteen years, the trade will reach, for the first time, very respectable dimensions.

Considering its fragrance and nutritive properties (for all preparations of cocoa are a true food, and valuable as tissue restorers and force producers), perhaps the small consumption is surprising. For our part, we prefer well-prepared cocoa to all other beverages, while indigestion, which is so frequently caused, or, at any rate, aggravated by the too liberal use of hot tea, does not follow cocoa. The cocoa trade is in a healthy and active state, and the wants of the general public are not likely to be neglected as long as so many leading English firms are busily engaged ministering to the national needs.

One of the best uses to which Ceylon chocolate can be put is to eat it when on bicycling or pedestrian excursions. We have it most convenient, and we believe that cyclists, who are often at a great loss for a portable and palatable food which they can eat without dismounting, will more and more trust to chocolate as their sheet-anchor. Long before our attention had been directed to the subject by a circular we were reading the other day, we had found out the value of dry and satisfying food when many miles from home and pressed for time.—*Hardwicke's Science-Gossip*.

THE SORT OF TEA WE DRINK.—£1 10s 6d, 6s 3d, 3s 8d, and 2s 8½d—these were the prices per pound, as sold in Mincing-lane, without duty, &c., of the teas that a "Star" man was drinking yesterday. It was in the London establishment of Messrs. Forster, Green, and Co. the big Dublin teamen, that this extravagant spree on tea took place. The primary object of our man's visit was to sample the £1 10s 6d tea, which was sold for £2 to a Leicester tea dealer, who is now retailing it at £3 3s. Some of it was sold in 1oz. packets at 5s per oz. There were only 15lb of this tea in the world, and there may never be such tea again. Previous to this no tea was ever sold in modern times in Mincing-lane at more than 10s or 12s a pound. This £1 10s 6d tea, therefore, has fairly eclipsed everything. It came from the Heathersett estate, Ceylon; and though this and other estates might supply us with such tea regularly, they are not likely to do so, as the cost is too great. In the first place it destroys the tea plants, the leaves being gathered just when they are beginning to sprout, and in the next place every one of these very tiny leaves is gathered by hand. As for the appearance of the tea, it is like very fine cut tobacco of a light colour. To an ordinary observer it doesn't look like tea at all. And as for the taste—well, to the amateur, it is disappointing at first, but after you taste another—say 6s 3d per pound—tea and then go back you begin to think there is something in it, after all. A good many points about the liquor and the leaves and the clouds the milk formed when added were explained by Mr. Holloway, Forster Green's London man, to our representative, who, however, was unable to follow him into the subtle distinctions he drew. One point of public interest he gathered, viz., that in London teatasters infuse the tea exactly six minutes; in Dublin, owing to the difference in the water, the time is eight minutes.—*Home Paper*.

MARIAWATTE AGAIN.—We learn that the yield of the now famous 100 acres of Mariawatta estate, which has given year after year 1,000 lb. or more of made tea per acre, has been, up to the end of last month, 1,100 lb per acre for the current year. This highly satisfactory record presents a hopeful outlook for tea on suitable land, while it is also proof of what high cultivation can do. True, Mariawatte's are not to be got for the asking; but the evidence of the fruits of liberal cultivation should not be lost on proprietors, the majority of whom seem content to believe in the hardness of the tea plant and to get what they could from it, without giving it back some of the profits, in the hope of a still larger income. We congratulate the proprietors and the superintendent on the continued prosperity of Mariawatte.—*Cor.*, local "Examiner."

DISAPPEARING CINCHONAS.—At the sitting of November 5th of the Paris Society, of Pharmacy M. Landrin, the great dealer in barks, and a good authority on cinchonas, presented a number of specimens from South America. One was a cultivated Bolivia Calisaya in very large pieces containing 3 per cent of quinine. It seems in some countries like Greece and other parts of Southern Europe they will pay 10f. a kilo. for bark in long slices, and offer only 4f. for smaller ones, which are just as rich in alkaloids. M. Landrin also had Guayaquil uncultivated red bark, containing 95 per cent of alkaloids; quills from South America veined like a serpent's skin; and other rare specimens. He added that cinchonas are now becoming scarce in their native country; some sorts will no doubt soon disappear altogether. So, while they are still to be had, it is well to present specimens to the college collections for the benefit of pharmacy students, for which kind attention M. Planchon thanked the donor in the name of the college.—*Chemist and Druggist*, Nov. 8th.

PREPARING FOR THE WINTER MOTH.—Mr. J. Masters writes to the *Evesham Standard* as follows:—"As the season of the year is approaching when the winter moth will be making its appearance, a few hints, by way of reminder to fruit growers, may not be out of place:—

"1. The wingless female moth will be soon making its ascent of the tree, to deposit its eggs for the future brood of caterpillars.

"2. The best proved method of intercepting the moth is to band the trees with cartgrease. Buy none unless guaranteed as free from tar. Numbers of young trees have been killed by injurious compounds sold as grease.

"3. Do not use oil in the grease to make it thin. If the daub is stiff, it will last the longer. It is important to have it sticky, and look after it and keep it so, otherwise the moth will creep over it.

"4. If trees are young and the bark is smooth and tender, some grease-proof paper should be tied next to the bark of the tree, and the daub placed on the paper. If trees are matured and the bark is rough, good grease will not injure the tree.

"5. Trees where grease-proof paper is used will not require so much grease, as the paper prevents the bark from absorbing it. If all the trees were banded with paper, it is probable that the saving of the cost of grease would be an equivalent for the cost of paper banding.

"6. Grease may be applied with the hand, or a thin flat piece of wood, or a small brush; in either case put on a thick layer of the grease.

"7. Grease banding should not be delayed after the second week in October, and will require attention until the end of November.

"8. The appearance of the moth may be known by taking out a light in the dusk of the evening when the male moth, if any are present, may be seen. If no male moths are seen, you need not trouble to grease-band the trees.

"9. Do not be discouraged if, after all your pains, some caterpillars are found; when numerous they are not to be exterminated in one season."—*Gardeners' Chronicle*.

CEYLON UPCOUNTRY PLANTING REPORT.
NUTMEG—WEATHER AND COOLIES.

Nov. 18th.

The present concern in the culture of *Nutmegs* gives an interest in their past history. It is like a stale joke referring to the order which came out from home, when mace was at a very high figure, that more mace was to be grown and less nutmeg. But is it history? Was such an order ever given, and is it not more likely that it was made in the East and fathered on the west? To be sure it is like the mistake of a smart man at home,—these fellows who know everything, and are prepared to advise the world: but this of course would only give it all the morepoint.

That the nutmeg does flourish in history, is undoubted, for I lighted on a reference to it while reading Lockey's "History of England," the other day. It is instanced in illustration of the extreme multiplicity and complexity of duties which obtained in England before Pitt took the matter in hand and brought order out of confusion. "It was noticed," says Lockey, "by one of Pitt's best officials that so trifling an article as a pound of nutmegs paid, or ought to have paid, nine different duties." Growers of nutmegs may rejoice that in these days all this is changed.

Our present weather is just perfection for tea flush, and most estates are strained to keep up with it: everything else too is ripening, and these months are certainly the big harvest of the year, and when a place cultivates more than one product, it is kept busy.

Coolies on the whole are about enough for the ordinary wants—a little pressure does no one any harm, keeping us from going to sleep, and waking into life faculties which otherwise might be rusting.

The rain however is still very short of want it should be, to be made up, no doubt, later on.

PEPPERCORN.

THEFT OF CACAO (AND POSSESSION OF SAME BY A PRIEST) FROM THE WARIAPOLA ESTATE.

IN THE POLICE COURT OF MATALE.

No. 5,611, October 27th.

Robert S. Fraser of the Wariapola estate vs. Piyadessa Unnassa of Tibbotumulla.

A CACAO PLANTER'S EXPERIENCE.

A. G. K. BORRON sworn, stated: That he has been a planter for twenty-eight years, eight of which he had a good deal of experience in cacao. He stated that the accused begged that Court to proceed to the pansala garden, when the Magistrate promised to visit the spot the next morning, which he did on the 31st ult. with Mr. Faulkner of the Suduganga estate. This gentleman also spoke of the difference of the seeds of the different varieties and of the trees on the Wariapola estate and the pansala garden.—The following is the JUDGMENT.

There can be no manner of doubt that the cacao seeds found in the possession of the accused were seeds of the Forestero variety of cacao. That has been established upon evidence that is unexceptionable and satisfactory. Mr. Fraser's evidence and that of Mr. Borron place this question beyond all doubt, and it is further proved that the seeds found in the possession of the accused were all immature and unripe. That these were taken from pods stolen from Wariapola estate there can be no doubt, upon the evidence in this case and upon what I myself saw on visiting that portion of the estate which adjoins the accused's pansala garden. Not that this item of proof is necessary under the provisions of section 2 of the Ordinance No. 22 of 1886, which constitute the bare possession of unripe fruit of the cacao an offence, but it is always most satisfactory to find that the marks of recent stripping on the trees from which fruit have been stolen make it all the more clear, that the unaccounted for possession of the seeds

is an indication that the seeds have come from pods stolen from the stripped trees. The prompt action taken by Mr. Fraser and his men led to the discovery of unripe seeds in the possession of the accused, for which possession the account given by the accused is utterly untrue. He stated explicitly that these pods had been gathered from his own trees that very morning.—Mr. Fraser very properly asked him to show the trees from which they had been gathered, and he showed to Mr. Fraser what he showed me when I visited the garden at his request,—trees of the criollo variety which under no circumstances could have yielded seeds of the Forestero variety. I have had the advantage of seeing the pansala garden, and it is only too obvious that the seeds found in the accused's possession could not have been the produce of those trees. I carefully examined the trees in that garden and except three or four plants which had borne no fruit, and two of which were only just beginning to bear, there were no other Forestero trees from which fruit could possibly have been gathered that morning. The clumsy attempt of the little stripling priest to show me a fruit alleged by him to have been taken from a tree which five minutes before I had examined in his absence, and on which I found no such fruit or anything worthy the name of fruit, was soon traced to what was obviously a theft committed by him from one of Mr. Fraser's trees, while we were walking about the pansala garden,—on the other side of which were Mr. Fraser's trees separated from our view by a lantana hedge and other trees. This only indicates the facility with which thefts are committed of fruit belonging to Mr. Fraser's estate.

It has been urged for the defence that others may have committed the theft. It is not necessary to entertain the thought of such a contingency, because the priest has not put that forward, but has stated that the seeds found in his possession were the produce of fruit picked by him from his own trees. That he stated to Mr. Fraser and the same statement he made to me. It was further urged that he was a blind old decrepit man. That he was old and somewhat feeble, I could see easily, but he certainly was not blind, nor anything like decrepit. I daresay he has put on the semblance of decrepitude to avoid the consequence of his guilt. No doubt his age entitles him to some consideration, and in meting out the punishment due to his case, I have taken that into consideration. Had he been a younger man I should have given him rigorous imprisonment as a substantive punishment.

The enormous ravages there are being committed by natives in the neighbourhood of coffee and cacao estates indicate well organized and systematic robbery of produce. Not only are the fruits stolen from the trees, but the bearing capabilities of the trees are sensibly diminished by the ruthless stripping of the fruits and the tearing away of the fruiting eyes of the trees.

I find the accused guilty and sentence him to pay a fine of fifty rupees and in default of payment to be kept at rigorous imprisonment for a term of three months.

(Signed) J. H. EATON, P. M.

TIMBER TREES.—Mr. A. Mendis Senanayake, Arachchi (he ought long ago to have been made Muhandiram) of Moratuwa, has been carrying on the list of the Principal Timber Trees in Ceylon, first drawn up by his father, Mudaliyar Mendis. The copy that has been sent us is very nicely printed with 156 separate trees with Sinhalese and botanical names (in some cases Tamil also) and a variety of information such as uses, average size of log, &c. Planters in need of such a list can, in a few days, secure copies on application to the *Observer* bookstore. It behoves Government Agent Dawson to look out worthy industrious Sinhalese men such as Mr. A. Mendis Senanayake—the respected son of a worthy father—for higher honours.

REVISED ESTIMATE OF INDIAN TEA CROP—CURRENT SEASON.

The Indian Tea Association has favored us (Messrs. Wm. Moran & Co.) with the following, giving the revised estimate for the current season:—

"In their circular of the 28th April last the General Committee gave an estimate of the out-turn of the present season's crop of Indian Tea based upon the following figures which they had been able to collect:—
Original Estimate of Crop of 1890.

	lb.
Assam	48,295,344
Cachar and Sylhet	33,385,680
Darjeeling, Terai and Dooars	22,817,270
Chittagong and Chota-Nagpore	1,514,800
Dehra Dun, Kumaon and Kangra	4,500,000
Private and Native gardens	4,500,000

115,013,094

"From the figures which have since been obtained a revised estimate has been prepared, based upon actual results to the 30th Sept., as follows:—

	Manufactured to 30th Sept. 1889.	Manufactured to 30th Sept. 1890.
Assam	31,680,136	32,923,787
Cachar and Sylhet	20,736,051	23,815,670
Darjeeling, Terai and Dooars	1 62,384,91	15,291,811
Chittagong and Chota-Nagpore	1,049,419	1,221,080
	69,700,497	73,252,348

Revised Estimate of Crop of 1890.

Assam	45,001,072
Cachar and Sylhet	34,477,770
Darjeeling, Terai and Dooars	21,070,453
Chittagong and Chota-Nagpore	1,768,716
Dehra Dun, Kumaon and Kangra	4,500,000
Private and Native gardens.. .. .	4,000,000

110,818,011

"The exports to Australia, America and other places for the past season amounted to 5,388,560 lb., and if this quantity, plus 10 per cent, together with the requirements of Northern India now calculated at 500,000 lb. be deducted from the revised estimate, there will remain about 104½ million lb. for shipment to Great Britain during the season of 1890-91 against 98 million lb. shipped there in 1889-90."

CINNAMON AND COCONUTS: PLANTING REPORT.

KADIRANA, 24th Nov.—From the 26th October to the 15th inst., 19·87 inches of rain have fallen in this district, so that wells and springs are replenished, and all outward appearances of the late drought have disappeared, though its consequences will be felt for more than a year to come. This rain, and the fine weather we have had for over a week past, have matured the "bud" there was on the bushes, and no doubt those who intend cutting for the "punchi mossama" will soon begin work. All Mr. Tudor Rajapakse's cinnamon estates in this district are to be leased, and as in the conditions there is no clause binding the lessee to carry out the arrangement not to scrape chips, a large quantity of these will be thrown upon the market which, in conjunction with the distrust and suspicion of bad faith already abroad, will probably lead to the cancelling of the agreement upon honour, which has still a year to run.

"LYSOL" is a new disinfectant which is prepared by emulsifying carbolic acid with ordinary fat or resin soap, and the tar acid is incorporated with the soap at the moment of saponification. It is said to be more active than carbolic acid by itself.—*Globe*.

POTATO CULTIVATION IN THE HILL COUNTRY OF CEYLON.

Mr. Nock of Hakgala Gardens is good enough to give us the following account of his recent experience—just to show that potatoes can be profitably grown on the hills of Ceylon, if good sorts and good seed tubers are used:—

"On 22nd of Aug. last I planted, in good friable soil, 48 tubers of each of the three kinds named below, and I lifted them yesterday with the following results:—

"OHESWICK FAVOURITE.—From 48 sets the produce was 482 tubers weighing 85 pounds. The twelve largest weighed 7 pounds and the largest single tuber 11½ ounces.

"IMPERATOR.—From 48 sets, 357 tubers were produced weighing 75 pounds. The twelve largest weighed 8 pounds and the largest single tuber 12 ounces.

"ADIRONDACK.—48 sets produced 457 tubers weighing 65 pounds. The 12 largest tubers weighed 6 pounds and the largest tuber 11 ounces.

"Every tuber of Oheswick Favourite and Emperor were quite sound. There were about 12 or 15 tubers of Adirondack that were diseased, but these were from a few roots at the bottom of the row where the soil was a little damper.

"A more even lot of tubers I never lifted and I attribute this evenness chiefly to the way the sets were prepared for planting, but in some measure it may be due to the very favourable weather during the time of growth.

"Every set was a whole tuber, and the average weight used was about 2 ounces; these tubers had been previously laid out in a room, exposed to the light, and occasionally turned—which had caused the eyes to send out very sturdy sprouts and when these were about one inch long they were planted in rows 2 feet apart, the sets being 1 foot apart in the rows. The manure used was a little bone dust, and wood ashes with a sprinkling of lime. The only other attention they received was to keep them free from weeds and to earth them up well.

"They were in the ground only 84 days and during that time 12·70 inches of rain was registered. This fell on 47 days, but on only 10 days did ·50 or more fall, On 27 days the fall was ·15 or less, so that this sort of weather just suited them.

"This is the fourth crop from a few tubers I brought on with me from Worcestershire, exactly two years ago, and I think this proves that with careful selection and preparation of "seed" tubers, that the potato improves in this locality, instead of deteriorating as I believe is generally supposed.

"Our rainfall for this month to date is only ·50,"

THE CEYLON AMERICAN TEA COMPANY.

The following is an extract from a letter from Mr. Stretch of Messrs. Darley, Butler & Co., dated London, 13th Nov.:—

In writing last week about the new Ceylon Planters' Tea Co. I had hardly got hold of my facts. Since then I have copy of the prospectus and full details of the proposed arrangements. The point which shareholders, or intending shareholders will require to be informed upon is how a dividend is to be paid on \$1,000,000 with a working capital of only \$200,000. The shares are divided as follows:

Working capital 10,000 shares at \$20	\$200,000
To old Co. 12,000 do do	240,000
To Promoters 28,000 do do	560,000

50,000 shares at \$20 \$1,000,000

I suppose when the Company is in full working order the working capital may be turned over 3 times a year so that the turnover would be \$600,000. It will require 10 per cent profit on that to pay 6 per cent on the total capital. What are the prospects of earning such a profit? I hear that the tea sold in the States is rarely sold under \$1 per lb

which of course would give a much larger profit, but in order to sell the quantity required they must reduce the price, I imagine. If it is possible to get agents in all the towns that it is desired to be represented in, a very small quantity sold annually by each agent will do it.

November 24th.—The more I look at the scheme of this Company the less objectionable it seems. I got so far as that it required to earn 10 per cent on its turnover to pay 6 per cent on its total capital when I last wrote to you I think. I have now got a step further, viz: that inasmuch as a man gets 2 shares for one, 6 per cent will be equal to 12 per cent to him and therefore 5 per cent on the turnover will yield equal to 6 per cent making a very feasible and workable thing of it. I have no doubt the thing is in the hands of respectable people and will with push and energy prove success." We hear from Messrs. Wattson & Farr this morning that they are successful in getting some good Agents and think the co-operative scheme will work very well.

BARK AND DRUG REPORT.

(From the *Chemist and Druggist*.)

London, Nov. 6th.

CINCHONA.—At the periodical auctions held on Tuesday a moderate quantity of bark was offered, the catalogues comprising:—

	Packages	Packages
Ceylon bark	... 1,675	of which 1,432 were sold
East Indian bark	... 323	do 268 do
Java bark	... 42	do 42 do
S. American bark	... 354	do 196 do

Total 2,393 do 1,938 do

It will therefore be seen that the Eastern barks offered over 85 per cent were disposed of, while the proportion of bark sold to the total offered was about 1 per cent. The auctions opened with fairly steady competition, but gradually the demand slackened, and holders occasionally accepted a slight decline on the previous rates for manufacturing barks. The tone of the market was barely steady, and the unit cannot be quoted higher than from 1½d to 1¾d per lb. Druggists' barks, however, particularly red shavings, were very well competed for and brought full prices. The assortment of bark was a poor one, especially that of Ceylon bark, ordinary Succi-rubra chips and root making up the bulk of the supply. But there were several parcels of good strong Crown bark imported from Bombay.

The prices were evidently considered low enough by some speculators to tempt them to secure a small quantity, and about 9 tons were thus bought through a firm of brokers. It should be well understood that the mere weight of bark purchased affords no guide whatever to the quintic yield represented by it, firms who by a small quantity of bark by weight frequently taking the richest lots and *vice versa*.

QUININE.—The point reached this week is the lowest which has been known for some months. At the close of last week about 20,000 oz of German bulk in the second-hand sold at 1s per oz., and the week opened with further sellers at that figure. Another parcel of 20,000 oz subsequently sold at 11½d per oz while for 10,000 February and April delivery 12½d was accepted; since then, however, the market has somewhat improved, and closes today with buyers at 1s per oz., but no sellers at that figure. The result of the Amsterdam bark sales may, however, affect the position of the article again. We hear of a sale of 5,000 oz second-hand German today at 12½d per oz for February.

THE ARTIFICIAL PRODUCTION OF SUGARS.

Barely have sixty-two years elapsed since the great German chemist Wöhler prepared urea artificially. Up to that date the opinion was generally held that all chemical compounds which are found in the bodies of animals or plants could not be made artificially. They, it was said, are the results of vital action, and the endeavour to prepare them in the laboratory was considered as impossible, and almost as wicked as to try to manufacture an homunculus. Wöhler's discovery at once dissipated that false notion and since his time the labours of chemists have resulted in the manufacture of hundreds of compounds formerly only obtainable by natural processes carried on in living organisms. The latest

and perhaps the most remarkable of these triumphs of synthetic chemistry has just been made known to us. The group of bodies termed by chemists the carbo-hydrates—because they are composed of carbon united with oxygen and hydrogen in the proportion in which those two elements combine to form water—contain the well-known series of sugars, gums, and starches. The chemical composition of these bodies has long been known, but a knowledge of their constitution—that is, the mode in which their several constituent parts are put together—has only recently been acquired. It is clear that until we know what is the structure of a complicated arrangement of atoms, it is useless to attempt to build up that arrangement. We must have a plan of the house before we can build it. Such a plan of the structure of the sugars is now in our possession, and their artificial production has therefore become a possibility, and in the hands of a distinguished German chemist, Professor Emil Fischer, of Würzburg, that possibility has just been converted into a reality. The various steps by which this great result has been accomplished can only be explained and appreciated by those familiar with the intricacies of modern organic chemistry. But the importance of the discovery is patent to all. The group of carbo-hydrates (sugar and starch) are, next to the albuminoids (eggs and flesh), the most important material needed to support animal life. Indeed, the vegetarians would, and perhaps rightly, place them first. Can we look forward to a time when the chemist will manufacture our sugar, when the sugar-cane and the beet-root will cease to be planted, because their products can be more cheaply manufactured from coal or wood? Results apparently as improbable have happened. Who could have foreseen that the thousands of acres upon which the madder-plaut grew in France and Turkey would now yield corn and hay, because it was found that the dye formerly obtained from that plant can be more cheaply made from coal-tar? So, too, indigo has been artificially obtained, and who can tell that a recent new process for its manufacture may not prove fatal to the indigo planter? That the process of making sugar artificially is now too expensive to compete with Nature is, therefore, no proof that cheaper processes will not be discovered; indeed, that this will happen may be taken for granted. So that, looking back to the enormous strides which chemistry has made during the last half-century, and seeing what has already been accomplished, he would be a bold man who should dare to define the limits of her power, or to declare that our grandchildren may not use artificial sugar to sweeten their tea, and that Jamaica may know the sugar-cane no more. From a biological point of view, too, this discovery is of deep interest and importance. We know nothing, or as good as nothing, of the processes by which sugar is produced in the plant, nor how this sugar is transformed into starch, fat, and woody fibre. Are these results due to a special vital force, or does this expression merely serve as a cloak for our ignorance, and will careful investigation show that these substances are built up in the plant by methods similar to those which are now successfully employed in our laboratories? That this latter is the true view is the belief of the chemist, and nearer towards that end the discovery of Fischer has undoubtedly brought us.

An interested physiological question now presents itself. Supposing that these artificial sugars were to become articles of common diet, what will be their effect on the animal economy? That two chemical compounds may possess the same composition, and even the same chemical arrangement of their parts, and yet act differently from a physiological point of view, is well-known. And still more likely will this be if the artificial sugar differs in composition from the natural one. The blood and tissue which are formed from the artificial carbo-hydrates may differ from those which are the results of the assimilation of the natural sugars. If the pig and the goose were fattened on an artificial diet, their fat might differ from that which

they now form; and the bee fed on manufactured sugar might yield another kind of wax.

But we may go one step further. We know that plants not only convert sugar into fat, starch, and woody fibre, but that in presence of certain minute organisms they form nitrogenous or albuminoid compounds such as the gluten of wheat. Supposing it were possible to feed plants or these minute organisms on artificial sugar, differing in their properties from their ordinary food, it might force the plant to manufacture a new kind of albumen. And then what new structures might not be expected to start up from the use of the new building material?

Chemistry would then, for the first time, bring her potent influence to bear upon the structure of organised beings, and the changes of form which would result might prove to be of the strangest and most unexpected kind—changes far more remarkable than all those, singular and far-reaching though they be, caused by processes of artificial selection or of cross-breeding. The revelations of science have already outstripped the marvellous. What yet remains concealed in her bosom defies the wit of man to foretell.

H. E. ROSCOE.

—*The Speaker.*

SEWAGE AND SUGAR.

Under this heading the *Pall Mall* has a paragraph which ought to promote a "fierce boom" as the writer says in Ceylon tea:—

Dr. Richardson told a horrid story on Saturday night in his lecture on the progress of sanitary science. Years ago, he said, the sewage of London, or part of it, need be taken to Jamaica in barrels to manure the sugar gardens. The exporters of sewage thought it would be a pity to waste their barrels, or to bring them back empty; so the self same barrels were filled with a return cargo of raw sugar. The story needs no comment, but it suggests two queries; first, whether we get rid of our sewage in a very much better way now, by turning it wholesale into the river; and, secondly, whether there may not be today many products of origin as tainted as was that of Jamaica sugar. Travellers for the interior of China tell very nasty tales about the personal habits of the coolies who tread the tea intended for the use of the "foreign devils." Doubtless boiling water removes a multitude of evils, but it does not kill imagination; and if the confiding British citizen could see the feet beneath which his Chinese half-pound had passed, there would be a fierce boom in "Indias" and "Ceylons."

A NEW CEYLON PROJECT.

Under the title of the Ceylon and Oriental Investment Corporation, Limited, a company has been registered, with a capital of £250,000, in 49,950 ordinary shares of £5 and 250 founders' shares of £1 each. Its object is to acquire, by purchase or otherwise, and to lend or invest money at interest upon the security of lands of freehold, leasehold, or other tenure, stock, crops, plantations, tea gardens, buildings, mills, machinery and plants, mines, mining claims and rights, and mineral lands generally; documents of title, warrants merchandise, and other property in Ceylon India or elsewhere; to carry on business as planters of tea, coffee, rice, cinchona, tobacco, or other produce. The subscribers who take one share each are:—G. G. Arbuthnot, 144, Winchester House, E.O.; H. C. Smith, Hay's Wharf, S.E.; O. E. Johnson, 59, Cadogan Square, S.W.; J. H. Thring, Alford Castle, Carey, Somerset; H. A. Hancock, 28, Mining Lane; A. Zimmern, 51, Lime Street, E.O.; S. H. Goodhart, 22 and 23, Great Tower Street, E.O. There shall not be less than three nor more than eight directors. The first are George G. Arbuthnot, Hamilton A. Hancock, Cyril E. Johnston, Charles A. Reiss, and J. Huntley Thring. Qualification, £500. Remuneration, £1,000, divisible.—*H. and C. Mail.*

CEYLON AND ITS PRODUCTS.

TROPICAL AGRICULTURE.

I have more than once, before now, favourably noticed the very admirably compiled "Handbook of Ceylon," periodically issued from the Colombo Press, by Messrs. A. M. and J. Ferguson; and the volume now before me for 1890-91 is in wealth of matter, arrangement, and general get-up, superior to any of its predecessors.

There are few colonies so fortunate in their chronicler. Certainly no tropical colony in the world is so well furnished with a complete directory, probably because no other colony has been furnished with such a Ferguson. For full 30 years the work has made its appearance at stated periods. At first (in 1859) a tiny booklet of 100 leaves modestly apologising for its "thickness"! Now, without a blush, its red and gold covers firmly clasp over 1,400 pages of closely-printed matter. And such matter! The carefully accumulated cream of 30 years' brain-work. The agricultural, financial, and statistical experience of a lifetime; all pertaining to the most successful of our Crown colonies, and contributing by its accurate information, not a little to the continued prosperity of this our leading Crown colony. Every public library, and every individual in any way connected with the Spicy Isle, ought to possess a copy of this comprehensive work.

But of even more interest to the general reader will be the complete volume for 1889-90 of the "Tropical Agriculturist," a copy of which has also reached me from the same press. This is, as far as I am aware, an entirely unique work. For while in Europe our press teems with "Farmer's Journals" and works on the agriculture and horticulture of our temperate regions, this is the only periodical devoted exclusively to Tropical products; a field at once so absorbing, interesting, and extensive, that the marvel is that its special advocate and chronicler has been so long in coming. Perhaps no man so admirably fitted for the work of editing such a periodical had before taken root in the Tropics. His keen observation, restless energy, and facility for extracting the essence of all that is known of every conceivable tropical product, gave John Ferguson a peculiar fitness for the post—a fitness which he labours so assiduously to improve.

Here will be found from time to time all that is interesting to planters, and all that pertains to the rich and varied products of tropical and semi-tropical lands, their cultivation and preparation for the market, where and how to sell or buy, and how best to use at home. From New Guinea to Peru every important scrap of information is gathered and husbanded, while the East and West Indies, Africa and Brazil, are ransacked for new, or suitable soil, in which to grow the old luxuries or necessities of modern life. Not many years ago the preparation of so common an article as tea was enveloped in mystery—now China itself has been turned inside out. A dozen years ago the cultivation of such precious plants as coco, cacao, cinchona, cubebs, cardamoms, &c., was little known; the varied preparations from the palm tree were little heard of, and the magnificent flora of these warm humid regions sealed up from the general reader. Now all is here treated in a manner at once attractive to the million, useful to the man of business, and deeply interesting to the scientist. Ceylon, indeed, is now coming to be recognised as the experimental garden, or model from *par excellence* for the tropics; and its lot may be to bring about many marvellous changes as to the source of our supplies. Twelve years ago, for instance, not an ounce of chocolate had ever been shipped from the East. True, our good old friend, Mr. R. B. Tytler, had for years his pet little chocolate field, which he liked to show to his special friends, and joke over the possible fortune of the future. And many a fair castle have I heard him build as the fragrant smoke rose like incense from his lips! But it was not till the collapse of coffee that he thought seriously of extending the cultivation of cacao and acquiring the necessary knowledge of its preparation. R. B. T. did nothing by halves. "I'm off to Trinidad to see how it's done,"

he wrote to me on 30th November, 1879, and three months later I find him writing—"Back again, full of acquired valuable information; damages, £200; well worth it. My next move will be to the East, to show them how to do it. It is important to give the new product a correct start on entering the market, and getting a good name from the first. *Lanka will owe me not a little, I assure you.*" Two years more, and my friend writes his last from Ceylon. "O for a crack with you! The coffee is played out, but the chocolate is magnificent, 800 acres planted on Palli, first planted bearing 8 cwts. per acre—115s 6d in London! (Trinidad only realising at same sale 90s.) Clear profit, 100s per cwt."

Mr. Tytler's estates continued to prosper, and are now among the best cocoa estates in the world; realising probably from £7,000 to £8,000 clear profit a year; but the full tide of prosperity came, alas! too late for my good old familiar friend. "Oh for the dream-days hack again!" he was wont to exclaim—"They were glorious realities—now it is the dregs, the apples of Sodom. Foggy neeps!

The annual export of cocoa from Ceylon has now reached 2,000,000 lb., paying the producer handsomely; but a new generation of planters has arisen who know not their benefactor. Meanwhile, it is curious to note that our friends in the West Indies are about to send a commissioner all the way to Ceylon to see "how the thing is done." Still more curious and startling is the case of tea, the export of which has now risen to over 40,000,000 lb., and in a few years more is estimated to reach 70,000,000; while it is positively painful to read the lamentations of Chinamen over their decaying industry. Albeit, John has, as usual, had but scant justice in this tea business, bandicapped as he is with a heavy export duty—a duty, by the way, for years collected by British officials to pay for our uninvited visit to Pekiou. In other words, the Chinese have paid their so-called indemnities in tea. Is it any wonder, under the circumstances, that the China leaf does not improve in quality or cleanliness.

COLONIENSIS.

—Aberdeen Free Press, Oct. 11th.

OUR TEA CROPS AND ESTIMATES.

It is well to put on record once more in an unmistakable way, how the figures stand in reference to our Tea Crops, or rather Shipments, and Estimates.—For the old Commercial Year 1889-90 (1st Oct. 1889 to 30th Sept. 1890) Messrs. Rutherford and Scovell estimated total shipments equal to 43,000,000 lb.

The *Ceylon Observer* estimated .. 42,000,000 "

Actual result 42,994,000 "

For the current Commercial Year (1890-91) estimates are as follows:—

Ceylon Observer's 51,000,000 lb.

Mr. A. E. Scovell's 52,000,000 lb.

For the Calendar Year 1891,—

Mr. H. K. Rutherford estimates:—52,750,000 lb.

This will, we believe, prove if anything below the mark, and our own inclination will be to estimate for 1891's shipments, at a million more,—

Ceylon Observer for 1891,—53,750,000

But we shall be better able to judge at the end of the present year. If, as we expect, the total shipments for 1890 will not be less than 45,000,000 or an increase of close on 11 million lb. on 1889, we should expect a rise of not less than 9 millions lb. in 1891.

But of more interest to our home readers is it to mention that the total shipments of Ceylon Tea to the United Kingdom in 1890 are likely to be about 4½ million lb. against 10½ million lb. from India in season 1890-91. In 1891, Ceylon will probably send close on 50 million lb. to the United Kingdom, unless a big trade direct between Colombo and New York, Colombo and Odessa set in, as well as a steady increase in the export to Australasia. In that case we may have less than 50 million lb. to send to London.

NOTES FROM CALIFORNIA.

Our readers will find much that is interesting in the following letter from a former Ceylon planter who has now settled down to cultivate "bean land" in far-off California:—

Rancho Santa Katrina, Saticoy, Ventura County, California, Sept. 9th.

It is a long cry from here to Ceylon, but I have no doubt the Postal Union is capable of carrying my good wishes for yourself and family and for the "Old Rag," for a perusal of which my soul panteth sometimes, to read of old friends and old familiar doings.

You will have doubtless heard of my moving here. I arrived at New York on the 18th June, and making Sacramento on the 25th of that month I made a stay of a few days in Northern California in the lovely valley of Loomis of the Citrus Colony, which by-the-bye is largely made up of English gentlemen. I was greatly pressed to stay, and was very much tempted to do so, as much for the proximity to the railway, the capital town, and fertility of soil as the social attractions but did not; I was afraid that though handsome returns could be expected I was hardly strong enough for the labour required.

The colony being the youngest in California, hired labour was hard to get and very expensive. What do you say to strawberries paying there at the rate of \$1,800 per acre! A man could only cultivate a few acres at a time, as you may suppose, the ground requiring constant cultivation and irrigation.

A truly lovely country nature-planted with immense live oaks and waving with natural grasses and wild oats self-sown. I had of course to rough it, sleeping double and washing outside, sharing the basin with half-a-dozen rough quarry-men, who slept in the grounds outside the express office (my hotel) in a tent. Having enough of that I took ticket for this country, and was staying some time with an old Ceylon friend, before moving into my own quarters, and an old acquaintance of yours of the name of J. G. Morrison who is married and settled here. The address bearing of my lotter is my own ranch of 40 acres of bean land. This land lies above the mouth of the Santa Olara river facing the grand Pacific, with the barrier islands of Auacapa (see map) and Santa Cruz on the right and the Guadaluasca range across the river to the left—with Red Hill mountain standing grand and bold in the clear soft blue of the sky.

My attention at present is largely engaged in the erection of a house and windmill,* having just completed the boring of a 264 feet well. All details of daily life have to be done by oneself,—ooking, grooming of the horses, wasbuing, dusting &c.; monotonous, continuous work but not too hard. The out-door work all can be done by one not too strong and who like myself has never done hard manual work before, with perhaps the one exception of ploughing—the original ploughing of the land. But this neighbouring farmers will do at a day's pay—generally from \$1.50 to \$2.00. I like the life, the country and the people (now that I know something of them) greatly and would not exchange with anyone. It has a glorious climate and room for 30,000,000 of people where there is not but 1½ million. I say, come one, come all. There is no need of American naturalization, one can stick to the old flag and yet take part in Brother Jonathan's dollars—pronounced *dart-lers*.

There is much to interest in this, one of the oldest historical spots on American soil. It was here Padre Junipero first landed for the conversion of the Indians, and finding a quiet sea, a fair harbour, and a populous, gentle, kindly people to welcome him, called it Buena Ventura—"good venture"—and here he erected the quaint old adobe (sun-dried brick) church which still stands in the main street of the town of Ventura (five miles for Santa Katrina)—enshrining (surrounded as it is with modern wooden buildings of every conceivable American bad-taste) in its somewhat gloomy interior

*Windmill power ought surely to be largely utilized in Ceylon.—Ed. T. A.

a life-sized figure of the Saviour, too realistic in its gory details but with an old-world pathetic beauty yet about it. The audience consists entirely of the Spanish-Portuguese-Italian community, and comprising a number of half-breeds. The Indians pure have long been extinct. The Padre is a curiosity in himself, has been many years here, and wears a beautiful beard down to his waist. He is said to be the only R. C. minister permitted to do so in America and required the Pope's dispensation. The old gentleman used to suffer from severe catarrh, and something warm about his throat was the only cure. There is lying all about me a fund of interesting information and gossip for half a hundred letters and which I shall be pleased to repeat, from time to time, to the readers of the *Ceylon Observer*.

REPORT ON THE PROGRESS AND CONDITION OF THE BOTANIC GARDEN, ADELAIDE, SOUTH AUSTRALIA, DURING THE YEAR 1889.

By R. SCHOMBURK, DR. PHIL., DIRECTOR.
Dr. Schomburgk, although verging on fourscore, is still at his post in charge of the beautiful gardens at Adelaide, and has issued his report for last year.

From this document we quote as follows:—

The rainfall in and about Adelaide during 1889 was the most copious on record, as may be seen from the tables of the Government Astronomer, an extract from which is subjoined. The largest quantities of rain fell in the months of April, May, June, August, and September.*

The atmospheric condition which prevailed during the summer months were abnormal, and this was the case during January and February also. Indeed, during these two months some of the most trying weather ever known was experienced. There were few hot winds, and the thermometer ranged between 90° and 106° Fahr. in the shade and from 150° to 160° in the sun. The quantity of moisture in the air was unusually great, and it rendered the climate for the time being as uncomfortable and as distressing as it is in Brisbane, and, at times, in Sydney. The beneficial effects of the season have extended over the whole colony, and have greatly tended to promote the progress of agricultural and pastoral enterprises, but more especially of the former, which sorely needed some stimulus after the bad effects of several previous dry seasons. The wheat crops in some districts would have reached 15 and 20 bushels per acre, or in many cases even more, but for the appearance of that scourge "red rust," which, in many places, destroyed whole crops, and in consequence the average wheat yield was only 7 bushels per acre.

The fruit crop was a fair average one, and the fruit itself generally of fair size and good flavour. The produce of the vineyards has also been satisfactory, both as to quantity and quality. In the Botanic Gardens the flower parterres, borders, and carpet beds have displayed a wonderful variety of colors, produced by the different flowers which flourished during the summer months, such as Amaranths, Zinnias, Portulacas, Tagetes, &c. Their appearance generally has been superior to anything previously seen in the garden, and has elicited the warmest expressions of admiration from the visitors to the garden. The roses, however, suffered greatly from the rain, and from the scorching sun in November and December, which destroyed the small flower buds, so that last year was not a favourable one for the development of the large collection of roses.

New Fodder Plant.—The wool lathyris—*Lathyris sylestris*, Linn.—No forage plant has ever created so much surprise amongst agriculturists in Germany as the wool lathyris. Although indigenous in both England and Germany, its valuable properties—long unknown—have only recently been discovered. The *Register* newspaper was the first to call attention to the plant by reproducing and extract from the

North British Agriculturist, which had been forwarded by Mr. J. Christison, of Clare, who expressed the opinion that it merited the attention of South Australian farmers. The *Register* truly observes—"That farmers may be pardoned for hearing with a feeling of caution, merging with distrust, of some wonderful new fodder plant, which will grow enormous and most profitable crops on even the poorest soils, and which seems able to grow luxuriantly in any climate. But the facts that have just come to hand should go far to convince even the most sceptical that a most valuable plant is now being placed at the service of Agriculturists." It is further said that—"The plant belongs to the order of *Leguminosae*, and, as such, is able to forage for itself in regard to nitrogen, of which it obtains abundant supplies either from the lower strata of soil or from the boundless atmospheric stores. Even in the poorest soils it grows a crop which will yield at least 4 tons of hay per acre. The nutritious value of the crop, as determined by chemical analysis, is about twice that of clover hay. The Prussian Minister of Agriculture has been so deeply impressed with the great value of this plant that a Government order has just been issued granting to every Prussian landholder who cultivates the plant on his waste land a subsidy of 30s. per hectare, a hectare being equal to two and a half English acres. As a consequence of this recognition of the plant all the available seed of the cultivated plant has been brought up at famine prices."

Having read this glowing account of this lathyris, I made it my duty to obtain some seed from Germany. It reached my hands in January, and, in order to test its utility, a few seeds were sown in a flowerpot. They came up well, and the plants have, up to the present time, grown luxuriantly. The plants have been well taken care of, so that their healthy growth can hardly, as yet, be taken as proof that they will thrive equally well in open ground. We must, therefore, wait the result of the experiments which have been made in this way. With the seed I received an official report, made by the director of the well-known agricultural college in Germany, at Poppelsdorf, near Bonn, upon the plant, which says—"The wool lathyris, or flat pea, is found growing wild in the forests here and there, especially on basaltic formations. The stalks trail along the ground often to the length of 15ft. The creeping roots also spread to an unusual length, and in consequence absorb from the poorest soil the most minute particles of nutritive matter contained in it for a great distance around the plant. It does not need any manure, and it resists drought. The wool lathyris obtains a great age, and a specimen of a cougener, the *Lathyris latifolius*, has grown for no less than seventy-five years on the one spot.

The wool lathyris has been experimented on and improved for several years by two gentlemen—Messrs. Wagner and Kühnemann—with the most satisfactory results. Even in the poorest soils the plants have considerably improved. For the first two years they grow slowly. During this period their rapidly spreading roots absorb the nourishing matter necessary for the development of the plants. After the time mentioned the growth is most remarkable, the crops yielding from 4 to 5 tons of hay per acre. The plant is also remarkable for its richness in proteinc contained in the straw, which has been found to range from 21 to 24 per cent. Plants cultivated in sandy soil, and in heavy clay, possessed from 24 to 26 per cent., and in some samples of the straw of the lathyris as much as 29 per cent. has been found."

The straw is richer in nutritious properties than any other, with, perhaps, the exception of lentil straw. A chemical analysis of some of the straw gave the following results:—

Proteine	13.97
Fatty matter	3.43
Woody fibre	37.98
Non-nitrogenous substances	39.00
Mineral matter... .. .	5.62

100.00

* The exceptionally high rainfall was only 30.872 inches not equal to that of our driest station in Ceylon.

The other day, on planting out the seedlings of the wood lathyrus in the open ground, I was agreeably surprised to note the wonderful development of the roots. Some of them were 18 in. long, and some as much as 2 ft., with a thickness equal to that of an ordinary writing quill. This fact confirms the statement of the director of the Agricultural College, that the roots develop and spread to an unusual length and depth.

The seed, as I mentioned, was sown at the end of January, and the plants were planted out in the commencement of June. The roots during that time had attained an extraordinary length and thickness. I do not think that there are many plants the roots of which in so short a period attain such a remarkable development. I believe that I have at length succeeded in introducing a useful forage plant, which, having regard to its unusual root system, is likely to suit our dry climate in an eminent degree.

I cannot avoid again calling attention to the well-known Cocksfoot or Orchard Grass (*Dactylis glomerata*, Linn.), and once more recommend it for more extensive cultivation than it receives. It is one of the most valuable of the grasses for permanent pasture that have been introduced into the colony. It is of vigorous growth, does well in almost any soil, and is much relished by cattle and sheep. It stands both feeding down and cutting down, and grows again with great rapidity. It is one of the most prolific grasses and possesses considerable nutritious properties, and is valuable for fattening purposes.

Museum of Economic Botany.—This popular institution loses none of its attractiveness, indeed, it is always made a favorite place of resort by the visitors to the garden. The large and valuable collection of exhibits contained in the building has been still further extended during the past year.

The continuous increases of objects in the museum makes it evident that we shall soon be much pressed for space in which the donations which are constantly coming in can be advantageously displayed. It is most gratifying to find that the collection forms one of the most attractive features of the garden. Visitors appear to be much impressed with the interesting features of the objects themselves, as well as with their simple and practical arrangement.

The Library has kept pace with the general extension of the objects for which our institution was established. A large addition has been made to the number of standard works, both botanical and horticultural, which are now available for reference. The latest issues of the reports of the Smithsonian Institute, and the reports of the Geological and Natural History Survey of Canada, possess the highest scientific value. The pamphlets issued by the different botanic gardens in botany, especially those issued from the Imperial Botanic Gardens at St. Petersburg, merit particular notice and attention.

THE COCO-DE-MER IN CULTIVATION.

With only one exception, the palms of the Seychelles have long since proved amenable to cultivation in our tropical plant houses. The genera *Stevensonia*, *Geschaffeltia*, *Roscheria*, *Latania*, *Dictyosperma*, *Acanthopanax*, *Hyophorbe*, and *Chrysalidocarpus*, which are peculiar to this small group of islands, and which rank amongst the noblest of a noble family, are all well known in European collections of palms, their cultivation presenting no more difficulty than that of tropical plants generally. The coco-de-mer or double coco nut (*Lodoicea seychellarum*) has, however, so far proved unmanageable under artificial treatment, notwithstanding that many attempts have been made to establish it at Kew and elsewhere. So long ago as the year 1827, Sir William Hooker published a series of figures and a description of the coco-de-mer in the *Botanical Magazine*, and recorded the arrival of living nuts of it at Kew, where, he says, "we cannot doubt of soon seeing them flourishing in our stoves." But they failed to grow, and although dozens of nuts have since been tried at Kew, not one ever got beyond the first stage of germination.

The absence from our collections of living examples of this most remarkable palm is most disappointing to all students of the order. At Kew we have lately been successful in establishing living plants of the Ita (*Mauritia flexuosa*) and Bussu (*Manicaria saccifera*) palms of the Demerara swamps, and the Doum (*Hyphene thebaica*) and Palmyra (*Borassus flabelliformis*) palms of Africa. These successes stimulated the desire once more to obtain a living plant of the coco-de-mer.

Application was therefore made in January last year, through the Secretary of State for the Colonies, for a supply of fresh nuts from the Seychelles, and at the same time directions for packing and forwarding the nuts were sent to Mr. C. Button, the Conservator of Forests at those islands. The Administrator, Mr. T. Risely Griffith, took a warm interest in the matter, and through his kind exertions several consignments of nuts were received, of which four germinated. Two of these are probably too weak to live, but the other two are in a most promising condition. The strongest has a radicle 3 feet 8 inches long, and 12 inches in circumference at the end where the plumule is developed. This is now a foot long, and is pushing a perfect leaf.

In a note by the late General Gordon on the germination of the double coco-nut, it is stated that the nut is planted horizontally, without the husk, when it sends out a sprout some 12 feet long, which pushes up the young plant at a distance of 12 feet from the nut. The longest "sprout" we have had at Kew has not exceeded 4 feet. Nor can it be made to grow horizontally, the point turning down perpendicularly however often its position may be altered. At Kew the nuts were planted in a bed of cocout fibre, and kept at a temperature of 80°-85° F. They were planted in June 1889.

Mr. Button had kindly undertaken to plant a nut in a Wardian case, and treat it according to our instructions until it had germinated and developed the plumule before despatching it to Kew. A nut thus treated arrived in July last in the most promising condition. The radicle is 1 foot 10 inches long, and the plumule is 7 inches in circumference at the base. It has a stout sheath-leaf, and a normal leaf 3 feet 2 inches long, 3 feet wide, with thirty-six folds. The midrib is curved, and the blade at present folded double. The texture is exceptionally firm, and the colour a deep green.

Full-sized trees of the coco-de-mer attain as much as 150 feet in height, with a smooth trunk about a foot in diameter. The leaves form an immense crown on the top, and each leaf is 20 feet long and 10 or 12 feet wide. The male and female flowers are on separate plants: the male inflorescence is shaggy like a huge willow catkin, its length being 5 to 6 feet by 4 inches in diameter; the female is from 2 to 4 feet long, and it bears from six to ten fruits, each of which weighs from 25 to 30 pounds. They take seven years to mature and sometimes hang two years on the tree after they are ripe. The process of germination extends over about two years. According to General Gordon, the trees begin to fruit when about forty years old, and attain maturity in 120 years.

Royal Gardens, Kew.

WILLIAM WATSON.

[The coco-de-mer is at present confined to Praslin and Curieuse, two of the islands of the northern group of the Seychelles Archipelago. It undoubtedly runs some risk of extinction from the long period which the nuts take to germinate, and from the fact that, the trees being of different sexes, isolated females may easily escape fertilization. Its cultivation in the Botanic Gardens of the tropics is therefore of considerable importance.

Plants have long flourished in the Royal Botanic Gardens at Peradeniya, and the following extract from a letter from the Director, Dr. Trimen, F.R.S., to Kew, records the interesting circumstance of a male plant having flowered:—

"Peradeniya, August 12, 1890.

"You will be interested to hear that one of our *Lodoicea* palms put out a ♂ inflorescence last month. The tree is thirty-nine years old. To my great dis-

gust, when the spike was about 6 inches long, some visitor cut it off with a blunt knife, and I found it on the ground. The flowers were all formed, and the structure exactly as described by Sir W. Hooker in the *Botanical Magazine*. I hope my other tree will prove ♀, but that is much younger."

Sir John Kirk also succeeded in establishing the palm in his garden at Zanzibar.

The Government of the Seychelles has long watched with care the preservation of the existing groves of the palm, and pains are now taken to fertilize the female plants artificially, and to plant the seeds.—W. T. T. D.]
—*Nature*.

MR. E. ELLIOTT ON THE COST OF PADDY GROWING.

Mr. Elliot writes in answer to enquiries from the local "Times":—

"You and others, I find, misunderstand the scope and intention of my experimental cultivation and the publication of the results. The primary object is of course to show those amongst whom we are working that, by using the ploughs and incurring some little additional outlay quite within their means, much better crops can be secured. At the same time I have endeavoured to discover the *cost of growing paddy*, working on a ready money basis. I have necessarily had to work rather expensively with native assistants, on whose outlay I have a very imperfect check and who do not stint the cultivation. In spite of this my Galle experiment worked to R16 per acre (exclusive of taxes), and at Nintaur it worked out to R17.50. The information thus acquired is, I think, valuable, for it refutes the absurd *estimates* of the cost of cultivation advanced by many, such for instance as that given by Mr. Panabokke for Saffragam to the Grain Tax Committee.

"I have also given the return I got at Nintaur and shown that I went into a village, bired at current rates a parcel of land, cultivated it, and made a profit of R694 on an outlay of R612 in under six months (rent and taxes were paid after crop as customary and so entailed no outlay.) This was done in an unfavorable year, but in an irrigated district. This is the broad fact I wish to make known. Everybody can utilize my figures and see how they would be affected by the surroundings under which he can, or does, undertake paddy cultivation—for instance the district in which he hires the land; if he can or will or is obliged to do without irrigation; if he has his own money and cattle to work with, or must burrow and if so at what rate.

"These differ in each case and in every district, and everybody must work them out for himself, I consequently made no allowance for cost of land, interest &c; and as for contingencies the crop was a moderate one. For machinery I had only 5 iron ploughs and 4 native ploughs costing altogether about R40, on which I have charged R10.75 for depreciation and repairs; they are available for future operations.

"I added particulars of my other experiments to be perfectly above board and also to shew that, even in an unprecedented year of failure, there had been secured a profit (exclusive of rent, but after providing for taxes) of R819 on an outlay of R1,441 from 84 acres of land.

"A man can and does in this district cultivate 7 to 10 acres at one time, so that if the cultivators had been also the owners of the lands each would have had R70 to R100 to go with; but if the cultivators were not the landowners they would have probably had to pay about this for rent and had nothing beyond their wages for the time they were employed.

"I have my own views regarding paddy cultivation as carried on by natives, but cannot enter fully into them here except to say that, the more I look into it, the more am I convinced 'it pays' and if carried out on a proper basis it is probably the best paying produce ever grown in Ceylon. Just as with tea, coffee &c., there are places and circumstances under which paddy growing will not pay, and where it ought not to be

tried; but this does not affect the real question. Still another branch of the question is whom does it pay as carried on by natives. This is a very difficult matter to say between non-resident landlords, money-lenders, and untrustworthy tenants; but because one cannot answer that question do not jump to the conclusion that 'paddy does not pay'. Again, in discussing the resources of these engaged in this branch of agriculture remember even in Ceylon "man does not live by paddy alone"—or by one cultivation per year. It is only one of his occupations in Ceylon.

Pray do not mix up my experiments with these considerations. My figures I think place beyond doubt that paddy can be made to pay handsomely. Others who have gone into the question and worked on a proper basis will tell you the same. Mr. Julian Dias told me recently it pays him 25 per cent. on the selling price of his field, and that no paddy land in the Western Province is worth less than R150 per acre—here R50 is a very good average price. The Kegalle Mudaliyar's experience also supports my views. If therefore any class allege paddy does not pay there are collateral reasons which must be searched for and examined, and the whole industry should not be decried wholesale, as is done in some quarters, because the expectations of any class interested are at times not realized."

THE BAMBOO.

There are countries where it seems to supply almost every human requirement, and where the feathery masses of its foliage, drooping, like the weeping willow over road and river and village, bespeak an ideal of life beyond the reach of less primitive communities. Here man is unspoiled by artificial wants, untouched by the march of thought or of science, and nature unsolicited supplies with lavish hand his simple needs. It is an ideal which it seems almost sacrilege to disturb, and in presence of which the highest aim of the foreign intruder should be to preserve its primary conditions intact. No better example can be cited of the land of the Bamboo than one of those Indo-Chinese provinces, of which Burmah is the best known to Europeans.

Like the fir in northern climates, it is the bamboo which here gives an unmistakable stamp to the rural landscape, while it is literally the framework and foundation of nearly every work of man. It is no exaggeration to say that the same jungles which give cover to wild animal life of every form and tribe, exert a beneficent influence also on every step of life of their human inhabitants.

The Burmese child plays with bamboo toys in a house of which roof and walls and floors are for the most part made from the same generous plant. Through boyhood and manhood and old age this helpful comrade is ever by his side. On land or water, in peace or war, in the homes of rich and poor, in art and manufacture, in the market and the field, at feast and funeral, this is the substance of all that man most needs and values for ornament or use.

Town and villages are built from its stems and leaves; the fisherman's rod, and float, and raft; the hunter's snare; it bridges the torrent, bears water from the well, and irrigates the fields. It is food and medicine for cattle, and even for men; and there is music, too, not only in the rustle of its leaves, but in its woody heart, from which more than one musical instrument is made.—*Blackwood's Magazine*.

THE PLANTING INDUSTRY IN JAVA.—Sugar crops in the native principalities of Java have all been gathered in with unsatisfactory results, owing to the prevalence of canker among the cane. Sugar planters have taken to planting larger stretches of ground with cane to make good the smaller yields. The tobacco yield shows a falling off, and prices have so gone from bad to worse that leaf from the island has become almost unsaleable at Amsterdam. Coffee on the other hand, promises well for next year.—*Pinang Gazette*, Nov. 7th.

COLONIAL CAREERS FOR YOUNG MEN VS. FARMING IN ENGLAND, IN A NEW LIGHT:

WHY NOT "ROUGH IT" IN RECLAIMING DERELICT HOME FARMS IN THE OLD COUNTRY?

The writer in the *Spectator* of "A Commentary in an Easy-Chair" has the following deliverance in reference to young men looking out for a career in tropical plantations, Australian farms, American ranches, &c.:—

"The one appear in our magazines and papers periodically accounts of the doings of the young men who go out to the Colonies, who work in ranches, and settle in the backwoods, generally reported by proud and happy fathers whose glory in their hard-working boys is too touching in its vicarious vanity to be lightly disturbed. And yet the life which is described to us with so many virtuous flourishes is the hardest life that can well be imagined,—a life without comfort, without solace, a hard struggle at first for the barest living, which slowly grows into rude plenty, and perhaps in the end to prosperity in the ordinary sense of the word, but at the sacrifice of almost all that is beautiful, and much that is good in life. Hard weather and hard work, the endless, ever-recurring routine of primitive life, the conflict with all the elements, and rudiments of existence,—still more the abandonment of everything that is above or beyond the common day: these are the conditions of that life, which in so many cases seems the only resort for the boys nurtured amid every sweetness and comfort, lodged and served and fed, and even educated, as well as Princes are and much in the same way. To arrive at independence and a primitive wealth at the end may be a satisfactory thing to think of; but the sacrifices that are made to secure this are overwhelming. I have often asked myself whether these youths might not do as well if they settled, say, on a derelict farm in England, where unhappily there are many, and worked it as they do their Colonial patch of land, or bit of primeval forest. Supposing they had the courage to make themselves cowboys at home? not only to scorn delights and live laborious days, but to scorn appearances as they would do on the other side of the Atlantic, and use their faculties here as they do there? Could this be done with the possibility of a home behind them, in which to take refuge for a Christmas, for a holiday now and then, which would keep them within touch of the life to which they were born, might not their native fields be as practicable as Manitoba, and the primitive living be secured, and the primitive advantages, without so tremendous a sacrifice? I do not pretend to have sufficient knowledge to answer this question; but it is one that seems worth asking at least. I remember the time when spade-husbandry and the reclaiming of waste lands were considered to be a new gospel with an answer to all social problems in it. Times change, and all the panaceas change. Miss Martineau, in her series of tales on Political Economy—tales which it would be so strange to read nowadays, though they had the greatest effect in their time—has one (at least) to prove the sinfulness and waste of village greens and commons, which were so much land lost to the commonwealth. Nowadays we cling to our commons, and think land never so well bestowed as when it is made into recreation-grounds and parks for the people. But even now, though I am told that corn does not pay the growing, there is something in the sight (or even hearing) of fields lying untilled and desert which gives an ache to the heart. Could not the primitive life of labour be accomplished on them as well as in Manitoba? No doubt there would be difficulties. There are difficulties in everything; but are they invincible? I am unable to answer the question, but it seems one that is worth the asking, practically, as well as in words.

I have heard at least of one kind of farm upon which an experiment has been tried with remarkable success, and which no doubt has preserved at least one (there may be many) young Englishmen from Manitoba or California. This is a pleasant farm established on a bit of moorland by a quick-witted and practical-minded member of the class aforesaid, in which

between birds, made ready to stock the coverts and furnish forth the battues of the sportsman, as well as the homelier necessities of the poulterer—necessities not unthought of, it is said, in the most aristocratic circles—and eggs, that make the birds, a few paternal acres (not at all adapted for corn-growing) have been made to produce a very comfortable income, with greater and greater possibilities for the future. This is one of the accidental possibilities which men occasionally strike out, when they have the instinct and spirit of success in them. And I think it very possible that Mr. Gladstone's suggestions about poultry and jam, though they have not been operative in changing the views of the farmer class, might equally answer in the hands of the youths predestined to be cow boys, if nothing better should turn up. There are, no doubt, many who would rather rear chickens at home and help to take away the reproach of England in the matter of fresh eggs, than herd the cattle in a ranch, or keep sheep on the Australian wilds, or pig in a log hut in Canada or California, through the most beautiful period of their lives. The jam might be trying if it required personal superintendence. One asks oneself whether one is justified in suggesting any such expedient in the face of the fact that there will not be standing-room in the British Islands within a few hundred years, according to the best calculations? This, however, scarcely matters so much when we reflect that, according to the same authority, a few hundred years more will see the same condition of affairs throughout the world, and there will be standing-ground nowhere,—in which case it does not matter very much, evidently, what we say. There will be peace in our day; and the world, so often threatened with all manner of catastrophes, has the chapter of accidents in its favour, and may go lumbering on for more centuries than any statistician would imagine. But in the meantime—why could not a ranch be tried in Essex, for instance, where I hear there is much unemployed land? If the boys are to be cowboys and farm-labourers upon whom we have spent so much care and love, why should they not buckle to, gird up their loins, and try it at home? It may be impossible; but, again, it might not be impossible. Of course the experiment would have to be conducted in the same way in which it would be conducted in Manitoba,—no gentleman-farming, but hard work according to the Colonial or backwoods type, in which places gentleman-farming certainly would not pay.

OUTLYING PORTIONS OF THE STRAITS SETTLEMENTS: PLANTING RESERVES.

We have received copy of a Sessional Paper embodying "Notes of Visits made by Sir J. Frederick Dickson, K. C. M. A., to the Settlements of Penang and Malacca and to the Native States of the Malay Peninsula during the period April-September 1890, while Administering the Government to the Straits Settlement," from which a few quotations will be of interest to Ceylon readers:—

April 13th, 1890.—Left Singapore in the "Sea Belle" at 1 p. m. with Lady Dickson, Captain Massy, R.A., A.D.C., and Mr. C. O. Blagden, Private Secretary, bound for Klang in Selangor.

April 15th.—The first thing in the morning visited the Botanical Gardens in company with Mr. A. R. Venning, who has laid them out with much taste and success.

May 14th.—Left Pouang Hill at 6 a. m. On reaching the road at the bottom found the Resident Councillor (Mr. A. M. Skinner) and other gentlemen waiting to accompany me round the Waterfall Gardens. They are making great progress; the collection of foliage plants is becoming one of large and varied interest, and the grounds are being admirably developed by Mr. Curtis, the Assistant Superintendent of Forests in charge of the Gardens.

June 21st.—Left Singapore in the "Sea Belle" for Tanjong Kling.

June 29th.—Accompanied by the Resident, Mr. Berrington and Mr. Perce, Acting Superintendent of Works, I rode up to Terachi in the morning. The road passes through a beautiful and highly cultivated country, village after village in well-cared-for compounds or orchards lying in the valleys up which the track runs. Ayer Sejnk in Terachi I was met by the Penghulu of Teraohi and the neighbouring Chiefs, who had created a *basie*, adorned with flowers and palms, in which breakfast was served.

The difficulties of traversing the Bukit Putus range by railway trace have been overcome, and I was able here to see how easy the trace will be down the Terachi and Muar valleys to Kuala Pilah, and how much the country, thickly populated as it is by a permanent Malay agricultural population, will benefit from the construction of a railway, which will reach Kuala Pilah in less than 22½ miles from Seremban, with a tunnel of 330 yards at Bukit Putus, where the line reaches its highest elevation of 713 feet above sea level (h. w. spring tides).

July 2nd.—Left Tanjong Kling in the "Sea Belle" and, after visiting the light-house on Pulau Undan, steamed on to the mouth of the Muar, where a launch was in readiness to take us up the river. At Bandar Maharaneé I was received by the Acting Resident, Tunku Otman, and by Messrs Garland and Faithful, who have been engaged on extensive waterworks for the supply of the town, and also on a narrow gauge line running at present 8½ miles along the coast to Parit Jawa.

The line is on a 2-foot 6-inch gauge, and though not yet ballasted, is open for regular traffic, and is earning, in addition to its working expenses, something under 5 per cent on an expenditure of \$75,000. It is proposed to extend it about 17 miles to Batu Pahat. The arc-nut groves through which it passes extend along the sea shore about 30 miles and have an average breadth of 5 miles. After a drive round the town I went up the line as far as Parit Makar, about 4½ miles from Bandar Maharaneé, and then returned to Malacca for the night.

July 19th.—Arrived off Kuala Pahang about 11 a.m. Found the "Porpoise" there, and was met by the British Resident, Mr. Rodger, in the launch "Ethel," which took us over the bar and up the river some 7 or 8 miles to the Pekan, where the river banks and the landing stage had been prettily decorated by the inhabitants, a beautiful arch erected by the Siamese residents forming the centre of the decorations. Later in the day walked round the town. The Gaol in particular is noticeable for the clever manner in which the simplest and cheapest materials have been used to make a secure prison. The palisade is made of pointed palm trunks which are fixed side by side in the ground and held together by transverse bars of timber, not nailed on to the uprights, but running through holes pierced in the palms and threading them together into a fence very difficult to scale.

July 22nd.—Found the "Porpoise" anchored off Tringganu about 2 miles from the shore, and took up a berth just inside her after passing a very numerous fleet of fishing boats putting out from the mouth of the river. We climbed up to the old fort which commands the Kuala. This looks more like an observatory than a fort, guns of obsolete patterns are mounted at all sorts of angles on slender wooden pillars and pointed to the sky like telescopes, but it commands a fine view. The town is of considerable size, and the large fishing fleet seen in the distance bears witness to considerable enterprise on the part of the inhabitants. The country inland and along the coast is densely covered with coconut palms, but it was evident that the beetle which has done so much harm in the Colony is in possession also at Tringganu, and a great many trees along the coast have been destroyed by it.

July 26th.—Reached Singora at 7 a.m. A Siamese dagoba on a conical hill makes a prominent landmark near the mouth of the river; groves of coconut palms and casuarinas (Malay *rhie*) were seen here along the shore, as at most of the places we visited in these parts, and as usual, too, the coconut palms near the shore had suffered considerably from the beetle. The natives say, however, that its ravages

are limited to a narrow strip of land next the sea. The Governor, whose great-grandfather was a Chinaman, is a very intelligent man, and shewer me several photographs of his own taking, and a good lathe with several very creditable productions of his own from it.

Retired from the busy part of the town is a well kept enclosure containing several Siamese Buddhist temples, some of them most elaborately decorated and extremely curious, and, in some of the details, beautiful.

Sept. 2nd.—Arrived at Penang at 8 a.m.

Sept. 3rd.—An interesting case of *latah*, or imitative madness, in some respects like "echo" insanity, was brought on board for Dr. Ellis to see. Saw the Superintendent of Police, Mr. Bell, in reference to the action taken in Executive Council yesterday, and after despatching letters to Singapore, weighed anchor at 11 a.m., leaving Mr. H. Trotter in charge during the absence of Mr. A. M. Skinner, whom I added to our party as Consul for the Siamese ports of the West Coast of the Malay Peninsula, with Mr. F. T. Thorold of the Perak Service as my Interpreter.

We left Captain Cameron in Penang to meet Mr. Kelly, late of the Indian Survey Department, who is going to carry out the Penang Survey on the system recommended by Colonel Barron, B.S.C. (see Sessional Papers, 1887, Appendix No. 11), and Mr. Bostock, who comes out from England to obtain particulars to enable Sir John Coode to report on the best system of wharves for improving the Port of Penang.

Sept. 6th.—Had an interview with Mr. John H. Bostock, who has come out from England to report on the best means of giving Penang Harbour such wharf and warehouse accommodation as the trade requires. Also with Mr. F. W. Kelly, late of the Indian Survey Department, who has taken service here to carry out the cadastral survey recommended by Colonel Barron, B.S.C.

September 10th.—Up at 5 a.m., and at an early hour we bade adieu to our kindly host, and sailed some two hours later than we had intended at 7 a.m. for Goh Mak, a low alluvial island formed at the mouth of the Punga River. Up the river we passed close under these perpendicular cliffs, which rise abrupt from the water's edge to a height of some 1,200 feet, clothed from foot to summit with small trees of great variety. Had a day amidst natural scenery which it would be difficult to find equalled anywhere in a ten hours' sail. Punga is a small State with some tin mines, and a population of Siamese, Chinese and (a few) Malays. The Raja is a veritable "Lord of the Isles," but the right to collect the edible birds' nests which are found here is in the hands of the Malay Raja of Kedah, not, as has been supposed, a survival of the Malay supremacy by sea of former days, but as a farmer of this part of the Revenues of Siam!

It was fortunately one of the days for the market held here twice a week, and the whole length of the main street was lined with stalls kept by Chinese men and by Siamese women, in which vegetables and fruits, fish dried and fresh, and various kinds of country produce in abundance were displayed for sale. Close to Tap Tian we had passed through extensive fields of splendid pepper vines—the finest grown in the Peninsula—owned chiefly by British subjects—Penang-horn Chinese. The pepper here is grown climbing on living dadap, on the Sumatra system, instead of on dead sticks like hop-poles. The soil is deep red laterite thoroughly disintegrated. Trang is closely connected with Ligor on the East coast, there being between the two places one of the routes across the Peninsula; and it was by this route that Antonio de Miranda de Azevedo, the second Envoy sent by d'Albuquerque to Ayuthia—the then capital of Siam—made his journey, going from Malacca by sea to "Tarangu" and thence by land with horses and draught oxen. The roads in the early part of the 16th century must have been better than now, as they are not good even for elephants and would be absolutely impassable for draught oxen. The population is Siamese, Chinese

and Malays, and here, besides the languages of these three races, there is spoken the patois known as Samsam, peculiar to the Siamese who have become Muhammadan.* The term "Samsam" is said on the spot to be a corruption of "Siam-Islam."

September 18th.—Went up the river to visit the graves of Mr. Birch and the soldiers who are buried with him at Bandar Bharu, and the monument erected to the former at Pasir Salak. Mr. Wray had kindly made excellent arrangements for the journey, and we left the "Sea Belle" at 6 a. m. and drove across the narrow neck of land behind Teluk Anson to Durian Sabatang, saving thereby five miles of river, and met there two of the Perak launches which had been sent round earlier with the servants and provisions. After an hour upstream in the steam-launches, we transhipped into three house-boats at Bandar, where the river shoals considerably, and, poling upstream, arrived at 8:30 at Bandar Bharu, seventeen miles above Teluk Anson. Here we were met by the Penghulu and headmen, and walked up to the enclosure containing the graves, which is about three hundred yards from the river, and is approached a well kept path bordered with flowering shrubs. The enclosure itself looks very nice and well-cared for. It is surrounded by an iron railing, and in the middle of a grass plot is an ornamental railing enclosing five graves with crosses of polished granite. They cover the remains of Corporal Fay, of the 10th Regiment, killed at Knala Biah on the 7th November, 1875; of Captain William Innes, R. E., killed at the same time and place; of James Wheeler Woodford Birch, British Resident, Perak, assassinated at Pasir Salak, 2nd November, 1875, aged 49; of Gunner R. Hardy, R. A., died in Perak, 17th December, 1875, aged 32; and of Private W. Smith, 3rd Regiment "The Buffs," died in Perak, February, 1876. There are also three unknown graves in the enclosure. On rejoining the boats, we went 7 miles higher up the river to Pasir Salak, arriving there at noon, and finding that preparations had been made for our visit. Raja Muea, the younger brother of the Sultan Abdullah under whose auspices the murder was committed, and who was himself exculpated when the murderers were brought to justice, met us with a large number of the natives at the landing place just opposite the monument. This stands about 30 yards from the river bank in a small enclosure and is an obelisk of unpolished granite bearing an inscription in Malay and English on a slab of white marble. The English words are:—

"This, the site of the Fort of the Marajah Lelah, and near the spot where the British Resident, J. W. W. Birch, was treacherously murdered on the 2nd of Nov. 1875, is ordered by the Government of Perak to be forever kept desolate and uncultivated."

RUSSIA AS AN OUTLET FOR INDIAN TEA.

To the Editor of the *Home and Colonial Mail*.

Sir,—I think a brief account of a visit which I recently made to the country of the Czars may not be without interest to many of your readers. The principal object of my journey was to endeavour to ascertain *on the spot* what were the prospects of introducing Indian teas into that country, and to this end I was greatly assisted by the kindness of friends, through whom I was furnished with several good mercantile and other introductions.

*The mixed Malayo-Samese people, commonly known as Samsams, form the bulk of the population in the lower parts of Ligor and Sengora and in the north of Kedah. Although entirely assimilated to the Siamese in speech, customs and religion these Samsams appear to be allied physically much more to the Malay than to the Tai stock. Yet their national sympathies seem to be altogether with the dominant race, and the people, especially of Ligor, have during the present century zealously co-operated with the Siamese in their persistent efforts to subdue the Malays of the neighbouring States.—*Encyclopædia Britannica*—Article "Malay Peninsula."

At Petersburg, whither I first directed my steps, I had an opportunity of discussing tea with several persons connected with the trade as well as with other commercial people, whose acquaintance I made on the *Bourse*. I was strongly advised, however, to proceed to Moscow, which is the chief centre of the wholesale trade. I accordingly went on to that city, and was sufficiently encouraged by what I saw and heard to remain there for eight days.

Here I had the advantage of the assistance, as well as the benefit of the experience, of Mr. Rogvine, the representative of the Ceylon planters, who had been at work, first for five or six weeks in Petersburg, and latterly in Moscow, introducing his Ceylon teas to the notice of the wholesale trade as well as to the large retail houses, such as Popoff, Kousnisoff, &c. &c. We visited (either separately or together) the principal tea merchants, and tasted with them samples of both Indian and Ceylon teas. By most of these firms I was very kindly received, more particularly by the firm of Wogau, by Bergmann Bros (who represent Fred. Huth & Co.'s house), and by the representatives of the Koenigsberg Commercial Association; also, both in Petersburg and in Moscow, by gentlemen who were formerly the tea specialists in the powerful house of Knoop, whom that firm made tea one of its specialties.

As was, of course, to be expected, most of the "trade" expressed the opinion (just as was done in England formerly) that it would take a long time to *change the Russian taste*. All, however, complained of the great deterioration which was taking place in the quality of China teas, while the Russian taste demanded, *no worse, but better* teas. Most of the firms appear to be kept well supplied with samples, both of Indian and Ceylon teas, by their London agents; but great expense and delay attends the introduction of Musters, while, owing chiefly to the delay, business in them is usually very difficult to carry through. The teas apparently which seem, most nearly, to approach the requirements of the are *medium or good Pekoes-Leaf teas without dust or broken*, either Ceylons or Darjeeling and Doars teas; but there were also Assam and Cacbar teas among the samples which appeared suitable.

Coarse Indians (i.e., Sonobong grades and lower); *pungent* teas, and teas with a *high fired* flavour, appear to meet with least favour; *tippy* teas, too are to be avoided. *Dark liquoring* teas are needed, because, although Russians drink their tea light in colour, this is effected by filling up a small quantity of strong extract with a large quantity of hot water from the Samovar. Everything appears at present to be favourable to the introduction of Indian and Ceylon teas. The duty of course, is high, about 1s 9d per pound; but the Government, while augmenting the duties on all other imports, has left tea alone. The exchange is favourable to importation and the gold premium (duty being paid in gold) is also comparatively favourable to importation. The Russians, both high class and low class, are, more or less *connoisseurs* of tea and their method of drinking it (without the addition of milk) is most in favour of teas possessing some pretensions to *quality*. The overland trade appears to be much on the wane, so that the prejudices of Russians against ocean-borne teas is being rapidly dissipated. The Government is, moreover, giving great encouragement to the importation of tea by way of Odessa, with the view of providing a return freight for the subventioned line of steamers (the Volunteer Cruiser Fleet) trading between that port and Vladivostock—the eastern outlet of Siberia and the Russian Central Asian possessions. These vessels, moreover, pass Colombo, and moderate inducement would no doubt lead to their touching also at Calcutta, or other Indian ports.

I leave the subject here, as this letter is already too long, but with your permission I may venture again next week to return to it, and make some further suggestions.—I am, &c.,

GEO. SETON,

14, St. Mary Axe, E. O.,

London, Oct. 22nd, 1890.

THE CUSTOMS' REPORT ON THE TEA TRADE.

The annual report of the Commissioners of H. M. Customs for the financial year, ending March 31st last will be interesting reading to those who are interested in the growth and development of the tea trade of India and Ceylon. From this report it appears that the gross amount of duty received upon tea was £4,490,695, a decrease of £139,621 upon that received in 1888-89. The report says:—

It had been so generally anticipated in the first quarter of the present calendar year, which corresponds with the last quarter of the financial year 1889-90, that a reduction would be made in the tea duty, that merchants and dealers became very cautious in effecting their clearances for Home consumption. The effect of this caution has been very apparent on the yield of this head of duty, and the decrease shown is more than accounted for by the difference in the amount of tea cleared in the quarter ended March 31st, 1890, as compared with the same quarter of the preceding year. This difference amounts to 6,000,000 lbs., equal to £150,000 in yield of duty. It thus appears that had it not been for the surplus of revenue which it was evident before the close of the financial year 1889-90 would be at the disposal of the Chancellor of the Exchequer, and upon which the anticipation referred to was founded, the receipt from the tea duty in 1889-90 would probably have only exceeded the actual receipt of 1888-89 by rather more than £10,000. This result cannot be said to be satisfactory from a revenue point of view, especially having regard to the importance of the tea duty as one of the principal sources of receipt, on account of the Revenue, under our charge. It is no doubt, however, to be traced to the displacement of Chinese by Indian and Ceylon teas, to which we have in recent years called the attention of your lordships in our annual reports, which has continued in an increased degree in the year 1889. It is not possible to trace with *absolute* accuracy the rate at which consumption of the various kinds of tea has proceeded in this country, because the official accounts have not hitherto been kept with a view of affording information on this point, but the following table shows the proportion contributed by China, India, Ceylon, and other countries, respectively towards each 100 lb. of tea imported into this country during the last twenty-five years. It must be borne in mind in examining this table as bearing upon actual consumption, that Chinese tea imported into this country is to a large extent exported again, whilst the bulk of the Indian tea imported is consumed in the United Kingdom.

OF EACH 100 LB. IMPORTED.

	China contributed. Per cent.	India contributed. Per cent.	Ceylon contributed. Per cent.	Other countries contribute Per cent.
1864...	92.55	2.34	...	4.61
1865...	93	2.50	...	4.50
1866...	93.74	3.88	...	2.38
1867...	91.81	6.07	...	2.12
1868...	91.77	5.89	...	2.34
1869...	90.86	8.07	...	1.08
1870...	89.06	9.17	...	1.77
1871...	88.25	8.91	...	1.94
1872...	86.80	8.89	...	4.31
1873...	83.81	11.23	...	4.91
1874...	81.98	10.12	0.30	6.90
1875...	85.31	12.87	0.08	0.74
1876...	84.03	14.99	0.05	0.93
1877...	82.65	16.50	...	0.85
1878...	80.88	17.20	...	1.83
1879...	76.94	20.76	0.07	2.23
1880...	76.43	21.81	0.08	1.68
1881...	77.33	21.66	0.08	0.93
1882...	72.65	25.43	0.24	1.45
1883...	70.27	26.06	0.90	2.17
1884...	67.22	26.55	1.03	2.20
1885...	65.84	29.55	2.00	1.51
1886...	62.99	31.85	3.10	2.03
1887...	54.00	33.15	5.89	1.96
1888...	47.45	40.34	10.10	2.10
1889...	39.48	42.93	14.70	2.19

The year 1864, with which the preceding table commences was the last year of the old rate of duty of 1s per lb., and in that year the total importation of tea

was 124,359,243 lb. In 1865 the duty was reduced to 6 per lb., and in 1866 the total importation of tea rose to 139,610,044 lb. In this increased importation India fully maintained her position. The importation from that dependency rising from 3,594,509 lb. in 1864 to 5,413,583 lb. in 1866, has continued to progress with rapid strides until, in the year 1889, she contributed nearly 43 per cent of the total importation of tea into this country. But the growth of the culture of tea in Ceylon has progressed in a manner even still more remarkable. It is only within the last ten years that this culture has been carried on to an extent appreciable in the export trade of the colony, and it was not until as recently as 1884 that she contributed 1 per cent of the tea importation into the United Kingdom. In that year the contribution of Ceylon amounted to 2,210,983 lb. and it has since mounted up year by year by "leaps and bounds" as shown by the accompanying details:—

1885	...	4,242,244
1886	...	7,144,313
1887	...	13,062,040
1888	...	22,509,564
1889	...	32,673,294

We may also point out that this advance both in Indian and Ceylon teas has been arrived at in face of the fact that the average price of these teas is considerably higher than the average price of Chinese teas. In 1889 the great bulk of the tea imported from China was Congou at an average price of 7½d per lb., whilst Indian tea averaged 10½d and Ceylon 11d per lb. Whilst, however, the displacement of Chinese by Indian and Ceylon teas has acted injuriously upon the Revenue, owing to the greater strength inherent in those grown in the latter countries, it would be incorrect to assume that tea beverage is decreasing in popular favour. The following figures show the consumption per head of tea leaf by the population for each of the last ten years:—

1880	...	4.57	1885	...	5.02
1881	...	4.53	1886	...	4.87
1882	...	4.67	1887	...	4.95
1883	...	4.80	1888	...	4.95
1884	...	4.87	1889	...	4.91

The figures for the calendar year year 1889, which were not disturbed by anticipation of the Budget to which reference has been already made, appear to indicate a fall in consumption of leaf, and to bear out our anticipations on the subject last year; but inasmuch as it requires a smaller amount of Indian or Ceylon tea-leaf than of China leaf to produce a given measure of tea beverage, and as the demand for Indian and Ceylon leaf is increasing, there is no reason to suppose that less tea beverage is, or it likely to be consumed.

BOGUS TEA.

The Commissioners of Customs have often had their attention called to the sale of tea at prices so low that it is manifest that the tea could not legitimately have passed through the hands of their officers; and in tracing out the history of such tea it has been ascertained, on fairly trustworthy evidence, that it has been obtained from the sweepings of warehouses, and sifted on the premises of the remover. This sifting is a somewhat laborious work, but, nevertheless, it is done by very cheap labour, and the sale of the tea, though at a very low price, yields a fair profit. So far as the Customs regulations go, no such tea in any quantity ought to leave the warehouse, because all split or damaged tea discernible is collected and thrown into what is called "the damage hole," for destruction. It is, however, necessary for the merchants and warehouse-keepers to clear the warehouses of wood, paper, nails, lead, and other refuse, and this is done by sale to carting contractors. In moving this refuse it is difficult, if not impossible, to prevent a quantity of tea from being taken up at the same time; and, in spite of all the care which the Customs officers may exercise, there is no doubt that a considerable quantity of tea in the course of the year does so leave the warehouse, and, of course, leaves without any duty being paid. In one or two cases where it was found that this tea was being largely trafficked in, the Board of Customs directed its seizure, and expressed a desire that the person sifting and selling it might be prosecuted; but, on the whole, it was thought

that, although the tea could not be said manifestly to have paid duty, yet that as it had not been removed furtively, and to a certain extent had even been taken with the consent of the Customs officers, it might be difficult to contend that it constituted "uncustomed goods," or that selling the tea could be sustained so as "a dealing with uncustomed goods," so as to involve a penalty. At the same time, it was manifestly injurious to the revenue that such a practice should be allowed to continue; and, also, there was no moral reason for it, because the removing contractor pays only for refuse and is not supposed to convert any of that refuse into an article by the sale of which in the market he would presumably displace an equivalent amount of the same article which would otherwise pay duty. It has consequently been enacted by the recent Act, that when any goods of a kind or description liable to a duty of Customs have been taken from a warehouse either with or without the permission of an officer of Customs, as unfit for consumption by reason of the mixture therewith of any other matter, the separation of such goods shall be deemed to be dealing with them with intent to defraud Her Majesty, and shall involve penalties accordingly.—*H. & C. Mail.*

PATENT LEGISLATION FOR A CENTURY.

The present century has been the time, and the United States the place, in which invention has made its greatest strides.

The growth of the patent system in the century which has elapsed since the first patent law was passed in 1790 has been enormous. Only three patents were granted the first year, and only fifty-five were granted under it before its repeal in 1793. The whole number of patents granted before 1800 was 256, a little more than one-half the number now issued weekly. The number issued in the last ten years from 1880 to 1890 was 195,451, or more than 800 times the number issued during the first ten years of the patent law. During the forty-six years prior to the passage of the act of 1836 the number of patents granted, exclusive of reissues, was 9,957, a number now exceeded in a period of six months. The number of patents issued by the office in 1836, after the date of the act establishing it, was 109, and the number for the fully year 1837 was 436. The whole number of patents issued in 1889 was 24,083. The whole number of patents granted since 1836 was 431,541. According to Mr. Smith's calculation, in fifty-four years the number of patents increased more than fifty-five fold, the receipts more than forty fold, the expenses more than thirty-two fold and the number of persons employed seventy fold. This increase has been truly wonderful. It speaks volumes for the growth of invention and the application of science to industry in the last century, and more particularly in the last half century.—*Bradstreet's*, Oct. 25th.

COTTON AND TEA.

We notice that some of our contemporaries have a length sounded the note of alarm respecting the inevitable effect that the recent rise in exchange will have upon many of the tea gardens. It must be manifest to the merest tyro that should the rupee rise to par or even remain at its present value those gardens that have kept afloat simply by selling in London to obtain the benefit of the exchange, must close, for it is not to be expected that either banks or agency houses will continue to advance funds to bolster up concerns whose prospects are hopeless. Such companies who possess flat or undulating land, not liable to wash, with good soil, favourable site with regard to communications and a superior *jat* of plants will no doubt, continue to hold their own, but a glance

at the dividend list is sufficient to shew that most of the older gardens, especially those planted on steep sandy *teclads* are doomed, and in fact several are now in liquidation, while others, unless they can raise money for opening fresh planting on favorable sites, must in due course follow suit; but as we have written above, the probability of such concerns being able to obtain pecuniary assistance is highly problematical. When the falling off in yield and quality is due to exhaustion of the soil and the *lay* of the plantation is moderately flat, we would reiterate the advice given some seventeen years back, viz. to dig well into the root finely pulverised lime stone, at the same time making either trenches or renovating pits between the rows of plants, which should be filled with blue soil, if available, mixed with vegetable refuse and also a due proportion of lime stone. But best of all the cocles should be introduced to stall their cattle for the night in one or more sheds, down the centre of which a drain should be carried so as to secure the urine in a tub, tank or other reservoir, and this, added to the other matters we have enumerated, well worked into a compost would go far towards stimulating the flagging vitality of the exhausted plants. Annually cutting back a certain area until the whole plantation has been thus treated, adopted in conjunction with high manuring, has proved beneficial, though, of course, diminished return would have to be submitted to until the cut back portion had re-grown sufficiently to bear plucking. All this, of course, means the raising of fresh capital and, probably, many shareholders would demur to what they, no doubt, would consider as throwing good money after bad, but unless they make up their minds to adopt some method of endeavouring to retrieve matters—and we venture on one or two suggestions—the alternative is bankruptcy, for that in the case of tea properties under the present outlook, is the true interpretation of the more eunuchous term liquidation. Upon those plantations where the plant is exhausted but the soil still retains a moderate amount of vigor, we would recommend the cutting back of the entire planting and the sowing between the rows in well manured pits, which could be easily and rapidly excavated by means of small sledges such as are used in ascertaining the character of the soil in river beds, with the best cotton seed available; for if it pays to grow cotton in the southern states of the U. S. A. with wages equivalent to R24 per month, it would surely do so in Cachar, at less than half that rate. Of course, some arrangement would have to be come to with the steamer companies for conveying the bales to a sea port at a reasonable rate, or if the companies declined to entertain any proposition for reduction in freight it would be necessary to raise funds for the purchase and equipment of one or more steamers and flats, on the co-operative principle. It is no use people arguing that cotton will not pay, as every cold weather an enterprising foreign firm locates its employes with gins and presses at Goalpara in Assam, purchasing cotton from the Garrows with highly profitable results.

It must be recollected that the difference in price between cotton and tea is, under the present state of the tea market, not so very great and, when it is considered that cotton needs but packing in gunny (costing but some 6 annas per bale) and that tea requires lead-lined chests, solder clamps, etc., the difference in laying down the two commodities is reduced to a minimum. Reverting to the question of cultivation it must be borne in mind that tea gives no appreciable yield till its fourth year, while cotton, being an annual, furnishes returns in nine months; though among the hill tribes who know nothing of manuring the *ghooms*, cultivated by them, are abandoned after three years—the soil being by that time considered exhausted. Were the system of cultivation, adopted in the cotton states, followed out in Cachar, Sylhet and Assam, the same fields would turn out steady even crops for twenty years and even should signs of deterioration become apparent, most of the non-paying tea concerns have sufficiently large tracts of forest to fall back upon, so that no anxiety on the score of want of area need be entertained.—*Indian Agriculturist*, Oct. 25th.

A RUSSIAN BUYER OF CHINA TEAS AND THE PROSPECTS OF CEYLON TEA IN RUSSIA.

I have had some talk with a Russian buyer of Ceylon teas, who is also taking a trip home in the "Iraouaddy." His knowledge of English is unfortunately somewhat limited, and his French, like that of most Englishmen, is also rather "rusty," but I learnt that he had had three or four years' experience as a tea buyer in Hankow and Foochow, and he was therefore likely to be able to express an opinion about the China tea market, and the prospects of Ceylon tea in Russia. Perhaps his ideas are a little biased, but it is well to hear both sides. While the exports of China tea to Great Britain have diminished so tremendously, and the quantity of tea sent down from the gardens had considerably decreased, he did not appear to think that there was an appreciable falling-off in the quantity sent to Russia, but if I understood him correctly he thought that in ten years English buyers would entirely give up buying China teas and would buy only from Ceylon and India. Many of the China growers, he said, are now rooting out their tea, and planting potatoes instead. But he does not think that the Russians will take kindly to Ceylon teas for several years, as our teas have not that peculiar aroma to which they are accustomed in the China teas, and of which they are so fond. We tried a few cups of Ceylon tea on board one afternoon, and he thought it was decidedly strong—too strong for the Russian taste. But that may have been the fault of tea we tried, or the fault of the brewing.

RUBBER IN BRAZIL.

PARA.—Messrs. Singlehurst, Brocklehurst & Co. write under date of the 5th inst.:—RUBBER.—Since our last advices has been almost constantly in active and general demand, causing our market to assume a most animated and strong position, in harmony with the stimulating features, which, in consequence of greatly reduced stocks, prevail for the time being at the American and European consuming centres. Buyers meeting the market liberally, all arrivals were immediately taken up by them, and frequently bespoken before the rubber had made its appearance, with the result that prices have advanced to 3\$300 per kilo. for fine and 2\$300 for coarse Islands rubber, while last sales of Up-river have been made at 3\$500—2\$500 for fine and coarse respectively. As there are no stocks available and arrivals have been small during the past few days prices are well maintained. Just now, however, buyers seem to have satisfied their immediate wants, and may resume larger operations on less spirited lines. An interesting census has been recently taken in the Purús river district, one of the most important regions for the extraction of rubber, which reveals a shocking result. Basing the estimate on the number of immigrants, chiefly from the neighbouring states who have gone to that district during recent years, it appears to have been considered that its population consisted of rather more than 40,000 souls. It has, however, been reported, on what is said to be reliable authority, that the number existing—including children—is only 16,000 souls. The mortality always considerable, and the most lamentable feature in connection with the production of rubber, is described as having been stupendous last year, especially on the Acre river, where the banks are plentifully sprinkled with crosses, marking the ravages of fever and disease. If this has been the fate of native immigration, what may be expected for Europeans should they ever venture to these parts?—*Rio News*.

SCHOOL OF AGRICULTURE, COLOMBO :

PRIZE DAY.

Yesterday (Nov. 29th) afternoon took place another of those pleasant gatherings which recur annually at the School of Agriculture in the Cinnamon Gardens. The entrance to the building was tastefully decorated and the school-room had much artistic labour bestowed on its decorations. The Hon. the Colonial Secretary presided, and amongst others present were the Hon. J. J. Grinlinton, Hon. W. W. Mitchell, Hon. Dr. Anthonisz, Hon. M. C. Abdul Rahiman, Messrs. H. W. Green, J. B. Oull, T. E. De Sampaio, Mrs. and the Misses Keitb, Mr. James De Saram, Dr. H. M. Fernando, the Maha Mudaliyar, Mr. O. Dreberg, Mr. and Mrs. Joseph, Messrs. C. Thomasz Walter Pereira, R. P. Jayawardena, Mrs. and the Misses Beven, Mr. and Mrs. Schrader, Mr. O. M. Fernando, Mr. and Mrs. Jeronis Peiris, Advocate Senathi Rajah, Miss Frédox, Mr. Rancesinghe, Mr. J. S. Drieberg, Mrs. and the Misses Attygalle, Miss Lindsay, Miss Drieberg, Mrs. and the Misses Grenier, Mrs. C. Drieberg, Rev. S. Lindsay, Mrs. A. de Saram, Dr. and Mrs. Asreappa, Mr. and Mrs. F. Dornhorst, Rev. T. O. Hillard, Dr. Bowles Daly, &c.

The proceedings commenced by the President calling upon the Principal (Mr. O. DRIEBERG, B.A.) to read his Report.

Report was of a very encouraging nature, and its reading was punctuated with frequent marks of applause from the audience. It alluded in terms of praise to the late Governor Sir Arthur Gordon, who had by his encouragement and patronage in previous years shown his interest in the work of the School. His Excellency Sir Arthur Havelock was prevented from presiding owing to pressure of work, but he had already shown his appreciation of the work carried on in the School by visiting it. The presence of Sir Edward Walker was an indication of the interest he evinced on behalf of the school. The report next proceeded to state the results of the operations carried on in the various provinces by the students who had been sent forth from the School. One of their men had been appointed as an agricultural instructor in the fever-stricken district of Walapane—the condition of which district the energetic Assistant Government Agent of Nuwara Eliya was endeavouring to ameliorate. That appointment made up a total of twelve students who had been employed as agricultural instructors—seven of whom were paid by Government and five privately. It was a matter for congratulation that the Government officials rendered valuable assistance to the cause of agriculture, notably the Government Agent of the Eastern Province, the Government Agent of the Sabaragamuwa Province, and the Assistant Government Agents of Matara and Kegalla. Another batch of students was leaving College on completion of their studies to engage in agricultural pursuits. It included some excellent young men, among whom was Mr. J. J. Koddipilly, who has had a brilliant career at the School. One feature of interest was the publication of a Monthly Magazine devoted to the interests of Agriculture; and this literary effort is appreciated by those for whom it was intended. The School Museum is growing in size, the Agricultural Discussion Society is well supported by both students and outsiders. A dairy has also been set on foot by the headmaster, Mr. Jayawardena, and experiments have so far been attended with success, and it is satisfactory to note that a long felt want has been supplied. Through the knowledge imparted in this branch of agriculture the students could gain a knowledge of the proper housing, feeding, and general treatment of cattle in health and disease. Another feature of interest in the report was the fact that a large variety of crops had been grown on the School grounds with the view of demonstrating the most approved methods. The report next referred to the willing help and ready assistance of Mr. De Silva, the second assistant, not only by teaching in the School but by his writings. Another student of last year's batch has been employed as a conductor on an up-country estate; and it was satisfactory for the Principa

to note that the advantages of employing such men consisted not merely in having an intelligent manager but also a disciplined and honest employee. The report concluded by speaking of the loss of their old Director, Mr. Green, to whom the School owed its existence and success, but they had also to welcome the presence of Mr. Oull, whose established reputation as an educationalist insured the successful direction of the Department of Public Instruction.

Mr. J. B. OULL, M. A., the new Director of Public Instruction, then rose and said:—Sir Edward Walker, Mr. Principal and ladies and gentlemen,—I congratulate myself in the fact that my predecessor, Mr. Green, has come amongst us this evening prepared with a speech. The School is pre-eminently a poem of his own composition; and the fact that I am so completely new to the use of the plough makes it impossible for me to comment on the nature or the results of the School in any way as adequately as I would wish. I congratulate you, Mr. Principal, on the record you have been able to present for the year. I learn that that there are 26 students on the roll, and the report of those students who have been sent forth to work in the various districts is entirely satisfactory. (Applause.) I leave it to my predecessor to comment upon the various modes of agriculture that are carried on in the island with unvarying success in the various provinces. As regards the School itself I note with great pleasure that it embodies one of the most noble feelings, and, what is best, it teaches the dignity of labour. (Applause.) Passing the compound the other day I was struck by seeing the boys engaged in manmottying and other kinds of operations, and in a country like this, such kind of work is eminently satisfactory. It has been wisely remarked that a man who makes a blade of grass to grow in a place where there was no grass at all is a benefactor to the country, and this is the great object of the Agricultural School—multiplication of the fruits of the earth; making nature yield more abundantly and tending to eliminate as far as human agency can eliminate the ill-effects arising from untoward climatic conditions in the island. (Applause.) Reading in connection with this subject a poem written many centuries ago, entitled, "Georgis de Virgil," I was struck with the rule laid down regarding ploughing in which the author recommends that as a preparation for ploughing one should take his coat off, and put his shoulder to the plough, and it is universally true that a man who cannot take his coat off and put his backbone into his plough is a very incomplete agriculturist. (Applause.) I will not occupy your time any longer in view of the speeches which are to follow; save to express my great gratification at being present here this evening and to express the interest I have always taken on behalf of the School of Agriculture. (Loud applause.)

Mr. H. W. GREEN next rose, and said that the students of the Agricultural School, unlike other ordinary educational establishments, were limited to a certain number. They had a great many applications for boys, but their number was limited to 23 in his time and now he saw it was 26. They only wanted a select number of boys, who had the interests of agriculture at heart. He read in the newspapers that one of the boys had been sent from the School to the clerical examination, but he hoped that the Principal would never allow this to occur again, for the one object with which the boys entered the School of Agriculture was to qualify themselves in agricultural knowledge and to go forth and spread forth that knowledge. When he first thought of an Agricultural School, he had many discouragements to contend with, but he was now glad to find that he had successfully broken the ice. There were eleven agricultural instructors, seven of whom were paid by Government and five privately, so that all their old students were not simply employed under Government. The improved plough had done a great deal to foster agriculture, and from the reports to hand, he found that the crops had more than doubled their usual yield by the use of the plough. They had sent out their young men to work with the improved ploughs and they had all

done good work. The other day he sent out a hard-working man to work in a place some 19 or 20 miles from Trincomalee. The people there were not inclined to work at first, but the speaker himself spoke to the people and told them that if they did work they could share the profits equally and so ward off starvation. At last they did set to work and they got a good return and shared the profits. He moved the instructor on to the next station, and the result was so eminently gratifying that here were several applications for the ploughs. Their object was to disseminate a knowledge of agriculture so that others might follow the example; for he found the Sinhalese people always ready to take advantage of opportunities offered to them. They wanted the young men to work. A good many had already taken advantage of employment on estates, and he was quite sure that the education received here would not be thrown away in vain. In conclusion he wished all success to the institution and wished the pupils good-bye. (Applause.)

The distribution of awards then took place according to the following list, each recipient as he came up to receive his gift being heartily cheered by his comrades:—

SENIORS.—Agriculture, Chemistry, Botany, Zoology, Entomology, English, History and Geography, Mathematics, and Practical Chemistry (the late Mr. de Soysa's prize) all gained by J. A. Kodippily; Veterinary Science was won by A. Drieberg; and Practical Agriculture by J. P. Ranasinghe.

JUNIORS.—Agriculture and Geology by P. V. Cooray, and Chemistry, Botany, English, History and Geography, Mathematics, and Field Surveying (the Grenier prize) all by E. M. Johannes.

THE PRESIDENT'S SPEECH.

The prize-giving over, Sir E. WALKER said:—Mr. Principal and ladies and gentlemen,—It gives me great pleasure to come here today and to make the acquaintance of the School of Agriculture and to join with you by your presence in the expression of encouragement to the masters who have been engaged in teaching the boys during the past year and congratulating the boys themselves on their course of study. (Applause.) I trust that those who have received prizes today will find in them an encouragement to persevere in after life and to exercise that industry which have enabled them to attain certificates. I am not altogether a stranger to the School of Agriculture. The deservedly high terms in which Mr. Green has spoken of the institution I am well aware of, as it has been my good fortune to have been much associated with Mr. Green, and from him I have from time to time heard a great deal of the School and have been much impressed with the zeal and the interest he has taken in it. (Applause.) I think the Principal in his Report has very rightly expressed regret at his loss, but it is not a very real loss after all, for you have in his successor a gentleman who has the interests of practical education at heart, and I feel sure that he would use his best efforts in furthering the work of agriculture. (Applause.) And you have Mr. Green in a position to help you at the Governor's elbow and as my principal colleague and assistant. As regards the work of the School I have heard of several accounts disparaging and discouraging the work and utility of the education given in this institution. Of course it would be difficult by statistics to show how valuable the School was, but I am of opinion from all the information I have gathered, that those boys who have been sent forth from this School into the various provinces of the island are doing good work in agriculture. (Applause.) I put the question to Mr. Drieberg when I came into the room whether during his travels about the country he had seen good work being carried on in agriculture as the result of the money spent on it, and he unhesitatingly answered in the affirmative, and I think we may take his opinion as one of considerable value. His opinion is, moreover, of an independent character, because he belongs to this country and it is not as if he were speaking of the results of his own labours, but of those who have gone before him. Some people have tried to

throw cold water over the school: but if the boys only worked quietly and persistently their labours would bear much fruit. (Applause.) The Principal has referred to a pupil who had gone to the district of Walspane. Well I know of no one who is likely to do more good to that unfortunate part of the district than one who would instil into the poor people there some knowledge of agriculture, and if he did that he would certainly accomplish more than what Government officials and Colonial Secretaries had yet been able to achieve. In conclusion I have only to express the great pleasure it has given me today in taking part in the prize-giving this year. (Loud applause.)

The Hon. Mr. J. J. GRINLINGTON followed, and in the course of a spirited address urged on the School the desirability of experimenting upon the system of transplanting paddy. In some parts of the country this system was a success, while in other parts it was a failure, chiefly because in many cases transplanting took place at the wrong time and the plants died. He hoped that the matter would occupy the attention of the Principal and his pupils, for transplanting was carried on on an extensive scale with various other products, and he saw no reason why they should not carry out experiments in transplanting paddy. With regard to the remarks which fell from the President and Mr. Green that cold water was being thrown on what they did by some people, he believed that these people were everywhere in the world, and the very men who had not lifted a finger to help them and had done all they could to discourage them would whenever they heard that success attended their efforts, say "We told you so." (Laughter and applause.) He counselled the young men not to trouble themselves about the criticisms levelled against them, but simply to work on steadily and success would assuredly follow. He was sorry to find that the Sinhalese natives were not giving that attention to cultivation which they did in the ancient days. In those days their one ambition was to possess and cultivate the land, but now the majority of the young men only tried to get educated and seek employment under Government on the smallest pittance. This, the speaker said, was what ought to be discouraged; and he thought the best thing for our young men to do was to put their shoulders to the plough and to give their attention to agriculture. (Applause.) In addition to agricultural knowledge a knowledge in mercantile matters was also indispensable. He would instance the case of those gentlemen in England, who were trained to agricultural pursuits in preference to a berth under Government, and he maintained that if the young men only considered the advantages to be gained from a knowledge of agriculture, they were bound to succeed in life. In conclusion the speaker proceeded to advocate technical training. The School was only in its infancy and they had heard of the success which had attended their efforts; and if success had attended efforts where difficulties had to be surmounted before, he had no doubt that a school for technical education would also meet with success. (Applause.) Without technical education the School could not prosper, and he would be very glad if technical education was brought to the very doors of the natives. (Loud applause.)

Mr. H. W. GREEN referring to Mr. Grinlinton's remarks regarding the system of transplanting said that that was the first thing he started with, as it was the system which brought out the best returns. In China and Japan this system of transplanting brought enormous folds, and even transplanting in the sandy soil at the back of the room resulted in a yield of 539-fold. Another great advantage in favour of transplanting was that 10 measures sufficed to plant out an acre of land whereas the people usually used two or two and a half or three buhels an acre. The system too could also be carried by means of a nursery in one corner of the field, and during a period of drought the cultivator would be able to water this small piece of ground from his chatty and thereby to tide over the period of drought without being starved (Applause).

The PRESIDENT said that in bringing the proceedings to a close he wished all the pupils a successful career. He might mention that in connection with the eleven students who had left the institution for the various provinces, the fact that five had been employed by private parties indicated that they had shown an independent appreciation of the worth of the School. (Applause.)

Three choarty cicers having been given to Sir E. Noel Wilker for presiding on the occasion, followed by rounds of cheering for the Principal and the visitors the gathering adjourned to the green, where light refreshments were partaken of: the Band of the C. L. I. V. treating the people to some excellent music.

A GIGANTIC AFRICAN COMPANY.—We believe (says Saturday's *Liverpool Journal of Commerce*) it is intended to float a very large company for the purpose of developing the resources of West Africa. The capital is to be placed at ten millions sterling, and amongst the likely promoters are the Duke of Westminster and Mr. Stanley.—*A. F. Press.*

HOW TO SELECT BANANAS.—A fruit-buyer said to me the other day—"Very few buyers know how to select bananas when purchasing them by the bunch. It's a very simple thing. Look at the thick end of the branch on which the bananas hang. If it is green the bananas will ripen slowly and lusciously and will be of good flavor. If the end of the branch is black the bananas themselves will blacken after a day or two and will ripen too fast and rot. Even if they are plucked the day after they are bought, and eaten, they will be mushy and the flavor will not be good."—*Jamaica Gleaner.*

BUG ON COFFEE.—Mr. Jas. D. Watson will not find Ceylon planters to agree with him in making light of green bug. He writes as follows to a Rangoon paper:—

The coffee pests are only two in number and they are termed in plain language—"Black Bug" and "Green Bug." But they have never been looked upon as great enemies to the coffee trees, and planters know well that wet seasons had to do with their production more than anything else. But I have never found a good handful of quicklime, thrown on the trees early in the morning, to fail, and the bug left the trees as they came. Of course, the quicklime or "*caustic lime*" must be applied when the dew is on the trees, and this could always be carried on up to 8 a.m., and 300 or 400 coolies get over a good acreage in the course of that time.

KIDDERED SARKASTIC.—The *Pouchow Echo*, referring to the poisoning of a tea party in England, the poisoning being traced to corrosive deposits in the urn, says:—"Worse and worse. We never did think well of Indian tea, but little did we suspect that there was actually poison in the cup. Here is a case where, owing to the accumulated deposits in the urn used for the purpose of making the tea, one hundred persons were poisoned by it! It is too shocking. That the tea used by the benevolent lady could not have been of China growth is amply proved by the fact that the Chinese never clean out their teapots, be they metal or earthenware, for the reason that a long-used teapot, never cleaned, is known by experience to add sweetness to the brew. Such a misfortune as the above would never have occurred had China tea been used. Its purity is a guarantee against such mishaps. Any deposit left is well known to be perfectly free from deleterious matter. No doubt the benevolent Miss White and the British public at large will run away with the idea that the deposits of all tea are poisonous. Poor China! it is a fresh case of the innocent suffering with the guilty."

INSECT AND OTHER PESTS: WHY THEY EXIST.

IMMUNITY OF TEA IN CEYLON FROM ENEMIES—POOR COFFEE—CURE FOR GREEN BUG—PUBLICATIONS OF THE AGRICULTURAL DEPARTMENT OF NEW SOUTH WALES—REMEDIES FOR NOXIOUS INSECTS—RUST ON WHEAT AND FRUIT TREES—LADYBIRDS AS ENEMIES TO BUGS—LOCAL APPLICATIONS.

NANUOYA, Nov. 27th.

In Miss Ormerod's works, in similar books published in America, in Dr. Maskell's book on scale insects in New Zealand, in a multitude of books of the same nature, and in the agricultural and horticultural papers and scientific reports which reach us from all parts of the world, but especially those from India, Australia and the United States, I have read carefully and noted information about insects injurious to cultivated plants and insecticides, including in the latter category insects which prey upon predaceous insects, such as "the ladybird"—

("Little fleas have lesser fleas to bite 'em");—so much indeed as to cause me to consider the mystery of such pests in nature as phylloxera and bugs, helopeltis and red spider, and hemileia and red rust, as a mystery only second to the existence of snakes vested with venom. I suppose the mystery is to be solved only by reference to the moral revolution which called forth the declaration:—"Thorns and briars shall the earth bring forth, and in the sweat of thy face shalt thou eat bread." If there were no difficulties to encounter or overcome, men would either sink into the slough of indolence, or imitate the pride of him who said, "Behold great Babylon which I have built." At any rate, we have to fight the adverse circumstances of our natural surroundings, as well as to enjoy their favourable characteristics. As yet at least, we in Ceylon have reason to be thankful that our new staple production, tea, should enjoy so much of immunity from insect or fungoid enemies. But "the enemies of the coffee tree" seem bent on pursuing their victim to extinction. The latest and worst foe is "green bug"; and in answer to the demand for a remedy, I feel bound to repeat, as the outcome of my reading, experience and reflection, that applications should be used specially calculated to smother the insects to death. No doubt powerful chemical agents, especially poisons, have their use, but danger to human life as well as vegetable vitality is involved in their application, and it really seems a question whether they cannot be dispensed with. Is it not a fact that the value of a mixture of grease and sulphur as a cure for the itch-insect consists in the smothering effect of the grease and but little in the actively destructive power of the sulphur? I have just been reading with great interest some valuable publications issued by the newly created Agricultural Department of New South Wales, of which the Hon. Sydney Smith, M.P., is Minister, and Mr. H. C. L. Anderson, Director. Both have gone to work with great energy and intelligence to collect and diffuse information, summoning for this purpose the leading agriculturists and horticulturists of the colony to a conference, at which valuable papers were read and discussed, differing views and experiences compared and conclusions arrived at. Remedies for noxious insects received much attention, and I have been much struck with the simplicity as well as the alleged efficacy of some of the suggestions offered as the following out of experience obtained. One practical orchardist stated that he kept his orange and other trees clear of scale insects by an application of nothing more

potent than diluted starch: diluted but of such a consistency as to form a crust over the insects and which remained over their bodies long enough to secure their death from suffocation. It would seem as if something more potent than starch or flour paste would be required to penetrate the body of the parent scale so as to reach the thousands of insects of several generations beneath, but the testimony was the starch sufficed, and, therefore, I advise a trial of rice flour, either alone or mixed with common gum (dammer?) or some viscid substance, the mixture to be sprayed or diffused by oir brushes or brooms, on to coffee bushes, and orange or other trees affected by bug, brown or green. In the case of coffee bushes, when not in fruit of course such arsenical poisons as London purple and Paris green can be applied, with much more safety to human life at least, than would be the case with orange trees bearing fruit, edible vegetables or tea leaves. Another simple recommendation was the use, as an application, of a decoction of gum (eucalypt) leaves; and an orchardist asserted that he had kept his trees free of "scale," by mulching them with gum leaves, which, when decayed were dug into the ground at the roots of the tree with good fertilizing as well as bug-resisting effects. The Australian eucalypts, especially blue gums, are now so common in Ceylon, that a decoction of the leaves and the leaves themselves as a mulch, that is as a covering for the surface around coffee, orange or other trees, can easily be tried.* If by such simple means success is not attained, then the more potent remedies (generally poisons) can be resorted to. A large proportion of such remedies were discussed at the Sydney Conference, in the light of local and general experience in Australia, as well as the large experience obtained and the comprehensive information collected in the United States, especially in Florida and California. The Codling Moth (*Carpocapsa pomonella*) so destructive to apples and pears especially formed the subject of the first elaborate paper published by the Department to which we have referred. Another apple pest, *Cacacia postvittana*, was also noticed, the larvæ of which have been found on several native plants, including *Grevillea robusta*. Birds, lizards and frogs are enemies of these moths, and with trap bands of canvas, the spraying of Paris green or London purple is recommended, in the proportion of 1 lb. of the poison to 100 gallons of water. The application of the arsenical solution is, of course, made when the fruits are quite small. What applies to apple trees applies to coffee, only that it is the leaves and twigs of the latter which are chiefly attacked. In a paper on rust in wheat, it is stated that last year the loss of farmers in Australia from this pest, so like *Hemileia vastatrix* in general appearance, was equal to £2,500,000 sterling. No such cereal as rust-proof wheat has been discovered, but some kinds are constitutionally able to resist the pest, and it was recommended that wheat should follow other crops, such as maize, sorghum, &c. Of course no such remedies apply to plants perennially in the soil. For peach rust, the washing of the trees with ferrous sulphate (green vitriol or copperas,) 1 lb. to 4 gallons water is recommended; also the dressing of the soil with the same substance, $\frac{1}{2}$ lb. for a tree, finely powdered, or dissolved in 2 gallons water. This poison can be applied to coffee trees,—with caution, of course. For the maize moth and the cotton worm, *pyrethrum*

* It is quite possible that a decoction of our coarse hill lemon grass, mana, might be efficacious as well as a mulching of the grass. In the old days of black bug, I remember wisps of mana grass being tied on the coffee stems.

extract, diluted in water, one to thirty, was found somewhat useful. A paper on microscopic nematode worms (*Tylenchus* and root gall) is perfectly appalling. The remedies for this pest are also good remedies for other plant diseases,—lime, and muriates and sulphates of potash and ammonium. In California, the threatened destruction of the orchards by the cottony cushion scale (*Icerya Purchasi*) the worst of all the bug tribe, was averted by the importation from Australia and the breeding and spread of "ladybirds" (*Vedalia cardinalis*). This scale-feeding insect might be tried as a remedy for green bug on coffee? There is a native "ladybird," but we do not know if it is identical with the Australian species which the Californian orchardists have found so great a benefactor. The losses caused in the United States by insects which ravage crops have been reckoned at £60,000,000 to £80,000,000 per annum! No wonder, therefore, if much capital, science and experiment have been devoted to the study of the life habits of the insects and the best means of extirpating them and of lessening their ravages, where extirpation is impossible. From an able paper by Professor Olliff, the New South Wales entomologist, I extract some valuable and suggestive passages:—

When man came to till and to cultivate, many insects which naturally fed upon the plants he grew found abundance of food, and multiplied accordingly. It has thus come about that the cultivation in large areas of one particular kind of plant has resulted in an increase of particular pests. To illustrate my meaning it is only necessary to instance the Cottony Cushion Scale (*Icerya Purchasi*, Mask.) of the orange, and the Hessian Fly (*Cecidomyia destructor*, Say) of the wheat, species which have caused immense havoc in America and in South Africa, where they have found abundance of food brought together by the orchardist and farmer. Apart from this inevitable increase of native or indigenous species, many others have been imported with plants and cuttings, and also in the ordinary course of commerce, from one country to another; for it is well known that some of the most destructive insect pests of Australia have been introduced accidentally from Europe and America and similarly some English pests came from the East, and some American pests from Europe. In these matters, indeed, a fair exchange may be said to take place, for we are responsible for sending a very troublesome creature in the shape of the Cottony Cushion Scale (*Icerya Purchasi*, Mask.) to our American cousins and to our brother colonists in South Africa. If we take only a casual glance at the destruction which occurs every year to our crops we shall perceive that if these ravages could be brought under control, by lessening the number of the injurious kinds whenever they appear in excess, the benefit would exceed anything of which we have any conception.

Of the many substances and compounds used as insect destroyers, the following are the best known:—Lime, sulphur, soot, salt, wood-ashes, corrosive sublimate, naphtha, naphthaline, turpentine, alum, carbolic acid, phenyl cyanide of potassium, green vitriol, ammonia, alkalies, benzine, vinegar, sulphuric acid, blue vitriol (sulphate of copper), hot water, &c. Most of these may be successfully used for specific purposes either dry, in liquid, or in vapour; but the three most useful insecticides of general application in use during the early days of economic entomology in America and up to within a few years, were undoubtedly tobacco, white hellebore, and soap. Tobacco water and tobacco smoke have long been employed against Aphides and other delicate insects, and are most useful. A quite recent advance in its use is by vaporising. The vapour of nicotine is most effectual in destroying insects wherever it can be confined, as in greenhouses. Thus the boiling of tobacco in such a greenhouse is as effectual as and less injurious to the plants than the older methods of syringing or of fumigation by burning. The vapour gradually arising from tobacco stems strewn on the ground and regularly moistened is likewise effectual.

White hellebore, either in dry or in liquid, has long been one of the most satisfactory insecticides against Saw-fly larvæ, otherwise known as false caterpillars; while syringing with soap-suds will kill some soft-bodied plant-destroyers, and when used as a paint on the trunks of trees is an excellent repellent against the parents of different borers.

More important, however, than any of these insecticides are the three now most commonly used. They are—(1) arsenical compounds, (2) petroleum, and (3) pyrethrum. The first act through the stomach, and are effectual chiefly against mandibular insects, *i. e.*, those insects with biting mouths; the second and third act by contact, and are therefore of more general application, affecting both those insects with mandibular or biting mouths and those with sucking or haustellate mouths.

The use of arsenic as an insecticide in the field dates from the year 1871. At the rate of 50 grains of arseniate of soda and 200 grains of dextrine dissolved in a gallon of water and this diluted at the rate of about an ounce to ten gallons of water, it furnishes one of the cheapest of insecticides at command, and various patented combinations of it have been extensively sold and used. Again, one pound of arsenic and one pound of sal-soda boiled in one gallon of water till the arsenic is dissolved, and diluted at the rate of one quart to forty gallons of water is also a good formula. The chief merits of arsenic are cheapness and solubility. Its demerits are its white colour, which makes it liable to be mistaken for harmless substances of the same colour, and its tendency to burn the plant. Paris Green or Scheele's Green has been more extensively used than any other arsenical compound, and is, on the whole, one of the most satisfactory insecticides.

A refuse obtained in the manufacture of aniline dyes, and known as "London Purple," is the third important arsenical compound.

It is used with diluents, either wet or dry, in the same manner as Paris Green. For some insects experience has shown it to be less satisfactory than Paris Green; for many others it is equally effective, and has the great advantage over Paris Green of being cheaper; of covering twice the ground, weight for weight; of being more soluble, less poisonous, more adhesive, and permanent in its effects.

The following receipt is recommended by Dr. Riley for certain pests, and other applications will suggest themselves:—Forty gallons of water, $\frac{1}{4}$ to $\frac{3}{4}$ lb. of London Purple (or $\frac{1}{2}$ to 1 lb. of Paris Green), three quarts of flour, [N. B.] the solid ingredients intimately mixed with the water by washing them through a strainer, sprayed upon the trees by means of a force-pump and nozzle, was found to effectively destroy web-worm. The effect of the poison is sometimes not observable until after three or four days. Care must therefore be taken not to overdo the spraying.

Petroleum, in its various forms, has long been recognised as one of the most effective insecticides known, all oily substances being particularly deadly to insects. Unfortunately, they are also injurious to plants, and they can then therefore only be applied after the discovery of suitable methods of diluting them so as to kill the insects without injury to the plants. Refined kerosene has been used to a limited extent, by forcible attenuation in water and spray, while some plants withstand doses of the pure oil. Of the various substances used in attempts to emulsify and mix kerosene with water, none are more satisfactory than soap and milk. An emulsion resembling butter can be produced in a few minutes by churning with a force-pump two parts of kerosene and one part of sour milk, or soap solution, in a pail; emulsions made with soap solutions being generally found to be the more effective. The liquids should be at about blood heat. This emulsion may be diluted with from nine to fifty parts of water which should be thoroughly mixed with one part of the emulsion.

The strength of the dilution must vary according to the nature of the insect to be dealt with, as well as to the nature of the plant; but, finely sprayed in twelve parts of the water to one of the emulsion it will kill most insects without injury to the plant. The spraying should be done by a force-pump through

cyclone nozzles; it is best done in the cool of the day, and where possible, in calm or cloudy weather; two or three sprayings at intervals of a few weeks being preferable to a single treatment.

The following is a good receipt:—Two parts of oil to one of soap solution or milk (the soap solution being made by dissolving from a quart to one pound of common soap, or whale-oil soap, in one gallon of water). The whole is violently agitated, at a temperature of about 100° F., by driving it backwards and forwards through a spray nozzle. The emulsion thus formed is diluted with nine parts of water. Flour or resin soap-wash is sometimes added to the kerosene wash, to give it greater adhesiveness, [N.B.] and 4 or 6 ounces of arsenious acid (or half a pound of arsenic, half a pound of sal-soda, boiled in half a gallon of water till the arsenic is dissolved, or half a pound of London purple) is sometimes added to each 100 gallons of the wash, to render it more effective.

Pyrethrum roseum and *pyrethrum cinerariaefolium*, two plants, natives of Asia and Europe respectively, have long been known to possess insecticide properties, especially the powder from the dried and pulverised flowers. This powder can be used in liquid solution and its action on many larvae is marvellous, the smallest quantity paralyzing and ultimately killing. As the insecticide property dwells in a volatile oil its influence in the open air is evanescent, in which respect it is far inferior to the arsenical products; but, being perfectly harmless to plants, it can frequently be used on vegetables where the more poisonous substances would be dangerous.

Of all insecticides to be used against root-feeding insects naphthaline, sulpho-carbonate of potassium, and bisulphate of carbon are the chief. It has recently been shown that naphthaline in crystal may be satisfactorily used under ground, destroying by slow evaporation. But bisulphide of carbon still holds the first place in France against *Phylloxera vastatrix*. Large quantities of the latter are now imported from England into Cape Colony for the purpose of treating the phylloxerated vineyards.

In the above extracts is summarized most of the information available regarding insecticides and their application. But as in Ceylon we have to deal at present specially with the green scale insect on coffee, I would repeat my recommendation for a trial of the simple remedy of rice flour mixed with water and gum or some viscid substance, applied of such a consistency that it may adhere to and kill the insects by asphyxiation. Essence of leaves of gums and mana grass might be added to the mixtures, or decoctions containing their acid and volatile oil properties might be sprayed on the bushes, after the adhesive matter has been on for some days, or at alternative intervals. For application the "strawonizer" promises to be useful, but a hand-pump with a nozzle will answer, or where the affected patches are limited, coir brushes might suffice. So much for the present, but I may recur to the subject.

INSECT AND FUNGID PESTS AND THEIR REMEDIES—
HOW TO CONQUER GREEN BUG—BIRD ENEMIES—HARE
—FLYING-FOXES—MONKEYS—RATS.

To revert to the N. S. Wales papers on insect and fungoid pests, it is stated that oidium on vines can be fought with finely powdered sulphur, while a paper by a German scientist is quoted, showing that the destruction of vines affected by *Phylloxera vastatrix* could be obviated by insertion amongst the vines of tubular poles, down which creosote was poured into the earth, so reaching and killing the insects. A small midge-like fly which attacked vines, peaches and other fruit trees was destroyed (as was the foliage and fruit) by a solution of carbolic soap mixed with tobacco juice. Had a viscid preparation such as birdslime been applied, the fly might have been killed without the

sacrifice of the leaves and fruit. Mr. Scobie, M.L.A. stated in a paper on pests:—

Of insect pests, in their different metamorphoses, we have the grape caterpillar (*Agarista glycine*), mottled red and white; also a large green kind; two kinds of grape grasshoppers; the boring grub in fruit-trees three kinds; the elephant beetles (*Orthorhinus cylindricornis*), also borers in the larval stage; and a smaller variety even more destructive than are the larger ones; two kinds of cicadae, large and small; two kinds of beetles, small, which attack China peaches principally, American blight and codlin moths on apple-trees, and the aphides on orange and peach trees.

The red-and-white caterpillar has been very numerous of late years, destroying whole vineyards for a season by eating up all leaves and fruit. The large green kind has not been so numerous but is of the same habits. Both kinds of grasshoppers attack the foliage almost from its first start; they hatch about the same time as the first sign of growth appears, and then spoil the young bunches till berries form, and again they nibble the skin of the berries when ripe, making them turn into raisins in a dry time, and mould at other wetter time. They also eat pieces out of much of the tree fruit in the same way.

The boring grub or borer pierces the limbs of trees, and lives on the bark, making a cover of its dry excrement, under shelter of which it works, and when disturbed goes backward into his bole. A small variety of a dark colour has much the same habit, but generally takes advantage of some small crack or knot to afford it cover, or otherwise eats its way into the pith of the smaller branches, if there be no other way by which it can get in, such as where a piece has been broken across or cut off. The large boring grub, which works in the trunk or large limbs of old trees, apparently living on the juice of the wood operated on, changes to a very large beetle with long feelers.

The larger kinds of elephant beetles are very destructive to old vines. The grub of this beetle lives on the sap of the wood of the vine during winter. In spring it changes to the beetle form, eats its way out of the vine, then travels about and lives on the buds even before or just as they begin to show the first sign of life. Sometimes they eat a hole in the centre by inserting their trunk, but mostly eating the eye clean up. Sometimes a beetle will travel completely round a vine, eating out every eye, thereby destroying all prospect of fruit. Even after the shoots are well advanced a great many break off because of being partly or wholly eaten through. The grub is readily found when one is pruning, as often, when a little strain is put on the branch operated on, it will break in consequence of the inside wood being so much burrowed through. The smaller and even more destructive variety—more destructive because of its greater numbers and different mode of attack—has only been known to us within the last ten years or so. It makes its appearance just as the vines commence budding, having apparently come to maturity in the ground, for there is no sign of this sort having bred in the vine. It creeps up the vine stock, and simply punctures the buds with its trunk, and if not carefully taken off will spoil the crop. It is about the size of a wheat grain, sometimes larger, and of the colour of the bark, and it takes a practised eye to detect it. Both varieties can fly, but wherever this latter variety appears it spreads slowly and surely, and, notwithstanding our best care, is increasing. Hand-picking is the only remedy we know of.

The two varieties of the beetle which attack the fruit, principally the China peach, are well known, and I will do no more than mention them.

The well-known cottony aphid, or American blight, is familiar to all apple-growers, and peach aphid on peach-growers; and we have many varieties of scale insects all more or less injurious.

When to all the above the deadly *phylloxera* is added, it will be seen that the Australian vigneron and orchardists have a severe battle to fight with insect enemies. One orchardist stated that the

codling moth destroyed 90 per cent of his fruit. Another orchardist stated:—

I have tried various remedies, viz., kerosene and water—1 of oil to 16 of water—syringed on cold, which kills insect pests, but I thought the oil stopped the pores of the leaves, and so somewhat injured the trees; I have also tried tobacco with sulphur, lime, and other remedies, but after experimenting for years I find that a mixture composed of soft soap—made with whale oil—blue oil, and sulphur is the best; sulphur and soap boiled together, oil added after, and syringed on to the trees at a temperature of from 140° to 145° Fahrenheit; if done during dry weather the trees should be syringed with cold water half an hour before using the mixture, so that the latter will adhere or be the more readily absorbed. I find that this mixture, put on properly, will destroy red and white scales, elephant beetle or borer, and all insect pests that I have had to deal with. If trees are badly affected they should be dressed in November, and again in early autumn. Scales multiply faster during autumn than any other time of the year. But we must quote in full the short but very important paper on the starch remedy,—the remedy of commonsense, and therefore of science, for scale insects:—

RED SCALE ON THE CITRUS TRIBE: HOW IT MAY BE EASILY AND INEXPENSIVELY REMOVED.

The following paper was sent in by Mr. J. Patterson, Tamworth, and was read by the Director of Agriculture:—

I have had occasion to use many insecticides for removal of red scale from orange and lemon trees, and I find that the simplest and most effectual is starch. It is prepared in the following way: 2 lb. of the ordinary household starch are dissolved in a little cold water, then about 2 quarts of boiling water are poured over the starch solution, and stirred until it is thoroughly mixed. Add to this 16 gal. of cold water and stir well. The insecticide is now prepared and ready to be applied to the trees.

The insecticide should be applied with a syringe when the trees are small, or with a spray pump, when the trees are large, and it will cause the following result: The foliage and fruit receive a coating of the starch solution, which adheres to the foliage and fruit, and smothers the scale, and in a few days it will come off in flakes, bringing with it the scale, leaving the foliage and fruit as bright and clean as if the trees and fruit had never been infected with scale.

The insecticide should be applied during sunshine, so that it may dry quickly, and adhere to the foliage and fruit, and carry out its destructive work as intended.

After the trees have been thoroughly treated with the insecticide they should receive top-dressing of stable manure to be dug in the following season, and the cultivator will find that his trees will produce large crops of superior fruit, and will repay him for the labour expended on them.

The grand merit of this application is that while fatal to the insects, it inflicts no injury on tree or foliage. Benzole, which will not mix with water, and "Quibell's insect destroyer" (?) when sprayed, killed the fly on vines and other fruit trees. So in regard to oidium. Grasshoppers or locusts are as destructive in Australia as in America. When we visited the St. Hubert vineyard in Victoria, grasshoppers were so thick on the earth that they rose in dense swarms as we walked between the rows of vines. It is curious to read that castor oil leaves and larkspur are inimical to these insects. One farmer destroyed millions by putting down straw for the grasshoppers to lay their eggs in, to which he then set fire. The same farmer was troubled by an insect, resembling the Jordan louse, and he said:—

A friend advised him to strip the trees down to the main roots, and to watch the stems carefully. He followed out the suggestion, and soon found out what it was that was killing the trees. The little insects came out in thousands. He made inquiries in order to find

out a remedy. He tried 3 oz. of sugar of lead, dissolved and mixed with a gallon of strong whitewash (ordinary lime and water), and, with this mixture, he painted the stems of the trees, and the pest was eradicated. Our strong belief is that painting with lime alone would, in this case, have been effectual. A member of the conference referred to the peach blight and uttered good commonsense about applying common clay to affected trees:—

A remedy he advocated was to keep the trees warm, and to paint the trees in the winter with a composition of lime and sulphur. This prevented the birth of the aphid in the early spring. Where a tree was badly affected, every bud should be brushed with an emulsion. For the woolly aphid pest he had heard that some gentleman on the Western line had discovered a sure remedy. Many nostrums were recommended for this pest, including kerosene emulsion. In the old country, in his younger days, a simple remedy was used. Clay was mixed with water to a fair consistency, and applied with a stiff brush to all the knobs which appeared on the tree. This was found to answer better than any of the expensive compounds now advocated, and he still used it.

Another fruit-grower said:—

The application of different specifics stayed the pests only for a short time, and the best mode of treatment was to wash the tree well with soapsuds, and then to apply a mixture of boiled oil and sulphur. This paint stayed the blight for fully six months in the year.

Again:—

Dr. Fiaschi, Richmond, said he had had some experience of the woolly aphid blight. An apple-orchard of his was so badly affected with it that he never could get a crop of fruit. He had tried all the remedies suggested, with the exception of liquid clay, proposed by Mr. Gelding. Heavy manuring was one of the treatments he made use of, but it altogether failed. Last year he had intended to have the trees rooted out, and to plant the land with vines, when a gentleman gave him a bulletin of the Californian State Board of Agriculture, wherein was suggested a summer remedy for pears and apples. It consists of the following ingredients:—Caustic soda (93 p.c.) 10 lb., potash 10 lb., tallow 40 lb., resin 40 lb. The directions given with the recipe were:—First: Dissolve the potash and soda in 10 gallons of water, and when dissolved place the solution in a barrel (50-gallon measure.) Second: Dissolve the tallow and resin together; when dissolved add the same to the potash and soda in the barrel, and stir well for five minutes or so. Leave standing for about to hours, then fill up with water, stirring well as every bucket of water goes in. Use the following day one pint to a gallon of water, and apply warm. He tried this specific, spraying the trees with it, and he obtained a splendid crop of apples. As to *oidium*, he did not think there was any cure for it.

Another expression of opinion was:—

It was of no use attacking the insect with poisons—they must stop its breeding. The fine starch mentioned by Mr. Patterson would be fatal, and Mr. Pye had found an application of soap mixture successful.

One gentleman said:—

Had sprayed the trees with a common syringe, with a mixture of unslaked lime and sulphur, three parts to one. If slaked lime were used it would be necessary to boil it, but by using unslaked lime the mixture boiled itself, and thus saved much trouble. It proved better than a kerosene emulsion, because it killed all the moss which grew upon the trunk of the tree.

As a friendly insect, in addition to the "lady-bird," the mantis, or "native lady," was mentioned. Again:—

Mr. Bradbury cautioned the Conference as to the use of dangerous poisons as remedies for pests. He suggested that, if poisons were resorted to, some steps should be taken to prevent the use of arsenic and strychnine by ignorant persons, for if only one or two were poisoned confidence in Australian fruit would be destroyed for years. Scheele's green, which had been mentioned, was a preparation of arsenic; and

so were other specifics which were occasionally used. One gentleman had recommended acetic acid, but it was not necessary to use such poisonous chemicals; there were a number of remedies less dangerous and equally as effective. London purple was an aniline product of coal tar. * All coal tar compounds were effective. Naphthaline and creosote were cheap, but difficult to use. Creosote was not soluble in water, but it was possible to make an emulsion of it with alkalis. Tobacco and nicotine were largely used as specifics, but they were too expensive. A mixture of caustic soda, tar, and resin had been suggested as a cure for apple blight. The first-named ingredient was a dangerous thing to have in the household, and the mixture, when prepared, was merely a resinous soap which could be purchased for a few pence, and thus all trouble and danger would be saved.

Mr. Stiemer inquired what strength of kerosene spray was required for the mussel blight (*Mytilus aspi porum*).

Mr. Thompson replied that the emulsion was prepared in this way:—To one gallon of milk, brought up to boiling point, add two gallons of kerosene. If preferred they could use half a pound of soap to a gallon of water, brought to boiling point, and the kerosene churned in that for some time. This, with nine or ten times the quantity of water, could be effectively applied with a common cyclone-nozzle.

The digging in of ashes round the roots of trees was said to prevent pests. I have quoted very largely already, but to make the information on insecticides complete I must add the following summary of the results of very dearly bought experience in America as to the best remedies for pests:—

INSECTICIDES.

The following notes by Dr. J. C. Neal, the Entomologist to the State Agricultural College, Florida, U. S. A., will be found of interest:—

Nothing has been done in practical entomology that has shown better results than the use of emulsions containing kerosene or insoluble poison held in suspension, and their application to infected plants in a fine spray by various atomizers and spray pumps. With one of these machines an insecticide can be brought into contact with the insect, and its feeding ground thoroughly impregnated with poison. It is needful that the spray be very fine, and that it be applied with force to reach every infected part, or the hiding-places of insects. For cases like infected buildings, as chicken-houses, that are usually very difficult to keep clear of mites and tick-fleas, the spray of carbolic white-wash, tobacco, kerosene, oil of tansy, &c., is easily applied.

I append a few formulas that have been tried and found to be valuable:—

I. SOLUTIONS.

1. Tobacco, 1 lb.; boiling water, 3 gallons, strain when cool. Very effective when used as a spray against flees, beetles, lice, aphides (plant lice), and ticks.

2. Quassia chips, 1 lb.; boiling water, 3 gallons. This very bitter solution is good for prevention rather than cure. Apply as a spray to rose bushes and to kill plant lice.

3. Pyrethrum: 1 ounce of the "Buhach" powder added to 2 gallons of cold water for cabbage, beets, tobacco, or any plant used for food, as this is not poisonous.

4. London purple, Paris green; actively poisonous. Use 1 lb. of the poison to 200 gallons water or other solutions. Dissolve a little flour paste in the water to

make it sticky. Stir frequently. Applied to trees, it is a sure cure for all insect plagues.

5. Bordeaux mixture: this, while primarily a fungicide, has some good qualities as an insecticide. It is prepared thus: 1 lb. sulphate copper, dissolve in 1 gallon hot water in one vessel; in another, 1 lb. rock lime is slaked in 1½ gallons cold water, and, when cool, pour into the copper solution and strain; add 2 gallons water, and it is ready for use. (Cook.)

6. To this, add London purple, 1 lb. to 200 gallons of the Bordeaux mixture. This sprayed over non-bearing grape, vines or tomato vines not in bloom, &c., will prevent rot and insect life as well.

7. Soap: 1 lb. resin soap to 1 gallon hot water. This, used as a spray, is often a valuable remedy for the attacks of small and soft insects. In fact it can be used to advantage for soft scales, when they are few. It should be often used to get the best effect.

8. Water in which tar has been placed acquires some value as an insecticide.

II. EMULSIONS.

(Soap is used as the basis of most of these.)

1. Stronger emulsion of kerosene: 4 lb. soap, dissolve in 1 gallon hot (boiling) water; remove from the fire and add 2 gallons kerosene while hot. Churn with a spray pump violently till the oil is emulsified; add 27 gallons cold water for use.

2. Weaker emulsion (Cook): 1 lb. soap, dissolve in 2 gallons hot water as before, but add only ½ gallon kerosene and dilute till 8 gallons solution are made. Adding ½ pint spirits turpentine to No. 1 increased its stability (Tracy). Allowing even 40 gallons of water to be added to 1 gallon of the emulsion and sprayed on tomato worms, it was very effective, and did not injure the plant in the least.

3. Emulsion 1: Adding 2 oz. of balsam of fir with the kerosene makes an emulsion that adheres better to the surface of leaves, and is slightly superior to No. 1 for the armoured scales.

4. Using emulsion 2, only substituting the same quantity crude carbolic acid for kerosene, is especially valuable for oak and pear insects.

5. The same formula, using oil of tansy or saffras 1 oz. in place of the ½ gallon kerosene, is efficacious for roaches, mites, ticks, bed-bugs, and pests.

III. ARSENICAL, RESINOUS, AND OTHER COMPOUNDS FOR SPRAYING.

1. To kerosene emulsion No. 1 add 1 oz. London purple, and mix well. Highly recommended.

2. Resin compound: Caustic soda, 1 lb.; resin 8 lb.; to make 32 gallons compound. Dissolve the soda in 1 gallon boiling water; take out half; add the resin slowly to the remainder and boil, stirring rapidly; when dissolved, add slowly the part taken out. Dilute till it will pass readily through a thin cloth, which should be always done. Dilute before using to 32 gallons. This alone is very valuable against most scales, but the addition of 2 oz. London purple makes assurance doubly sure against even the dreaded *Icerya*.

3. White arsenic, ½ lb.; sal soda ½ lb.; water, ½ gallon; boil till a solution is made, then dilute to a gallon. 1 quart of this to 50 gallons resin compound—use on peach, pear, and plum, either after fruit is gathered or just as bloom has fallen.

IV. POWDERS.

1. While slaking 1 peck fresh lime, add 1 quart kerosene, sift out lumps; apply lightly to cucumbers, melons, and tomatoes, for beetles and squash-bugs.

2. 50 lb. land plaster, mix 1 pint crude carbolic acid; sprinkle over leaves and vines for aphides and beetles.

3. Pyrethrum: This, the powdered flowers of the pyrethrum, when fresh, is especially valuable if sprinkled on infected leaves, or in boxes, drawers, &c. House flies and mosquitoes are easily subdued by closing up the room tightly and slowly burning in it a spoonful of the powder. It is slightly narcotic, but not at all dangerous to human life. For infected cabbage, lettuce, celery and the like, or tobacco, it is the best insecticide we have, involving no danger if eaten.

* London Purple is a refuse obtained in the manufacture of aniline dyes, and consists of lime, arsenic, and carbonaceous matter. It was first used against insects in America in 1878, and is there much prized on account of its cheapness as against Paris green which costs twelve times as much. It is more soluble, less poisonous, more adhesive and permanent in its effects, and of a decided colour. It is now imported by Elliott Bros., O'Connell-street.—Editor.

4. Tobacco: This insidious narcotic is valuable in the destruction of plant-lice, mites, &c. Applied as a powder or by its fumes it often is quite beneficial.

Bisulphide of carbon, like chloroform, is highly volatile, but its vapour, unlike that of chloroform, is very explosive. Bins and corn cribs can be easily rid of ants, weevil, rats, mice, beetles, &c., if the room be made air-tight, and occasionally filled from the top with the vapour of bisulphide of carbon. This is the only way in which our farmers ever will keep corn, peas, &c., from insect attacks.

Of course kerosene and such arsenical poisons as Paris green and London purple are chemically active, but for the destruction of green bugs, if we were troubled with the pest, we should feel much inclined to try a decoction of gum leaves and mana grass, brought up to a sticky consistency by mixing starch or flour, gum, clay and lime, with some sulphur added. If a covering of this stuff were applied to the green bugs in dry weather and left on for a few days, I believe the parent scales and their enclosed progeny would be smothered to death and come off in flakes with the preparation. If inclined to stick, the application and the insects could be washed off, with water, or a decoction of gum leaves or coarse lemon grass.

In Australia the fruit growers have other enemies than insect or fungoid pests to contend with. One authority states that birds, including the improved sparrow, are still worse, insectivorous birds often feeding on friendly insects, such as the mantis. Imported hares, too, are hurtful, but most destructive of all are perfect clouds of the large frugivorous bat known as "the flying-fox," which are so cunning that it is difficult to lessen their numbers by powder and shot or even dynamite. Neither birds nor bats, I believe, have ever been known to meddle with coffee berries, on which however, monkeys and jackals have been known to feed, while the jungle rats in one year destroyed £10,000 worth of coffee in the region whence I write. Bandicoot rats have occasionally rooted up a few tea trees; but, on the whole, it is seldom that so large an expanse of one cultivation as the tea fields of Ceylon compose has been so little affected by injurious animals, birds, insects or fungi. Long may this happy immunity continue!

THE DIFFERENCE IN THE RAINFALL AT THE BEGINNING AND THE END OF NOVEMBER—THE RAINFALL AT NUWARA ELIYA, HAKGALA AND ABBOTSFORD AND OF OTHER PLACES—EXPLANATION OF DIFFERENCES IN RAINFALL—VARIATIONS IN MEAN TEMPERATURE AND IN MAXIMUM AND MINIMUM SHADE TEMPERATURE—HEAT IN THE SUN—NOCTURNAL RADIATION—CEYLON "PEAT"—THE ALLEGED DISCOVERY OF BITUMINOUS COAL AND ANTHRACITE ON ROTHSCHILD ESTATE—HOW TO TREAT PEATY SOIL—EFFECTS OF A HAILSTORM ON TEA AND CINCHONA—HAIL IN INDIA AND OTHER COUNTRIES—CAUSES OF HAIL—CHANGEABLE WEATHER.

NANUOYA, Dec. 1st.

This morning I mentioned the contrast between the early portion of November, when we were all asking "What has become of the north-east monsoon?" and the latter portion, of the month during, which the answer has been emphatically given in the shape of thunder-and rain-storms, with occasional semi-gales of wind. The figures for rainfall and rainy days will show how striking the contrast has been. From Nov. 1st to the 16th, rain fell only on 5 days and on three of these the measurements were only 5 cents on 2 days and 2 cents on 1, the total for the 16 days being only 75 cents of an inch. From the 17th to the 30th, on the other hand, the rainfall, on 11 days has been 8.80 inches, 5 out of the 11 rainy days giving such storm quantities as 1.38, 1.47, 1.36, 1.48, and yesterday 2.09. This latter burst sent the rainfall of November up to 9.55

against a 7 years' average of 7.37; the total for the 11 months of the year being 85.93, against an average of 84.32. We are thus 1.61 inch above our average quantity, while our rainy days number 190 against 192. Unless, therefore, December turns out an abnormally rainy month, we are likely in 1890 to realize very closely our 7 years' annual average of 92.11 inches of rainfall on 209 days: only slight rain falling on fully one fourth of the number. At an elevation of about 5,800 feet and facing the south-west, this gives us 5.14 inches more than Hakgala (altitude 5,581 and facing the north-east) receives and 5.95 less than is deposited at Nuwara Eliya, which is situated between the two monsoons, at an elevation of 6,240 feet above sea-level. The averages of the three mountain stations are:—

Nuwara Eliya	6,240 feet	98.06 inches:
Hakgala	5,581 "	86.97 "
Abbotsford	5,800 "	92.11 "

There is here a graduation according to elevation, but the principle by no means holds generally good the river valleys below the three stations getting from 100 to 150 inches of rain, while the ranges which face the south-west monsoon, at an elevation of 3,000 to 4,500 feet, get 200 inches up to 250. Theberton estate, Maskeliya, with an annual average of 217 inches, is only 3,315 feet above sea-level, while Padupola, believed to be the rainiest station in Ceylon, is still lower down. The region round about Nuwara Eliya, protected from the extreme moisture of the south-west monsoon vapour-clouds by the Adam's Peak ranges, is fortunate in enjoying the happy mean for tea cultivation of 100 inches down to 80. Even 70, well distributed, suits this most cosmopolitan of plants.

The disproportion of rainfall to elevation is easily explained by the relative positions of mountain ranges to the course of the sea-vapour-laden monsoon winds, but it is not so easy to understand the varying rate at which MEAN TEMPERATURE decreases with varying altitudes. The difference of level between the observatories at Colombo and Nuwara Eliya is 6,200 feet (the Colombo observatory being 40 feet above mean sea-level), and the reduction of mean temperature, in proportion to ascent, is from 80.7 at the sea station to 57.7 in the mountain sanatorium, a fall of 23 degrees, or 1 degree for every 269 feet of altitude. This fairly agrees with the formula we have seen in books on meteorology. But when we come to compare Colombo with Hakgala at 5,581 feet, with a mean temperature of 61.2, the reduction of temperature is only 19.5, or 1 degree for each 291 feet. The higher temperature in this case, compared with Nuwara Eliya, apart from difference of elevation, may be due to the fact that the great isolated mountain is densely forested, and faces the warm valley of Uva? But Badulla, 2,225 feet altitude and 72.8 mean temperature, is in that warm valley, and yet the reduction of temperature, as compared with Colombo, is in this case 8 degrees, or a fall of 1 degree for every 273 feet. Very different indeed is the case of Kandy, elevation 1,696 feet and mean temperature 75.9. This is only 5 degrees lower than Colombo, or only a fall of 1 degree in 332 feet, against 269 in the case of Nuwara Eliya. Can this great difference be due to the sheltered position of Kandy and the heat of the sun reflected, during the day, from the white, quartz sand of the roads and the undarkened whitewash of the houses? The differences, hitherto, in the rate of depression for altitude have not been excessive, but we are utterly puzzled when we come to compare Badulla with Kandy. For an elevation higher by only 529 feet, the fall in

temperature, at Badulla, is 8 degrees, or 1 degree for every 176 feet! I suppose radiation of heat into space in the clear weather which so largely prevails on the wide plain in which Badulla is situated, and evaporation from the surrounding paddy-fields, affect the minimum temperature largely and so reduce the mean? But what a contrast when we come to compare the low mean temperature of Badulla with the comparatively high mean temperature of Hakgala. The higher elevation of the great Uva mountain above the capital of the Province is no less than 3,356 feet, and yet the temperature is lower only by 11 degrees, or only 1 degree for every 305 feet. Against this we have so rapid a fall as 1 degree for every 165 feet, for the 669 feet which Nuwara Eliya is higher than Hakgala: Nuwara Eliya being 4 degrees colder. We cannot doubt that the more intense cold in the case of the sanatorium is due to its situation in a grassy, damp plain, favourable to the reduction of temperature by radiation of heat into space on clear nights and the large evaporation of moisture by means of the tropic sun-rays, and of winds which, in the north-east monsoon months of December to March, are frequently quite dry and therefore ready to absorb all the moisture they meet. Hakgala, on the other hand, besides the influence of the warm valley of Uva and its lower elevation, is clothed with forest; so that, where the observatory is situated, radiation and evaporation are both at a minimum. Of course forest and forest land cleared and planted, in Nuwara Eliya, have warmer temperatures than the exposed position where the observations are taken. The proof of this is the wonderful luxuriance with which tea grows on the edges of the ancient lake basin, up to 7,000 feet on the slope of "One Tree Hill." The final average of all the varying deductions I have drawn from the Ceylon Meteorological Report for 1889, is a fall of 1 degree for every 258 feet of altitude, against the 269 feet for every degree of lowered mean temperature between the two stations of Colombo and Nuwara Eliya. Taking the round number of 1 degree for 270 feet, the mean temperature of the summit of Pidurutalagala, the loftiest point in Ceylon, may be taken at about 50 degrees; of the summit of Adam's Peak, 52 degrees. Considering the prevalence of cloud, the minima of the mountain tops may not be lower than the minimum of Nuwara Eliya, where freezing point is occasionally attained on clear nights. If our calculations are approximately correct, the difference of mean temperature, between Mannar with 81.5 (the highest mean temperature recorded) and Pidurutalagala summit is 31.5; between Colombo and the culminating height, 30.7, and between the capital and the "Sri Pada" on Adam's Peak, 28.7. These are approximations founded on the known differences of mean temperature, between Mannar with the highest observed mean of 81.5, and Nuwara Eliya, the lowest, with 57.7. Maximum shade temperature is quite another matter. The highest at Mannar in 1889 was only 98.5 in September. But Trincomalee with a mean shade temperature of only 80.7 (nearly the same as Colombo) occasionally exceeded 100 deg. in six out of the 12 months of 1889, the extreme of 101.7 being attained on May the 12th. For extremes of heat, therefore, Trincomalee takes the lead of all stations in Ceylon, although inferior to Mannar for sustained average heat. Contrasted with the maximum shade temperature at Trincomalee in 1889, we have the Nuwara Eliya minimum of 36 deg. in January. When we come to "heat in the sun"—what the meteorologists call "Equilibrium temperatures of solar radiation," but about which they do not feel

by any means so confident as in regard to shade temperature, we actually get a maximum of 165 degrees at Jaffna and 164 deg. twice at Trincomalee, once at Anuradhapura and once at Vavuniyanvilankulam in 1889. That represents, approximately, the amount of sun-heat which finds its way to the surface of the earth through its atmosphere. The contrasts to such figures for solar heat are those for "temperature of nocturnal radiation," the minimum of which at Nuwara Eliya in January and December was 32 deg. against 37 deg. at Hakgala in December, and 62 deg. at Colombo in January. But I must defer further notice of the interesting Report on the Meteorology of the island for 1889, issued from the Surveyor-General's Office, because, before returning "from the Hills," I must answer as I can the following question respecting the best mode of cultivating "peat":—

"Can you name me any book in which I could obtain any knowledge of peat and its culture? Dr. Angus Smith of Manchester I believe read a paper on the subject some time ago." The pseudo-peat of Ceylon was, no doubt, specially meant, a substance which exists in varied conditions from the fairly good deposits at Muturajawela, near Colombo, up to the more or less decomposed reeds and rushes and grasses in the ancient lake bed of Nuwara Eliya. We have not, to my knowledge, true peat or lignite in Ceylon, and I await further information as to the alleged discovery of associated bituminous coal and anthracite on Rothschild estate, Pussellawa. A small fragment which I procured and sent to Mr. Alexander Murray was pronounced by that gentleman to be anthracite. But if the small specimens produced are not due to the action of fire on British coal used on the estate, we surely might expect that, ere now effectual measures would have been taken to set at rest the reality or reverse of an alleged discovery (in which Mr. LeMesurier has faith, but which Mr. Geo. Armitage, I believe, doubts) culminated, if real, and if the substance should be found in quantity, to be of such immense value to Ceylon, especially to its staple tea industry. About the alleged Rothschild coal discovery, more will, no doubt, be heard; and meantime, to return to a much lower carboniferous formation which we have in Ceylon, as a preliminary to answering the question fully I told my correspondent that he could not go wrong in resorting to drainage and the application of lime. That is what is mainly desiderated in the case of the peaty swamps of Nuwara Eliya and the upland savannahs generally. Of course if forest soil could, at any ordinary expense, be added, so much the better. In any case the drainage and turning over and aeration of the swamp soil and the burning of portions into ashes to be applied to the rest would be certainly beneficial. I have not seen the recent paper on peat culture, to which I was referred, and I have not the most recent authorities here to consult, but I feel certain that I have indicated the main principles of treatment: drainage, aeration, lime, ashes and, if possible, fresh soil or clay. Bone dust, superphosphate, and even sulphate of lime, if they could be afforded, would be still more valuable additions to the peaty humus. In confirmation of my views, I find on referring to Johnston and Cameron's Elements of Agricultural Chemistry and Geology, 11th Edition, 1878, the following passage: "We know that by draining off the sour and unwholesome water, and afterwards applying lime and clay, the surface of peat bogs may be gradually converted into rich corn-bearing lands." The process thus described was very familiar to me in my youthful days in the Highlands of Scotland, where vast expanses of moors and mosses, in the

Black Isle (Eilandhu) of Ross-shire were redeemed by the application of clay found close at hand and lime imported from "the South." The clay from which bricks have been made at Nuwara Eliya could be utilized for redeeming the peat land, and if some of the clay as well as some of the peat could be burnt and the carbonized matter or ashes applied as a surface dressing, so much the better, I venture to say. And some of the superfluous peat in the swamps thrown up from deep drains could also be used with advantage in forming composts for the Nuwara Eliya vegetable and fruit gardens and even the tea estates. There can be no better absorbent of excrementitious and ammoniacal matters than dried peat, or peat ashes. In the work I have referred to the constituents of a peat compost are thus given:—

Dry earthy peat	... 40 bushels.
Ammoniacal liquor from gas works	20 gallons.
Bone dust	... 7 bushels.
Sulphate of magnesium	... 1 cwt.
Sulphate of sodium	... 7 bush els.
Common salt	... 1½ cwt.
Quicklime	... 20 bushels.

These materials were, by a Mr. Fleming, mixed together and put into a heap, allowed to heat and ferment for 3 weeks, then turned and allowed again to ferment, when the compost was ready for use. On referring to the *Penny Cyclopædia*, I find that eighty years ago Lord Meadowbank gave directions for a rich peat compost, by means of alternate layers of peat and farmyard manure, rotten fish and other animal matter of all kinds being added and lime or ashes being scattered over the heap before being covered up to ferment. The principles in each case are the same, the special value of the peat consisting in its absorbent qualities.

The great object in Nuwara Eliya, of course, will be to convert the swamps into grass lands; meadows or lawns; and for this purpose, drainage and levelling will constitute the main preparations, a comparatively slight surface application of lime and clay sufficing. For the cultivation of vegetables and of fruit and ornamental trees, more elaborate and expensive treatment may be necessary. The peaty formations near Colombo were in the coffee factories used, mixed with coffee chaff, for steam engine furnaces, and the peaty stuffs in Nuwara Eliya and upcountry generally might be useful in tea factories, if compressed in moulds, turned out and dried like bricks, or rather like the forms in which fuel peat is prepared in so many parts of the world. Peat might also be used to absorb and deodorize petroleum, when used as a fuel. Peat-litter is valuable in stables and when thus saturated with ammoniacal matter as manure for gardens. Peat is largely humus; and moist humus, or the water in which humus is dissolved, is a powerful dissolvent of mineral matters. Hence peat would rapidly assimilate bones, coprolites, pieces of limestone &c. Peat used as litter in stables or for closets would act not only as an absorbent but as a deodorant. Peat after being used in closets and urinals has produced wonderful results in orchards and vineyards. It follows that if peat is to be cultivated *in situ*, the more of ammoniacal matter, with potash, lime and phosphates, that can be added, the better. That peat, especially such peat as we have in Ceylon, contains all the elements of plant life, as I have seen asserted in articles read by me for the purpose of this notice, I do not believe. What I do believe is that by the abstraction of moisture, by aeration and the addition of mineral matter in the shape of clay (or forest mould) lime, ashes, bones &c., the carboniferous substance can be converted into rich orchard soil or beautiful and profitable meadow land.

While I am writing, a letter and specimens of cinchona and tea leaves are sent up from "the lower division," to show the effects of the hail which I mentioned as accompanying the thunder, rain and cyclonic wind-storm of Friday last, when the coolies complained that the crystals of congealed moisture "burnt their feet." On the upper portion of the estate no appreciable damage seems to have been done, but here is the report from 1,000 feet further down in the valley of the Dimbulanda, where the small tornado was more violent even than what we experienced:—

"I send some twigs of cinchona and tea to show you what damage the hailstones did. I was extremely disgusted to see the tea bushes looking so shuck in places this morning, and at first could not make out what it meant. Fortunately the storm must have passed over the place in wavy streaks as only occasional patches are much injured, otherwise the damage might have been very serious. As it is we may feel its effects for a little, though not to any great extent, I hope. I can now understand what a severe hailstorm means to our Indian friends. The young soft leaves on the tea seem to suffer less than the old hard ones. A few which I enclose look as if they had been at Waterloo."

The writer might well think of the effects of showers of shot in battle, for the cinchona and tea leaves which accompanied the letter are riddled and torn after a fearful fashion, as you will see from the specimens I enclose. The first block of this estate (Abbotsford) was purchased just a score of years ago this month; and during the whole of its history since, we have had no such visitation as is now recorded. We have heard stories of big hailstones elsewhere which we considered apocryphal in some of their sensational details; especially a tale from Haputale of lumps which remained unmelted for a couple of days in the coolies' lines; but we now believe in the potent reality of hail, the product of the "long-looked-for-come-at last" electricity? or of the sudden fall of cold air from the higher air into the lower, owing to sudden and limited local atmospheric depression? Curiously enough Blanford, in his work on the climates of India and Ceylon, says nothing about the formation of hail, which is frequent and destructive to tea plantations in the valley of the Brahmaputra and elsewhere in Assam, while in Northern India the hailstones are sometimes of such a size as to kill large numbers of cattle and even prove fatal to human beings who have been exposed to their violence. Hartwig, in his "Aerial World" states that in temperate climates hail storms are frequent on the plains, while in tropical countries hail rarely occurs under 1,800 feet altitude? Hail in the mountain region of Ceylon seems more prevalent on the eastern or north-east-monsoon-side, than on the western; the phenomenon being not uncommon in Uva, where it has sometimes occurred on a scale which involved considerable damage to crops. Hartwig in his "Aerial World" states:—

"Hail is beyond all doubt one of the most enigmatical atmospheric phenomena, as it is one of the most destructive. No meteorologist has been able yet to explain in a perfectly satisfactory manner how hailstones of such considerable size are able to form in the clouds in so short a time, and often in the most sultry weather. On Volta's Theory the hailstones are successively attracted by two clouds charged with opposite electricities, and thus grow until they fall; but if the hailstones were thus attracted, it seems much more probable that the two clouds would be mutually attracted and would unite.

"The sudden irruption of cold air streams into a hot atmosphere charged with aqueous vapour, or the rarefaction and consequent refrigeration of the air produced by the rotary winds, have likewise, been called in to explain the mysteries of hail; but the most sagacious theories have hitherto found more

opponents than adherents; and not one of them is free from serious objections. Evidently there are influences at work in the clouds which we are not yet able to measure, and the causes of many of the revolutions of which they are the scene are still as unknown to us as they were to the philosophers of ancient times."

One thing seems certain, however,—that the phenomena of thunder and hail are closely connected and that the conditions which favour discharges of electricity favour also the formation of hailstones. This view is supported by the following extract from the valuable compilation already quoted:—

"The chief characters which distinguish hailstorms from ordinary thunderstorms are the peculiar rattling noise which precedes the fall of the hailstones, the whitish colour of the cloud-stripe in which the latter are formed, and a darkness which Tessier compares to that which is occasioned by a total eclipse of the sun. According to Professor Mincke's observations, single flashes of lightning and abrupt thunder claps are not so common at the beginning of a hailstorm as a continual discharge of electrical light and an uninterrupted rolling of thunder. After a thunder cloud has rained for some time, the danger of a destructive hailfall is generally past. In most cases hailstorms begin with the phenomena above described; a thunder-clap of surpassing violence ensues, then follow single heavy drops of rain, succeeded by single small hailstones, and by the pelting hard shower which, with short periods of intermittence, and accompanied with thunder and lightning, generally lasts but a few minutes."

The above description very closely applies to our short, sharp cyclonic thunder-hail-and-rain-storm of Friday, which lasted less than half-an-hour, depositing in that period over an inch of rain, mixed with the hailstones which burnt the coolies' feet and riddled the leaves of a few of our cinchona and tea plants. As an atmospherical phenomenon, such a compound storm is interesting, once in a way; but one occasion in a score of years, for the recurrence of similar conditions, will suffice to excite feelings less pleasant than those of scientific curiosity. The fall of hail from the atmosphere, so destructive of vegetable, animal, and even human life and property in some parts of the world, seems as great a mystery as the vesting of certain snakes with venom and certain fishes with benumbing electrical powers.

NANUYA, Dec. 3rd.

Considering that our *abizzias* are a year younger than the Nawalapitiya trees and grown at an altitude about 3,000 feet higher, they do not compare badly. The details of some are:—

Height 85 ft.	Cir. of stem 5' 10"	Single stem
" 75 "	do. 5' 5"	Do.
" 75 "	do. 6' 7"	Branches into 3 at 6 ft. from ground.
" 78 "	do. 5' 8"	Do.

The growth of these trees in both localities is surely phenomenal.

The forests around us, sloping up to Nuwara Eliya are putting on more and more brilliant colouring every day. Wo part, this morning, from them and "the Hills" with regret.

CINNAMON CHIPS.—The recent of today's meeting with its miserably poor attendance of five persons, shows to our mind that not only was no abiding interest felt by the majority in the movement to put a check on the export of "Chips," but that the agreement honorably entered into, cannot virtually have been kept as promised. The meeting very wisely therefore considered it expedient that the agreement should be cancelled. The only gentlemen present besides Mr. Jardine, Chairman, were Messrs. J. W. de Soysa, Fonseka, (father and son), M. Cockburn; and Mr. de Mell looked in after the meeting was over,

CATTLE TREATMENT IN MADRAS.

The Madras Agricultural Department has hitherto had a branch specially devoted to the investigation and treatment of cattle disease. This, we regret to see, is now to be abolished. It is the old story of efforts made on the ryot's behalf and rendered futile by the ryot's insuperable apathy. In the presence of the stock inspectors, as Mr. Hazelton, the Inspector of Cattle Diseases in the Presidency, tells us, their advice was frequently adopted, but directly they left the neighbourhood, it was found that no further trouble was taken. "Nearly all the stock inspectors complain of the little assistance they receive from the village officials; and as the stock inspectors can hardly hope to become personally acquainted with the majority of the ryots of the district, this want of interest on the part of village officers, in a subject which so nearly concerns them, has a very marked effect on their work." The Local Government has accordingly come to the conclusion that any attempt to directly combat cattle disease is, in the existing state of feeling among the farming classes, practically useless. To those who recognise how much the welfare and prosperity of the mass of the population depend on the improvement of agriculture, and how important to this end is a good and healthy breed of cattle, this example of stupid indifference set by the Madras ryots is distinctly depressing.—*Pioneer*.

KELANI VALLEY: HEAVY YIELD OF TEA IN THE VALLEY.—Ruwauiwella Division, Dec. 1st.—I never saw the tea in the K.V. looking better. I fancy if "Burra Esjur" could see it now he would retract his opinion of four years ago—that the places would never keep up their yield. I know of more than one place that with still a month of its year to run has given over 600 lb. per acre. One place the day I was there got an average of 23½ lb. a cooly from eighty pluckers off an 8-day flush. Mr. Hardie has resumed charge of Durane, and Mr. Kingsford has returned to Madalf tenne. I hear there is to be another change in the district shortly.—*Local "Times"*.

NUWARA ELIYA CARP.—We call special attention to Mr. LeMesurier's letter in another column which shows the good service done to the island by the fish culture experiments with which the Nuwara Eliya Assistant Agent has so closely identified himself. Not only private individuals, but Government must bestir themselves to take full advantage of the ample supply of fry now available for stocking ponds and tanks. An item in the Supply Bill report is "R2,000 for the purchase of freshwater fish for stocking the rivers, lakes and tanks in the interior"; but is due advantage being taken by Government of the carp fry available at Nuwara Eliya and could any better fish be got for local purposes in tanks, &c.?

QUININE.—The London market has been very quiet this week, and almost the only sale reported is of a parcel of 5,000 oz. German from the makers at 12½d per oz. January delivery. On the spot we make 12d per oz. the nearest quotation. The imports of quinine into the United States during the ten months of the year were 2,850,000 oz., against 2,168,000 at the corresponding date of last year. It is reported that the departure to Europe from New York, during the last days of October, of a representative of one of the American quinine-works has given rise to a good many rumours as to the cause of his visit. In some quarters it is believed that his mission is connected with a plan to revive the effort to organise a combination of the producing interests of Europe and the United States. The Java Cinchona Planting Company, "Kertamanah," in Amsterdam, has paid a preliminary dividend of 6 per cent for the year 1890.—*Chemist and Druggist*, Nov. 15th.

COFFEE LEAF DISEASE.

At a meeting of the Wynaad Planters' Association on 5th November last, among other business (Mr. J. F. Jowitz being in the chair) it was noted:—*Leaf Disease*.—The Honorary Secretary read a letter from his London agents saying that experiments with the hand power Strawsonizer were not as yet sufficiently complete to enable the makers to put it on the market.

The Honorary Secretary stated that a member of the Association had recently returned from Naples where he had had an interview with Col. Giuseppe Novi, who has recently experimented on the *Phylloxera*, and was anxious to experiment on the *Hemileia Vastatrix*, that he had brought back with him a ton of a mixture for the treatment of the *Hemileia* which he had placed at the disposal of the Honorary Secretary. Another member of the Association writing from Rotterdam promises the translation of a pamphlet lately published there on the propagation of the *Hemileia* fungus.

THE AMSTERDAM CINCHONA AUCTIONS.

AMSTERDAM, November 6th.

At the cinchona sales held here today a large quantity of Java cinchona bark, containing the enormous equivalent of 741,000 oz. quinine, was offered for sale. The greater part of the holders showed themselves willing to make concessions, and 4,281 packages sold at a decided decline, the average unit being only 8 cents per half kilo, or about midway between 1½d and 1¾d per lb., less by about 8 per cent. than the price of Tuesday's London auctions. The following is the range of prices paid:—Manufacturing barks, quill, broken quill, and chips, 10 to 70 cents (=1½d to 12½d per lb.); ditto root, 18 to 58 cents (=3½d to 10½d per lb.); druggists' barks in quill, broken quill, and chips, 8 to 78 cents (=1½d to 1s 2½ per lb.); and druggists' root bark, 12 to 22 cents (=2½ to 4d per lb. The principal buyers, in order of their purchases, were Messrs. C. L. Schepp & Zoon, Rotterdam; Messrs. Matthes & Borneester, Amsterdam; the Brunswick Quinine Works; and the Amsterdam Quinine Works.—*Chemist and Druggist*.

ARTESIAN WELLS AT QUETTA AND MADRAS.

Artesian wells are being bored successfully in various parts of Quetta, and one in Sir R. Sandeman's compound is worked by a windmill (an American patent) much to the astonishment of the natives.

A bore at Negapatam has been sunk to a depth of only 200 feet which in the country of Artois itself would have been considered extremely moderate and far below the average. With a bore of this depth the water rose to within one foot of the ground surface, thus practically demonstrating that an artesian spring had been struck. In the Madras Presidency at least wells have not been bored to any great depth and great advantages might accrue if the Negapatam Councillors persevered in their efforts to sink the bore deeper, even though it may not be clear to them that better results would be achieved. The Government order on Dr. King's Report promises help from Provincial funds as an inducement to the Councillors to continue work. As it now stands the well is a success in as far as the two essential requisites of a water-supply, namely, quantity and quality, have been secured.—*Indian Engineer*.

It is rumoured that the mission of the Director of Public Works, Mr. MacBride, who is leaving for India shortly, is to inspect work done in Artesian wells with reference to the requirements of the Jaffna Peninsula and other parts of the island.—*Ed. T. A.*

PIGEONS AND BEES.—Says a writer in the latest *Cornhill*:—An American passenger pigeon passes the Atlantic Ocean in two days and two nights, flying at the rate of 1600 miles a day. A curious account is given of a race between bees and pigeons, in which the first bee finished a quarter of a minute before the first pigeon, three other bees beat the second pigeon, and eight bees and eight pigeons made a dead heat over a course of a league.

THE NEW COCONUT PRODUCT.

Paragraphs have been going the round concerning a new manufactured product of the coconut, which is spoken of wrongly as "coconut butter." Being regarded as a butter, and produced at about half the average market price of ordinary butter, some writers have fallen into the error of regarding it as a new adulterant of dairy produce, and a rival to margarine. In the first place it is not a butter in any sense of the word, and in the next it is not at all likely to be employed as an adulterant by reason of its peculiar flavour and colour. It is, in fact, a vegetable lard, and as such is intended to be used in cooking, and perhaps in pharmacy. The natives of India use a large quantity of fat under the name of "ghee," answering in colour and quality to our "lard." It is the product of buffalo milk, and inasmuch as Hindoos will not use any animal fat, and the Mahomedans avoid the use of hog's lard, this ghee is the only article in use throughout India for culinary purposes, and it is rather dear, for there is a large demand for it, and the supply is limited. The newly-introduced coconut fat is said to be both a better and cheaper article which cannot fail to commend itself to the Hindoos and Mahomedans, and so come into extensive use throughout India as a purely vegetable product.—*Burgoyne's Monthly Prices Current*.

THE NEW DIMBULA COMPANY, LIMITED.

REPORT, SEASON, 1889-90.

The Directors have pleasure in presenting their Fifth Annual Report.

The yield of coffee, cinchona, and tea, has in each case exceeded the estimate, and good prices have been realized. The quality of the tea is well maintained. The reports received by the Directors of the present condition and unfavourable future prospects of the coffee cultivation have induced them reluctantly in consent, as a precautionary measure to have a portion of the remaining coffee land interplanted with tea. Cinchona has been suffering from repeated attacks of caterpillars, which have caused some mortality among the trees. Tea is progressing satisfactorily, and the Directors anticipate a substantial increase in productiveness during the present season. The accounts now presented show a surplus of £4,661 after crediting "Tea extension fund" as usual, with a proportion of the cinchona proceeds, and after writing off a due proportion of the "Factory and Machinery Account." The Directors propose a Dividend at the usual rate of 8 per cent per annum, on the A Shares for the year ending 30th June last, one-half of which was paid in March last. In accordance with the hope held out at the last General Meeting, the Directors were able to pay 2 per cent on the B Shares in March last, and they now propose a further payment in reduction of the cumulative dividend accruing on these shares of 4 per cent. The Directors have much pleasure in recording their appreciation of the energetic and efficient manner in which the Manager and Superintendents continue to conduct the affairs of the Company in Ceylon. Mr. Carver having retired from the Board, the Directors have elected Mr. William Herbert Anderson, late of Holyrood estate, to fill the vacancy.—By order of the Board, J. SWAN, Secretary. 52, Gracechurch Street, London, E. C., Oct. 27th.

THE NEW DIMBULA COMPANY, LIMITED.

CEYLON TEA IN EGYPT.

The *Egyptian Gazette* of 19th Nov. contains the following paragraph:—

We draw the attention of our readers to the advertisement of the Ceylon Tea Growers' Association for which Messrs. Edgar Kirby and Co. are the agents in Egypt, with Mr. Fleurent as sub-agent at Cairo and Mr. J. Slavick as sub-agent at Port Said. Ceylon tea has made its way of late years in public favour; the Egyptian market has not been overlooked and the honour of being the pioneers of the Ceylon tea trade in Egypt belongs to Messrs. Edgar Kirby and Co.

The advertisement referred to is as follows:—

THE CEYLON TEA GROWERS' ASSOCIATION, COLOMBO.

Sold in leaden packets of $\frac{1}{2}$ lb. and 1 lb. Each packet bears a facsimile of the "Chief Brand" without which none is genuine.

Sub-Agents.

Cairo.—E. J. Fleurent, opposite the Credit Lyonnais. Port Said.—Jas. Slavick.

Sole Agents for Egypt,

Edgar Kirby & Co., Maison Bolanachi, Alexandria.

N.B.—Seven one-pound packets of our best Ceylon Tea sent postage free to any part of Egypt.

Just below this advertisement appears another, as follows:—

CEYLON COOPERATIVE TEA GARDENS Co.

Thés de Ceylan Sans Mélange.

En paquets de 1 lb. enveloppés de plomb sur les terrains de récolte à Ceylan, ou en boîtes de 10 lb.

Seuls agents à Alexandrie: Mel'or & Co.

Do. au Cairo: Walker & Co.

The more the merrier!

CINCHONA CULTIVATION IN JAVA.

Mr. van Romunde's report for the 3rd quarter of 1890 on the Java Government Cinchona Gardens states that the weather had been changeable, the east monsoon having been, as in 1889, very abnormal. The continuous rain on the Tangkoeban-prahoe had interfered with the growth of the plants. Stirring of the soil had been carried on vigorously during the quarter. A commencement was made with the planting of strips of land to form belts between the four establishments on the Malabar mountains. The caterpillar plague again gave great trouble, except in the closely planted gardens, and these were therefore cropped as little as possible. The crop of bark for the year was so far 250,000 half kilograms, of which at the end of September 177,369 pounds had been despatched to Tandjong Priok. At the sales in July and August in Amsterdam of bark of the 1889 crop, the average prices per half kilo and per unit of quinine sulphate were 8 and 9½ cents. On account of the want of dry weather in 1889, and excess of rain this year, the ledgeriana blossoming and fruiting was interfered with, and consequently the numerous orders for seed could not be executed. Sales of seed could not therefore take place before November and December.

ORANGE-GROWING is now a considerable and increasing industry in some parts of California. And by last report of the British Vice-Consul at Los Angeles an orange orchard of ten acres there, in eight years from planting, will pay for all the outlay and leave the owner a profit of £190 or thereabouts. After that it will yield a return to the owner of not less than £1,000 per annum. Good suitable land with water-right can, he says, be bought at £60 to £70 an acre. The crop at Los Angeles, which last year reached 27,000 tons, will this year reach 35,000 tons.—*A. P. Press.*

FRUIT CULTURE.—There is an interesting paper in the *National Review* on "Fruit Culture in Worcestershire," by Mr. Parkinson, who mentions, among other interesting facts, that one earwig biting a hole into one apple may cause a whole roomful of stored fruit to go rotten.

PURE CEYLON TEAS VS. IMPURE TEA BINS AND "CLEANSING FIRES."

That the second is incompatible with the first goes without saying. Then how to keep the second *constantly pure* and without much trouble is the question. Mr. John Hughes, the Chemist, has already told us how to purify metal tea-pots—clean them well out with hot water and while the moisture still clings to their interior drop in a live coal and close the lid—the resultant steam will, in five minutes, thoroughly cleanse *metal* tea-pot. Carry the same idea out with regard to tea bins. Speedily sponge down the sides, then rapidly place on two bricks at the bottom a piece of iron, the size of half a brick, brought to white heat in the Sirocco, close down the lid and make airtight, and the virtue of "cleansing fires" is at once secured.—*Cor.*

THUNDERSTORMS.

ROBERT H. SCOTT, IN "LONGMAN'S MAGAZINE."

A flash of lightning a mile in length is nothing very extraordinary, and it is therefore not to be wondered at that experiments to bring electricity down from the clouds are very dangerous, and have frequently had fatal results. Soon after Franklin, in the last century, had made his famous experiment with a kite, and proved that electricity existed in a thunder-cloud, natural philosophers generally began to imitate him. One of them in St. Petersburg, a Professor Richmann, arranged in apparatus to collect this electricity. On the first occasion of a storm he went to his laboratory to observe the effects. A ball of fire was seen to leap from the apparatus to his head, and he fell lifeless. Having thus got some idea of the force exerted by lightning, it may be interesting to the reader to learn something as to the means we possess of guarding ourselves, or rather our houses, from injury. A flash of lightning really consists of a discharge between two objects, say two clouds, or a cloud and the earth, oppositely electrified, the charges on which suddenly combine, with the manifestation of light and heat. Lightning conductors are contrivances by which the electricity of the earth is allowed to escape quietly into the atmosphere, where it meets with electricity of the opposite character from the clouds, and the two neutralise each other quietly, without any explosive discharge, or, in other words, without lightning. I need not go back to the first principles of electrical science and explain why it is that electricity passes most easily through metals, and escapes with greater freedom from sharp points than from rounded knobs. Assuming these elementary facts, I may say that on any object, such as a house or other building, the electricity tends to accumulate itself on all projecting portions of the roof, &c., and especially on the highest points of it.

The ideal complete lightning-rod system would call for a sharp-pointed copper rod erected at each of these projecting pinnacles, and rising above it, and would then connect all of these separate points by copper rods, and eventually carry down a stout copper rod to the earth. Care must be taken that due attention is paid to certain main precautions:—(1) The point of the conductor must be kept sharp; (2) the section of the conducting-rod must be sufficient to allow the electricity to pass along it; (3) the rod must be perfectly continuous; and lastly (4), the rod must be efficiently connected with the ground. 1. The sharpness of the point is insured by gilding it or coating it with some metal which resists oxidation. 2. As to the section of the rod, about half an inch in diameter is sufficient for

all ordinary buildings. Bars are not usually employed, as it is difficult to bend them over cornices, &c.; accordingly, either wire ropes or tapes are taken. The wire ropes are more liable to corrosion from wet getting in between the strands than are tapes, so that the latter are generally preferred. The metal used is always copper, being less oxidisable than iron, and being reasonably cheap and a very good conductor. 3. The continuity of the metallic connection from the highest point of the rod to the ground can only be secured by having as few joints as may be, and by making those joints as true and firm as possible by soldering. The joints should be examined from time to time, for it is often found, on examination of old conductors, that while the copper wire or tape is quite sound along its straight reaches, at the bends or joints corrosion has set in. As a chain is no stronger than its weakest link, a corroded conductor, such as has been described, is perfectly useless. 4. The earth connection.—It is not easy in all cases to insure that this is satisfactory. Electricity will not pass at all so easily into dry earth as into wet earth, and merely plunging the end of the rope or tape into wet earth is not sufficient. The conductor from the building should be soldered at its end to a large sheet of copper, say at least two square yards in area, buried in damp soil, or else soldered to the water or gas mains, so as to insure that a large surface of metal is in contact with damp earth.

Supposing that the whole system of protection against damage from lightning has been properly planned, the work should be carefully tested after its completion, because injury to it often occurs at the very last, owing to accidental causes, or to the carelessness of workmen. Conductors should also be examined from time to time, throughout their whole length, to make sure that all the joints are sound. Care should also be taken that the earth in which the terminating plate is buried is kept thoroughly moist. If any of these particulars be neglected, the conductor will be practically useless, and will afford no protection to the structure. The extreme practical importance of security against lightning must be my excuse for having been more diffuse over the object of lightning-conductors than over other details of the phenomena and effects of thunderstorms.—*Public Opinion.*

INDIAN TEA IN PARIS.

All who are interested in the progress of the tea industry in India will be pleased to hear of efforts being made to open new markets for the yearly increasing production of the country. The Indian tea planters too long neglected this work, but during the last few years they have been striving to make up lost ground. By far the most interesting and important of these undertakings is that which is being conducted in Paris. Paris is important as being not only the capital of France, but the centre of the world of fashion, although, in the interests of British tea-growers, we must regret that up to the present fashion has not set in favour of tea.

Under the auspices of this movement one of the first tea cafés in Paris has been opened at 12, Rue Anber, centrally situated near the Opera House, and it is certain that it will be a boon to those who love good tea, well made and served. In order to associate this new departure with the Indian Palace, the designs have been prepared by the same architect, Mr. Purdon Clarke, C.I.E., F.R.I.B.A., who is probably better qualified than any other man in Europe to show what can be done in the adaptation of Indian architecture to European requirements. The facade, an arcade of three entrances, is in the Mogul

style. It consists of a carved framework in Deodar filled with panels of highly decorated Indian glazed tiles. Above are two inscriptions in Hindustanee and the words "Au Palais Indien." The front of the interior is divided into two parts by an ornamental carved screen filled with lattice work. At the back is a spacious saloon. There is a separate entrance to each of the front divisions, one of which is used as a shop for selling dry tea, and the other as the tea restaurant. It is hoped that this will compare favourably with even the most handsome cafes in Paris. The Indian style is carried throughout. Opposite the partition mentioned above, there is an elaborately carved divan in a recess also filled with lattice work and carving. Between the front salon and the larger room behind are three beautiful Indian arches, both sides of which are covered with carving. The larger saloon represents the tent of an Indian prince; the walls and ceilings are draped with rich stuffs, and the light is softened by being admitted through three windows of stained glass. These windows recall those formerly existing in the old palace of Joypur. In panels the names of the leading tea districts—Assam, Cachar, Sylhet, Dooars, Kangra, and Kumaon appear in striking colours. It will be felt that all this is a brilliant and appropriate setting for the Indian tea of excellent quality which is the only kind supplied. So far as we know this is the first shop or restaurant in Europe the decorations of which are exclusively Indian. As an example of how easily the rich art of country can be applied to European requirements we hope the restaurant may be popular with many who are not so deeply interested in the tea question.—*Times of India*, Nov. 5th.

WYNAAD PLANTING NOTES.

Like Mr. Micawber, we are beginning to hope that "something is going to turn up," for the weather has been so extraordinary and so unusual, that we can only suppose (according to your "Native Observer") that the Shastras must have predicted it. Perhaps we can also tell us what results are to be expected! Continual downpours have kept the country as green and luxuriant as in mid-monsoon; plants, which are usually withering by now, have again sprouted up in fresh life. There is a rush of new wood on the coffee trees, and spike is showing up. We heard unmoved, of cinchona clearings being planted up during the last week in October; and those who were shaving (trees) experienced phases of despair, only to be understood by the spectacle of heaps of bark becoming "discolored," for lack of sunshine to dry it properly. But during the last few days there has been a delightful change, and we are having bright days and cool crisp mornings and evenings, without the usual accompaniment of east winds. It is great relief to us; for we began to dread a renewal of the leaf disease from continuous wet. Our coffee is, as usual, looking "splendid for next year." It should console us for the wretched disappointment of the present crop, to notice that an idle season has apparently invigorated the trees very markedly. Fields which a few months ago seemed fit, only to abandon, have burst out again in a splendid show of new wood and leaf. If only we could feel sure of seasonable blossoming showers, we might be eased of a great load of anxiety, for the trees give every promise of a fine crop in '91. Over that of '89 we may draw a melancholy veil. With most of us, even our lowest estimates have been reduced, and "reduction" in everything else, is the alarming result—alarming, because coffee now-a-days must be coddled—or go out,—so that it is after all but a doubtful economy to cut down, absolutely, necessary expenses. The lowness generally affects our labour. Crop is nearly over in most places already, and it is very difficult to employ the usual gangs. The labour question has been an unpleasant one all this year. Our coolies (heavily advanced of course) should have been in during the latter end of May, but very few arrived before August, and many are only now putting in an appearance. Consequently we had to struggle through our weeding and planting,

with any gangs we could get from the coast, and our Lordly Canarese complain, because, "they've got no work to do," and threaten to take contracts in other districts, oblivious, seemingly, of what they still owe us. * * * The ambona disease still continues in places, but has not destroyed all faith in the product. New clearings have been opened in the district for ledgers, and a great deal of Liberian coffee, and pepper has also been planted. The pepper crop does not seem to be particularly good this year. Let us hope that it, as well as coffee, meditates doing us a good turn in the coming season. I think we deserve it.—*Madras Times*, Nov. 22nd.

NOTES ON ESSENTIAL OILS.

(From Messrs. Schimmel & Co.'s Report)

EUCALYPTUS OIL.—The production of eucalyptus oil in Algeria, which only amounts to about 2,000 kilos a year, is said to be capable of considerable extension, and even at the low prices it must be a very lucrative industry, if one may judge from the experiments which have been made in Leipzig with French material, the price of which was greatly enhanced by the enormous rate of railway carriage. It is also said that in Algeria the cultivation of *Eucalyptus rostrata* is steadily gaining ground, although this species is of slight value only for the manufacture of oil. Oil of this variety has not hitherto been known in commerce. With reference to an observation by Mr. P. W. Squire, in the *Chemist and Druggist* that an oil has frequently been met with in commerce lately which was offered as *Eucalyptus Amygdalina*, but which contained no phellandrene, and was dextrogyre instead of levogyre to polarised light, we have ourselves noticed that the oil bought direct from Australia recently contained only a small percentage of phellandren and was weakly dextrogyre. We are of opinion that the leaves of different varieties of eucalyptus are no longer kept carefully separated in Australia during the distilling operation, and that consequently the names under which the oils are brought into commerce do not always correspond with their origin. On the occasion of the recent Berlin Congress three new varieties of eucalyptus oils distilled by us were exhibited. These oils are not yet found in commerce, but one or the other of them is about to make its appearance. These oils are the distillates of *E. decubata*, *E. maculata*, and *E. maculata* var. *citriodora*, all of them of a fine melissa-like flavour. In the meantime large samples of distilled oil of *E. maculata* var. *citriodora* have been received from Queensland. This oil has been distilled by Mr. Jeffreys Timbury. Not only does its flavour agree with that of our distillate, but its other properties also are so much akin to it that there is no doubt of the identity of its origin. Its s.g. at 15° is 0.873; about three-fourths of it has a boiling point of 205° to 210°, small quantities vapourising somewhat below or above this temperature. The fraction having a boiling point of 205° to 210° consists of almost chemically pure citronellon. Upon agitating the oil with a solution of bisulphite of soda the mixture becomes strongly heated and forms a fairly hard mass, from which, after washing with ether and decomposing with a solution of soda, pure citronellon separates. The parts of a lower boiling-point than 200° (about 4 per cent. of the whole) showed none of the characteristic reactions of cineol (eucalyptol), and it may therefore be taken for granted that this body is wanting in the oil of *E. maculata* var. *citriodora*. The thoroughly rectified oil is colourless, has a pleasant flavour of melissa, and, presuming the price not to be too high, will be useful in perfumery and soap-making. Unfortunately, we are quite in the dark as to the price, and therefore will scarcely be possible to make any sales until April next year. There is no doubt that the oil has a very much finer flavour than citronella oil, and if its price should lie between 2s. 6d. and 3s. 6d. per lb. it may find a considerable employment; if it is dearer however, it will only be used on a smaller scale. [In January of this year we had a communication from our Melbourne office regarding this oil, in which it

is stated that "the leaves are carefully separated from the young shoots, and the oil distilled from them alone. In its own district it is being used as a substitute for glichulus oil for medicinal purposes. Oil distilled from the older leaves not separated from the stalks Mr. Timbury calls 'commercial oil' of *E. citriodora*, and sells it at 3l per gallon. The pure oil is put up for retail sale in bottles, sold wholesale as follows:— $\frac{1}{2}$ oz. 9s; 1 oz. 15s; 2oz. 28s 4oz. 48s per dozen, pint bottles, 20s each. Mr. Timbury states that the oil is a powerful disinfectant and deodorant, even the aqueous solution deodorising the most offensive matter. The yield from a ton of moderately dry leaves is about 520 oz. of oil, from fresh leaves about 270 oz. There is only one other lemon-cented eucalyptus." It would appear from this that there is little hope of the oil coming down to 2s 6d. or 3s 6d. per lb. We may also recall the fact here, which we stated as long ago as May, 1886, that the leaves of old and young trees alike of *E. amygdalina* and several varieties thereof, as well as the leaves of other species, are gathered by the hushmen collectors, who have no botanical knowledge; hence there arises considerable variation in the physical properties of the different brands of Australian *E. amygdalina* oil. —Ed. C. and D.]—*Chemist and Druggist.*

A VEGETABLE CONDUCTOR OF ELECTRICITY.

Some very interesting letters and notes have recently been appearing in *Reis and Rayyet*, a very smartly-conducted Calcutta paper, in reference to an old and curious custom of the Hindus of Bengal. It seems that from time immemorial it has been the custom of the Hindoos to place on the roofs of their houses a plant, the identity of which appears to be disputed among Indian hot-nuts, some calling it a Cactus, whilst others declare it to be a *Euphorbia*. One of the correspondents is quite mistaken when he says that the Cactus—which we will assume the plant to be—helps to draw the electric fluid into the house by the attraction of the electricity in the cloud above, whether there be a Cactus plant or not. The Cactus only serves to scatter the electricity of the house into space, and thereby to neutralise that of the clouds, for these two electricities are of two kinds. The Bengalee name of the plant grown on the roof is *bāj-hāran*, i.e., a preventative of lightning—a fact which conclusively proves that the Hindoos are acquainted with the useful property of this sort of plant. It is not at all improbable that the ancient Hindoos, who displayed so much learning in other matters, should have been acquainted with the principles of electricity; the explanation is now lost, but the custom remains. An absurd, an idiotic reason is given in Hunter's *Dictionary*, in which it is seriously stated that because the Cactus protects their grounds from stray cows and goats, it will also similarly protect their houses from lightning: the idea is preposterous.

The custom of placing a Cactus on the roof is based on a highly scientific principle, viz., that of the "power of points." Electricity escapes far more easily through a pointed conductor than through a round one. For this reason the end of the brass conductors in an electric machine are mounted with brass knobs. The principle of saving a house from lightning with a metallic-pointed conductor and with a prickly Cactus is the same. When a cloud highly charged with electricity passes over a house, the house becomes charged with electricity of an opposite kind through induction, and these two electricities attract each other. Lightning is only the result of this mutual attraction, when a portion of the electricity of the cloud attracted by that of the earth below strikes the house. But if the house is provided with something having points, the electricity of the earth escapes into the air through these points, and neutralises the electricity of the cloud and thus the discharge cannot take place. The plant which the Bengalee and other Hindoos grow on the roofs of their houses has hundreds of sharp-pointed prickles. The more the number of points a conductor

charged with electricity has, the more easily the electrical fluid escapes from it. Therefore, in this respect, the plant in question is far better than an ordinary conductor which has only one point. Nowadays, the conductor of a house is provided with four or five points. The great drawback in the use of the Cactus is that it cannot have proper connection with the earth; the connection is chiefly through bad conductors. Still, something is better than nothing.

The subject is one of considerable general interest, and deserves careful investigation and enquiry. The custom does not appear to be observed in Upper India, but in Bengal it is a very common thing to see this plant in a tub placed on the house-top. This plant is not only held sacred, but is reputed to possess important medicinal properties.

The editor of *Reis and Rayyet* states that the plant used on the housetops is not the India Cactus so suggestive of the hooded serpent, and appropriately called Nagphani, in Bengal, and Nagkali, on the Coromandel coast. That plant, though common enough, is neither sacred, nor, so far as we know, used as a medicine against snakes in this province.

The plant prized as a protection from lightning is the *Tekátárij*. It is not a Cactus but a *Euphorbia*. The subject is certainly one in which more light is needed. —A TRAVELLING BOTANIST.—*Gardeners' Chronicle.*

ON THE USES OF CURRY LEAVES.

By DR. P. S. MOOTOOSWAMY, F.L.S., TANJORE.

The curry leaf tree (*Murraya Koenigii*, Spreng), belongs to the natural order Rutaceæ, and is remarkable for its fragrance. It is a small tree with pinnate leaves, leaflets alternate, ovate, somewhat serrated, panicles corymbiform, terminal, calyx 5-cleft; petals 5, spreading; berry 1-celled, 1-seeded; flowers small and white, appearing in the hot weather. The tree is well-known throughout the plains of Southern India, where it grows in the jungles on the lower and mountainous slopes. It is also cultivated in gardens on account of its leaves, which are very fragrant and much used by natives for seasoning their curries. Some gardeners make their living by the daily sale of the fresh leaves, and coravers, a class of wandering dealer, bring the dried leaves, with those of *Solanum pubescens*, from the jungles and take them for sale from place to place. The vernacular names of the tree allude to it as "curry leaf" because of its use as a condiment, and in Sanskrit it is called the "fragrant neem," and other one or other of these names it is known throughout India, Burma, and Ceylon.

The leaves are the only part of the tree, in this part of the country, employed in native medicine, and their properties are aromatic, stomachic, stimulant, astringent and tonic. They retain their medicinal properties even in their dried state. The leaves are indispensable in seasoning native curries, broths, and pepper water for their daily consumption. It enters as a principal ingredient in their curry-stuff or condiment taken with the rice. In the absence of fresh leaves, dried leaves are purchased and stocked for the cold season. A seasoning preparation, called *vadagam* in Tamil, is made and kept for daily use in almost every house, except those of Brahmins, who do not use onions in their diet. It consists of onions in large quantity, while the other ingredients form smaller proportions. These are garlic, cumin, fenugreek, mustard, turmeric, and curry leaves. These are well beaten down in a stone mortar and made into a mass, from this a number of large balls are rolled up and dried in the sun. They are smeared with castor oil every morning as they are exposed, and after a few days will become dry enough to store. Curry leaves are also used for flavouring chutneys.

Persons suffering from dyspepsia and diarrhoea resulting from indigestion, make a broth from the leaves. They are first broiled with ghee, and after the addition of a little tamarind and salt, water is added,

and the whole boiled. I have found this decoction check the complaint at once.

A useful preparation for allaying vomiting and purging in children is the following. Curry leaves, tamarind, neem, country gooseberry, morinda, of each one ounce, sweet flag and ajwain, of each one drachm, water 12 ounces. The dose of this is half an ounce twice a day.

The green leaves rubbed up to a paste and mixed with buffalo's tyre (butter-milk) have been given with success in adult dysenteric cases. The dried leaves enter into a compound powder largely used as an astringent. The seven articles are as follows, with their botanical, English, and Tamil names.

<i>Murraya Koenigii</i>	Curry leaves dried	Karuvempillai.
<i>Mangifera Indica</i>	Mango seeds	Manqa palavirai.
<i>Solanum pubescens</i>	—	Soondry kavathu.
<i>Trigonellia Fennugrecum</i>	Fennugreek	Vendayam.
<i>Phyllanthus Emblica</i>	Country gooseberry	Nelli-kai.
<i>Feronia elephantum</i>	Wood apple	Velampalam.
<i>Carum copticum</i>	Omum	Omum.

Equal parts of these drugs are finely powdered separately and then mixed. The dose for children is 3 to 5 grains in honey, and for adults 15 to 30 grains in buffalo's tyre. This powder is much resorted to by native physicians in the treatment of dyspeptic diarrhoea of children attended with flatulency. It is very singular that native doctors, ignorant as they are of the therapeutic action of medicine, never combine opium or other narcotic preparation in their administration of remedies in diseases of children.

D. Roxburgh mentions that the bark and root of the plant under reference are applied externally to cure eruption; and the wounds made by the bites of animals. A decoction of the leaves is used in fever mixtures, mixed with other aromatics and bitters.

A clear transparent yellow oil is sometimes extracted from the seeds and is known as Simabolee oil.

A chemical examination of the leaves has been made by Mr. J. G. Pr. bble, and will be found in the *Pharmacographia Indica*, vol. i., p. 263-265. From the analysis it appears that the leaves yield to distillations a small quantity of volatile oil resembling that obtained from the leaves of *Egyle Marmelos*. Ether extracted 7½ per cent. of resinous matter, and a further quantity was removed by alcohol. The resin was greenish black in colour, amorphous, and freely soluble in chloroform, bisulphide of carbon, benzol and amylic alcohol, less soluble in glacial acetic acid, and petroleum ether, and almost insoluble in acetic ether. It gave an emerald green coloration with sulphuric acid, and yielded picric acid when oxidized by nitric acid. The aqueous solutions of the ethereal and alcoholic extracts contained an acid principle darkened by iron salts, but not precipitated by gelatine. The bitterness of the leaves is due to a glucoside provisionally named *Koenigin*. The crystals were sparingly soluble in water and alcohol, and the solution was precipitated by tannin lead acetate, and feno-so-ferric salt, but not by alkaloidal reagents.—*Pharmaceutical Journal*.

BRITISH GROWN TEA.

TO THE EDITOR OF THE "MANCHESTER COURIER."

Sir,—It is said, and truly said, of a great living orator, that he made statistics eloquent. He so well understood and so dexterously employed the fine art of language that the humdrum figures of a Budget were bright and fresh and full of pleasant surprises. We wish we knew the secret of making attractive the figures which, with your kind permission, we would lay before your numerous readers. To bespeak their interest in our statistics we would state by way of introduction that these figures claim attention, because they affect the reader's pocket. They also touch another equally susceptible spot—the palate, and they

also appeal to his patriotism. As the last remark may excite surprise, we at once explain. It is the object of these figures to show to what a large extent the British tea drinker has already deserted China, to confirm him in that course, to urge him to deal another blow at that collapsing trade; to show that by a continuance of this preference for Indian and Ceylon teas he will be immensely assisting his countrymen, who are tea planting and tea farming in those great dependencies. That's where the patriotism comes in. Support your colonial fellow-countrymen, who on the hillsides of Assam and the Chingalese valleys are bringing science and method to bear—as well as compromising their livers—in order to send you tea which, as many British housewives are fully aware, is not only superior in flavour to China tea, but keeps its flavour much better. The almond-eyed Ah Shin does not send you his best tea. He never did. He has always used at home far better tea than he sells us. Thanks to our Anglo-Indian planters, John Chinaman's best is now more than equalled by Indian tea at less money. The China tea grower is in a bad way. He finds himself implacably thrust aside. Stung by the thought of a ruined industry, he promises to mend his ways. Trust him not. He will fool you again if you give him the chance. Now for the figures:—In 1838, for the first time, this country received more tea from India and Ceylon than from China. Go back 35 years to 1854. The quantity of China tea used in Great Britain was nearly 62,000,000 pounds, and the quantity of China tea used in 1889 in Great Britain was just over 61,000,000 lb. In 1854 however, the 62,000,000 lb. represented our total consumption, as China was our sole source of supply. But in 1889 we used 185,000,000 lb., of which India supplied 96,000,000 lb., and Ceylon 28,000,000 lb. Or to put it in another form. Of this 185,000,000 lb. consumed in 1889, India supplied 52 per cent, Ceylon 15 per cent, and China only 33 per cent. The first six months of 1890, 1st January to 30th June, show a further decline of China tea, a further increase in consumption of British grown tea, the figures being—Indian 54 per cent, Ceylon 16 per cent, and China only 30 per cent. The exports from China this season to October 30th are more than 25 per cent less than in 1889. The quantity of tea used annually per head of population in Great Britain shows the following increase: 1849, 1.81; 1859, 2.67; 1869, 3.63; 1879, 4.68; 1889, 4.91. Note how small is the increase in total consumption during the 10 years 1879-89 when compared with the preceding decades. Indeed it is calculated that during the last seven years the average consumption per head of population has remained stationary. This fact is naturally regarded with rueful eyes by Chancellors of the Exchequer, but it admits of a simple and satisfactory explanation. There is no decline in the demand for tea. This would be abundantly demonstrated if the number of gallons or cups of tea could be ascertained as easily as the weight of tea. Indian and Ceylon being so much stronger than China tea a greater number of cups can be made from the same weight of tea. Indian tea more especially possesses that quality quaintly described by an old Irish woman as "taking a powerful grip of the second water." The secret then of the enormous and yearly increasing popularity of the Indian tea may be found in its economy, in its absolute purity, and its exquisite flavour. It is also free from those deleterious qualities which sometimes produce so unpleasant an effect after drinking China tea. People find that instead of using the same quantity for a brew that they would of China tea, half the quantity is sometimes more than sufficient. It has been calculated that the British public, while consuming a larger number of gallons of tea in 1888, saved in that year £1,000,000 through using Indian tea instead of the weaker and less carefully cultivated article. In China tea culture has become desultory, careless, unscientific. In India tea is better grown, better manufactured, and vigilance, method, science, are having their natural reward. It is true that having fairly distanced China as a competitor, some complaints have arisen that the Indian tea industry is not at the moment so promising

as it at one time appeared. The gardens areas prolific as ever, the labour supply is improved, the demand is increasing every year, but Ceylon tea is so treacherously good that some Himalayan planters have feared that the competition of that favoured island is going to some extent to rub the gilt off the gingerbread. But an analysis of the balance sheets issued by 24 of the more prominent concerns shows that they yielded an average of nearly 7 per cent on the invested capital, and 17 out of the 24 concerns have reserve funds saved out of past profits, which aggregate more than their paid up capital. Not at all bad as times go, and if the Indian tea industry never does worse, the planters will have little cause to complain. Of Ceylon and its marvellous climate and bounteous soil all travellers speak with enthusiasm. It has been held by some to be the Roman Taprobane referred to by Milton in the great vision of Roman power in "Paradise Regained."

From India and the golden Chersonese,

And utmost Indian isle Taprobane:

Dusk faces with white silken turbans wreathed.

By others it is considered to be the local representative of the Paradise of Scripture. If not, travellers say it at least ought to have been, as no place on earth better supports the Paraisaical characters. And then does not Ceylon boast her "Adam's Peak"—named after the universal progenitor—a mountain more than 7,000 feet high, which, however, ranks only fifth or sixth in the mountain scale, the highest being over 8,000 feet above the sea level. The dimensions of this Eden of the terraqueous globe are about one-sixth less than Ireland. Scotland also affords a scale of comparison; Scotland containing a trifle more than 30,000 square miles and Ceylon 24,500. Great already in performance, Ceylon is still greater in what she promises, and well merits the admiration of those ardent travellers who describe her as the most gorgeous jewel in the imperial crown.—Yours, &c.,

BROOKE, BOND & Co.

—Manchester Courier.

THE ASIATIC QUESTION IN MAURITIUS AND NATAL.

The *Natal Mercury* is afraid that colony being overrun with "Hindus" to the same extent as Mauritius. Here is an extract from a recent editorial:—

We find in the *Commercial Gazette*, of Mauritius, of September 30th, an article that deserves the serious attention of all who are interested in what is known as the "Asiatic question." Mauritius, it must be remembered, is an island that cannot be said to have had any aboriginal population. Its people are either immigrants or the descendants of immigrants. They are the offspring of European occupation, and are only "native" in the sense that whether they be white or coloured they have for so many generations, as the case may be, been born on the soil. Thirty years ago the population of the island was represented by the European creoles—mostly of French extraction—by a few British merchants and planters—the two classes forming the aristocracy of the community—and by a much larger proportion of Asiatics from India and China, who represented the "lower" and labouring classes. At that time the island presented a picture of sugar plantations, owned by European colonists and worked by coolie labourers, with a modicato admixture of colonial creoles, and in the towns and villages of small "Malabar" and Chinese traders. A large breadth of the soil was still covered by forests that added to the beauty of the landscape and tempered the conditions of the climate. There had been occasional epidemics of cholera; but as a rule the health of the island was fairly good; the fever period only made its appearance in 1864. Little by little since then the Asiatic element has more and more taken possession of the soil, and fever has more and more established itself in the community.

Now we find a journal fairly representative of public opinion in a colony whose only industry has

been developed by means of Indian labour, deliberately proposing that the supply of that labour shall be arrested, as a measure of sanitary and social salvation. Which may be the "neighbouring colony" from which it is proposed in future to draw the stream of immigration we are not told, nor does it matter. Mauritius, as we have said, has no vast reservoirs of native population to draw upon, and the proposition, therefore, as compared with our own case is all the more striking and suggestive. Such an experience and example cannot possibly be ignored. The Indian population of Mauritius—an island of some 713 square miles—numbers, say, 317,121. It has overrun and swamped the island. It has denuded it of trees; it has corrupted the climate, and it has driven out European trade from the hands of all but a few wholesale firms; in other words, it has converted a European colony into an Asiatic settlement. These are startling and ominous facts, and they ought to command the gravest attention of our legislators. Mauritius is witnessing the full fruition of evils of which we already see and feel the beginning in Natal.

THE PERFECTION OF CLIMATE IN AMERICA.

From an American friend, a merchant—who has hitherto been settled in Philadelphia, we have the following under date 3rd November:—"Last winter my wife's lungs seemed ailing and we spent the cold months in the south. The change had a beneficial effect, but our doctor here thought the splendid climate and high altitude of Colorado was needed, so we spent the summer there. I think my better half has scarcely a trace of lung weakness today, and we enjoyed Colorado Springs so much that we are going to settle there permanently. I have been much in Virginia, and have travelled extensively (elsewhere) in this country, but have never seen such a climate as that of Colorado, nor so charming a place for residence as Colorado Springs."

THE CULTIVATION OF THE COCA PLANT, and the manufacture therefrom of the drug known as hydrochlorate of cocaine, is to be tried as an experiment at the Government cinchona plantations in Bengal. The suggestion that it might be advisable to attempt the manufacture of this valuable and costly drug in this country, came some months ago from the authorities at the India Office.—*Bombay Gazette*.

TECHNICAL EDUCATION IN INDIA—One of the most admirable features in the scheme of technical education worked out by Mr. Mackenzie in the Central Provinces, is the prominence given to instruction in the principles of agriculture. For this purpose, as we noted some time ago, a primer for use in primary schools was recently drawn up by the Director of the Agricultural Department, and it has now been determined to make instruction in this handbook compulsory in all rural schools. Already the Inspector-General of Education reports that the subject is very popular both with the pupils in these schools and with school committees in rural tracts. The great difficulty is to provide teachers who can impart the lessons of the primer in the vernacular, which is obviously the only medium by which the classes in the rural schools can be reached. For this purpose a vernacular class for teachers will now be added to the English agricultural class at Nagpur; an additional teacher with a diploma from the Poona College of Science will be employed for the purpose of giving to selected masters from the village schools a course of practical instruction in the primer through the medium of the vernacular; and, finally, small scholarships will be provided for the teachers so selected, so that two may be sent in from each district half-yearly for a six months' course at Nagpur.—*Pioneer*.

RUBIES AND SAPPHIRES IN SIAM.

We (*Bangkok Times*) hear from London that the Rubies and Sapphires of Siam Company have appointed a Mr. Gibbons as their general agent in this country and that he has already started for Bangkok. Mr. Gibbons, it is said, will also act as local agent for the Gold Fields of Siam, Ltd. From a reliable quarter we hear that the Rubies Company has been satisfactorily floated in London with a capital of \$300,000, and that from the preliminary arrangements already made at Krat and Chantaboon, the shareholders will probably make a good thing out of it.

MAURITIUS.

PORT LOUIS, Nov. 8th.—SUGAR, THE WEATHER AND THE CROP.—The season is very favourable for manipulation, and the mills are working with great activity. In certain quarters the yield is far superior to that of last year, whereas in others, the contrary is the case. We believe that we are in a position today to predict that the general production will be below that of last year.

VANILLA.—There has been a good demand for fine qualities. We have to quote the sale of a few lots first quality at R16 to R17 per kilo above 6 inches 2nd quality at R14 to R15 per kilo above 6 inches. We fully confirm our valuations as regards the outturn of the coming crop which will not exceed 14,000 kilos.

ALOE FIRRE.—Remain nominally quoted from R240 to R250 the ton for first qualities. But very few factories continue at work.

COFFEE.—Owing to successive arrivals, market for this article closes dull and good quality of Ceylon is selling at R56 to R60 per 50 kilos. Réunion may be quoted nominally at R60 and mixed triage qualities R35 to R50 per 50 kilos, according to quality.—*Merchants and Planters Gazette.*

CARP FISH FOR, AND IN, CEYLON.

Mr. W. R. Tringham of Nuwara Eliya, deputed by the Assistant Government Agent, came down to Colombo on a special mission to meet the S. S. "Ma'da" and take charge of a consignment of Carp ova of a new species sent from Madras—the Nilgherries doubtless. But when Mr. Tringham got on board, it was to find that all were dead, to judge by the putrid stinking water in the receptacles. Had they been in order this consignment was to be taken to the lakelet in the Pavilion ground, Kandy.

However, Mr. Tringham's trip to Colombo was not quite wasted, for he brought down with him some lively specimens of our Ceylon Carp to place in the fountain basins in Gordon Gardens. This has been done successfully; but today Mr. Tringham found one of them had been attacked and damaged considerably, possibly by a crab. However the others seem all right.

THE JAMAICA BLUE BOOK.

THE GOVERNOR'S MINUTE ON THE DEPARTMENTAL REPORTS.

We (*Jamaica Gleaner*) have received the Departmental Reports of the Colony for the year 1888-89. In summing up his report on these, His Excellency the Governor remarks:—

The year 1887-88 marks the end of a period of depression. It opened with a deficit in Public Revenue of £12,628 and closed with a surplus of £30,054. This surplus had increased by the end of the year under review to £56,538. The growth of prosperity thus indicated has

been maintained, and promises to continue. The preceding précis of the reports of the various Departments, which treat in detail of the different subjects under which the business of the Island is classed show how steady an improvement is maintained in every Department. The number of Schools has increased from 771 in 1888 to 826, and Industrial Schools are about to be erected, at Hope Botanical Gardens for boys, and at Shortwood Female Training College for girls. The establishment of these schools will obviate the necessity of sending more waifs and strays to be brought up in the Boys or Girls Reformatories where they are exposed to the contaminating effects of association with vicious and criminal children. The Government Savings Bank shows an increase of 185 in the number of Depositors, and of £14,963 in the total amount of deposits.

THE FRUIT TRADE AND THE ABANDONMENT OF SUGAR.—The fruit trade, especially that in bananas, is daily expanding and to meet the wants of the local growers the telegraph system is being rapidly extended. The cultivation of sugar shows a decrease as steady as that of bananas shows an increase, and there seems every probability that the cultivation may be further restricted. The cause of the abandonment of the estates is attributed to the low price of sugar, and in some cases to the difficulty of obtaining labour. No doubt heavily incumbered sugar estates belonging to absentee owners do not pay under the present system of cultivation of the canes and manufacture of sugar and rum. But with the separation of the business of manufacture from that of cultivation, and the concentration of the planters' attention on the improvement in the cultivation, and the quality of the cane, sugar growing would be a safe and profitable investment. It is much to be regretted that the cultivation of sugar estates should decrease for the sugar cane, unlike the banana, cannot be destroyed by a hurricane, and this offers a steady field for labour in the event of such a calamity. The difficulty of obtaining labour is no doubt serious. That there is difficulty is not to be attributed to the laziness of the population but rather to their determination to invest in land, and to work upon it for their own profit. The consequence of this determination is a gradual migration from the plains to the hills, where land can more readily be secured, and where a very thriving peasant proprietary has sprung into existence, and these owners have become the principal producers of rum.

THE CAPABILITIES OF THE ISLAND.—But however satisfactory are the statistics of the Blue Book, they can give no idea of the value of Jamaica as a whole or of the extreme beauty and great capabilities of the Island. Of the area of 4,193 square miles, but 646 square miles are flat. The remainder is mountainous, and in the East the Blue Mountains attain the height of 7,000 feet. The mountains are composed of white and yellow limestone, carbonaceous shales, granitic and conglomerate rocks, with alluvial valleys. The climate is particularly healthy if ordinary precautions necessary in the tropics are observed, and while in the mountainous interior the temperature ranges from 60 deg. to 75 deg., even the tropical temperature of 80 deg. to 85 deg. near the sea level, is assuaged by the sea breeze during the day, and the cool land breeze that at night flows down from the hills.

With such variety of temperature, aspect and soil, the range of production is very wide and the Island offers excellent investments for agriculturists with comparatively small capital.

COCONUTS AND CINNAMON IN CEYLON.

KADIRANA, Dec. 6th.—Nice showers since the 1st, and promise of more; a little over 2 inches have fallen already this month. Almost before one bud on the cinnamon bushes has matured, another has made its appearance, and promises to be a pretty heavy one. This is rather rough upon those who wait till the first bud matured before commencing planting; while those who worked through the bud law, scored. Coconut crops continue to be good, but next year must see a great falling-off in yield. Mr. J. D'S. Raja-

pakse, Shroff Mudaliyar of the Negombo Kachcheri has become the lessee of Mr. Tudor Rajapakse's cinchona properties in this district at, I believe, £6,000 per annum.

NOTES ON POPULAR SCIENCE.

BY DR. J. E. TAYLOR, F.L.S., F.G.S., &C.
EDITOR OF "SCIENCE GOSSIP."

Messrs. Carter, the well known English seed merchants, have raised a new kind of barley, with branched spikes, resembling the Egyptian wheat one sees in old Biblical pictures. Now, a branched barley, with a short stout haulm to support it, might turn out a wonderful result to the grower. We want some young agriculturist to back his own opinion, and go in for trying a few acres of it. He might select the best seeds from the best plants, and sow them for results. If he succeeded, he would make money—if he didn't he would be no worse off than if the mildew had destroyed his crop. This branched barley was raised from a "freak," and there is no reason why many "freaks," should not be utilised. A Massachusetts farmer had several lambs born, with short, stumpy legs. His flocks had legs too long, as a rule, for they were all over the country, like so many greyhounds. Fences could not keep them in, and they caused both a good deal of trouble and a great deal of blasphemy. So the cute Yankee breeder saw his chance. He bred from the short, stumpy-legged sheep that could not possibly wander; and in this way was raised the now celebrated breed of "Ancona sheep."

The United States Government have established at Washington a hospital for diseased plants. It differs from ordinary hospitals in this respect—that the injuries and disorders from which the vegetable patients suffer are purposely inflicted on them by the doctors of the establishment, in order that the nature of their complaints may be studied, and methods for curing them may be discovered. It is under the well-known Department of Agriculture, which has agents in all parts of the States, whose business it is to collect specimens of diseased plants, and to forward them to this Vegetable Hospital. It is now known that nearly all the diseases of plants are caused by parasites, of which nearly fifty thousand different kinds are recognised. The parasites are carefully studied, and are developed in a gelatine culture. Healthy plants are then inoculated with them, and the progress of their various diseases is in this manner carefully studied. By this process, Professor Gallagher, who is at the head of the laboratory, has found it possible to thoroughly understand and cope with 12 different diseases of the grape-vine alone. A cure has also been found for the "fire rot," which turns the limbs of pear trees black, and rots them quickly. It is stated that the professor has similarly found means of attacking and ridding the fungoid parasite which causes the potato disease.

The following is a capital recipe for naturalists who collect:—To preserve the colours, shapes, &c., of tropical fishes, corals, sea anemones, jelly-fishes, &c., make a mixture to suit of glycerine and gum. Both are mixable with alcohol, but care is required in the operation.—*Australasian*.

THE LANKA PLANTATIONS COMPANY.

There is no Plantation Company connected with this island whose Directors afford such full and detailed information to their shareholders and the general public as do those of the Lanka Company. We have been favoured with a copy of their latest Report which will be found in another column, and which proves no exception to the excellent practice hitherto observed. This Report is well worthy of attention from all who take an intelligent interest in the great planting enterprise of the Colony. The Lanka Co. has had an unusually trying experience, because its existence is coincident

with the decline and fall of the coffee production of the island. No one at the time the Company came into existence believed that the splendid properties taken up on its behalf, could have suffered as they have done, and that too, notwithstanding the most careful supervision and liberal cultivation. Again, the Directors, naturally enough under the circumstances, refrained from launching into "tea" so early as they might have done, and as we know was urged on them from this end. Indeed, their then Ceylon Manager who devoted himself to the interests of the Company in the most earnest, indefatigable way, was able to place within the Directors' offer, at an early stage in our tea history, some splendid bargains in tea—notably a well-known Dolosbage estate then in the market for £25,000—but Ceylon tea planting was scarcely regarded in London at that time as beyond the stage of a speculative enterprise and with all their trying experience of coffee and cinchona, it is no wonder that the Lanka Directors were chary of another bold venture. Now, however, that the tide has turned for our planting enterprise, the Lanka Company holds an exceptionally strong position with no less than 1,468 acres under tea, 980 still remaining of good coffee, and 371 acres of very valuable cacao which last yielded a crop considerably above the estimate in the season reported, so making up a considerable proportion of the receipts. In respect of coffee, it is worthy of note and as shewing the hard luck in every way of earlier years, that while for 4,991 cwt. sold in 1881-2, only £16,000 was got, for one-third that quantity—or 1,649 cwt.—in 1889-90, no less than £8,145 was obtained. In other words the average price netted for our old staple has risen nearly fifty per cent in eight years. We may hope then that in every sense the corner has been turned, and that both as regards crops and prices, a good time is before the Lanka Plantations Company. The Directors and shareholders undoubtedly deserve well of Ceylon, and we trust the dividend declared on the present occasion is but the harbinger of returns which will more than make up for all past losses. *Floreat Lanka!*

THE FALL OF 14.47 INCHES IN 4 HOURS IN MEDAMAHANUWARA CONFIRMED.

HAS IT EVER BEEN EXCEEDED?

Rangala, 9th Dec.—Please tell your Koslanda correspondent that the 14.47 inches of rain really fell in Medamahanuwara in 4 hours (no practical jokes, &c.) and was correctly measured, being confirmed by two adjoining estates, one superintendent measuring 12.62 and the other found his gauge full at 11 inches. Had this gauge been large enough I expect it would have shown a heavier fall even than 14.47, as it generally gets the heaviest rainfall in the district.

[The greatest fall recorded for Colombo is 11.90 inches in 24 hours on 4th-5th May 1876; and for upcountry, but also for 24 hours, 18.80 inches at Padupolla. We suppose, therefore, this fall at Medamahanuwara to be unique in our meteorological records?—Ed. T. A.]

COFFEE IN WYNAAD: THE OLD STORY.

We hear very unfavourable accounts of the outturn of coffee in Wynaad. Estimates formed when the blossom had set, have turned out most disappointing; instead of so many tons only a few bushels have been picked.—*S. of I. Observer*, Nov. 29th,

THE LANKA PLANTATIONS COMPANY, LIMITED.

Directors:—George Allen, Esq., Sir R. P. Harding; Edward Pettit, Esq., Sir Herbert Bruce Sandford, K. C. M. G.—Agents in Colombo—Messrs. J. M. Robertson & Co. Secretary—Mr. William Bois.

Authorised capital, £200,000 in 15,000 Ordinary shares of £10 each, and 5,000 preference shares of £10 each.

REPORT.—To be presented at the Tenth Ordinary General Meeting of the Lanka Plantation Company, Limited, to be held at the Offices of the Company on Wednesday, the 3rd Dec., 1890, at 3 o'clock in the afternoon.

1. The Directors submit their Report for the twelve months ending 30th June last, together with the Balance Sheet and Account of the Company made up to that date.

2. The Coffee Crop was 1,649 cwt., against an estimate of 1,438 cwt., and the amount realised therefrom was £8,145 2s 9d, a return of 18 cwt. less than last year, but upwards of £416 more in value. The following statement shows the quantity of and the amount realised in each year since 1881, omitting fractions of hundred weights and pounds.

Years.	Ampittikande.	Arnhall.	Fruit Hill.	Fordyce & Garbawn.	Godakalak.	Kappahannock.	Rillammlle.	Thotulagalla.	Yattawatte.	Total.	Average Net Price.	Proceeds.
	cwt.	cwt.	cwt.	cwt.	cwt.	cwt.	cwt.	cwt.	cwt.	cwt.	£	£
1881—1882...	687	687	304	598	563	1008	96	1044	83	4991	66/11	16,704
1882—1883...	590	1154	463	256	494	293	210	1350	83	4476	74/9	16,735
1883—1884...	595	975	100	487	314	793	251	1262	211	5873	61/10	16,618
1884—1885...	891	619	189	311	683	768	322	1483	49	5499	59/	16,241
1885—1886...	316	550	71	433	273	319	75	640	23	2416	66/8	8,080
1886—1887...	621	564	63	304	518	384	117	829	10	3425	86/1	14,891
1887—1888...	489	84	(all tea)	424	268	324	78	234	11	1601	79/10	5,910
1888—1889...	189	195	"	59	384	439	68	409	11	1667	92/3	7,728
1889—1890...	161	215	"	217	393	63	41	536	..	1649	98/8	8,145

3. The Cinchona Bark shipped has been 62,298 lb. which has been realised, and has produced £83 907 1d. A slight improvement in this market has taken place, and at present there seems some prospect of a further advance. The Directors therefore propose to harvest more of this product if the prices become satisfactory.

4. The quantity of Cocoa estimated was 600 cwt., and the crop produced 684 cwt., realising £3,223 3s 3d. The cocoa trees are looking well, and there is every prospect of a larger return than has hitherto been obtained.

5. The cardamoms have produced 5,596 lb. nearly twice the estimated quantity (3,000 lb.) The amount realised was £298 7s.

6. The tea received from the Fordyce, Gonagalla, Fruit Hill and Ampittikande estates has amounted to 231,999 lb. (of which 33,650 lb. only was made from

purchased leaf), in addition to which 1,050 lb. were sold in Ceylon. The proceeds amounted to £10,050 15s 4d, and it is hoped that a larger return will be obtained this year without purchasing outside leaf. The green leaf sold from the estates where the Company have no factories was 112,030 lb.

The following Statement shows the acreage and state of cultivation of the Company's Estates on the 30th June last—

Estate.	Coffee.	Cinchona.	Tea.	Cocoa.	Cardamoms.	Rubber and Sapanwood.	Grass.	Pattana.	Forest.	Total.

* Partly in Coffee.

The Directors regret exceedingly the death of Mr. J. T. White, who was their esteemed colleague for nine years, and whose experience in Ceylon was of considerable value. As the Shareholders are aware Mr. White retired at the last meeting and it was not considered necessary to fill up the vacancy then created.

Mr. Gerge Allen and Sir Herbert Bruce Sandford retire on this occasion, and being eligible offer themselves for re-election.

Mr. John Smith, the Auditor (a Shareholder), also retires and offers himself for re-election.

The Directors regard the system of management, which has been in operation during the year 1889-90 as very satisfactory, and they believe that the best possible results have been obtained, and they hope the improvement which has taken place in the position and prospects of the Company will be maintained. Every economy which can with safety be effected is brought under their notice and gradually the cultivation of Tea is being extended. During the past year 200 acres have been planted, increasing the acreage of the Tea Gardens from 1,268 to 1,468 acres.

TRADING ACCOUNT FOR THE YEAR ENDING 30TH JUNE,

The opinions expressed by the Directors at the last Meeting have proved to be correct; for the year 1889-90 has resulted in a profit of £7,292 4s 6d—not a large amount certainly, but sufficient to have enabled the Company to pay a dividend of 3½ per cent. on the Ordinary Shares had not the dividends on the Preference Shares to the amount of £330 14s been in arrear and a debit balance of £1,458 0s 5d to be discharged, both these sums having been satisfied, the Directors are able to recommend the payment of the dividend of 6 per cent. on the Preference Shares, and also of a dividend of 3s per share on the Ordinary Shares.

The Directors believe the estimates of crops and of expenditure for 1890-91 have been made with the greatest possible care, but the uncertainty as to the rates of exchange which will prevail precludes the formation of any reliable opinion as to amount of profit which will be gained.

A summary with the details and the report of the Agents may be seen at the office. By Order,
WILLIAM BOIS, Secy.

No. 8, Old Jewry,
15th Nov. 1890.

THE LANKA PLANTATIONS COMPANY.

(Communicated.)

The Lanka Company, in common perhaps with the several ventures in Uva, has been representative to a great extent of the many instances in which concerns which flourished exceedingly in the old days of successful coffee planting found themselves face to face, when that form of cultivation failed, with the necessity for its gradual abandonment and the planting of the several estates it possessed with the tea plant. To effect this the lapse of years has been necessary, and such profits as could be made during this period, had to be devoted to the operation we have referred to. That this has been at length fully accomplished,

and that the cost of doing so has now been entirely met and the resultant indebtedness wholly wiped out, is significant of what it has been possible for wise administration and judicious moderation with respect to current profits to effect. And the result to the exercise of such administration and of such judicious moderation is now to be seen in the strong position to which, as you well remark, the Lanka Company has at length attained. It commenced the operations of the current year wholly free from the debt which has for so long weighed upon it, and its directors will be at liberty to divide the anticipated profits among its long-suffering and patient shareholders.

That this end has been achieved is convincing as to the remunerative character of the local tea-planting industry. No more striking proof, indeed, of this could be found than the rehabilitation of the Lanka Company affords. It surpasses in the efficiency of this proof even the large dividends that Tea Companies of more recent establishment have been able to declare. I feel every confidence that ere long the announcement which the Lanka directors are able to make will be followed by that of similar results by those of the several Uva Companies who have had to struggle against adverse conditions of a similar type. When this consummation has been fully attained we may expect no longer to see the list of dividends declared by Ceylon Tea Companies qualified by the inclusion in it of what have been to all appearance—so far as the uninformed British public could judge—of perfectly negative results in the case of some such Companies. I can feel no doubt that this improved state of things must have a very marked effect upon the general credit assigned to our local enterprise, so that it must conduce to a further extension of tea cultivation in Ceylon. It is to be hoped that Russia, America and Australia may speedily become large customers for Ceylon tea direct, so as to take off a goodly part of our yearly increasing exports.

When noticing the Reports issued of recent years by the Lanka Company you have expressed your appreciation of the very full information they contained as to the prospects of its several properties. The giving of this information was, as regards the generality of similar reports, a wholly new step, but one which has been fully justified by the proof now afforded of the accuracy of what was predicted. At times during the troublous period through which the Directors have now successfully passed, their course of action has been strongly criticized. No doubt it was a hard trial to the shareholders to have to wait year after year without return for their investment, but the logic of accomplished facts will now have fully justified the wisdom of the course to which at times so much exception was taken.

COFFEE V. TEA.

(By an Old Hand.)

Tea planters would do well to study the relative positions of these staples as regards deliveries (consumption) in the non-producing countries of Europe and America. Some idea may be formed of the vastness of the coffee enterprise by reducing to lb. the enormous deliveries said to have taken place in Europe and America in one month, March last, viz 62,000 tons = 133,000,000 lb. — *Vide* Rucker & Bunnatt's Coffee Circular published in *Ceylon Observer*, 1st Dec. 1890. The above weight is about equal to the annual deliveries of Indian Ceylon tea combined, in the countries mentioned. Ceylon's coffee contribution for 1890 will be only about 4,000 tons for distribution in all countries.

Gow, Wilson & Stanton, in their circular dated 14th Nov. 1890, state that as regards home consumption of tea as taken from all the bonded warehouses in the United Kingdom for 5 months—1st June to 31st Oct.—China actually increased by half-a-million lb. as compared with the previous year. For the same year and for the same period Ceylon tea increased by 3 millions only, say at the rate of 7-15th millions only for 12 months! New markets are, therefore, urgently wanted.

Tea and coffee differ but little in the value per lb. just now, e.g.:-

1 cwt. = 112 lb. @ 1d. = 9s. 4d.

@ 11d. = 102s. 8d.

102s. 8d. = 1 cwt. tea at present average price of 11d per lb.

104s 6d = present price per cwt. of Ceylon middling plantation coffee.

DRIFT TIMBER.

To judge from all recorded facts, Ceylon would appear to be in the direct line of some ocean current or currents setting direct from Burma or the Malay Peninsula. At all events, if such currents do not flow in a direct line thence, the effect of a combination of them is to carry drift timber from these Eastern and North-eastern shores to those of Ceylon. And it further appears to be certain that these currents impinge finally upon the north-eastern coast of this island.

Unless it be upon some such conclusion, it would be impossible to account for the number of teak logs which are occasionally drifted ashore along the line of coast in which Mullaitivu may be said to be the centre. We believe that it is chiefly along this line of seaboard that the *fotsam* and *jetsam* of such logs occur, and as they arrive sometimes in considerable numbers, it may fairly be concluded that they have all had nearly the same starting point. All the timber which is so cast upon our north-eastern shores possesses evidence of having been felled and prepared for transport. It does not consist of merely the trunks of trees which have been uprooted by some natural force, the logs in every instance almost, having the holes at their ends which have been cut for the purpose of permitting traction. We know that trees so cut in the timber forests of Burma and the Malay Peninsula are allowed to float down the rivers from the sites where they are obtained to the coast line, and it is conjectured that it is such pieces as escape arrest at the river mouth which float seawards on their western journey and eventually come to land, as we have said, along our eastern, and specially on our north-eastern coasts. Everyone knows the value of Rangoon teak. It is preferred here, as elsewhere, for very many purposes, and consequently possesses a high value. Our *Government Gazette* often contains advertisements of sales being made of such timber; but as a matter of fact, we learn that all drift timber washed ashore from the sea is treated as "wreckage" under the first clause of Ordinance No. 5 of 1861, and the net proceeds realized by its sale are credited not to our general revenue, but to the Imperial Government. The amount is trifling however. We cannot give the exact sum so credited for timber alone; but the following are the sums credited to the Imperial treasury on account of unclaimed wreckage of all kinds since 1835:—

	R.	s.		R.	s.		
1885	...	759	80	1888	...	162	06
1886	...	277	96	1889	...	225	51
1887	...	375	73				

We have been told that during the late Mr. Dyke's administration of the Northern Province it

was the exception rather than the rule for the drift timber which reached the very extended shores of that province as it was constituted under that able officer's régime, to be offered for public sale. The autocracy of Mr. Dyke's ideas, dictated his resolution to deal with these wind-falls from the ocean after a fashion of his own. It was his belief that he could effect a greater service by using up the material upon useful public works than by offering it to the biddings—at that date of a necessarily restricted character—of the few Jaffnese who felt inclined to offer for the timber! The logs were, we are told, all brought to the impounding ground at Jaffna and used by the then Government Agent for such purposes as seemed to him to be good! The fact may, and doubtless does account for the very free use of Moulmein teak in the public buildings in and around Jaffna. As an instance of such free use, it may be noted that the principal portions of the pretty little mission church at Chundikkuli are entirely of this valuable timber, and we have heard that the Missionaries of those days had little or no difficulty in procuring free grants of it for the construction or restoration of other mission churches or buildings. But under the changed circumstances of the last twenty years, it is not desirable that this free hand in dealing with public property should be continued, if indeed it has been continued. We have no doubt, however, that with Mr. Dyke's rule the system we have mentioned came to an end, and that the Imperial Treasury is now credited, as noted above, with the full amount realized by the sale of these waifs of the sea; but how if my "Lords of the Treasury" in England heard of Mr. Dyke's mistaken disposal of their "wreckage" property up to thirty years ago?

MR. WESTLAND'S BRICK TEA.

We have submitted the cake of brick tea to Lieut. de Frisch, the Russian Consul, who has kindly given his opinion as follows:—"It is not nearly so hard—so well pressed—as the brick-tea used in Russia; it is much smaller (a fault easily remedied); the Russian bricks are usually $\frac{1}{2}$ lb. each in weight, marked (like chocolate) by indentations so as to break off easily into six pieces; the bricks are usually of a greyish colour, Mr. Westland's is black. The tea of the latter is, however, very good." We have no doubt that Mr. Westland would very quickly come up to the proper standard with his brick tea, if there were due encouragement, or if he could protect his mode of working for a few years, at a reasonable rate. But until our tea trade with Russia more fully develops and until our exorbitant patent fees are reduced, there is not much encouragement. However, as regards brick tea making, we hear there are locally other "Richmonds in the field."

BARK AND DRUG REPORT.

(From the *Chemist and Druggist*.)

LONDON, Nov. 20th.

CINCHONA.—At Tuesday's auctions a fair average quantity of bark was offered, the catalogues embracing.

	Packages	1,610 of which	2,204 were sold
Ceylon bark	966	do	789 do
East Indian bark	81	do	61 do
Java bark	233	do	...
S. American bark			
Total	2,770	do	2,051 do

The assortment was a poor one, and consisted very largely of *Succirubra* barks from Ceylon and Southern

India, common to medium chips and spokeshavings being particularly prominent. The highest price paid for manufacturer's barks was 10d per lb., and that only or one or two lots. A dull tone prevailed throughout the auctions, and prices were generally easier, especially for fine druggists' barks. The average unit may now be placed at 1 $\frac{1}{4}$ d per oz.

The following were the quantities purchased by the principal buyers:—

	LB.
Agents for the Mannheim and Amsterdam works	122,257
Agents for the Frankfurt O/M and Stuttgart works	88,829
Agents for the Brunswick works	87,232
Messrs. Howards & Sons	59,575
Agents for the American and Italian works	38,854
Agents for the Auerbach factory	30,102
Mr. Thomas Whiffen	65,256
Sundry druggists and speculators	60,405
Total quantity sold	510,510
Bought in or withdrawn	137,312

Total quantity offered ... 647,822
 QUININE very quiet: the only business we hear of this week is 10,000 oz. second-hand German bulk at 1s per oz. the nearest quotations now are 12d Per oz. sellers, 11 $\frac{1}{2}$ d buyers, no business.

SOILS AND THEIR TREATMENT.

We have marked for extract into the *Tropical Agriculturist* an interesting review from the *North British Agriculturist* of what is evidently a very valuable handbook on soils, by Dr. Fream, the historian of the Rothamsted experiments. A point in favour of the Ceylon planters seems to lie in the fact that the roots of tea and other perennial plants, such as are cultivated so largely in Ceylon, are ever in the soil, so reducing the loss of nitrates, to a minimum, probably. It is in fallow land in Europe that the loss of nitrates from drainage is greatest. On the other hand the capillarity of our mountain soils, at any rate, is not increased by the beneficial action of earth worms. We have seen the "castings" of a large species on patanas, but the earth-worms so common and so beneficially active in Europe, seem to be absent from, or very rare on, estates. We do not suppose that the existence and action on some lowcountry estates of white-ants are considered in the light of compensation. In the absence of the soil-digesting and tube-forming worms, *tith* by means of agricultural implements would seem to be the more imperative. But here are several of our most experienced tea planters asserting that they have seen no good results, from forking of the soil on their estates! All our preconceived ideas having been in favour of the mere stirring of the soil, even without the burying of prunings or the application of manure, we are, we confess, unwilling to abandon them, even on such testimony as that of "C. S. A.," "T. C. O.," and other men of equal experience. The stiffness of our soils, which enables them to so great an extent to resist wash, surely renders tillage the more necessary? As regards coffee cultivation and the good effects of merely opening up the soil, there is the famous case on record. A planter dug the usual holes for manure, which he expected the Colombo Agency house to despatch. For some reason the supply of manure never arrived and the holes were left open, except for the loose soil washed back into them. *The following crop was one of the best ever gathered on the estate.* We should like to see the question of forking tea soil further discussed by such planters as "G. A. D.," "T. M.," "A. L. C.," and others, and reasons given for what is undoubtedly a heresy in general agriculture, before we give in our adhesion to the new faith. What will Dr. Voelcker say to the dis-

covery that tillage apart from manure confers no benefit on tea? He will probably ask for the essential difference between tea and all other cultivated plants.

THE UTILISATION OF BONES IN AGRICULTURE.

About the latter end of 1889 it pleased the Government of India to display an interest in the export of animal bones from India. The Government of India was under the impression that exports of bones were on the increase. From statistics of trade, however, we learn that as regards this Presidency, at any rate, there was a fall instead of a rise in exports, as the average shipments per annum during 1884-86 were 3,528 tons, while the annual average during 1886-90 was 2,772 tons. This fall is attributed to a diminution of the Ceylon demand, which is now met more from Australia. At one time, the island obtained almost all its supplies from this Presidency, but it now draws largely from Australia. Looking at matters as the Government of India does, the decrease is matter for pleasure rather than regret on the part of Madras. The gentlemen who study matters from Simia know that bones may be largely used for conversion into manure, and the careful guardians of India's agricultural interests manifest anxiety concerning the "threatened drain of the manurial resources of the country." As regards Madras the dread appears to have been groundless, but it has not been without good results. A report was called for some months ago on the sources whence bones for export are obtained, the extent to which they are collected in the Mofussil, their treatment before shipment, etc.; suggestions were invited for the utilisation of bones as manure in this country; and a summary was asked for of any experiments made. This has brought to the front a considerable amount of information that will interest many, and may be found useful.

Collectors report that bones are not generally used in this Presidency as manure for agricultural purposes, except on Coffee plantations on the Nilgiris, the Shevaroy Hills, and in parts of Malabar and Tinnevely. Bone manure, it is said, is occasionally applied to coconut trees in the Tanjore district. In South Canara bones in an unbroken state are sometimes burned at the foot of indifferent jack and coconut trees. But most of the bones collected are exported, the greater part going to Ceylon and a few to the United Kingdom. The Tinnevely and Malabar districts head the list with about 1,200 tons and 2,000 tons, respectively, of exports annually. Ganjam, Kistna, the Oeded districts and Kuraool exhibit very small exports, the highest being about 400 tons from Cuddapah. Godavari exports from 340 to 430 tons annually; Vizagapatam from 100 to 250 tons; and Nellore about 100 tons. Most of the Southern Districts export about 150 to 200 tons. In Madras a single dealer has been exporting about 200 tons annually to Ceylon, during the last ten or fifteen years. In regard to the above supplies it is stated that the bones are collected by chucklers, pariahs and other low castes, who dispose of the carcasses of cattle. Sheep and goat bones are rejected in some parts, because they are light, and do not sufficiently reimburse the collector for the cost of getting them together. When the collector has got his supplies ready he conveys them to the Sea Coast, and there sells them to dealers at whatever rates he can get. Apparently the price has recently ranged about 2 annas per Madras maund, equivalent to, say, R11 per ton. On this the dealers have to make a profit before selling to shippers. Owing more, perhaps, to the greater demand than to the increased difficulty of delivering supplies, on the Nilgiris prices are much higher, raw bones being delivered by contractors at a cost of R30 to R3 per ton; while bone dust runs from R40 per ton as high as R70, according to situation.

As a rule the bones are simply dried and broken by hand before exportation. In Malabar, however, and to a

small extent in South Canara, they are crushed by machinery and converted into meal for use as manure. They are generally steamed first. Experiments made in this country and elsewhere have established long ago that bones are rendered more active as manure by being mixed with lime, saltpetre, cattle-manure, oil-cake or sulphuric acid, as well as by disintegration, steaming and reduction to ash. And it is mentioned as a proof of the value of bone manure that a Native gentleman tested half an acre of wet land (unmanured) with 375 lb. of bone ash when transplanting paddy seedlings, the cultivation and irrigation being as usual. An adjoining plot of an acre, also previously unmanured, was cultivated without the addition of any manure. The former yielded 720 measures of paddy and 1,260 lb. of straw, i. e., 1,440 measures of paddy and 2,520 lb. of straw per acre; while the yield from the unmanured acre was 828 measures of paddy and 2,352 lb. of straw per acre. The increase due to bones ash was thus 612 measures of grain and 168 lb. of straw in one acre. After an experiment made by Mr Lawson of mixing sulphuric acid with coarsely powdered bones and applying them to cinchona plants, it was found that the alkaloids exhibited marked improvement, and other experiments have fully established the advantage of using bone manure. As, in addition, considerable quantities of bones are consumed as bone-charcoal in the Su ir factories of Aska, Nellikuppam and Tutuoorin, set would appear that bones might be much more utilised than they are at present, if collection and preparation were systematically conducted.—*Madras Times*.

ROUNDABOUT PAPERS.

COCONUT ESTATES: EUROPEAN *versus* NATIVE.

There are a great many coconut estates owned by Europeans in Ceylon, and particularly in the Eastern Province, and their methods and modes of cultivation are so different from those adopted by the native owners, proprietors, or village-holders, that it may not be uninteresting to your readers to have laid before them a short account in explanation of the particular ways in which each side work, and the results consequent upon them.

The Englishman begins by thoroughly felling, clearing, and burning his land, leaving as many stumps and large branches on the ground as possible, which will, when thoroughly decayed, go far to enrich the soil in the future. He then lines and holes his land afterwards, planting the young trees in the holes about 23 feet apart, (or about 90 plants to the acre), which experience has shown to be the proper distance, so that the branches of the tall palms do not lock, or overshadow each other, thus allowing (in the future) the sun at mid-day, morning, and evening to warm the soil, for it is found that, if trees are planted closer, it interferes in a great measure with their bearing capacity. The young plants are selected with an eye to their strength and general appearance, a plant with a weedy stem and thin foliage being rejected, one with a thick stem, strong well-set and early dark green branches being all that is required.

Next comes the watering, which must be carefully done, (except of course in the rainy season or when timely showers moisten the ground) for three full years, or even four, after planting.

The proper watering of the young plants is of the utmost importance; each young plant should get a full chaty each time, or from 3 to 4 gallons, and the neglecting of this may in the future have very disastrous consequences. To entrust this portion of the estate work to coolies would be madness, as in order to evade their proper amount of watering, they will divide the contents of one chaty between two or even three plants, and the water will not be nearly sufficient to saturate the roots of the young plants. It is, therefore, necessary to employ an estate watcher, or a Cingany, to supervise the watering gang, when there is some chance of the work being well done.

The trees having once tided over all the hindrances incidental to coconut planting, such as beetles, black and red, porcupines, and wild pigs, and having grown to 4 or 5 years old, they are left to nature, and even then they are liable to beetles and lightning, which prostrates many a fine young and old tree.

Englishmen manure their trees by turning into the ground between the rows all that the trees drops, and tying 4 or 5 cattle at the foot of each tree, where a sufficient trench has been previously made. These cattle are tied there every night, for 3 or 4 nights running, and then removed to a fresh tree, the manured tree having its trench carefully covered up, for the soil to take in.

The nuts are picked once every three months in the season, being taken to the 'barbacues' or drying ground, split into halves with one stroke of a large hatchet, and turned kernel upwards and left to dry in the sun; while at night the kernels are turned downwards to keep the dew from them. After 3 or 4 days' drying, the kernel begins to shrivel in the shell, and men, women, and children are employed to scoop them out into heaps. This is called the 'conra', and is ready for sale, and will fetch from £3-10 to £4 per canly of five hundredweights.

The native estate owner, or village coconut garden proprietor, opens and plants his land in about much the same manner; but he puts in his plants very much closer, so that one acre of land holds from 100 to 120 young plants not very correctly lined or even properly holed. In many instances he will even plant two trees in one hole, but the result will be that they will never bear properly. When once the plants require no watering, he will on large properties leave them to shift for themselves, letting thorny scrub and jungle grow around them, and otherwise neglecting the property; so that it very soon deteriorates in value and bearing capacity. He will never put bark into the ground or bury what falls from the tree, or otherwise manure his property, so that nothing ever goes under the soil. But in village gardens, which are kept splendidly clean, and where they are constantly burying dirt and rubbish, the trees come on splendidly and bear beautifully, giving large crops. I stood near a village tree when they were picking nuts, in the spring of last year (1888), and counted 203 ripe nuts picked from one single tree.*

—*Times of Ceylon.*

RAIN.

The following paragraphs are found in an article in *The Missionary Review of the World* for July, 1890, and are from the pen of the well-known missionary philanthropist, Dr. John L. Nevins, of Jhefoo. The subject of the article is "Famine and the Work of Famine Relief":—Famine is the result of two opposite causes—drought and flood—which may be referred to one and the same cause, the unequal distribution of the rainfall, producing drought in some places, and floods in others. In that part of Eastern Asia which includes the great empires of Hindustan, China, and Japan, the alternation of the winds of summer and winter are so marked as to produce what are called the northern and southern monsoons, to which the climatic peculiarities of this whole region are to be largely attributed. During the winter months the northern monsoon blows almost continuously, and sometimes with great violence, from the Arctic regions to the tropics. Early in the spring the tropical winds, charged with moisture, commence moving northward, at first confining only for a few degrees of latitude, but gradually asserting their supremacy, and extending farther and farther northward, until, in July and August, they constitute the southern monsoon, which, on the entire coast of Asia, extends from the tropics to forty degrees

of north latitude. The region in which the southern monsoon and the colder breezes of the north meet, like two opposing armies alternately advancing and retreating (the colder atmosphere condensing the vapour with which the southern monsoon is surcharged forms the rain-belt, which, as it advances step by step to the north, brings what is called the rainy season). The rainy season reaches Ningpo and Shanghai, in Central China, the latter part of May, when the rain is almost constant, while north, in the province of Shantung, the sky is cloudless. This monsoon, after discharging its moisture in the south, often continues its course northward for several degrees of latitude with great violence, and almost as dry as the groove of the desert. In the latter part of July, and nearly the whole of August, when the air in Central China has risen to high temperature, the southern monsoon blows past that region, holding its moisture in suspense until it is condensed, and falls in Northern China and Manchuria. These two monsoons, with the fluctuations in their force and temperature, produce the very irregular rainfall of the rainy season. In one section of country there is sometimes such an excess of rain as to form destructive floods, while in an adjacent region, north or south, there is a comparative deficiency. Sometimes the rain falls gently for days, and at other times in such volumes that it is impossible to distinguish objects at mid-day a few hundred yards distant, and water-courses half a mile in width, in which the stream had shrunk to a little rivulet, requiring only a few stepping stones for the foot traveller to pass, in an hour's time becomes a rushing torrent, overflowing its banks, and rendering all passage, for the time being, impossible."—*Chinese Times.*

COFFEE PLANTING IN GUATEMALA.—Coffee trees, transplanted from the nursery after a year's growth from the seed, are usually planted 9 feet apart, making 484 trees to the acre; but where the soil is exceedingly rich, at an altitude of 3,000 feet above the sea, they are placed 12 feet apart to prevent interference with each other's luxuriant foliage. Each tree produces 1 to 2 pounds of the berry in *oro* (that is, after being cleaned and polished and ready for the market), according to the soil and temperature, so that the product of an acre of coffee trees would be from 484 to 968 pounds in *oro*. At the present price of 23 cents per pound the result would be \$111.32 or \$222.64 per acre, which, at the average cost of 5 cents per pound for production and transportation to the seaboard, would show a net profit per acre of \$87.12 or \$174.24, according to richness and adaptability of soil and condition of temperature. —*American Grocer.*

THE MANUFACTURE OF RUBIES.—What is the use of exploring unknown and dangerous countries for rubies when the secret of their artificial production has been discovered? This was the question which the Academy of Sciences discussed on the report of M.M. Frémy and Vernouil, who for some time past have been making chemical experiments in the manufacture of these stones. More valuable than mere theory was the fact that the two chemists exhibited some hundreds of specimens of the glittering red crystals they had succeeded in producing. The rubies were admitted by all to be much superior to anything hitherto manufactured. No little danger, however, attends the process. The chemicals have to be fused at a heat so intense that M. Vernouil during the course of the experiments nearly lost his sight. While manufacturing rubies the two chemists found that at a certain stage of the operations crystals of the colour of sapphires were produced, but the hue hitherto obtained has not been equal to the tint of the real gem.—*P. M. Budget.*

* This is rather a tall order.

Correspondence.

To the Editor.

FORKING OR DIGGING TEA—NO. I:

Deo. 1st.

DEAR SIR,—In answer to "Pervert" I have to state that I have seen it tried in many districts, and I cannot say that I have ever noticed any beneficial result in forking alone. In fact as your correspondent mentions I also have noticed a marked falling-off in Tea after forking; this I believe is owing to its being *overdone*, for the breaking of nearly all the feeding roots within 10 inches or a foot of the soil must seriously check the vigour of a tree for a time. Of course from digging in manure the results are well-known to be most satisfactory, and I have also seen digging in prunings in every alternate line tell most favourably on the tea bushes, but *general* digging I have not found good, but I believe if carefully done in every *alternate* row on certain stiff soils at the proper time, it cannot but have a beneficial effect on the tea. V. A.

No. II.

Nov. 30th.

DEAR SIR,—I have found no good results whatever follow forking, unless the operation is accompanied by the application of manure. I have tried it in tea of different ages, and in different soils, with equally unsatisfactory results. T. C. O.

No. III.

DEAR SIR,—Your correspondent "Pervert" is quite right in saying, that there is a great diversity of opinion on the merits of forking tea, the effects of the operation being anything but calculated to inspire *general* confidence.

In Dolosbage with a wet subsoil and heavy rainfall,—the two things, one would say, that were *not* conducive to the success of such a system of cultivation,—several planters swear by it, and in the course of my wanderings I often hear of good results following the forking up of the soil in other districts; but *personally* I am rather disposed to agree with your correspondent, and I have no desire to renew the experiments I have made.

Digging in the prunings and rubbish on the ground, I think does good, especially if *showery* weather is expected. ALPHA.

No. IV.

DEAR SIR,—Digging, in my experience, shows no results whatever on the tea, unless manure is thus applied, when paying results always follow. I would only fork up every other line. C. S. A.

No. V.

Lower Ambagamuwa, Dec. 7th.

DEAR SIR,—I have in my career as a planter had a big share in the digging and forking up of the soil, both in coffee and tea land. My nine years' experience of this work with the latter product is certainly contrary to that of "Pervert." Digging is scarcely at all needed where the soil is of a friable nature unless for the sake of economy: if you were renovating such soil by applying manure, digging it in you will find pay better than the old-fashioned holing system. I say digging is a *sine qua non*. It is perfectly true, and I admit that forking up will and does, as a rule, throw back the flushing tendency of the tea; but this is only what one must naturally expect. Take any other shrub, dig about it in a similar way, whatever its yield is to be you will invariably, nay always, find it on the diminishing after such a process, and for such a time only as your shrub has had to battle with the effects of disturbed

nature. But what about the after results? Comment is unnecessary. In 1884, a field of 12 acres tea 2 year old was to all appearance stunted and far from having a healthy appearance, I resorted to digging as a last resource before finally abandoning the field. In six months after digging, it beat my most sanguine expectations, and today that same field is yielding a considerable crop. This was purely a root-bound field, the soil requiring to be broken up; once the roots had free play the bushes naturally grow and filled out. Digging ought to be periodically carried out where our soil is so apt to get oaked up. Apart from this, it is one of nature's requirements. I believe digging up the soil has been in vogue since the creation; does not the good old Book teach us "Break up the fallow ground, dig about the roots"? —Yours truly, C. J.

CEYLON TEA CROPS AND FUEL SUPPLY.

DEAR SIR,—Looking over the Directory I find you estimate quantity of tea to be exported in 1891 at 54,000,000 lb.

I believe the quantity of wood fuel required to make 100 lb. of tea averages about 60 lb., so that fuel is becoming a very important item.

The Forest Department has done a great deal, but undoubtedly thinks too much about showing a profit on its working; but after all "Heaven helps who help themselves," and so proprietors should secure waste land in the neighbourhood of their estates and factories and plant quick-growing suitable trees.

When demand for fuel reaches 14,286 tons a year, it will be a serious matter for those who have forgotten to look ahead.—Yours, TEA POT.

THE WATCH COMPASS.

DEAR SIR,—I am surprised that "Astro" thinks that the watch could never be made to revolve around its hour hand in northern countries. Let him take a circular piece of pasteboard, lay a wire across it, fastening it on by gummed slips, and then pointing the wire to any quarter of the heavens see if he cannot twirl the disk. The hour hand of a watch corresponds to the wire, and the possibility of revolving the watch around it as if it were an axis, does not depend on the latitude of a place. This makes it plain that the watch does *not* "adjust itself" to the plane of the sun's daily path." It can however be adjusted by taking care to keep that point of the dial which is to indicate south higher than any other point, while the hour hand is pointing to the sun. This might easily be neglected if attention were not called to it, as I believe has not been done thus far, and it would vitiate the whole experiment, and might give a serious error. This omission made the original rule practically valueless. The required adjustment introduces a complexity which lessens the advantage of the watch compass, and "Astro" admits that for five months in these parts the rule has to be altered and for other four months is only approximate. The fact is that anyone with a little ingenuity can tell the points of the compass quite accurately by simply noting the position of the sun, if he only knows the time of day —Yours truly, ANOTHER YANKEE.

THE NUWARA ELIYA CARP AS FOOD-SUPPLY:

SUPPLY OF FRY FREELY AVAILABLE FOR CULTURE IN PONDS, TANKS, &C.

Nuwaru Eliya, Dec. 6th.

DEAR SIR,—Will you allow me through the medium of your paper to draw attention again to the excellent food supply that the Nuwaru Eliya carp (the Prussian carp) yields.

In Nuwara Eliya they do not grow to any size, probably in consequence of the cold, but at lower elevations they thrive well and multiply amazingly.

Some that I sent in the fry-stage to a gentleman in Deltota last year are now $1\frac{1}{2}$ lb. in weight, and are excellent eating; and the experience of another gentleman in Dimbula, who also had some, is to the same effect.

Any pond will do for them, and if a stream of water runs through it, so much the better.

To insure a supply of fish for the table they should be constantly fed with boiled rice or brewer's grains, when they will rapidly increase in size and become so tame that they may almost be lifted out of the water with the hand.

Any number of fry can be had here. They are easily transported; the only thing necessary being a large chatty slung on a pole with two coolies to carry it.—Yours faithfully,

C. J. R. LE MESURIER.

COFFEE CULTURE:—GREEN BUG AND ITS TREATMENT ON THE AGRAPATANAS.

DEAR SIR,—I should be very glad to respond to the request you make in *Observer* of 1st inst., could I give any more information on the subject, but really I have not much to add to what I have already given, for the simple reason that the comparatively little "bug" that we have had on these estates for the last two years or so has disappeared so quickly and done so little damage, that I have not found it necessary to do anything to it. I think this has been the general experience with good coffee about here, though I know from correspondence that I have had this has not been the case in some other quarters, and to such I strongly recommend the kerosene emulsion treatment supported by good manuring, if they wish to keep up the coffee and get crops. I believe that one of the principal reasons why we have had such comparatively mild attacks of bug is to be attributed to the earlier appearance of leaf-disease for the last few years compared with previous ones, for, I have carefully noticed that the bug begins to show signs of unhealthy life and dying off as soon as this disease really sets in. For the last few years leaf-disease has reappeared much earlier in the year than previously, and the bug has had a much shorter life than when it attacked us several months later. Of course the coffee has only been kept in really good heart by good cultivation. We have kept only the best fields, the rest having been planted up with tea year by year. It goes without saying that where there is not good cultivation the trees are altogether unfitted to stand the combined attacks of even a mild dose of bug and leaf-disease year after year and yet bear profitable crops. When I first commenced to apply the kerosene emulsion and lime, the "bug" was in full force and rampant; and I have already explained, that no other treatment (and I tried many experiments) succeeded in both saving the crop and leaving the coffee in good bearing condition. In fact, I lost some very fine coffee bearing heavily side by side with what I treated with kerosene emulsion, and which is still to the front, having given several good crops since then; and though this year's crop is a small one, yet the trees are healthy and promising, and this in spite of a bad attack of grub last year. There are other estates not far from this who can show similar results from following similar treatment, followed with good manuring. Still I think it is more than ever becoming a question as to which pays the better, with such tea as we have in this district, and the good yields per acre we are getting

will show what even good coffee has to compete with. You ask for details of cost of application, but I think I have already given you this in a previous letter. The first year (the worst) was some R10 an acre including all cost of labour and materials on some 300 acres treated as I fully explained.—and the next year was about R5 with only part application of lime on some 150 acres; we have spent very little indeed since then.

The labour question would be to some an important one, for where there is much tea it generally takes all the labour to pluck at the time of the year that we get this bug worst, say April-May. Yes the coolies took some time to get into the most economical way of carrying on the work and required a good deal of looking after, but they gradually found it easy enough, or at least this was the case with the picked gangs whom I put on to "follow up" the first general application. We first went straight through all affected coffee, with all hands—merely sprinkling with lime the trees not attacked with bug, then I put on several small gangs of men to follow behind to wash off (simply 'unhinge') is all that is actually required) any bug that was left and to watch for the re-appearance of new life until the leaf-disease came on, when I found nothing further was needed.

I would just mention that as lime is supposed to be bad for tea I tried a thick mixture of liquid cowdung on the principle advocated in the interesting letter "From the Hills" *i. e.* to smother the bug. All I can say is that it seems to have been effectual, but I have not done it on a large enough scale to test the cost. It should be done in dry weather; Of course on some estates this would not be available, and it is a question whether it would not be most valuable as manure.* W. B. J.

"COFFEE is being cultivated successfully in Bavaria," we read in the latest *Graphic*. But it must be a new species of coffee plant—an annual—to judge by the description which follows:—"It ripens well and has an excellent flavour, though tasting more bitter than the original tropical product. The plant is sown in the spring on sandy soil, and produces a delicate blue blossom about July, while the berry becomes ripe in August, being then a pale yellow." We should like to see this coffee, "sown in the spring" and blossoming a delicate blue in July!

FAILURE OF TOBACCO EXPERIMENTS.—In an order which it issued, the Madras Government "regrets to learn that the results of the experiments conducted by Mr. Caine in the growing and curing of tobacco during the last two years have proved to be so unsatisfactory. The reports of the several firms, to whom samples were sent by the Board for opinion, show that the leaves, when cured, were decidedly defective in the qualities required by the European market, and the very poor prices obtained in the local market for the indigenous tobacco, grown under the personal supervision of Mr. Caine, are evidence of the inferiority of the leaf to that raised by the natives themselves." The Government is not prepared to re-engage the services of Mr. Caine.—*Pioneer*. [The question now is, can success be expected in Ceylon, such as has not been attained in India?—Ed. T. A.]

* Of course, if there were no bug, but the double advantage of the application is that after smothering the bug and falling to the ground it is still valuable as manure. But how can even the best coffee survive the external attacks of green bug, which gives way only to *Hemiteia vastatrix*, while the subterranean enemy grub gives way to neither?—Ed. T. A.

LEAF WITHERING.

(BY THE "PERIPATETIC PLANTER.")

I have been asked recently what is the best temperature at which to wither leaf. This is a bigger question than appears at first glance, and a reply should not be given didactically, without being supported by a statement of, at least, general principles, even though detailed reasons might be, perhaps, wisely omitted. I should prefer to devote a special article to the question, so that each point might receive its proportionate share of attention, but this I cannot find time for this week. It would involve a consideration of the other question, Why do we wither? and that goes into chemical as well as mere physical changes which we seek to bring about. Suffice it for the present that I think I could show good grounds for never withering at a temperature much above 94 deg.—100 deg., unless a current of air passing over the leaf, by reason of the dryness and velocity of that air, produces a degree of rapid evaporation which by cooling the leaf when it comes in wet neutralizes the extremely injurious effect of the excessive temperature, and this latter neutralisation depends so much upon the air being of a low "relative humidity" (i. e., being very dry) and also so much upon the leaf being wet not dry, and upon careful attention on the part of those in charge of the operation, that if a perfect degree of wither can be accomplished in say 5 hours, in the worst weather with the wettest leaf, with no higher temperature than between 86 deg. and 94 deg. without risks from carelessness. Lack of attention, then, as the room will be vacant for the evening's pluck—the morning's being withered and removed, in the 5 hours—there seems to be no sufficient reason for preferring the more risky higher temperatures. Of course in competent, careful hands a high temperature (with a high velocity dry air current) may be fairly safe—it has yet to be proved so, and is against accepted views—but the additional anxiety and attention required would be a drawback to many, who would rather be not so tied to watching the progress of the wither. I was asked the question, as with a higher temperature than the Blackman system is at present worked at, four or five times the quantity of leaf might, of course, be withered in the same space and with the same appliances—provided the temperature could be maintained, at a reasonable cost in extra fuel, and provided the quality of the Tea were not damaged. Why run the risk and incur the extra expense in fuel? Where is the sufficient reason for doing so? With a temperature between 86 deg. and 94 deg., each "Blackman" in a room has, in dry weather, withered 66 maunds of leaf in 3½ to 4 hours; and in wet weather has, in the same room, done 33 maunds in the same time between these safe temperatures. Surely those quantities are good enough when the absence of risk and certainty of perfect quality in the "wither" are considered. Whilst speaking of this point, I would correct a mistaken impression or two which I have met with. Trays are by no means necessary with the system referred to. In many factories no trays are used. The racks are fixtures; in some cases made of tiers of Hessian cloth, in others, of open fabric woven like wire mesh, but made of hemp. In others they are of woven wire mesh; but in each case the fabric is stretched from end to end of the rack—and the leaf is swept off, or jerked off by tapping the under side. In some cases the fabric is stretched on rollers, and wound up, the leaf being spread at one end, and the fabric rolled out as the leaf is spread. The leaf in like manner is taken off by again rolling the fabric, which drops the leaf into baskets at the end.

Next, a factory having no loft above the Manufacturing Room, in many cases employs a good deal of its valuable space, for work such as boxmaking, &c., which can just as well be done in an adjoining building. If this space is thus cleared, and if racks are then erected therein for withering, and the necessary cutcha baffles erected in their proper positions, the ground floor is as good for withering by warm air current as any loft would be—and it is surprising how much leaf can be withered in a small space thus won

for the purpose from an employment which can be just as well conducted elsewhere. Some factories are already so planned to wither all their leaf in spaces thus saved. When speaking just now of one propeller having withered 66 maunds of leaf in 3½ to 4 hours, I should have added, but in this case the racks were withered and emptied and re-filled from a store of leaf. Usually, sufficient space and rack area is provided to make one spread do for the morning's leaf, and one spread for the evening's as usual.

Another mistaken notion I have come across is, that all the leaf will get withered at the same time, and that the rollers won't then be able to work it off fast enough! This I fancy comes of the use made of the words "uniform wither" in the literature of the system. This notion is far from the case. Each rack should wither uniformly, so that the boys will not have to pick and choose different tiers of the same rack in removing the leaf. That would leave too much to the boys, and cutcha leaf might get mixed with withered leaf and spoil the "roll," &c. Each rack can be made to wither uniformly from top tier to bottom tier, by attention to details in erecting the "cut" and baffles. But the racks will wither one after another (by no means all at once) in their order as they stand near the warm air inlet, or distant therefrom—and thus there is no fear of withering too fast for the "rollers,"—and the current can, of course, be stopped at any time if there is any sign of this in dry weather.—*Indian Planters' Gazette.*

CEYLON TEA IN AMERICA: THE TEA COMPANY.

The following correspondence has been sent us for publication:—

New York, Nov. 7th, 1890.

Messrs. Darley, Butler & Co., Agents & Secretaries, Colombo.

Dear Sirs,—Since writing you on the 25th ultimo, we have your esteemed favour, 2nd ultimo, contents duly noted, also copies of the "Times" paper, containing the copy of Mr. Arthur's letter, and the remarks of the editor, &c. We find that Mr. Arthur, who has been the agent here of a man named Davidson, has gone back to England, and his "Sirocco Tea shop" is said to be closed, and is reported to have been a failure. We are quite averse to going into lawsuits, but it seems rather provoking, that we should be subjected to the attacks of a lot of people who seem to have no especial reputation at stake, and are backed up by [by a portion of] your press. We have taken up the tea business in good faith, but if your press and people intend to spend their time in vilifying us, the quicker we get out the better, as we are not at all dependent upon the matter, either financially or in any other way. It might be well to state to your people, that the only salary paid to anyone in this country, is to Mr. Pinoo, and that only enough to keep him in very comparative comfort. If the Company is a success we expect to make some money; if a failure, we will lose time as well as money. Mr. Grimston will no doubt ere this reaches you have explained his views about all matters here fully, and we trust to the satisfaction of all concerned, and we trust no time will be lost in advising us, as to all the matters relating to the final settlements with your Co.—Yours very truly, (Signed) WATSON & FARR.

P. S.—Enclosed we hand you copy of our last letter to Messrs. Darley & Butler, which will give you some points as regards the stock, &c., &c.

(Extract from Messrs. Watson & Farr's letter to Messrs. Darley & Butler).

New York, Nov. 7th.

Messrs. Darley & Butler, London,
Dear Sirs,—Your esteemed favour 17th, 22nd, and 25th and 29th ult. duly to hand and contents noted,

We note that you are executing the order for tea, and some will no doubt come forward in due course. As to the statements and letters of Mr. Davidson and Arthur, we can only state that they are in the main lies, and that where any truth appears, it has been so perverted that it is made rather worse than lies. We have tried to find Mr. Arthur, but are advised that his "Sirocco Tea Shop" is closed, and that he has gone to England. The enterprise has proved an utter failure we are told. We have just sent the following cable—"Arthur's tea shop closed, has left country, notify *Times*, we hold them responsible for statements." While we are decidedly averse to enter into law suits, it seems rather hard that we should be subjected to attacks from parties who seem ready to go to any length to damage the prospects of the Company. We have received copies of your *Times* with full letters from Ceylon, and are writing the old Company in detail.

In regard to the surplus shares, after the holders of shares in the old Company are settled with and after the Company is floated and the two hundred thousand dollars (\$200,000) working capital is raised by selling ten thousand shares at par and giving away to purchasers of same, one, two, three or more shares of the surplus, as may be necessary as bonus, commission &c., the balance is to be divided between ourselves and the parties interested with us in putting the Company through and pushing it to success.

And of course as the stock is full paid, and unassessible, we can do what seems best for the interests of the Company in giving away shares by way of bonus &c. or by selling stock for the benefit of the Company at any price that seems best and without subjecting the purchasers to any personal liability for the debts of the Company, and you explain to intending investors that they are not subscribing to shares of the Company but they are buying them out and out full paid up, and without any further liability for calls or debts of the Company.

As no salaries are paid to anyone here interested in the stock of the Company, excepting only to Mr. Pinco, and this only enough to support him in very modest comfort, we and our friends look for our pay "should the Company prove a success" in the surplus stock we may have been able to retain. If the Company fails, we get nothing, that is nothing but abuse, of which, by the way we seem to be receiving a fair share now "on account."

The \$200,000 was not actually under-written, but could be realized at once under certain conditions. We have already placed some good blocks of stock and are placing same from day to day, in the meantime furnishing funds ourselves, relying upon being repaid in the near future by making a success of the Company.

In regard to your remarks about the people who are interested in the Tea Estate Company, we would say that we shall be pleased to have them take an interest in the matter, and think it may prove to their interest to take some shares in the Company. People interested as they are in the general welfare of Ceylon would do well to look into the matter carefully, and we would say to you, that as we wish to interest the Ceylon people of London in our Company, you may consider that you are at liberty to propose special terms as to number of shares they should have as bonus, upon buying some Treasury stock. This only applies to specially desirable people of which you must be the judges, as our policy is not to sell any stock except to those who will be of benefit to the business of the Company not solely selling out stock with the object of securing the capital required. Our plan may not act quite so quickly, but we will have a better assurance for a regular and increasing business. We remain, yours truly,

(Signed) WATSON & FARR.

New York, November 11th.

Hon. J. J. Grinlinton, M.L.C., Colombo, Ceylon.

Dear Sir—In accordance with the understanding with you when you were here that this Company should define its position with regard to selling

pure Ceylon tea, unadulterated and unmixed, we now beg to advise you that this Company undertakes to sell only the pure and unmixed Ceylon teas—it being, of course, understood that our Ceylon and London Agents supply us with only the above articles.—Yours faithfully, for Ceylon Planters' Tea Coy., (Signed) R. E. Pinco, Secretary, for Ceylon Planters' Tea Company, (Signed) S. Ellwood May, President.

New York, November 11th.

My dear Mr. Grinlinton.—I enclose herewith a document as requested in your last letter to Messrs. Watson & Farr. You will kindly note that my fellow-shareholders here have done me the honor to elect me—at this, the most critical time of the Company's existence—its President, which fully establishes Mr. Pinco's position as taken by him, as regards myself when he was last in Ceylon. You will no doubt remember that some of your journals criticised him at that time.

I also take this opportunity to state that the Company formed here into which the old Company is merged, has not only been carefully formulated by the Company's counsel, but that I have, individually, at different intervals employed three representative attorneys of this city to go through this whole affair and give me their opinion as to its being unquestionably fair, honorable, legal and in every sense honest to all concerned. When you take into consideration that the promoters do not, as usual, agree to put a certain amount of stock in the Treasury, but do agree to use enough stock to raise \$200,000 in cash, for the Treasury, and in the interim got nothing for their labor, and are called upon to spend their own money and take many risks, you can well understand that they do not propose to permit the sort of abuse that one of your papers, without investigation or hesitating, published; although to those who are posted it is too absurd and ridiculous to injure any one. It would seem as though the press of Ceylon should have the interest of the planters at heart, and not publish something that might be copied by our enemies and the opposing interests, and thus have it appear that the situation of this company in Ceylon is as outlined in the "Times of Ceylon." Someone should make it plain to the journals of your island that our success has a very bad effect upon those who have been unsuccessful, and it arouses their petty jealousies and they are very apt to write libellous untrue statements, especially as in the case of Mr. Arthur who has left the country and cannot be made amenable to the laws.

I would also call your attention to the fact that when the promoters of this company have succeeded in raising the \$200,000 in cash they then receive for their work, money expended, etc., what may be left of this paper, and must then spend years to make it pay good dividends as well for themselves as for all the other stockholders, before they get a particle of remuneration. When the planters of Ceylon thoroughly understand this whole matter we feel that they will do everything they can to aid this great undertaking which, whatever occurs to the promoters and workers here, must necessarily benefit them. I have recently called the attention of the Directors of this Company to the fact that our work here already has started up others in importing from London Ceylon Teas and selling them here. It gives me great pleasure to inform you that our plans are well received here and we are almost daily procuring new stockholders and good reliable selling agents.—I am, dear sir, yours very cordially,

(Signed) S. ELLWOOD MAY.

The Hon. J. J. Grinlinton, M.L.C., Colombo, Ceylon.

SATURDAY'S MEETING RE CINNAMON CHIPS.

AGREEMENT CANCELLED.

The meeting convened by Mr. Jardine for the purpose of considering whether the agreement entered into by cinnamon proprietors re cinnamon chips upon honour was to continue in force or to be cancelled

was held on Saturday (Dec. 13th) at 2-30 p. m. in the rooms of the Ceylon Association. Mr. W. Jardine was in the chair, and there were also present Messrs. S. R. De Fonseca, J. W. C. De Soysa, M. D. Cockburn, C. F. Fonseca and Jacob De Mel.

The CHAIRMAN said that the object with which he had convened the meeting was to enable them to decide as to whether the agreement that was signed by a large number of cinnamon proprietors should continue in force or be declared cancelled. There was a widespread feeling of suspicion and dissatisfaction abroad that a great many who had signed the agreement upon honour had not kept to their word—in fact their word of honour was to them a matter of far less value than the few rupees they got by selling chips. He had received letters from some, and in the course of his personal communications with others, he was assured that the majority of those who signed the agreement upon honour had not kept to it. In the face of this and of the fact also that the export of chips had not decreased but was quite equal to that of other years he thought it necessary to convene this meeting so that a decision might be arrived at as to what was to be done. Mr. Tudor Rajapakse's cinnamon estates had been leased, and there was no clause in the lease to refrain from exporting chips. Since that lease he had heard that several owners of cinnamon estates had commenced to scrape chips, and only the other day he received an enquiry as to whether it was a fact that the agreement was cancelled. He had certainly expected to have seen a larger attendance of those interested in this question than were present that evening. The small attendance showed a great lack of interest in the question and it also led one to believe that very many cinnamon proprietors had determined upon the course they had intended to pursue. When the question was first mooted and the agreement was entered into there was an impression prevailing in the minds of many that quite a quarter of a million lb. would be suppressed, but in that they had been disappointed, for they saw by the returns that there was no diminution whatever. It was now a question for the meeting to decide as to what course they intended to adopt in the matter, and in conclusion he invited the meeting for an expression of their views.

Mr. S. R. DE FONSEKA rose and said he had no doubt that the meeting would agree with what had been urged by the Chairman. It was a fact that many who had signed the compact had not kept to it, and the fact of their absence from the meeting showed that they took no interest whatever in the matter and that they were determined to scrape chips, for if they did take an interest in the cinnamon trade they would use their very utmost to increase the price of the spice. He believed that all interested in the spice would be thankful to Mr. Jardine for the interest he had taken in the matter, and for his part he was sorry to find the majority of their friends not inclined to support such a laudable object. He thought now that there was no other alternative for them but to scrape chips, for it would not do well for a few cinnamon proprietors only to refrain from scraping whilst the majority of them scraped away to their heart's content.

Mr. M. D. COCKBURN followed, and said that it was quite clear to him that cinnamon chips should be priced in the same category as cassia. It was apparent to him that cinnamon chips did not go in opposition to ordinary quill bark, and that the two qualities were put to totally different purposes. This could be instanced by the range of prices at the August sales, when, notwithstanding the large exportation of cinnamon chips, the price of quill bark went up, so that it was quite clear that the chips did not at all go in opposition in the London market to the ordinary quill cinnamon. But the only quality that benefited and would benefit by the suppression of cinnamon chips was the superior quality. The price of that superior quality went up at the February sales and also at the August sales, but it only went down a trifle at the last sales. Leaving that out of consideration he saw no reason why only a portion of the proprietors should refrain from scraping chips whilst the ma-

majority had not adhered to the compact. It was quite clear that they determined not to keep to the compact, and therefore he thought the remainder should also be allowed to scrape away to their hearts' content. He therefore begged to move the following resolution, viz.:—"That in view of the widespread feeling existing that a large number of those proprietors who signed the agreement upon honour, not to scrape chips for two years, had not kept to the compact, it is considered expedient by those present at this meeting that the agreement should be cancelled."

Mr. S. R. DE FONSEKA seconded the motion, and it was carried.

A vote of thanks to the chair terminated the proceedings

CASSAVA IN FLORIDA.

(Editor, "Louisiana Planter.")

I see an article from a gentleman of your state on this plant, in one of our Florida papers. It is a plant in which I feel a deep interest—an interest which has no depreciation in my estimation after twenty years of cultivation and use. For stock of all kinds, in domestic use, that will eat the sweet or Irish potatoe, or any other root, nothing, I am satisfied, will compare with it for relish and nourishment; and as a feed for fowls no root can possibly equal it. In fact, the finest fowl yards imaginable can be made with the cassava plant. I have a stalk nearly three years old which has not been killed by frost, and could have had acres of such, as the frost does not kill here on my sand hill. The idea for a fowl yard is to plant an intended spot of any desired dimensions with the stalks which are used in short sticks for seed, and let it grow eight or nine months, at least, before turning in the fowls. The spreading boughs of the plant supply shade and protection from hawks, and the roots, as soon as the fowls learn where they are, will furnish half their feed. The roots usually grow at a slight angle—seldom perpendicular—and can be exposed to view by removing a little soil. If chipped a little, they are so white that the fowls will not be long in sampling them, after which they will do their own grubbing, and in doing so will get meat with their bread, as many worms and insects will be unearthed in securing the roots.

It is half feed for horses, mules, oxen, and milch cows. No beast ever showed more desire for corn or anything else than cows do for cassava roots, once accustomed to eating it; and it is the handiest thing to feed them on you could well imagine. A horse's appetite, if delicate, can be improved on it sooner than on anything else. I have made the finest bacon and lard largely on it and sweet potatoes that I have ever used. Corn and peas will do so better. It makes a fine reminder of oyster fritter if grated, seasoned well with salt and a little soda, and fried nicely. Fine pudding, custards, and bread can be made of it, and with fresh meats, as a stew, it is hard to excel when sliced thin and well cooked. No root is healthier as a diet. For starch it can hardly be excelled. As a feed simply for cattle and horses we would not on any account do without it. Florida, of course, is best adapted to this plant, except further south, but I believe the day will come when it will be found to be profitable anywhere that sugar cane will pay. I have an intended manual for farmers, yet in manuscript, on *cane, cassava, peas, and sweet potatoes*, which, if I were able to get into print, would give all the instruction on cassava that need to be known in all its cardinal features. I wish some pretty fellow would take pity on me and print a few thousand copies of it; possibly he and I, too, would clear expenses on it, and somebody else make a profit growing crops by its instruction. As to the yield of a cassava crop planted correctly and fertilized highly, it is something incredible. A gentleman in this county grew one root which weighed something over fifty pounds at about one year from planting the seed stalk. On a calculation of fifty pounds to the hill, each occupying a square of four feet, which gives 2,705 hills per acre, I get 135,250 pounds, which gives a fraction over sixty-seven and one-half tons per acre,

One cent per pound is what I have always sold the root for in the market, which would figure up the handsome sum of \$1,352.25 per acre. But let us reduce it sufficiently in price and production to figure but one-fourth in dollars and cents, and we have left yet \$338.06½. This would, of course, to an extravagant reduction and could not fairly be allowed. But, extravagant as it may appear, I am soundly convinced of the fact that every acre a man can cultivate, which he has stock, fowls, and folks enough on the farm to consume, will yield him a profit per acre of \$500 annually, while \$50 for fertilizer and expense for the cultivation per acre will fully meet all the cost.

Midland, Polk County, Fla. S. W. CARSON.

CASAVE OR YUCA IN CUBA.

In a recent number of the *Planter* there is what appears to be an error copied from an exchange, which although perhaps of no great importance, should not pass unnoticed, for however trivial an error may be, it is always worthy of correction, and more so when it promises to become general. I refer to the manner in which the word *casave* is misspelt and misapplied. It has legitimately no direct reference to the plant I presume it is meant to designate, nor to its root, and it would be quite as proper to call wheat by the name of bread. *Casave* is an Indian name adopted by the Spaniards and means simply a kind of cake made from the root to which the word is being erroneously applied. The plant and its tuber are both called *yuca* in Spanish, (pronounced *you ka*, with the accent upon the first syllable,) and it has the same aboriginal origin as the misnomer. Throughout the British West Indies I believe both plant and root are universally called *manioc*, and to avoid confusion it would perhaps be well to adopt the same name in the United States, although the Spanish word is more concise, more euphonic, and has the right of priority. *Yuca* was one of the four or five plants cultivated by the Indians of Cuba when the ill-requited Columbus discovered the new world, and strange to say, it was cultivated by these savages with far greater recognition of its requirements than is shown by their more civilized successors. This is abundantly evinced by the detailed description left us by one of the quaint authors of those primitive eventful days, and I regret not having the account at hand to enter more fully upon the subject. The aborigines made their *casave* by first taking off the outer and inner skin from the roots, rasping or pounding them to a paste almost, and spreading this in a thin layer upon a smooth flat stone previously heated, producing thus a sort of large, round wafer which could be kept a long time and enabling them to undertake long journeys, without preparing food upon the way. *Casave* eaten with honey seems to have been the staff of life of those inoffensive Indians, fit denizens of a land that harbored no wild beast nor venomous reptile, (not human,) and where even the honey bee had no sting, and can only defend itself by a square rough and tumble fight, which the unfortunate aborigine, more stingsless yet, was too meek to attempt with his merciless invaders. The Indian, it is said, was long ago "improved off of the face of the earth," but the little Cuban bee still holds its own, bravely defending its home in the forest trees, its diminutive single entrance with a restless sentinel always in the breach, stopping the way against its imported adversary.

Casave, although in all probability very nutritious, can hardly be considered a delicacy, and the taste for it is apparently an acquired one: it is, however, still common in Cuba and often sold about the streets.

There are several varieties of *yuca* in which the root differs greatly, some of them indigenous and others probably imported. One called here the *sour*, or *agria*, is said to be the root from which the Indians in some of the islands manufacture poison for their arrows, but this seems at least doubtful. The leaf of the plant has a unique shape, and a *yuca* "patch" when about half grown is a pleasant sight. In this stage the lower leaves still reach the ground, the

foliage forming a hemispherical mass, making rows of verdant domes, which are generally very regular and symmetrical in form. Where not exposed to frosts the plants may be left growing for several years, and the crop kept in the ground instead of being stored, with the further advantage of increasing all the while, but during the wet season the roots become watery and less palatable. One variety is quite bitter until about a year old, when it loses its unsavory flavor and preserves its edible qualities better in wet weather than other sorts. The *yuca* should undoubtedly be grown as a regular crop in the United States wherever the climate permits, for it is an excellent tuber, better probably, more productive and nutritious than the potato, resembling it in many of its other qualities. It is a good food for all animals, including man, and in Florida, or at least in the southern part, where it can be kept in the ground throughout the winter, it might be made the basis of a large industry in the manufacture of starch, of which it yields about 2 per cent, superior in quality to that in common use. *Yuca* starch resembles arrowroot very much, and, I believe, can only be distinguished from it in the form of the grain and by microscopic test, and may be used for the same purposes.

The process of extracting starch from *yuca* is very simple, and the requisite machinery, although differing from that generally used in the manufacture of the commoner kind, is neither complex or expensive. Starch might be made in Florida from this source upon as large a scale as sugar; also "British gum," which this root yields, I believe, by the simple addition of a due proportion of sulphuric acid, for no decoloration is needed. *Yuca* starch, if well washed, is undoubtedly superior for any purpose, and would meet, when its qualities are known, with a more ready sale at a higher price than the product of wheat and potatoes.

If any of your readers in that state wish to do so they can test this new industry in a small way at very little trouble or expense. The roots should be at least a very old, and from some varieties the yield will be greater after the second year's growth. They should be well washed and the two skins removed, particularly the outer one, for otherwise its finer particles will get mixed with the starch and are not easily separated. The roots may then be rasped or grated into a tub with a common hand grater made of punched tin, and for convenience of large size. To effect this operation on a large scale, a rasp may be made by securing sheets of punched tin upon two wheels made of board, and secured upon a wooden axle about five or six inches apart, to be turned by a crank while the roots are pressed endwise against the surface, in an inclined box of the same width as the rasp. The grated mass should be mixed with water and strained through a cloth fine enough to intercept all the particles of fibre. The residue may be washed until it has yielded all its starch and the refuse fed to the pigs. The starch will soon settle to the bottom of the vessel in which the liquid is placed, and then the water should be drained off. This should not be deferred too long, because a yellow deposit will then be found upon the surface of the starch, which must be washed away at some loss, although this will not be very great, for the mass is firm and compact. The starch should be again mixed with water, (before it sours, as it will if left too long,) strained and settled anew, in order to purify it. After this it has only to be spread in the sun to dry. If the *yuca* is of good quality, the product obtained will be a fine, white powder, which will go much further than the common article. Any farmer may in this way supply his family for a year with little labor.

The cultivation of *yuca* is simple and requires no feed but the stalk, which, when dry, will also furnish fuel. It should be planted in rows about six feet apart and some appropriate crop sown between. The plant requires little moisture, and any excess if long continued is very pernicious. It should, therefore, be put into the ground toward the end of the rainy season, in order to give it a fair start before the winter droughts commence, and it is better to bank the land

into ridges before planting, for the double purpose of securing good drainage and a sufficient depth of loose soil for the free development of the roots.—SANTIAGO DOD.—*Louisiana Planter*.

ORANGE CULTIVATION:—THE SATSUMA.

Not many years back, any orange was simply an orange, with but one main distinction of variety, given as to whether it came from Messina or from Havana. Then the Havana oranges, regardless of size, shape, color or quality, were the top notch, and supplied the desires of those wanting the best.

The opening of orange culture on a commercial scale in our own Florida has changed all this, and practically driven the foreign fruit out of the market, save as poor crops at home or especial cheapness give it entrance. And our orange lovers have learned to distinguish, even in the North, between the many varieties received from Florida, and frequently between the same variety grown in different localities in the flowery state.

The writer well remembers his first acquaintance with one very distinct orange, the Mandarin type, which, from an abunant crop, strayed into the interior Pennsylvania markets a few years ago. The peculiar flattened shape attracted the eye, and a closer examination established the little fruit firmly in the favor of many who then first obtained it. The varieties of the species to which all of this type belong (*Citrus Aurantium nobilis*) are many, and much superior to the original form which pleased us. All possess the peculiarity of a loose skin, readily removed without breaking the skin of the interior segments.

The Satsuma—also called Oonshiu, Kii Seedless, etc.—is probably the highest development of the Mandarin type. It is a pretty orange of the flattened shape of the class, but with a rougher skin than either the Mandarin or Tangerine. This skin is a reddish orange in color, and of peculiar leathery texture. The segments are but loosely adherent, so that the orange is readily eaten out of hand without spilling the juice; this, however, is characteristic of the species, as is also the peculiar looseness of the skin, which has caused these varieties to be called "kid glove" oranges in the market, from the facility with which the skin is removed. The impression that a good orange cannot be enjoyed gracefully will not be verified in the case of this type; the small, delicate segments can be separated and eaten without in the least soiling the hands or face. It is practically seedless; some specimens have one or two small seeds. Being without the rank and somewhat "fishy" odor of the type, it does not offend the nostrils, while it surely tickles the palate; the flavor is something surprising. I have frequently handled sections of a Satsuma, without comment, to friends not acquainted with it, waiting in silence the exclamation, sure to come: "Why it tastes like a cherry!" Sometimes the impression was that of a strawberry flavor, and I have noted two or three entirely distinct bouquets, if they may be so called, in the same fruit. To most people this orange is delicious, and other varieties, however good, lose their desirability in comparison with it.

The Satsuma is said to have been introduced into Florida about 1880 by Mrs. General Van Valkenburgh, who brought it from the island of Kiusiu, one of the Japanese group. Since, it has also been introduced by way of California, under its Japanese name—Oonshiu or Unshiu. There is no difference, although many claims have been made as to the superiority of the California sort. A critical comparison of the fruit of each shows them to be identical. It is another one of the many excellent things which our Japanese friends are discovering to us, and for which we should be grateful to the "Yankees of the East."

The tree is rather dwarf, and reclinate in habit, the branches drooping to the ground, resembling somewhat a Kilnarnock willow in this respect. It is entirely thornless, and marvellously productive—a tree planted but four years on the grounds of R. D. Hoyt, at Bay View, Florida, had on it 625 fruits early in December. This tree, which is illustrated herewith

from a photograph, was $4\frac{1}{2}$ feet high, and about 7 feet through. This dwarf habit renders the fruit easy to gather, and the tree is exceedingly handsome and attractive in appearance, as may be imagined.

A remarkable feature of the Satsuma when budded on *Citrus trifoliata* stock is its hardiness, which is yet an unknown quantity, as none have ever succumbed, even where the ground has been frozen several inches deep. It is suggested that it may introduce profitable orange culture into Texas; trees of Satsuma set there several years ago have done remarkably well. Indeed, it is possible that in a sheltered spot the variety may be hardy as far north as Delaware, and by acclimation come yet more into the so-far-forbidden land for orange culture; who knows! With a hardy stock and a still hardier bud, the elements are certainly favorable for an extensive widening of the "orange belt."

The commercial importance of the Satsuma cannot be overestimated. The past winter one nurseryman disposed of his crop at \$9 per box, wholesale, in New York, and the demand is certainly limited only by the supply, as the peculiar features of the fruit create a taste for it in any one favorably impressed at first, even where there is a dislike for the original Mandarin type. The expense of growing a crop must be less than for other varieties, so that even when the vastly increased production reduces prices, there will still be a profitable margin. The variety keeps fairly well, and packs very attractively, owing to its peculiar skin.

There has been extensive planting of budded Satsumas in Florida in the last two or three years, particularly since the trees have been offered by nurserymen at reasonable prices. A large production of the fruit may therefore be expected in the next few years, when all the country will have a chance to become acquainted with this fine variety.

Owing to the dwarf habit of the Satsuma it is admirably adapted to pot culture; moderate sized plants grown for two years only in greenhouses in Virginia have produced 40 to 60 fruits each, and make a very handsome display when set with the oddly shaped oranges. Indeed, there can be but little question that this is one of the most valuable introductions of many years among citrus fruits.

J. HORACE McFARLAND.

VIRTUES OF THE PAPAW.

(Editor, "*Farmer and Fruit Grower*.")

It is probable that many people who have read of the singular qualities of the tropic papaw dismissed the subject as entirely too fanciful for serious attention. So I at first regarded the claim that a tough beef steak, wrapped in the bruised leaves of the papaw for a few hours, would become tender. However, after much delay, I decided to try if the fruit would not assist digestion, a reasonable deduction if the fruit or leaf would digest tough beef out of the stomach. I soon found the fruit a perfect remedy for indigestion. I made many inquiries but found nobody among the old settlers in Manatee and Dosoto counties who had heard such a claim for the papaw before. But at Fort Myers, Lee county, I found nearly all the old residents knew of its valuable properties. A doubt with me arose that if so potent might it not be dangerous in some way. But the necessity for a remedy for indigestion led to some months' use of the fruit for that purpose (and I must say they are very agreeable "medicine"), and instead of any ill effects or necessity for their continued use as I fancied might result, they seem to have nearly, if not entirely, cured the chronic indigestion from which I have suffered for seven or eight years, and which grew worse, very perceptibly, each year, though good physicians were consulted and their remedies tried, with no permanent improvement. This sounds like a patent medicine certificate, but I do not see how I can draw attention to so important a matter in a better way. I wish to induce people to plant at least half a dozen of the trees for each case of in-

digestion and cure themselves. North of Fort Myers the plants or trees will need some protection from very hard frosts. But I have seen plants with half a bushel of fine fruit when not over four feet high, and not, I think, quite two years old. Such plants or trees can easily be protected in any part of Florida. The seed must be planted very shallow, barely hidden with the soil, and the plant set out when about one foot high. Where the soil is rich and the trees are to be protected from frost, they may be set as near as four feet apart, but more room would be better. I cannot learn how high they might grow eventually, the highest at Fort Myers being near twenty feet. Should they grow beyond any practicable covering, new plants might be started to take the place of those that get killed by passing out of shelter. For indigestion eat as much of the fruit at supper as you wish. It being better, where fruit is scarce, to make its use as near continuous as possible. The green fruit seems as effective (or more so), for indigestion as the ripe. The taste is much like that of the musk-melon. They are also called melon-papawa, and are, when ripe, from the size of a large hen's egg to that of a half-gallon measure. I am told that very differently shaped fruit grow from the seed of a single tree. Some of the trees have no branches, while others have from one to a dozen. Some writers say they have no branches, but many do. The tree is quite novel and ornamental; well worth all trouble of propagation as a novelty, or as a fruit, or a medicine, or to make tough beef tender. A South Florida party proposes to use them in canning Florida beef for market. I have not a seed or plant to spare at present. Almost anyone at Fort Myers could procure seed if called on for them and postage sent, or I will send seed in a month or two if anyone desires to test the matter. W. E. DRISCOLL.

Manatee, Fla., June 16, 1890.

INDIAN EXPORTS.—For the first six months of the current commercial year, namely, April to September 1890 inclusive, the export of certain staples in which we are interested, have compared with past years as follows:—

Export for first six months of three seasons:

	1888.	1889.	1890.
COFFEE cwt.	210,814	80,520	113,203
TEA lb.	42,326,269	44,301,931	44,309,341
CARDAMOMS lb.	109,978	77,024	51,407
PEPPER lb.	3,824,526	3,079,543	4,850,106
CINCHONA BARK lb.	646,022	263,133	401,638
COCONUT OIL gals.	775,437	792,747	387,851
CAOUCHOUCO cwt.	6,057	7,060	6,665

In Cinchona Bark, coffee and cardamoms, India is not making progress, while coconut oil has fallen very low this year in exports.

THE EFFECT ON PLANT-LIFE OF GROWTH AT HIGH ELEVATIONS.—From a communication on this subject by M. Gastou Bonnier, detailed in the *Comptes Rendus* for September, we extract the following results of comparative researches in experimental physiology made by that gentleman. Experiments made on two exactly similar plants, subjected to the same external conditions, showed that the functions in a specimen cultivated in an alpine climate are so modified that the amount of feeding-power as represented by assimilation and chlorophyllous transpiration is increased; while in a plant grown in darkness, respiration and transpiration seemed slightly modified or even diminished. Therefore, we may conclude, that during the short season at high altitudes, plants elaborate more frugally the nutritive principles which are necessary to them than do corresponding plants of the same species at lower elevations. These experiments serve to explain the presence of the larger relative quantity of sugar, starches, essential oils, colouring matter, alkaloids, &c., which are found in plants native to a low elevation, when these are grown in an alpine climate, as all these products are directly dependent upon chlorophyllous assimilation, that is to say, on the greater vigour and sound health and nutritive power shown by the plants when at a high elevation.—*Gardeners' Chronicle*.

WESTLAND'S PATENT TEA-BREAKING AND SIFTING MACHINE is doing very good work, we are glad to learn, and there is considerable difference for the better between the teas turned out from it, and those of the different grades sifted by ordinary sieves.

BONE MANURE.—Professor S. Cooke, of the Poona College of Science, has patented a process for the manufacture of artificial manure from bones with the aid of raw materials found in every Indian village, and he has, moreover, proved its efficiency by practical experiments conducted on his own farms at Panbhani and elsewhere.—*Madras Times*, Dec. 18th.

VEGETABLE BUTTER.—A new artificial butter has made its appearance on the French market, which has already been heard of and, it is said, will be introduced in England. It is made from coconut oil, purified with alcohol and bone-black. The washing with alcohol removes the unpleasant aromatic principles and all tendency to rancidity. The washings are used for making artificial flavouring essences employed for liquors and confectionery. As the usual tests for margarine fail with the new counterfeit butter, analytical chemists are devising methods for identifying coco-butter (not cacao-butter) and cow-butter "oocotised."—*Chemist and Druggist*.

NORTH CACHAR, Nov. 22nd.—Gardens are shutting up very fast indeed. A little rain now would be a godsend, and would carry us on into December, but as it is, the quantity of leaf from trees and its fact off all plants save indigenous, is almost nominal. Just starting the cold weather deep hoeing—turning up the ground in fine big lumps. Kitchen gardens are coming on, and there will be lots of English vegetables presently.—What a treat! Weather exquisite and all the more enjoyable after the awful past season. Not the least prospect of any rain. River steamer service apparently made up its mind to tread on the British planters' tail as often and as hard possible, and neither to beware or have a care. But *non* verrons.

UTILIZATION OF BONES FOR MANURE IN BOMBAY.—There are 7 bone mills in Bombay and 1 at Thana. The latter is a large one, recently opened by Messrs. Croft & Wells. Bones are brought by itinerant dealers chiefly Musulmans, who employ the low-castes of villagers to collect them. These petty dealers either sell direct to exporters, who employ the Bombay mills, or to larger dealers. It is estimated that some 10,000 tons are annually collected. The prices paid in Bombay vary from R35 to 45 per ton, but are rising. Conversion to one-inch bones costs about R2½ and to bone meal about R5. The prevalent prices last season in England for the prepared bones were £1-10 and £5 respectively. The imports by sea of bones to Bombay for export to England come chiefly from Cutch and Kathiawar. The rail imports are larger. The difficulty of collection in the Konkan has so far prevented much export therefrom.—*Madras Times*.

M. M. FREMY AND VERNEUIL have presented another paper to the Académie des Sciences, Paris, on an improved method of manufacturing rubies. Instead of employing pure alumina, they now use chromated aluminas, alkalis with carbonate of potash, which does not impair the purity of the crystals, while facilitating their formation and enhancing the beauty of their colour. Other improvements have been introduced, especially in lengthening the time of the reaction to a week or more, thus engendering hard, rhombohedral crystals of a large size. A gas furnace is used in place of a coke one, and thus a constant temperature of 1,300dg. C. can be maintained for weeks. Large crucibles, giving more than three kilogrammes of rubies at one operation, are now adopted. M. M. Apport, the well-known glass-blowers, have allowed the investigators to make use of their furnaces and they have thus been able to prepare rubies which are in part sapphires, or crystals, red on one side and blue on the other, a phenomenon sometimes found in nature. The same change will also produce crystals entirely red, and others wholly blue, perhaps owing to a difference in the oxidation of the chromium.—*Globe*.

GEM WASHING PLANT.

It has been pointed out to us that *Engineering of April 25th* last contained an account of "Diamond Washing Plant," with a series of engravings which afford a very good idea of the machinery employed in excavating, transferring and washing the clay deposit in which diamonds are found and which doubtless afford some idea of the kind of machinery now being sent out by the Ceylon Syndicate to be used at Rakwana. The illustrations show the Diamond Washing Plant for the Bulfontein, Kimberley and De Beer's mines, and they certainly show the elaborate nature of the machinery. From the letter-press we quote as follows :—

The whole machinery is erected on a high bank of tailings, levelled for the purpose and connected by an inclined tramway with the depositing floors below, on which the blue ground brought from the mine is caused to pulverise. The trucks containing the pulverised ground are hauled up this incline by an endless chain driven by intermediate gear from the same engine which drives the rest of the machinery. Arriving on the level bank, these trucks run along the tramway P and are tipped into the inclined screen A, through which the fine ground passes into the feeding hopper of the dry elevator B, whilst any lumps or stones too large to pass the screen are returned along the tramway Q for further exposure on the depositing floor. The fine ground lifted by the dry elevator is equally distributed between the two revolving screens U U, which are slightly inclined, so that any lumps too coarse to pass the mesh pass out at the ends of the screens, and are similarly returned to the depositing floor along the tramway S. The screens are generally formed of stout square steel wire, woven into a mesh with $\frac{3}{8}$ in. openings. This is in Bulfontein Mine, where the average size of diamonds is smaller than in the other mines. In Kimberley and De Beer's mines the mesh is generally 1 in. square. A spray of clean water is kept playing on the outside of the revolving screens, and a certain quantity is also fed into the hoppers of the screens where it meets the dry ground from the elevator, so that what passes the mesh of the screens is in the form of a puddle and is ready for treatment in the rotary machines E E into which it directly runs. These machines are each 14 ft. in diameter, being formed like mortar mills with an inner and an outer rim, the latter about 18 in. high, the former about 9 in. In the centre of the machine is a stout upright shaft resting on footstep bearing, and to this shaft by suitable attachments are secured eight radial arms extending so as almost to touch the outer rim of the machine. Each radial arm carries five or six vertical steel tines which are set to within about $\frac{1}{2}$ in. of the bottom of the machine. The inlet for the puddle is by an inclined shoot from the apron under the screen discharging through the outer rim of the machine, whilst the outlet is over a weir cut in the inner rim. Since the effect of the revolving knives is to throw everything towards the outer rim, it follows that all the heavier particles tend in that direction, whilst only the light refuse passes over the central weir. The speed of the machines is about nine revolutions per minute. As it occasionally happens through careless feeding, or other causes, that diamonds are carried over the central weir, the second pair of machines, or safety pans F F, which are an exact duplicate of the pans E E, receive all the tailings from the latter, and treat them over again before they pass through the overflow of the safety pans to the wet elevators W W, which deliver them on to the spoil bank. At the top of each of these elevators are inclined screens which separate the coarse mud from the muddy water, the latter being returned down the shoots V V to the feeding hopper of the revolving screens, where it mixes with the clean water, and forms a puddle of proper consistency, a matter of the greatest importance as if the water is too clean light stones accumulate in the machines, raising the level of the deposit

therein, whilst if the water is too muddy heavy stones may flow away in it, and in either case diamonds are liable to be carried over the weir.

In this connection, and as showing the great necessity for the introduction of machinery into our gemming districts, we may mention that the splendid catseye recently bought by a Moorman and valued at many thousand rupees, is supposed, for good reasons, to have been picked up by a workman of the Akuressa Syndicate, who, of course, bolted with it, leaving his balance of pay unclaimed. The announcement that a large catseye was in the market followed a few days after the disappearance of the workman referred to!

THE DUTCH BARK MARKET.

AMSTERDAM, Nov. 26th.—Cinchona.—The sales to be held in Amsterdam on Dec. 11th will consist of 4,536 bales and 135 cases (about 388 tons) Java bark, divided as follows :—From Government plantations, 521 bales, 48 cases about 50 tons; from private plantations, 4,015 bales, 87 cases, about 338 tons. Druggists' bark Succirubra quills, 135 cases; broken quills, and chips, 427 bales; root, 77 bales; officinalis, broken quills, chips, 62 bales; Ledgeriana, broken quills and chips, 2,725 bales; root, 996 bales; hybrids, broken quills and chips, 164 bales; root, 85 bales. Total, 4,536 bales, 135 cases.—*Chemist and Druggist.*

CEYLON UPCOUNTRY PLANTING REPORT.

PRIZE ESSAYS ON THE FERMENTATION OF CACAO—THE WISDOM OF THE WEST INDIES—BUTTERED CACAO—INGENUITY OF THE MOORMAN—HOW TO INCREASE THE WEIGHT OF CACAO—APULTERATION.

Deo. 17th.

The Ceylon grower of cacao will receive a new sensation if he gets the December number of the *Tropical Agriculturist*, and reads the "Prize Essays on the Fermentation of Cocoa," taken over from the *Trinidad Agricultural Record*.

In Ceylon we too have had at times a rage for Prize essays; but anything that ever issued here could not be compared for a moment with this batch of practical beauties, which represent the wisdom of the West Indies. They are the nearest things as oracular and pretentious deliverances, to the lectures which the tea experts used to confound us with in the past, and which we all regarded with becoming awe. When I was done with the reading of these West Indian essays, and had noted the diversity of opinion which existed on the commonest matters of cacao curing, and how every man seems to do that which is right in his own eyes, and becomes an authority in consequence, I could understand how it was that a Commissioner was not sent here to learn our method, so that on his return he might establish some kind of principle among them. As it is they have methods which run from three hours to fifteen days; and the unfortunate who goes to these papers for practical guidance will be at his wits' end as to what course to follow. What these West Indian planters are suffering from is a plethora of knowledge, and the crying want among them is how they can best unlearn.

They are nothing if not scientific. Read a passage like this :—"The vicious fermentation in this vat (No. 1) induced by 'saccharomyces cerviciei' is accompanied before removal probably by a commencing lactic fermentation, the ferment of which is 'penicillium glaucum'

This is decidedly high feeding, and there is more or less of it in all the essays.

It is hardly to be wondered at that a class of men who are capable of producing the above and understanding it have many trade secrets in connection with cacao curing. "Tansuan," the *nom de plume* of one of the writers, surely carries off the

palm in his butter dodge, which is as ingenious as it is original. "On the morning of the sixth day," he says, "get some good quality of butter, wash out all the salt thoroughly, and rub the cacao with it. About three cents worth of butter is sufficient to each bag: the butter will give the cacao an agreeable perfume without destroying the chocolate aroma, and will prevent mildew, one of the greatest enemies that cocoa planters and shippers have to contend against."

There is an appendix to this essay, and "Talisman" has a note on bittered cacao. He feels that his may not commend itself to the common intelligence, be received with derision, in fact, and like the Roman who appealed unto Cæsar, he appeals unto science. "The application of butter to cocoa &c. may excite the risibility of some people," he says, "but I have tested it well; and cocoa which has had butter judiciously rubbed on, can be shipped without fear of mildew to any cold or damp climate. The milk of the cow must have some latent virtues antagonistic to the little germs or microbes which infest damp cocoa."

In manipulating cacao, and doctoring it for the market, the Moorman has always been considered to be an expert. He discovered the use of the annatto dye for brightening up a dark sample, and now that this little dodge has been found out, and local buyers are in a position to checkmate it; his active mind has been at work again, and the same results which the annatto formerly produced, he can and does bring about by jak sawdust and lime. When this the latest plan is tripped up, he will devise something else. This kind of ingenuity, which is so marked a feature of the Moorman mind, has rather a deteriorating effect upon character, and has earned for the Lebbes and Saibos the reputation of sharp practitioners.

But as compared with our West Indian rivals the Moorman is nowhere; and he has but to transfer himself to Trinidad, or Grenada, to have his character renewed, and receive a moral whitewashing. What the Moorman does in the closet, the West Indian cacao planter unblushing carries out on the housetop. For example, the essay which received the first prize has the following passage, showing how weight of cacao may be increased, and colour heightened:—"The husk is certainly much more brittle in washed cacao, and does not therefore protect the bean as it should: it weighs also considerably lighter, but this might be made up by re-coating the bean with a mixture of starch, gum tragacanth, and boric acid. This would be preservative, and improve the look of the cocoa very much: colour might be added if desired. If so it should be red earth, and not common colouring material, because earth coating is recognized as legitimate." Legitimate! who in the world recognizes red earth as a substitute for cacao? Just fancy a state of things where the above adulterations are current and advocated! The Moorman would starve among them, he would find his occupation gone.

It is pleasing to find one of the essayists protesting against the adulterations current, and pointing out what the result would be.

We know how the "Heathen Chinese" mixed his teas with all kinds of abominations, and how he has been driven out before the pure article which is produced in Ceylon and India. Ceylon cacao too has the highest place in the world's market; and while, doubtless, this is greatly brought about by our being in possession of the Caraccas variety, that it is pure like our teas, must also have an effect, for doctored cacao, like doctored goods generally, don't pay.

There is a great deal more in these essays that might be written on. But enough; let those who would learn more of cacao curing in the West Indies betake themselves to the *Tropical Agriculturist*.

PEPPERCORN.

KEROSENE as a therapeutic agent is highly spoken of by Dr. H. A. Gross in the *Medical World*. It cures almost all pains, from toothache to gout and rheumatism. It is deodorized in this manner: Take of coal oil, 1 pint; nitric acid, 1 ounce. Let it stand for a week and pour off the supernatant oil. It does not in the least smell like coal oil.—*Sugar-Bowl and Farm Journal*.

SALE OF ESTATES.

We learn that Agra-oya estate, in the Lower Dikoya district, has just been sold on a cash offer, the terms of which have not yet transpired. A well-known estate in North-East Matale with a small area of tea is also about to change hands:—the sales in both cases will mean fresh capital and fresh blood.

The Fiscal's sale of Hyndford estate, Nawalapitiya, —which is likely to become a very valuable tea property by-and-by—has been delayed for the present.

SAMBAS R WEST BORNEO, AND GOLD FINDING.

(From a Correspondent.)

As I see a notice in a late number of the *Observer* of the map of Sambas (west division of Borneo), it strikes me that perhaps you might like to have a translation of the account of Sambas to which the map was attached. "Bij dit artikel beboort een kaart" is the note under the heading of the leading article in the *Indische Mercur* of 1st November last. It consists of a short but clear account of the present state of this portion of Netherlands India and a sketch of its history from the first settlement of the Dutch there in 1609 when the East India Company entered into a treaty with the Sultan of Sambas up to the present time. On my way to Java I met the then Assistant Resident of Sambas (it was then only an Assistant Residency), and we were fellow-passengers to Batavia on board a Dutch schooner, the "Katerina Kornelia," belonging to McLean, Watson & Co. and called after Mrs. McLean. Mr. Gibson formerly of Ceylon who married one of Colonel Watson's daughters was in Sambas a short time ago, and to the best of my belief he is there now. If this account of Sambas, with its description of the manner of collecting gold, will be of any use, I will send translation. [By all means send it to be given in *Tropical Agriculturist*.—Ed. T. A.]

PLANTING NOTES.

MANA GRASS EXPERIMENTS AND STANLEY-WRIGHTSON TEA CHESTS; MR. ROGIVUE AND CEYLON TEA IN RUSSIA.

LONDON, Nov. 28.

At length there appears to be almost a certainty that the perplexing doubts respecting the several experiments made here with mana grass from Ceylon will be satisfactorily cleared up. We hear that the gentlemen who sent home the fourteen hundred-weights of this grass, the failure of trials made with which my letters reported, has written home expressing the opinion that very probably the failure of his shipment to the Stanley-Wrightson Syndicate has been due to the fact that he had carefully removed all the stalks before making it. Of course, it is the stalk which contains the strong and long fibres; the leaf fibres only serve to mat the former under treatment. The two small lots with which the minor laboratory experiments were made with such success contained all the stalk of the grass. It is no wonder that Dr. Evans, the analyst employed, said he could not recognize the large consignment as identical in character with that he had at first had under his hands. A small lot of the stalk is to be sent home for distinct experimenting, and the Syndicate entertains no doubt that Messrs. Curtis & Harvey will give them a sufficiency of the one ton of the grass they are expecting to continue further trials with. You will understand that it would have been just as easy to make straw paper with the ears and leaf only of wheat, as to make mana paper from the blades of mana grass alone. It may be hoped, therefore, that ere very long it

may be possible for me to send you reports fully conclusive as to the future of the maua board industry which we hope to see commenced among you.

Just as this pleasing solution of its puzzling difficulty has reached the Stanley-Wrightson Syndicate, it has been in receipt of further most satisfactory testimony as to the efficiency of its tea chests lately arrived and now arriving home with tea from Ceylon and India. There has been shown to me this week a letter from Mr. Rutherford which informed the Syndicate that the tea belonging to the Ceylon Tea Plantations Company—a lot from far-famed Mariawatte—which had been received at home in its special chests, had sold this week for 10½d at the auction as against 10d for similar tea from the same estate which had come home in wooden chests. If such a result could always be relied upon, there would be no need to consider the extra cost of the patent chests in comparison with those of wood. This important testimony by no means stands alone, as other recipients have written that the tea reaching them has arrived in splendid condition in the Syndicate chests. You will see that from both the above-mentioned circumstances, the prospect before the new tea boxes is brightening materially. A few improvements in the details of putting the chests together is all that seems to be now wanted to insure a really brilliant success.

Nothing seems to have been heard of Mr. Rogivue since he started again for the Continent and Russia. Doubtless he is by this time once more in St. Petersburg, and our sympathies are fully with him in his endeavour to secure co-operation with the Russian Minister who has taken the initiative in official action respecting the introduction of Ceylon tea. During the present week I met an old friend just home on a brief holiday from Shanghai, and on my asking him how he was getting on with his trade in China, he said:—"Last year was something too awful; but this year we are doing a really good trade." On my asking him how that could be with the English market for China tea so depressed, he remarked:—"We don't want the London market in the least; Russia is taking every bit of the good tea we can send her and at good prices." When told by me of Mr. Rogivue's Mission, and of the recently reported action of the Russian Minister, my friend seemed to be considerably taken aback. After a few minutes of thought—evidently not pleasant thought—he observed:—"I don't believe the Russians will ever take to drinking the tea either of India or Ceylon. They can never suit the Russian palate, nor, even if they could do so, will the Russian system of making the infusion in samodvans, admit of either of those two powerful teas being used. I predict a Russian would at once spit out any India or Ceylon tea so infused." My answering remark was that time alone could show; but that at all events the arrangements sought for by the Russian official indicated a want of satisfaction with their present supply of China tea. On this my friend remarked that he should go to St. Petersburg himself, and see what was going on. He had evidently taken the alarm, in spite of his protestation that the growths of Ceylon and India could never prove acceptable to the Russian people.

BARK AND DRUG REPORT.

(From the *Chemist and Druggist*.)

London, Nov. 27th.

CINCHONA.—Nearly 200 bales of Guayaquil bark were included in today's sales, and a considerable proportion of this sold, with fair competition at steady rates: Fine thin quill 1s 5d; good stout short and mossy 1s 1d to 1s 3d; mossy chips, mixed with quill 9d to 1¼d; ordinary rusty and damaged, from 9d down to 3d per lb. Several lots of Loxa also found ready buyers: Good bright quilly 1s 7d; fair broken ditto 1s 5d; small and broken 9d to 1¼d; very mouldy and dull, from 2¼d to 3d per lb. Of South American Flat Calisaya, 78 bales bright, but rather small were bought in. For the sound bark 1s 6d per lb is wanted, and an offer of 1s per lb was not entertained. There were also 16 bales (2,085 lb)

cinchona from the West Coast of Africa (St. Thomas), in fairly good druggists' quills of a Calisaya character; the best lot of this sold at 7d per lb. For 5 cases very fine strong bold Java druggists' quill (*Succirubra*) 8½d was refused, though 9d would be accepted, while 38 cases good short East Indian druggists' quill were bought in at the nominal price of 1s per lb.

CINNAMON.—At the quarterly auctions which took place on November 24th about 3,000 bales were placed in sale. The market was quite flat, and only about 925 bales found purchasers, at a decline of fully 1d per lb on good cinnamon, and from ¾d to 1d per lb on ordinary grades.

ESSENTIAL OIL.—At today's auctions 20 cases Citronella in tins sold at ¾d to 13-16ths d per oz and 4 cases of Winter's Lemon grass oil were bought in at 2¼d per oz.

QUININE.—Prices have been easier this week, and we hear of sales of about 40,000 oz. of German bulk quinine on the spot at 11½d to 11¾d per oz.; while the Brunswick agent is said to have sold 25,000 oz. for April-March delivery at 12d per oz., but has now no more available at that price. The other German agents quote 1s 1d per oz. as the lowest price.

CROPS IN INDIA

BARON TELEGRAM TO THE GOVERNMENT OF INDIA, REVENUE AND AGRICULTURAL DEPARTMENT, CALCUTTA.

Week ending 29th November.—Rainfall nil in Northern and Ceded Districts, Kurnool and South Canara; good in Tanjore and South Arcot; elsewhere very slight. Standing crops generally good except in parts of Nellore, Cuddapan, North Arcot, Chingleput, South Arcot, Tinnevely and Malabar, where they are withering. Coffee affected by leaf disease in Nilgiris. Want of rain greatly felt in North Arcot, Chingleput and Tinnevely. Locusts appeared in parts of the Ceded Districts, North Arcot, Nellore and Chingleput, but very little damage reported. Outturn of grains generally middling to average. Prices rising in eleven districts, falling in nine.

THE CRY OF THE CEYLON CACAO PLANTER.

How long shall we suffer supinely
And bear the diurnal disgrace,
Controlling our passions divinely
And wearing a smile on our face?
Shall we palter with procrastination,
Obeying Humility's rules,
And suppressing our just indignation,
Be set down as—fools?

Is it right we should wait any longer
In hopes we have suffered the worst?
Think justice will prove herself stronger
Before we are utterly curst?
Can we hope for decreased degradation
While decently doile and dumb,
When there settles on every plantation
This criminal scum?

Shall we hope with intelligent natives
That Honesty soon shall o'erspread
The people: the code legislative's
Penalties all become dead?
May we trust that the deep concentration
Of thought shall control every thief,
And keep him outside the plantation?
It passes belief.

Already too long we have tarried,
There must be no further delay,
For the lawless ruffians have harried
Estates by night and by day.
We cannot compete against numbers,
For even Jupiter nods:
While the worn-out manager slumbers
They prey on his pods.

If fear were true wisdom's beginning
We might have some hope,
But Justice to strangle their sinning
Has no proper scope.
She threatens, in case of detection
In thieving and fraud,
o' each felon her fullest protection,
Free lodgings and board!

SUGAR PALM IN FLOWER.

One of the group of palms in the triangular space between Muirburn House and the banyan tree, Park Street, is reported to be in flower. The palm is *Arenca saccharifera*, and it may be of interest to watch the development of the flowering. From the *Treasury of Botany* we quote as follows:—

S. saccharifer, the Areng, is a very common palm in the Indian islands, and on account of the variety of its products is of great value to the natives. The black horsehair-like fibre surrounding its leaf-stalks, called Ejoo or Gomuti by the Malays, is converted into cordage, employed for thatching, plaited into ornaments, &c.; a large supply of toddy or palm-wine is obtained by cutting off the flower-spikes, and this when inspissated affords an abundance of sugar, or when fermented a capital vinegar: considerable quantities of sago, of a rather inferior quality is, also derived from this palm, and several other products of minor importance.

COLOMBO TEA SALES FOR THE YEAR 1890.

The last public sale of tea to be held in Colombo during 1890 took place today, and brought up the total quantity of tea sold during the year to 6,114,525 lb., as compared with 4,627,762 lb. sold locally during 1889. Taking our shipment this year as 43* million lb., the quantity sold locally represents 14 per cent of this—the same percentage as was sold in Colombo last year—so that relatively to the increase of shipments the sale of tea in Colombo is not growing at all. The figures showing the quantity of tea sold in Colombo for the past three years compare as follows:—

	Offered.	Sold.	Percentage to total shipped.
1887-88 ...	3,579,047	2,783,429	13
1889 ...	6,841,529	1,427,762	14
1890 ...	8,867,510	6,114,525	14

Of this quantity sold locally, about 3 million lb. have been this year purchased for, and shipped to markets other than London, and the average rate paid for the whole of the tea for the year has been 43½ cts. The following table compiled by us will show the weekly quantities offered and sold, whilst the averages of each sale have been kindly supplied to us by Messrs. Forbes & Walker, the well-known Colombo brokers:—

LANKA PLANTATIONS COMPANY, LD.

CACAO, COFFEE AND TEA.

The ordinary general meeting of the shareholders of the Lanka Plantations Company, Limited, was held, on Wednesday, at the offices, 8, Old Jewry, E.C., Sri Robert Harding presiding.

In moving the adoption of the report the Chairman said that the advice which they had received from their manager continued to be of a character which would lead them to hope and believe that the current year would certainly not be worse than the year under review. He did not desire to be too sanguine, because they had had many disappointments previously; still, he thought they might consider that the company had now turned the corner. They now had between 1,400 and 1,500 acres of tea under cultivation, the average produce of which was about 300 lb. per acre. Therefore, they would have 450,000 lb to dispose of next year, which would, no doubt, give them very satisfactory dividends. The greatest economy had been exercised by their superintendent. The year's working had resulted in a profit of £7,292, which was sufficient to pay the dividends on the preference shares for the present and the previous years, and also 3s per share on the ordinary shares. That was a better state of things than they had had for some years past, and he believed it was the beginning of more prosperous times.

Sir Herbert B. Sandford seconded the motion. Mr. Bayford pointed out, in the course of a long speech, that it was unwise, in the present position of the company, to pay a dividend, but that it would be far better to reduce the debt of the company.

The Chairman having replied, the report was adopted.—*H. & C. Mail* Dec. 5th.

A VISIT TO CHILAW:—COCONUT CULTIVATION.

Our chief point has reference to the steady extension of cultivation wherever there is unoccupied ground along the fifty miles of road to Chilaw. We saw evidence of a change, since our last visit in September 1888. The fruit-trade—specially in plantains—between the Chilaw district and Colombo is growing in importance. All round—in and about—Chilaw town, the little fields of tobacco are very well-defined, the young plants being at present the objects of great care in watering morning and night. Beyond Chilaw, the new Telegraph wire is conspicuous on its way to Puttalam; when carried to Mannar, it will give an alternative line—a very important matter—between that point and Colombo.

A wide span is required to carry the wire over the Deduruoya; but we found that river—the next to be bridged we should think—far less in depth and breadth of water than we had anticipated at this time of year. This reminds us to remark on the neatness and yet great strength of the new Toppu girder bridge beyond Negombo: it rests on substantial iron piles screwed into the bed of the Mahaoya. The bridge bears the name of the respected Factory Engineer, and is a great improvement (though rather narrow inside) on the old wooden bridge, and especially on the ferry we crossed two years ago.

Finally, we have to remark on the important scene of Coconut Cultivation in the Rajakadalwa district north of Chilaw. Mr. G. D. Miller, the pioneer, and the sole European planter who has ventured down there, has now demonstrated to the satisfaction of some of the best authorities in the island that the climate and soil are well suited for coconuts. Mr. Miller's own four and five years' old palm trees, notwithstanding the prolonged drought after the South-West monsoon of this year, are most promising, and this gentleman will shortly have 1,000 acres planted altogether, on the group of plantations under his care. There is no reason, we believe, why the coconut palm should not be planted and succeed alongside the thirty miles of road to Puttalam. The character of the soil makes up to a great extent for the short rainfall. Mr. Jardine who rather shook his head on his first visit with us in September 1888, a few months ago on a second visit, quite changed his opinion and he has reported very favourably of the prospects of the Rajakadalwa and Toynbee plantations. Here then is a planting industry established in a remote district, mainly through the indefatigable exertions of one man, and the amount of good he (with his fellow-proprietors) have done to the poor people around him, both Sinhalese and Tamil in affording them welcome employment and in stimulating them to give more work to their own gardens, cannot be overestimated. All success, say we, to Rajakadalwa and its spirited, hardworking proprietor Mr. G. D. Miller.

AGRICULTURAL COMPANY OF MAURITIUS announce an interim dividend of 1s per share, or at the rate of 10 per cent. per annum, for the half-year ending Sept. 30th, payable, tax free, on Dec. 24th at the Alliance Bank.—*O. Mail*,

THE KOLA NUT.—The wonderful stories that have been told of the properties of the kola nut are more than confirmed by our Consul at Bahia, who has written a special letter to Lord Salisbury on the subject. The West African carriers at that port, who use kola, and carry the bean wrapped in banana about their persons, are not physically speaking superior men to the Brazilian negro; yet the African, through constantly masticating kola can, we are assured, endure fatigue which no Brazilian traveller can withstand. Where it takes eight Brazilian negroes to carry a load with difficulty, four African porters carry it cheerfully, singing and chanting as they trudge along, each with a bit of kola bean in the mouth. As a rule the kola-eating African gangs who labour at the hard task of unloading vessels earn, we are told, twice as much as their competitors. The beans, which are described as unpoisoning and in no way injurious, are said to act as a nutritive, and quench thirst; yet they are not strictly a stimulant. The supply at Bahia comes from Lagos. It is best soon after it is gathered, and is sold according to freshness at twopence or threepence for each bean. It appears that the attention of the Government of India has already been called to the extraordinary properties of kola nuts, and practical information has been supplied to them from the authorities at Kew.—*A. F. Press*,

THE I. M. S. "INVESTIGATOR" AND THE COCOS ISLANDS.

The I. M. S. "Investigator," which is now in harbour, has recently been surveying the Great and Little Cocos, islands to the North of the Andamans, which must not be confounded with the Cocos, or Keeling Islands, to the South of Sumatra. Both islands are uninhabited and belong, we believe, to a Rangcon Barrister who has leased them from Government for fifty years as a speculation. Forty years ago or more an attempt was made to effect a settlement on the Great Cocos, which is 6 miles in length by 2 miles in breadth, by three Europeans, one East Indian and eight Burmese; but the project had to be abandoned as seven of the party succumbed to fever. The island is surrounded by a strip of white coral beach, on which grows an almost continuous belt of coconut trees, whence its name is doubtless derived. Within the belt is nothing but forest and jungle. Up till now it has always been supposed that neither of the islands contained any fresh water. In 1874 a very careful examination was made, but without any drinking water being found, although it was said by some natives that a good tank did exist somewhere. Curious to say, the officers of the "Investigator" have now discovered fresh water on both. One officer also bagged a strange specimen of a teal, which has been sent to Calcutta for identification. Dr. Alcock, the ship's Naturalist, during the time that he has been on board has been paying special attention to marine biology, a science which may be said to be still in its infancy. Dr. Alcock has made some important discoveries both during last season and this. The most interesting discovery, perhaps, is that of highly luminous deep sea crustaceans, which were dredged at a depth of 3,000 feet on the voyage round from Bombay. According to a correspondent this is believed to be the first positive proof that the source of light in the dark abysses of the ocean is the self-luminosity of the animal inhabitants. A large prawn lying in a bucket of sea water on deck was observed to be shining brightly, and, being seized, it emitted copious clouds of phosphorescence from the orifices of the genital glands. By the light of this luminous secretion Mr. Alcock was able, though otherwise in perfect darkness, to see the details of the interior of the bucket, and his own hands as well as the position and shape of the animals in the bucket. After the removal of the animal the water remained luminous for some time. Other crustaceans were also luminous, but to a less extent. Dr. Alcock's name as a marine biologist is likely to be heard of frequently in the future, for he has the most favourable opportunities of pursuing his work of scientific research. The Government of India has provided him with expensive apparatus necessary for dredging the deep sea bottom, and the Bay of Bengal as a field for investigation has so far been hardly touched except round the coasts. It can hardly be doubted that its tropical waters contain many wonders, which so far have never seen the light of the sun.—*Madras Mail*, Oct. 19th.

PROGRESS IN THE NEGOMBO DISTRICT.

COCONUT AND IRRIGATION—COIR FIBRE—OIL, &c.

We congratulate Mr. Akbar, the spirited proprietor of Katukande coconut plantations (600 acres in cultivation) on the banks of the Mahaoya, on securing the services of Mr. Wm. Lawrance late of the Badulla district, as his Engineer and Manager. Mr. Lawrance is a practical engineer trained in one of the first establishments in Aberdeen, and he has also had prolonged experience as a planter. Katukande is a very important charge; for besides the estate, Mr. Akbar has a large Coir Fibre Mill employing some 400 people on the property, and it is also the scene of most

interesting Irrigation experiments, the pumps being worked by a 30 horse-power engine. It is now Mr. Akbar's wish to erect an extensive Saw-mill, the machinery for which is all ready for Mr. Lawrance to see put together.

Apart from Katukande Mr. Akbar owns the Hunupitiya Oil Mills in Negombo under the care of Mr. James Brown as Engineer and which do an extensive business.

Furthermore, this enterprising Ceylonese gentleman is just maturing his plans to run a paddle steamer early next year between Negombo and Colombo, the passenger rates by which are likely to be so moderate as one, half and quarter rupee each, according to class. We heartily wish all success to the steamer, to Katukande, its mills and pumps, to Hunupitiya and to Messrs. Lawrance and Brown in Mr. Akbar's service.

SENDING TEA DIRECT TO LONDON.

Among the various proposals put forward lately to improve the present state of the tea trade, none strikes one so obviously absurd as that of sending all tea direct to London. That London at present rules the other markets is admitted by even the men who suggest this, "Proprietor" in his very practical letter touched the root of the matter when he remarked:—"I am of opinion that so long as an increasing quantity of tea is yearly poured upon one (the London) market, the sterling price for the same is not likely to rise! This to every one with the slightest knowledge of supply and demand is obvious. With the present state of prices can the producer afford to ignore a single outlet, Calcutta, Bombay, Australia, New Zealand, the Cape, or any other, no matter how small the quantity wanted? Is it not to his interest to encourage competition from every market in a place where he has at least some slight touch? The idea of a small proprietor being left to the tender mercies of the London market with the entire crop going there—no competition—is suicidal. The saving of importers' profit is brought forward, but what guarantee have we that it would reach the proprietor. It is extremely doubtful if these profits are worth having. I am told that one has only to know the names of the many firms who have given it up during the last six years,—one very notable case fresh to memory—to be sure that in this branch, as in every other, the keenest competition exists. Added to which there is no secrecy about it, as the prices of all teas sold in public auction in London appear in the catalogues, many copies of which are weekly sent to India to all large firms. Enquiring the other day in order to find out what was being done to push Indian tea, I was informed that most of the large firms in Calcutta have a "buyer," who, during the off season, is sent to various places, London, Australia, New Zealand, America (this last, my informant added, will certainly increase its consumption) in order to study the different requirements, and push Indian teas generally, by sending suitable grades, and that these are the men who are reported to "come out" every year to import tea, and the only people, so far as I could learn, who are doing anything to open the fresh markets we so much need.

Ceylon men certainly set an example to us, in the way that the producer is always ready to respond to any effort in the above direction. India seems content with the comforting idea that at some future date Ceylon is "going out." The tea certainly has been leaving the country in alarmingly increasing quantity for the past five years, and many gardens in India seem nearer "going out" point than their despised competitor. As a producer, I would certainly prefer to sell my tea at a market where competition from all centres comes in; and it does not strike me as likely that those above mentioned will send to London for what they want. In any case the increased charges, freight, etc., would not come out of the consumers' pockets, and

it is certainly not desirable for the supplying of these places to fall into the hands of one or two of the largest owners or agents. I have not yet found a producer with a thorough knowledge of both markets advocate it, although the steady sellers in Calcutta number among them many names of men who have not the reputation of making mistakes. It is reported by experts both in London and Calcutta that this year's crop is a very poor quality one, and I suppose this must be accepted, as it is borne out by the continual bad weather reports from nearly all parts. This, together with the high exchange (how we used to grumble at 1-4½), is said to account for the exceptionally low prices, and it is to be regretted that both causes should come together. Probably economy could be effected in small ways, and it would be well for all interested to look to his, but one fact remains that until London is relieved from the weight of tea that at present goes there, prices cannot rise to any extent. Fresh markets must be opened, certainly none abolished, or many of the smaller gardens will either be closed or become absorbed by their larger neighbours. A remark I overheard the other day struck me rather forcibly: there are some gardens in India that produce such tea as will never increase the consumption, and by quantity only help to reduce prices, and if some of these did go to the wall, it would not be an unmixed evil.—*Englishman.*

THE TOBACCO INDUSTRY IN NORTH BORNEO.

You will, I daresay, have noticed by the Singapore and other papers, during the last two years, that considerable attention has been attracted to the Western Division of Dutch Borneo, principally on account of the numerous gold and diamond mining concessions taken up there, and also in connection with the concessions or contracts of land for tobacco planting, these latter being almost entirely confined to the Sambas district of Western Borneo. It may interest your readers to hear what has been done in the way of planting there.

As in the Straits and British North Borneo, so in Sambas, the credit of giving a start to planting belongs to the ex-Ceylon Planter. Towards the end of 1887 a Syndicate was formed by a few gentlemen in Singapore, to apply for and take some gold mining concessions in Sambas, and young W—— was sent across to get the necessary documents signed. While in Sambas, the Sultan, hearing he was a planter, advised him to have a look at the land in the Sangauw district, some four to five day's journey up the Sambas river, and where the Sultan had been experimenting with Liberian Coffee, Pepper, and Oacao. W—— acted on this advice and was so much taken with the quality of the soil and the general appearance of the country that on his return to Sambas he applied for 10,000 bows of land in the Sangauw district for the Syndicate he represented, and it was granted on fairly reasonable terms after a few months. Samples of the rich, chocolate-coloured soil brought over by W—— to Singapore were shown to practical Sumatra tobacco-planters, who without exception expressed the opinion that better soil for tobacco could not be desired, and the only doubt was as to whether the climate of Sambas was suitable or not.

In a short time a Syndicate was formed in Singapore for the purpose of carrying out the experiment on a proper scale of, say, 80 to 100 fields, and an experienced Dutch Deli planter was engaged to carry out the work.

The first opening was made at "Simedoem," 12 miles by cart-road from the Kampong Sangauw, where river carriage ceases, the cart-road being constructed partly by the estate and partly by the Sultan. Nothing could be finer than the soil on this estate, and the work of clearing, roading, and draining &c., was carried out in the most approved Deli manner. Here I may remark that from what I have seen and heard the general run of such work as roading and

MARKET RATES FOR OLD AND NEW PRODUCTS.

(From Lewis & Peat's London Price Current, December, 18th 1890.)

THE MAGAZINE

OF

THE SCHOOL OF AGRICULTURE,

COLOMBO.

Added as a Supplement monthly to the "TROPICAL AGRICULTURIST."

The following pages include the contents of the *Magazine of the School of Agriculture* for January:—

TECHNICAL INSTRUCTION.

N an able article in the *Westminster Review* of July last by Professor Andrew Gray, an attempt is made to state what technical education really means. "First, then," says Prof. Gray, "technical education is education principally in the theory and the application of the scientific principles which underlie ordinary industrial operations, from the general economic laws which regulate commerce and trade, to the theory of the tools and processes of the craftsmen.... It is the assimilation of a carefully-reasoned out and coherent scheme of instruction in the general elementary principles of mathematics, mechanics, chemistry, economic and natural science, with their applications, including also modern languages, literature and history, a scheme which will make the workman a thinker, a self-directing intelligence, instead of a dull lifeless machine. The notion is much too prevalent that such education being useful is, therefore, necessarily a lower kind of education than that contained in the traditional curricula of our public schools and universities. It is also too much the habit of mind of those who have been trained, or more frequently those who, having spent some little (time) in the Academic groves, and having breathed the same air with scholars and philosophers, only fancy they have been trained, in the old Humanities, to regard all instructions in the great departments of human knowledge which modern civilization and scienti-

fic discovery have called into existence with contempt, or at any rate, as unworthy the attention of a man of 'culture.'"

These words come with great force from a writer of Prof. Gray's experience, and should go far towards the end for which the article, from which we quote, was written, namely to dispel a considerable amount of misapprehension as to the meaning and scope of technical education. Even in the case of agricultural education in Ceylon there has been this feeling of contempt referred to above, and ridicule, as stated by the speakers at the recent prize distribution held at the School of Agriculture; and a good deal of gratuitous but unwelcome advice is continually being thrown out, while some are ever ready to censure every effort made in this direction. One critic has gone the length of saying that the funds available to the School of Agriculture have been misappropriated! The founder of the School of Agriculture was evidently not one of those who, according to Prof. Gray, misapprehended the meaning and scope of technical education in agriculture, when he formulated his scheme of education for agricultural students in Ceylon, so as to make them "thinking, self-directing intelligences." It is a trite saying that the prosperity of a country depends upon the state of its agriculture, but it is none the less true, and was well illustrated in the history of our own Island. And it is for the education of the natives of this country in agriculture that some would grudge a modest expenditure on the part of the Government; this too at a time when the necessity for such education is being recognized in every part, even the remotest, of the globe.

But it is an encouraging thought that the rulers and leaders of the people are among the patrons of technical education; and with such words as the agricultural students heard from the speakers at the School of Agriculture last month,

impressed on their minds, they should not mind the attempts of a few ill-willed critics who delight in obstructive work, to discourage them.

The School of Agriculture has for one thing, as stated by the new Director of Public Instruction, fostered an intelligent pride in good honest work and a sense of its dignity, and its *alumni* are setting an admirable example to the students of the coming Technical Institute, the expected benefits of which are thus well summed up:—"The systematising of the instruction and training of our craftsmen, extending already existing industries, creating new ones, assisting the development and bringing about a more economic utilization of the resources of our country."

OCCASIONAL NOTES.

His Excellency Sir Arthur Havelock, who since his arrival has been going through most of the public institutions in Colombo, paid what may be said to be a surprise visit to the School of Agriculture on Monday the 11th November. He was accompanied by Mr. Gerald Browne, P.S. and Mr. H. W. Green, late Director of Public Instruction—Mr. Cull, the present Director, being absent on inspection duty in the Southern Province. His Excellency spent a good while in looking over the chemical laboratory, inspecting the newly-started dairy, and walking over the grounds, part of which was occupied at the time with paddy, Indian corn, sugarcane, arrowroot, turmeric, three or four varieties of cultivated grasses, native yams, beans and other vegetables. Some ploughing was also done with the improved "Cingalee" plough before His Excellency by one of the students. Before leaving Sir Arthur expressed himself "much interested in this useful institution."

On Tuesday morning, the 11th November, Mr. S. Davies, travelling agent to an American firm of implement makers, accompanied by Mr. W. H. Davies of Colombo, visited the school with the object of demonstrating the use of some new agricultural implements. A trial was first made of two hand implements known as the "Planet Jr.," double-wheel and single-wheel hoes. These were so constructed as to be furnished with various attachments for ploughing, moulding, drilling, harrowing, cultivating, raking and skimming. These little machines are as perfect implements as could be wished for, and did their work most admirably. The "Planet Jr." double-wheel hoe, which is furnished with two wheels, and weighs 40 lbs. is priced at £3-3 sterling, while the "Planet Jr." single-wheel hoe, furnished with a single wheel and weighing 26 lb costs £1-11-6 sterling. They are well adapted for all crops sown in rows, and would save an infinite amount of time and labour in the cultivation of such crops as Indian corn, arrowroot, sugar-cane, as well as in vegetable garden cultivation. A trial was also made with a horse hoe (attached to two buffaloes) which could also be fitted for ploughing, cultivating, &c. This implement weighs 65 lb and cost £2-15 sterling, and is, we learn, being much used in tobacco and sugarcane cultivation. Mr. Davies had just returned from India, where he introduced the

new implements, which he assured us were having a very rapid sale.

Mr. A. E. Colton claims to have discovered in the *Lathyrus Silvestris* "the fodder plant which successfully resists not only the most severe droughts, but also frosts, and deriving its moisture, carbonic acid and ammonia from the air, and air alone, grows luxuriantly, perennially producing enormous quantities of the finest possible fodder; the plant which in course of years will cover throughout the world the vast areas of arid, uncultivated, and at present mostly uncultivated land, supplying abundance of the most nutritious fodder to countless millions of horses, cattle, and sheep; the plant which will promote the permanent prosperity and progress of stock-farming and agriculture to a certain degree unknown before; the plant which will in due course form the greatest source of national wealth to every land."

In the *North British Agriculturist* of November 19th, Sir John Lawes, "the Isaac Newton of Agricultural Science," contributes an article on Nitrate of Soda. Dr. Lawes dissents from the view which many Chemists are inclined to take that the nitrogen of the root-crops is obtained by the plants from the atmosphere. His own experiments point to a very different conclusion, and he maintains that where root-crops can do without nitrogen if only supplied with phosphates, the soils are in a high state of fertility and contain a sufficient amount of nitric acid for the use of the crop. The result of a very long series of experiments account for two facts: One is, that a given weight of nitrate of soda yields a much larger increase of roots than the same weight of nitrogen in sulphate of ammonia; the other is, that whereas it is necessary to apply potash in addition to phosphates when we use salts of ammonia, there is no such necessity when we apply nitrate of soda. Dr. Lawes finds it difficult to explain why the nitrate is independent of any addition of potash, as soda is not found in the ripe seed, however abundant it may be in the growing plant, and it is therefore tolerably evident that it cannot take the place of potash in some of its more important functions. Even in the potato there is no soda. Although nitrate has a marked influence upon pastures, cereals, and roots, its action is most uncertain upon leguminous crops; it should not, therefore, be employed for them. Dr. Lawes unmanured four course rotation, commenced in 1848 showed that the Swedes which gave the largest crop the first year gradually diminished in yield, till now though these are good plants they form no bulbs at all. The unmanured wheat and barley, on the contrary, have all through this period produced fairly good crops, averaging 30 bushels of barley and 28 of wheat, and consequently taking up large quantities of phosphates from the soil. The necessity for supplying phosphate of lime to turnips, concludes Dr. Lawes, is not because the soil does not contain it, but because the plant cannot take it from the soil. Soils manured with nitrate of soda should be kept specially free from weeds owing to the great avidity which they have for this manure. Of course as the weeds decay, the nitrogen in the form of nitric acid is

returned to the soil, but this takes time, and so far as the crop for which the nitrogen is intended is concerned the effect of the manure is lost.

At last there is a fair prospect of a Technical Institute for Ceylon. The following paragraph is from the report of the Sub-Committee of Council on the Supply Bill for 1891:—"The Sub-Committee strongly approve of the recommendation which has been made by the Government for the establishing of a Technical Institute in Colombo, and for the appointment of a Superintendent thereof. The services of a competent officer may, it is hoped, be secured for Rs.5,000 per annum, and the Sub-Committee readily agree to the addition of provision therefor." This should delight the hearts of Mr. H. W. Green and the Hon'bles W. W. Mitchell and J. J. Grinlinton, who have long advocated the claims of Ceylon for such an establishment.

In the 36th annual report of the Ceylon Planters' Association, we read with reference to cotton, that "both by Europeans and by Natives it is being tried more or less experimentally in various parts of the Island, and in some cases with considerable success. Valuable addition has been made to the literature of the subject, notably by the prize essays published in the *Ceylon Independent*. The cultivation is simple and inexpensive, while under favourable circumstances the yields are quick and very considerable. Insect pests and a wet climate are the two difficulties which will probably prevent any large cultivation throughout the planting districts. But it seems probable that in the drier parts of the country the enterprise will be profitable to the native in his chena and to European companies in large plantations.

INDIGENOUS FOOD PRODUCTS: CULTIVATED AND WILD.

BY W. A. DE SILVA.

Melastomaceae.

36. *Melastoma Malabathricum*, L. Sin. Bowitya, Katakaluwa.

This is a shrub which grows wild in the hotter parts of Ceylon, and especially abundant near streams and marshy grounds. The shrub grows to the height of from 5 to 8 feet; the stems being thin and covered with an ashy yellowish bark having a coarse surface. The stems are branched into small twigs which bear the leaves and flowers. The leaves which are green, have three prominent ribs, entire margins, and are of an elliptical shape; the surfaces of the leaves being hairy. Clusters of regular flowers, having a purple corolla, are borne on the twigs, and these give place to a fruit covered with a coarse leathery covering which bursts when ripe and exposes a bluish-coloured pulp divided into five or more carpels and containing very small seed.

This pulp is eaten by children, and it stains the mouth a blackish colour, hence the Sinhalese name Katakaluwa, and the generic name *Melastoma*. The pulp is of a sweetish, very slightly aromatic taste, by no means unpleasant. Un

some districts the plant is found to such a large extent, and the fruits borne in such large quantities, that the latter may with advantage be used in making preserves and jams.

37. *Memecylon Capitellatum*, L. Sin. Welikaha.

This is a low shrub which grows wild in the lowcountry of Ceylon. In some rare instances the plants grow up with a single stem to about six to eight feet. The stem, though thin, is very hard and flexible; the leaves are dark green and are of an ovate shape, with an acute apex and entire margin. The whole leaf has a shiny appearance. The flowers are borne in clusters on the stem and are of a violet colour. The fruits are round and small, and borne in clusters containing from fifty to hundred crowded together. These when young are of a pale green colour, but when ripe become jet black, and when crushed show a blue colour. The black pulp surrounding the seed is eaten. This pulp is of a sweetish taste, and stains the mouth blue. Like the last-described fruit this may also be used in making preserves.

The leaves and chips of roots and stem of this plants are used in dyeing.

Cucurbitaceae.

38. *Luffa Aegyptiaca*, Mill. Sin. Nyanwetakolu.

This is a perennial creeper which grows even in high elevations in Ceylon. Sometimes it creeps to great lengths. The leaves are palmatifid and are covered with soft hairs. The flowers are monoecious. The fruits are cylindrical in shape and attain a length of from 9 to 12 inches; in an unripe state they are cut into small pieces and made into curries. When ripe the fibro-vascular bundles are developed and the fruits become hard and leathery.

39. *Luffa Acutangula*, Rox. Sin. Darawetakolu.

This is a cultivated vegetable which is generally found in villages, but it also grows wild in some places. It is a creeping plant with a thin green-coloured stem and dark-green palmatifid leaves. The flowers are monoecious. The fruits are from 9 to 12 inches in length, narrow at the base, but gradually increasing in diameter towards the extremity. The fruit is covered with a thickly-veined epicarp, which in a young state is very soft, and sharp angular ridges are formed on the surface of the fruit. In a young state the fruit is esteemed a good vegetable, and is hence grown to a large extent in the native vegetable gardens. In the markets these fruits fetch from half-a-cent to a cent each. A creeper produces many fruits and continues to bear for nearly two years.

40. *Momordica Charantia*, L. Sin. Kariwila.

This is a creeping plant with a very thin wiry pentagonal stem, having a large quantity of branches and leaves. The *M. Charantia* is largely cultivated in native vegetable gardens, but it also grows wild. The leaves are dark-green and palmatifid, and the flowers monoecious. The fruit differs in size in different varieties, is succulent, and has protuberances on the outer surface. In shape it is long and angular.

In an unripe state the fruits are of a green colour which turns to yellowish-red when they are ripe. The seeds of the ripe fruits are covered

with a scarlet pulp, are flat, and peculiarly shaped. The testa of the seed is marked as if it had been engraved. The fruits which are much used as a vegetable are esteemed on account of their reputed medicinal properties. They have a bitter taste. The degree of this bitterness seems to vary with the surrounding conditions under which the plants are grown. The curries and different preparations made from this fruit, though relished by many, are unpleasant to some owing to the bitter taste. The leaves of this plant are said to be a good vermifuge and are used with other substances in cutaneous affections.

41. *Momordica Dioica*, Rox. Sin. Toombakariwila.

This is a perennial creeper, with a thin much-branched stem, growing wild in the warmer parts of the Island. It is never, or very rarely cultivated. The leaves are similarly shaped to the *M. Charantia* above described, but are smaller in size and lighter in colour. This plant is dioecious. The fruits are small, rounded in form and have a succulent pericarp, of a light green colour, covered with small protuberances which give the fruit a characteristic appearance. It forms a good edible vegetable, having none of the unpleasant characters of the preceding species. It is also considered to have many medicinal properties, and is always recommended to invalids.

A yam is found at the root of this plant which is used by Native Medical Practitioners in the preparation of different medicines, and especially those used for snake bites.

THE LAWS OF CEYLON RELATING
TO AGRICULTURE

(Ord. No. 21 of 1867 amended by 2 of 1873 and 2 of 1887.)

II. *To Promote the Maintenance and Extension of Paddy Cultivation in this Island.*

"Proprietor" means, except when otherwise provided, the proprietor of paddy lands only, and includes the cultivator or person in actual possession of any such land.

"District" means any Corle, Pattu, Village or other subdivision of a province as the Government Agent thereof may deem convenient.

I. *Meetings to form Irrigation Districts.*

1. The Government Agent of any province may, whenever he thinks it advisable or upon a requisition signed by not less than ten proprietors call a public meeting to form an irrigation district for the encouragement and extension of paddy cultivation.

2. In case the extent of the District should render more meetings than one necessary, the Government Agent may form several divisions of each district and hold a meeting at each division.

III. The Government Agent to give notice of such meeting, at least one month before the day fixed for the meeting, stating its object and calling on proprietors to attend in person or by proxy in writing.

III. Meetings to be held at the time and place appointed, in the presence of the Government Agent. Every proprietor present, either in person or by proxy in writing, is entitled to declare to the Government Agent,

(1.) Whether he wishes that the district should be constituted an irrigation district within the meaning of this Ordinance.

(2.) Whether he wishes that the Ordinance should for that end be carried into operation with the aid of headmen or of Village Councils, or of both.

(b.) After explanation by the Government Agent of the results that would follow, according to this Ordinance, from the different modes of carrying the Ordinance into operation, if the proprietors determine to adopt the aid of the Village Councils, it shall be lawful for them to appoint a Committee of not more than twelve nor less than three persons to be associated with the Government Agent for the purpose of drawing up rules for the enforcement of ancient customs or for advising him in matters connected with the irrigation of the district.

(c.) Where more meetings than one are held for any district, each division to be allowed to appoint its proportion of the Committee to make up the number of the entire district.

(d.) Minutes of meetings to be signed by the Government Agent and to be deposited in the Kacheeri, and certified copies thereof to be transmitted to Government.

IV. Objections to votes to be decided by the Government Agent; such objections and the decisions thereon to be recorded in the minutes.

V. Majority (of two-thirds at least) to determine all resolutions proposed at meetings.

VI. Districts and rules under No. 9 of 1856 and No. 21 of 1861 to continue. Proprietors to have power to change their determination in respect of the questions referred in the 3rd section both as respects the districts constituted under the above Ordinances as well as under the present. Such fresh determination to be binding until altered again.

VII. Where proprietors cannot be convened, the Government Agent to draw up rules for the enforcement of ancient customs, and to carry this Ordinance into operation with the aid of headmen.

VIII. Acts done in contravention of the said customs or rules to be investigated by the headmen or by the Village Council according to the election made by the district under the 3rd section of this Ordinance.

II. *Headmen.*

1. One or more headmen shall be appointed, if the result of the meeting under section 3rd of this Ordinance be in favour of such a course, to attend to all matters connected with the irrigation of the district, and to prevent the infraction of rules in reference thereto.

II. (1.) Headmen shall be appointed by a majority of proprietors present either in person or by proxy.

(2.) Government Agent to have power to dismiss any headman guilty of misconduct.

(3.) Vacant offices to be filled up by headmen elected by majority of proprietors.

(4.) Till such election takes place, the Government Agent may appoint provisionally.

III. 1. Headmen may take prompt action, where such action is necessary, to prevent damage accruing to any proprietor by any act committed in breach of the rules and report it to the Government Agent.

2. If possible, before taking such action, the Government Agent must be communicated with, and his instructions awaited.

IV. Expenditure incurred by any headmen in consequence of the act of any party must be paid by such party on the production of a certificate by such headman from the Government Agent; in case of non-payment within 10 days from the service of the certificate, the Government Agent shall proceed to recover it as provided in the 6th division of this Ordinance.

V. Headmen to be paid for their services; proprietors refusing to pay to be proceeded against as provided in the 6th division of this Ordinance.

III. Rules for Enforcing Customs.

1. Rules for the enforcement of ancient customs to be framed by the Committee appointed under the 3rd class associated with the Government Agent. The rules framed to be transmitted to the Governor for the approval or disallowance thereof by him and the Executive Council. After approval they are to be published in the *Government Gazette*, and in the district in such manner as the Government Agent shall seem expedient. After such publication they are binding on all proprietors of land, provided they be not repugnant to or inconsistent with the true intent and meaning of this Ordinance.

II. Rules may be amended or repealed in the same manner as the original rules were framed.

IV. Village Councils.

1. (1.) Village Council may be convened by the Government Agent.

(2.) Notice of it to be given in the village where the party complained against resides, or where the act complained of was committed.

(3.) The Government Agent or some person deputed by him to enquire into the complaint with the assistance of a Village Council.

(4.) If the party complained against be adjudged guilty by the Village Tribunal, and if the verdict be concurred in by the Government Agent, he shall be fined any sum not exceeding £3.

(5.) The enquiry to take place in the presence of the accused party, except in case of wilful absence after receiving notice.

(6.) Sentence not to be executed unless confirmed by the Government Agent. Proceedings of inquiry presided over by a Deputy to be forthwith submitted to the Government Agent for confirmation.

II. 1. Village Council to consist of not less than five nor more than thirteen men selected by the President of such Council from among the proprietors of paddy lands in the district.

2. Government Agent or some person deputed by him shall be President. President shall conduct and keep a record of the proceedings and shall have a casting vote.

III. Proceedings to be summary and free from any formalities.

IV. Proceedings of Village Council not subject to appeal or injunction.

V. Penalty for breach of rules to be recovered in the manner indicated in the 6th division.

VI. Village Council may direct appropriation of penalties for the payment of damages incurred by the aggrieved party.

VII. Penalties to be paid to the Agent, and by him applied as directed by the Village Council, and the balance to be expended in carrying out this Ordinance into execution, and for such other purposes of irrigation works within the district as the Government Agent and the Committee appointed under the 3rd section shall determine.

V. Construction, Repair and Improvement of Irrigation Works.

I. (1.) When it is necessary to construct repair or improve any work connected with the cultivation of paddy lands, the Government Agent to call a meeting at his own instance, or on the application of three or more of the proprietors, of those likely to be benefited by such work, and to determine by a majority of their votes whether it is desirable that such work should be constructed, repaired or improved, and whether Government aid is necessary for such work.

(2.) Where Government aid is not necessary, a majority of the proprietors shall determine the rate of subscription in money or contribution in labour payable by each proprietor towards the work.

II. (a.) Where Government aid is necessary, the Government Agent to make application for such aid specifying

(1.) The allotments likely to be benefited by such work.

(2.) The names of the proprietors of such allotments.

(b.) The Governor, if he think it expedient, may order plans and estimates of the work to be prepared and refer the same to a Board consisting of the Government Agent of the province (and not any Assistant Government Agent), the Surveyor-General, and the D. P. W. for report on the advisability of the undertaking.

(c.) After receipt of report the Governor may sanction the performance of the work, and such sanction to be published in the village by beat of tom-tom.

(d.) After such publication the allotments of land (as set out in the specification of the Board as aforesaid, and which said specification shall be conclusive on the point) and the proprietors thereof are bound to repay the cost of the outlay as provided hereinafter.

(e.) Such cost to form a first charge on the several allotments and to take precedence over all mortgage, hypothecations and encumbrances whatsoever.

III. Government officers shall execute the work, option being left to the proprietors to execute the earthworks.

IV. (a.) The sum expended by Government in the execution of the work shall be payable in ten yearly instalments.

(b.) The Government Agent to assess the amount due from each allotment of land including the allotments belonging to the Crown.

(c.) The Government Agent shall thereupon issue a requisition to each proprietor calling upon him to pay the amount due from him on specified days in each year.

(d.) If any proprietor be absent from the village, or if from any cause the requisition cannot be served on him, the Government Agent shall order it to be affixed in some conspicuous place in the allotment, and the Government Agent shall further cause a notice to be published in the

village, by beat of tom-tom on three different occasions, specifying the allotments which will have to contribute towards the cost of the work, the sum each allotment is assessed at, and the time within which the different instalments are to be paid.

V. Lands required for irrigation purposes shall be acquired according to any laws now or hereafter to be in force for the acquisition of land for public purposes; the sum paid as compensation for such land shall be included in the cost of the work to be recovered as hereinafter provided.

VI. Plan or survey of channels made under the authority of the Surveyor-General shall be deemed conclusive proof of the facts exhibited therein, unless satisfactory proof to the contrary be established.

VII. The Government Agent may order verbally or in writing any person obstructing or encroaching to remove or abate such obstructions or encroachments upon channels, ponds, tanks, etc.; or non-compliance with such order the Government Agent may cause such obstructions and encroachments to be removed or abated; and for this purpose the Government Agent or any person thereto authorized by the Government Agent may enter into any garden, enclosure or other premises, and to do such things as may be necessary. The costs incurred in effecting such removal or abatements shall be recovered from the party on account of whose non-compliance with the order the costs were incurred.

VI. Recovery of Money under this Ordinance.

I. If default be made in the payment of any instalment due in repayment of the amount expended by the Government on the construction, repair or improvement of any irrigation work, the Government Agent or any person authorized by him in writing may seize the allotment of land herein declared bound and specially chargeable with the repayment due by it of the amount expended by the Government. If any person refuse or neglect to pay any other sum which he is made liable to pay under this Ordinance, any property belonging to him and situate within the province or district may be seized. If the amount due together with the costs and charges payable under section 3rd of this division shall not be previously paid, the Government Agent shall proceed to sell the allotment of land or property so seized, by public auction, at any time not less than 2 days from the time of such seizure.

II. Person making the seizure may place and keep a person in possession of the land so seized pending the sale.

III. The Government Agent may demand from the person by whom money is due aforesaid, or from the owner or joint owner of any property seized the several sums of money mentioned as follows:—

(1.) For cost of proceeding to the land of the person in default in order to seize the same, a charge not exceeding one shilling for every pound due.

(2.) For keeping a person in possession a charge not exceeding one shilling a day.

(3.) For the expenses of sale a charge not exceeding 6d. in the £ on the net produce of the sale.

IV. Overplus, remaining after the deduction

of the above charges, to be restored to the owner or joint owners of the property sold.

V. (1.) Certificate of sale granted by the Government Agent to be sufficient to vest absolute right and title to and interest in the land sold in the purchases free from all encumbrances, whatsoever any law or custom to the contrary notwithstanding.

(2.) Such certificate shall be liable to the stamp duty fixed on conveyances of immovable property and to any registration or other charges authorized by law, such duty and charges being payable by the purchaser.

Miscellaneous.

1. Customs certified to by Government Agent to be *prima facie* evidence of their existence.

2. Powers given to Government Agent may be executed by any Assistant Agent.

H. A. J.

(To be continued.)

THE SUNFLOWER PLANT.

(*Helianthus Annuus.*)

BY W. A. DE SILVA.

The sunflower is a perennial, slightly woody plant, growing to the height of from three to four feet. It belongs to the composite family. The flower heads which are very gay in appearance mostly are borne on the top of the plant, though a few are also borne on the small twigs given out from the leaf axils.

The cultivation of the sunflower as an ornamental flowering plant is common in the temperate and tropical climes, but it is also being largely cultivated as an agricultural product in parts of Russia, Turkey and other countries.

The sunflower, as its name in many languages signify, is associated in the minds of many a people, more or less with the sun. There is a popular belief that this flower is attracted by the sun in such a way, that it turns round from east to west, facing the course followed by it. But careful observations have proved that this idea is a fallacy, and the power of the sun is not greater on the *Helianthus* than on any other plant.

The uses to which this plant is put to at the present day are many. Among these the chief one is the oil which is produced. The seeds contain a large percentage of a fine oil, as good as the best sweet oil. This oil is used for culinary as well as lubricating purposes.

The seeds which have a milky taste are also valued as a good food for poultry and birds, and is esteemed much for their fattening properties. It is said that it is a desirable food for man too.

A fine yellow dye is prepared from the large golden petals of the flowers. This dye may with advantage be used in colouring silks and other light materials.

The leaves are also of some use, and a kind of cigarette is manufactured from them, which is used to a large extent, as it is reputed to have some medicinal properties.

The whole plant is considered to be a febrifuge of great value. A decoction made from the leaves and stems of this plant is said to be very

efficacious in cases of malarial fever. It is said that this plant surpasses even quinine in this respect.

The cultivation of the sunflower for the purpose of obtaining oil has been attempted in Ceylon, but not with much success. The plant grows well in many parts of the Island, and it is worth while making further experiments not only for the sake of the oil, but for utilising its other products more fully. If such experiments are attended with success, the plant ought to prove a paying garden crop.

It is said that this plant serves as good fuel, and that it has been used for heating stoves. Perhaps this new use might induce some to make further trial whether it could be cultivated with profit.

NOTES FROM A TRAVELLER'S DIARY.

Andiyagala was the place I mentioned last in my notes. About 5 miles' journey, from this place, brought me within sight of the Kalá-Balalu Wewa, which presented an appearance which I did expect. The tank was almost dry, the sluices having been opened to irrigate the fields below. A great part of the thick forest which once covered the bed of the tank is still there, devoid of its green foliage. The fallen leaves and the felled trees were lying beneath the shallow water emitting an odour peculiar to the decomposition of vegetable matter. The following inscription appears on a granite slab at the main or the Yóda-Ela sluice:—"This sluice, originally constructed in the reign and by order of King Dhātu Sen, about A. D. 460, was, after many centuries of neglect, rebuilt in the reign of Her Majesty Queen Victoria A. D. 1886."

The very existence of the town of Anuradhapura seems to depend on this tank, without which most of the other tanks in the vicinity will be dry, and paddy cultivation, in consequence, will have to be abandoned. It seems a pity that a permanent supply of water cannot at present be maintained in this tank. The natives in the vicinity have a peculiar aversion to drinking well water. They say the tank water tastes better. There seems to be some truth in this, for I found that in most cases the well water had a brackish taste.

The town of Anuradhapura, which was, at one time, one of the most thickly-populated cities in the East, looks now more like an ill-kept Park than anything else. The place is interesting botanically as well as archaeologically. Interesting water plants and ferns and trees of various descriptions could be seen here. The oldest historical tree in the world is also here, but it now seems much degenerated. The town has a small Botanical Garden. Several varieties of cotton have been tried, and the Egyptian variety seems to thrive well.

The paddy-fields at Anuradhapura are quite a sight worth seeing when under crop. Some of them were the best that I ever saw. Extraordinarily high yields has always been the result of judicious cultivation; coconuts and plantain also seem to thrive well here.

Most of the tanks in the interior villages were almost dry, and at a place called Mahadiwul-wewa, near Madawadchiya, I saw a splendid crop of paddy in a dried portion of the tank. This sort of cultivation is called in Sinhalese 'Káwala Wepiréma.' The yield is very high owing to the exceptional fertility of the soil; but the superstitious belief of the people is that the "demon" has an aversion to eating this paddy and he therefore does not steal it!

BUILDING MATERIALS.

SECTION I. STONE (*continued*).

By A FACTORY APPRENTICE.

Decay and Destruction of Stone.—The great agent of destruction to building stones is the damp or the water supplied by the atmosphere directly or indirectly. The precautions to be observed are very simple. "The first and foremost rule is never to employ a porous absorbent stone in the ground, or in elevation; unless in the former case it be maintained constantly wet; or in the second case, the absorption of moisture from the ground be prevented by the interposition of some impermeable material. Porous stones should never be used for parts of a building where water may lodge." Various other causes give rise to the decay and destruction, such as:—1st. Oxide of iron if allowed to remain in any notable quantities. 2nd. The crystalline sulphate of lime in consequence of the sulphuric acid they contain. 3rd. The silicates and the sulphates of iron so often met with in building stones. Decay and destruction of stone is also caused by nitrification which takes place near damp ground.

"Not only does this nitrification throw off the minute and less adherent particles of the building materials, whether they be of stone or brick, but it is also able to detach any protecting coat which may be put upon them if the adhesion of that coat to the subacent material should not be of a very energetic nature. Let the adhesion be ever so energetic, if once the action of nitrification should have been established, it must run its course, and the amount of evil it is capable of producing will simply depend upon the quantity of organic matter originally contained in the materials or susceptible of being absorbed by them from the atmosphere."

Preservation of Stone.—It is always advisable to guard against any sort of decay setting in to a building stone, since to arrest its progress after it has been once allowed to establish itself is impossible.

The following are some of the precautions observed to prevent stone decay:—1. By painting. 2. By the injection of oleaginous fatty or waxy matter. 3. By washing the face with a solution able to convert the material into an insoluble non-absorbent substance. 4. By filling in the pores of the stones with an insoluble material which should effectually exclude water.

There are strong objections raised against the process of painting, as the oil evaporates and the stone become again exposed to the atmosphere, and so the process has to be renewed.

The second process, namely, by the injection of oleaginous, fatty or waxy matter can only act

mechanically by closing the pores of the stone. This coating like painting itself has to be renewed, since it is gradually detached from the stone.

The third process, that of washing the face with a solution able to convert the material into an insoluble non-absorbent substance, is one "in which the carbonates of lime are washed with a solution of an alkaline silicate, as silicate of soda or potasse with a view to converting them into silicates of lime through the elective affinities of the lime and the silica. One objection to it is that the silicic acid is a slow one, and when the surfaces washed in the manner described are exposed to the rain, it is by no means rare to find the solution carried away."

The fourth process is to clear the stone from dust or other extraneous matter and make it absorb as large a quantity as possible of the silicate of soda or potasse. When the solution has dried into the stone a second wash should be applied consisting of the chloride of calcium.

(To be continued.)

PRIZE DAY AT THE SCHOOL OF AGRICULTURE.

Yesterday (Nov. 29th) afternoon took place another of those pleasant gatherings which recur annually at the School of Agriculture in the Cinnamon Gardens. The entrance to the building was tastefully decorated, and the school-room had much artistic labour bestowed on its decorations. The Hon. the Colonial Secretary presided, and amongst others present were the Hon. J. J. Grimlinton, Hon. W. W. Mitchell, Hon. Dr. Anthonisz, Hon. M. C. Abdul Rahiman, Messrs. H. W. Green, J. B. Cull, T. E. De Sampayo, Mrs. and the Misses Keith, Mr. James De Saram, Dr. H. M. Fernando, the Maha Mudaliyar, Mr. C. Drieberg, Mr. and Mrs. Joseph, Messrs. C. Thomasz, Walter Pereira, R. P. Jayawardana, Mrs. and the Misses Beven, Mr. and Mrs. Schrader, Mr. C. M. Fernando, Mr. and Mrs. Jeronis Peiris, Advocate Senathi Rajah, Miss Prédoux, Mr. Ranesinghe, Mr. J. S. Drieberg, Mrs. and the Misses Attygalle, Miss Lindsay, Miss Drieberg, Mrs. and the Misses Greuier, Mrs. C. Drieberg, Rev. S. Lindsay, Mrs. A. de Saram, Dr. and Mrs. Asreappa, Mr and Mrs. F. Dornhorst, Rev. T. C. Hillard, Dr. Bowles Daly, &c.

The proceedings commenced by the President calling upon the principal (Mr. C. DRIEBERG, B.A.) to read his Report.

Report was of a very encouraging nature, and its reading was punctuated with frequent marks of applause from the audience. It alluded in terms of praise to the late Governor Sir Arthur Gordon, who had by his encouragement and patronage in previous years shown his interest in the work of the School. His Excellency Sir Arthur Havelock was prevented from presiding owing to pressure of work, but he had already shown his appreciation of the work carried on in the School by visiting it. The presence of Sir Edward Walker was an indication of the interest he evinced on behalf of the school. The report next proceeded to state the results of the

operations carried on in the various provinces by the students who had been sent forth from the School. One of their men had been appointed as an agricultural instructor in the fever-stricken district of Walapane—the condition of which district the energetic Assistant Government Agent of Nuwara Eliya was endeavouring to ameliorate. That appointment made up a total of twelve students who had been employed as agricultural instructors—seven of whom were paid by Government and five privately. It was a matter for congratulation that the Government officials rendered valuable assistance to the cause of agriculture, notably the Government Agent of the Eastern Province, the Government Agent of the Sabaragamuwa Province, and the Assistant Government Agents of Matara and Kegalla. Another batch of students was leaving College on completion of their studies to engage in agricultural pursuits. It included some excellent young men, among whom was Mr. J. J. Koddipilly, who has had a brilliant career at the School. One feature of interest was the publication of a Monthly Magazine devoted to the interests of Agriculture; and this literary effort is appreciated by those for whom it was intended. The School Museum is growing in size, the Agricultural Discussion Society is well supported by both students and outsiders. A dairy has also been set on foot by the headmaster, Mr. Jayawardana, and experiments have so far been attended with success, and it is satisfactory to note that a long felt want has been supplied. Through the knowledge imparted in this branch of agriculture the students could gain a knowledge of the proper housing, feeding, and general treatment of cattle in health and disease. Another feature of interest in the report was the fact that a large variety of crops had been grown on the School grounds with the view of demonstrating the most approved methods. The report next referred to the willing help and ready assistance of Mr. De Silva, the second assistant, not only by teaching in the School but by his writings. Another student of last year's batch has been employed as a conductor on an upcountry estate; and it was satisfactory for the Principal to note that the advantages of employing such men consisted not merely in having an intelligent manager but also a disciplined and honest employee. The report concluded by speaking of the loss of their old Director, Mr. Green, to whom the School owed its existence and success, but they had also to welcome the presence of Mr. Cull, whose established reputation as an educationalist insured the successful direction of the Department of Public Instruction.

Mr. J. B. CULL, M.A., the new Director of Public Instruction, then rose and said:—Sir Edward Walker, Mr. Principal and ladies and gentlemen,—I congratulate myself in the fact that my predecessor, Mr. Green, has come amongst us this evening prepared with a speech. The School is pre-eminently a poem of his own composition; and the fact that I am so completely new to the use of the plough makes it impossible for me to comment on the nature or the results of the School in any way as adequately as I would wish. I congratulate you, Mr. Principal, on the record you have been able to present for the year. I learn that there are 26 students

on the roll, and the report of those students who have been sent forth to work in the various districts is entirely satisfactory. (Applause.) I leave it to my predecessor to comment upon the various modes of agriculture that are carried on in the Island with unvarying success in the various provinces. As regards the School itself, I note with great pleasure that it embodies one of the most noble feelings, and, what is best, it teaches the dignity of labour. (Applause.) Passing the compound the other day I was struck by seeing the boys engaged in mamotyng and other kinds of operations, and in a country like this, such kind of work is eminently satisfactory. It has been wisely remarked that a man who makes a blade of grass to grow in a place where there was no grass at all is a benefactor to the country, and this is the great object of the Agricultural School—multiplication of the fruits of the earth; making nature yield more abundantly and tending to eliminate as far as human agency can eliminate the ill-effects arising from untoward climatic conditions in the island. (Applause.) Reading in connection with this subject a poem written many centuries ago, the "Georgics" of Virgil, I was struck with the rule laid down regarding ploughing, in which the author recommends that as a preparation for ploughing one should take his coat off, and put his shoulder to the plough, and it is universally true that a man who cannot take his coat off and put his backbone into his plough is a very incomplete agriculturist. (Applause.) I will not occupy your time any longer in view of the speeches which are to follow, save to express my great gratification at being present here this evening, and to express the interest I have always taken on behalf of the School of Agriculture. (Loud applause.)

Mr. H. W. GREEN next rose, and said that the students of the Agricultural School, unlike other ordinary educational establishments, were limited to a certain number. They had a great many applications for boys, but their number was limited to 23 in his time, and now he saw it was 26. They only wanted a select number of boys, who had the interests of agriculture at heart. He read in the newspapers that one of the boys had been sent from the School to the clerical examination, but he hoped that the Principal would never allow this to occur again, for the one object with which the boys entered the School of Agriculture was to qualify themselves in agricultural knowledge and to go forth and spread forth that knowledge. When he first thought of an Agricultural School, he had many discouragements to contend with, but he was glad to find that he had successfully broken the ice. There were eleven agricultural instructors, seven of whom were paid by Government and five privately, so that all their old students were not simply employed under Government. The improved plough had done a great deal to foster agriculture, and from the reports to hand, he found that the crops had more than doubled their usual yield by the use of the plough. They had sent out their young men to work with the improved ploughs, and they had all done good work. The other day he sent out a hardworking man to work in a place some 19 or 20 miles from Trincomalee. The people there were not inclined to work at first, but the speaker himself spoke

to the people and told them that if they did work, they could share the profits equally and so ward off starvation. At last they did set to work, and they got a good return and shared the profits. He moved the instructor on to the next station, and the result was so eminently gratifying that here were several applications for the ploughs. Their object was to disseminate a knowledge of agriculture so that others might follow the example; for he found the Sinhalese people always ready to take advantage of opportunities offered to them. They wanted the young men to work. A good many had already taken advantage of employment on estates, and he was quite sure that the education received here would not be thrown away in vain. In conclusion he wished all success to the institution and wished the pupils good-bye. (Applause.)

The distribution of awards then took place according to the following list, each recipient as he came up to receive his gift being heartily cheered by his comrades:—

SENIORS.—Agriculture, Chemistry, Botany, Zoology, Entomology, English, History and Geography, Mathematics, and Practical Chemistry (the late Mr. de Soysa's prize) all gained by J. A. Kodippily; Veterinary Science was won by A. Drieberg; and Practical Agriculture by J. P. Ranasinghe.

JUNIORS.—Agriculture and Geology by P. V. Cooray, and Chemistry, Botany, English, History and Geography, Mathematics, and Field Surveying (the Grenier prize) all by E. M. Johnannes.

THE PRESIDENT'S SPEECH.

The prize-giving over, Sir E. WALKER said:—Mr. Principal and ladies and gentlemen:—It gives me great pleasure to come here today and to make the acquaintance of the School of Agriculture and to join with you by your presence in the expression of encouragement to the masters who have been engaged in teaching the boys during the past year and congratulating the boys themselves on their course of study. (Applause.) I trust that those who have received prizes today will find in them an encouragement to persevere in after life and to exercise that industry which have enabled them to attain certificates. I am not altogether a stranger to the School of Agriculture. The deservedly high terms in which Mr. Green has spoken of the institution I am well aware of, as it has been my good fortune to have been much associated with Mr. Green, and from him I have from time to time heard a great deal of the School and have been much impressed with the zeal and the interest he has taken in it. (Applause.) I think the Principal in his Report has very rightly expressed regret at his loss, but it is not a very real loss after all, for you have in his successor a gentleman who has the interests of practical education at heart, and I feel sure that he would use his best efforts in furthering the work of agriculture. (Applause.) And you have Mr. Green in a position to help you at the Governor's elbow and as my principal colleague and assistant. As regards the work of the School I have heard of several accounts disparaging and discouraging the work and utility of the education given in this institution. Of course it would be difficult by statistics to show how valuable the School was,

but I am of opinion from all the information I have gathered, that those boys who have been sent forth from this School into the various provinces of the island are doing good work in agriculture. (Applause.) I put the question to Mr. Drieberg when I came into the room whether during his travels about the country he had seen good work being carried on in agriculture as the result of the money spent on it, and he unhesitatingly answered in the affirmative, and I think we may take his opinion as one of considerable value. His opinion is, moreover, of an independent character, because he belongs to this country, and it is not as if he were speaking of the results of his own labours, but of those who have gone before him. Some people have tried to throw cold water over the school: but if the boys only worked quietly and persistently their labours would bear much fruit. (Applause.) The Principal has referred to a pupil who had gone to the district of Walapane. Well, I know of no one who is likely to do more good to that unfortunate part of the district than one who would instil into the poor people there some knowledge of agriculture, and if he did that he would certainly accomplish more than what Government officials and Colonial Secretaries had yet been able to achieve. In conclusion, I have only to express the great pleasure it has given me today in taking part in the prize-giving this year. (Loud applause.)

The Hon. Mr. J. J. GRINLINTON followed, and in the course of a spirited address urged on the School the desirability of experimenting upon the system of transplanting paddy. In some parts of the country this system was a success, while in other parts it was a failure, chiefly because in many cases transplanting took place at the wrong time and the plants died. He hoped that the matter would occupy the attention of the Principal and his pupils, for transplanting was carried on on an extensive scale with various other products, and he saw no reason why they should not carry out experiments in transplanting paddy. With regard to the remarks which fell from the President and Mr. Green that cold water was being thrown on what they did by some people, he believed that these people were everywhere in the world, and the very men who had not lifted a finger to help them and had done all they could to discourage them would whenever they heard that success did attend their efforts, say "We told you so." (Laughter and applause.) He counselled the young men not to trouble themselves about the criticisms levelled against them, but simply to work on steadily and success would assuredly follow. He was sorry to find that the Sinhalese nation were not giving that attention to cultivation which they did in the ancient days. In those days their one ambition was to possess and cultivate the land, but now the majority of the young men only tried to get educated and seek employment under Government on the smallest pittance. This, the speaker said, was what ought to be discouraged; and he thought the best thing for our young men to do was to put their shoulders to the plough and to give their attention to agriculture. (Applause.) In addition to agricultural knowledge, a knowledge in mercantile matters was also indispensable. He would instance the case of those gentlemen in England

who were trained to agricultural pursuits in preference to a berth under Government, and he maintained that if the young men only considered the advantages to be gained from a knowledge of agriculture, they were bound to succeed in life. In conclusion, the speaker proceeded to advocate technical training. The School was only in its infancy, and they had heard of the success which had attended their efforts; and if success had attended efforts where difficulties had to be surmounted before, he had no doubt that a school for technical education would also meet with success. (Applause.) Without technical education the School could not prosper, and he would be very glad if technical education was brought to the very doors of the natives. (Loud applause.)

Mr. H. W. GREEN referring to Mr. Grinlinton's remarks regarding the system of transplanting said that was the first thing he started with, as it was the system which brought out the best returns. In China and Japan this system of transplanting brought enormous folds, and even transplanting in the sandy soil at the back of the room resulted in a yield of 539-fold. Another great advantage in favour of transplanting was that 10 measures sufficed to plant out an acre of land, whereas the people usually used two or two and a half or three bushels an acre. The system too could also be carried by means of a nursery in one corner of the field, and during a period of drought the cultivator would be able to water this small piece of ground from his chatty and thereby to tide over the period of drought without being starved. (Applause.)

The PRESIDENT said that in bringing the proceedings to a close he wished all the pupils a successful career. He might mention that in connection with the eleven students who had left the institution for the various provinces, the fact that five had been employed by private parties indicated that they had shown an independent appreciation of the worth of the School. (Applause.)

Three hearty cheers having been given to Sir E. Noel Walker for presiding on the occasion, followed by rounds of cheering for the Principal and the visitors, the gathering adjourned to the green, where light refreshments were partaken of: the Band of the C. L. I. V. treating the people to some excellent music.

GENERAL ITEMS.

Mr. H. S. Holmes Pegler, Author of "The book of the Goat," writing to the *Agricultural Gazette* on the milking properties of goats, says that two quarts a day is a fair average for a good milker. A goat which was exhibited at the Royal Aquarium Show and won the milking prize gave nearly a gallon a day. In Switzerland and Malta much attention has been given to the improvement of the milking qualities of goats. Regarding quality, Mr. Pegler says that in almost every case goats' milk is richer than of the cow; heavy milkers, however, as a rule supply a comparatively poor yield. In order to compare the comparative richness of the milk of the goat and the cow, an analysis was made of the milk from a Cashmere goat belonging to the Queen, and that of a Shorthorn cow, winner of

the Champion Cup in the milking trials at the Dairy Show of 1888. While the goats' milk was found to contain of water 80.72 per cent, fat (pure butter) 6.93, and solids other than fat (casein, sugar, and ash) 12.35; the cow's milk gave the respective percentages of 87.56, 3.63, and 8.81. The sample of goats' milk thus showed 7 per cent less water, while it contained nearly twice the quantity of pure butter fat, and half as much again of other solids. Besides its richness and nutritious property, goats' milk has the merit of being extremely digestible, and is accordingly recommended by medical men as a diet for invalids and children. In Ceylon goats are of no great importance as milk-producers among the natives, though the Hindu and Mussalman classes use the milk to some extent. The value of the milk as food for invalids and children is, however, recognised even here.

Says the Melbourne *Leader*, in an article on valuable vegetable products:—The Indian Areca-nut is regularly eaten every day in the year by 100,000,000 of the population. There is an annual importation of upwards of 30,000,000 lb. from Ceylon, the Straits Settlements, Sumatra, and they are exported in considerable quantities for the use of the Indians living in Zanzibar, Aden, Mauritius, China, and other countries. The fresh nuts have intoxicating properties and produce giddiness. These objectionable properties are much diminished by heat and by drying, and many cautious people decline to use any except nuts which have undergone a process of cooking and are known by their colour. The original wild nut was intoxicating, but the only nuts now used are from cultivated trees, and these are milder. They are only intoxicating when unripe, and then but slightly. The nuts are eaten with the betel leaf, the praise of which is sung in ancient Hindu books which attribute to it no less than 13 valuable properties which are duly enumerated. Modern medical men vouch for the fact that essential oils of betel leaves are highly beneficial in catarrhal affections and throat inflammations. Further researches into the properties of the nut and leaves are evidently called for, because their preparations by native methods are a good deal regulated by superstitions. The betel leaves are mixed with other spices used with lime to form *pan*, with which the nuts are eaten. An organic poison can be extracted from the nut, and when this is injected under the skin of rabbits and cats they die a few minutes; but the same may be said of a great many vegetable productions, the Kola-nut inclusive, which are usually regarded as harmless. Even the lettuce contains such a poison. The arecanut is grown on a palm which is supposed to be indigenous in the Malayan peninsula and islands, but is not now found in a wild state. The Indians no doubt indulge too freely in the use of the arecanut and betel leaves, but for exceptional use they may be found to be medicinally beneficial. If the reverse be the case, further investigation is demanded on behalf of the 100,000,000 betel eaters. It is a popular idea among betel-chewers that the chewing mixture has digestive as well as antiseptic properties.

Mr Johansson, a Swedish Engineer, claims to have invented the simplest and most rapid machinery by which new milk can be converted into butter. The process takes less than three minutes, and the machine could deal with 1,500 pounds of milk per hour. Mr. Johansson received the highest award at the Royal Agricultural Society's Show last year.

A trial of ploughing by means of electric motors is about to be made on the property of the Marquis de la Laguna. The power of a waterwheel of some 20 H. P. will be employed, and the implement for working the land is expected to work at a distance of 3 miles from the generating dynamo.

During the year 1889-90, says the *Madras Times*, there was a general rise in the prices of the principal food grains and horsegram throughout the Madras Presidency as compared with the two previous years.

The value of charcoal to plants is not so much as a fertilizer as an absorber of ammonia both from the atmosphere and the soil. It is further claimed for charcoal that it prevents attacks of insects and fungi.

The British Consul at Bahia has more than confirmed the wonderful stories told of the properties of the Kola-nut. The Kola-eating Africans who labour at the unloading of vessels are said to work and earn twice as much as their competitors. The beans which are described as un-intoxicating and in no way injurious, are said to act as a nutritive and quench thirst: yet they are not strictly a stimulant. The beans are best soon after they are gathered, and are sold according to freshness at twopence or threepence each bean. At the request of the Government of India practical information regarding the extraordinary properties of Kola-nuts has been supplied by the authorities at Kew.

Dr. Henry Baker of Michigan remonstrates vigorously against the proposal to discard the fumes of burning sulphur as a disinfecting agent. He shows by tables and diagrams the controlling power of this disinfectant, and attributes its alleged failure as such to the use of too little sulphur. The burning of 3 lb. of sulphur to the thousand feet of air space is sufficient to destroy the germs of contagious disease in a closed room, without extra moisture in the room. In support of his position he quotes the results obtained by recent French experiments in this field.

The members of the Indian Agricultural Conference were unanimous in urging that educational primers of an agricultural character should be introduced in all primary schools, and also that arrangements should be made for the supplying of a high-class education in Agricultural Science to all who desired follow it out.

THE

TROPICAL AGRICULTURIST

MONTHLY.

Vol. X.

COLOMBO, FEBRUARY 2ND, 1891.

[No 8

LEAD FOR LINING TEA CHESTS.

considerable amount of discussion has of late taken place as to how far it may be possible to substitute various forms of linings for tea chests in lieu of the lead which has almost from time immemorial, been used for that purpose. The objections that may be taken to the use of lead for this purpose are many and various. Chief among these is the item of cost, and, scarcely secondary to that, the weight for which land carriage both up to the estates and down to the port of shipment has to be paid. There are those who further maintain that lead packing for any articles of an alimentary nature is to be deprecated, it being urged that, although in a degree insensible to observation, the introduction of a certain amount of lead poisoning most injurious to human system, may be due to the practice.

We may, we believe, leave this last objection out of consideration; for although we do not deny that the contact of lead with food destined for human consumption is injurious, we doubt exceedingly if it has been proved that the tea packed in lead linings has ever imbibed from it any deleterious quality. The two first objections we have mentioned are, however, of gravity fully sufficient to justify the desire felt for the provision of some efficient substitute for these lead linings, for they are—all experience teaches us—not only weighty, but sometimes costly and troublesome to prepare. On this account alone we have welcomed, and are yet prepared to welcome, any suggestion likely to be of effect in offering an efficient substitute for lead. Of late, reports reaching us as to the satisfactory results of shipments made in lead paper, as also in artificial parchment, would seem to have indicated that such a substitute had been found. But the mention made in our London Letter by last mail of a recent experience must compel us

as yet to suspend a favourable judgment on this point. We are told that an expert tea-taster of eminence was able to at once pronounce, not alone as to the material used for enveloping the tea submitted to his judgment, but even as to the character of the enclosing chest. Such a result can have but a single meaning, viz., that the lining—in the case under notice, lead paper—was not impervious, and that it had permitted to pass through it and to be absorbed by the tea some inherent taint in the material of which the chest was composed.

Confirmation as to this has been supplied to us from other correspondence, which asserted that several of these lead-coated paper linings, when examined after receipt at home, were found to be perforated with innumerable small holes, the fact leading to the conclusion that the film of metal placed upon the paper had been too thin to resist the action of the acids exuding from the material of the chests, though, the perforation being so minute, they might have been caused by the action of damp alone. But it matters little how minute these perforations were. They may not have been as "deep as a well nor as wide as a church door"—to quote Shakespeare,—but what they lacked in size they made up for by their number, and it must be evident that any lining liable to become so affected must be untrustworthy, and that its use is therefore out of the question when so much of financial return to our planters is dependent on their produce reaching its several markets in a perfectly sound state. We learn from home that the fact of failure is fully recognized by those who have hitherto made trial of this proposed substitute for lead, and that they will abandon the further use of it.

We may conclude, therefore, that as yet what we require has not been found, and that we shall do wisely for the present to stick to our old and well-tried lead linings, however weighty the objections to their use may be. But our London Correspondent has sent to us by the mail a specimen of a newly-manufactured material on the possible success of which some hopes may be built. It would seem that, while sheet lead such as we use at present is unnecessarily thick and heavy, the leaded paper errs in the other extreme, that of the film of the metal being too thin. Possibly, therefore, a remedy is to be found in some material which shall provide the *juste milieu*. This the specimen of lead foil—as it is termed—that has been sent to us seems to provide. It apparently has body enough to resist the action of either a moderate amount of acid or of damp, while the paper lining added to it—if, indeed, it be paper—would prevent any contact between the tea and the lead. It is said to have the further

useful quality of uniting closely when a heated iron is simply passed over it, and our correspondent tells us that he has seen the edges of two pieces of this material so united. This facility will be much appreciated when it is compared with the labour of soldering the ordinary lead lining. Trial shipments are, we are told, to be made with this lead foil, and we hope they may have successful results. "When one door shuts another opens" goes the old saying, and we should welcome the assurance that we have to give up the hopes entertained of several lead papers hitherto tried, we may have the alternative before us of another possible solution to the difficulty our tea-growers now experience.

ANOTHER CASE OF THEFT OF CACAO FROM THE WARIAPOLA ESTATE; MATALE.

R. S. Fraser of Wariapola, Complainant, vs. Bandia of Hapuvida, Defendant.

CHARGE.—That the defendant did commit theft of five cacao pods (unripe) of the value of R1-25 property of complainant.

ROBERT SCARLETT FRASER sworn.—This accused was caught stealing in my cacao garden. His father was convicted of stealing cacao in my garden and was sent to jail for six months. The accused pleaded guilty and stated that he was drunk and did not know what he was doing. [The learned Magistrate thought it best to examine Mr. Fraser as to the story of the accused of being drunk. I saw the accused soon after he was caught. My conductor and watcher caught him. He lives in a block of land adjoining my cacao fields, but there is a paddy-field intervening at one end. He was not drunk in the least when he was brought up, though at times he simulated drunkenness. When he had occasion to speak, he spoke very freely. There was no smell of liquor on him. He walked perfectly freely and spoke freely and when standing stood perfectly steady but kept his eyes closed. Cacao is constantly stolen from my estate without any trace of the thieves.]

JUDGMENT.—I find the accused guilty under the 368th clause of the Ceylon Penal Code. The cacao produced is perfectly unripe cacao; and though the value is not great the extreme prevalence of the offence in Wariapola demands the highest punishment I can give. I find the accused guilty and sentence him to undergo rigorous imprisonment for a term of six months.—(Signed) J. H. EATON, P. M. Dec. 29th, 1890.

In the case wherein Mr. W. S. Marshall, the superintendent of the Vicarton estate, charged his kanakapulle, Supaiyah, with neglect of duty and disobedience of orders, the accused was sentenced on both counts to two months' rigorous imprisonment. The accused has given notice of appeal. Full particulars will follow.

MR. SCOTT BLACKLAW ON BRAZIL.

CASABRANCA—COFFEE CULTIVATION—A HEAVY BEARING ESTATE—THE COLONISTS AND THEIR WAGES—MOCOCA BRANCH OF RAILWAY—PROVISIONS—SAO JOSE—END OF THE RAILWAY JOURNEY—TRAVELLING ON MULEBACK—TROLLIES—ROADS—AN ADVANCING TOWN—"COMETS"—RIO PARDO—GUAXUPE—LABOUR SUPPLY—GOVERNMENT ELECTIONS—THE EMPEROR'S PALACE—THE PROVISIONAL GOVERNMENT—EXCHANGE.

Rio, Nov. 2nd.

Casabranca is a considerable town on the Mogyana Railway, 171 miles by rail from Sao Paulo. Coffee planting was begun here about 1878, and as formerly mentioned the principal pioneers here were the Prados. The Fazenda of Antonio Prado, late minister of Agriculture, is not far from the town. I have mentioned

that coffee is only planted on high lands, that is on lands at four or five hundred feet above the level of the surrounding country. Unless planted on these, coffee gets killed by the yearly visitations of frost in the cold months, extending from May to September. This Fazenda, named Santa Veridiana, has thus a commanding aspect, and the green hills closely covered with coffee trees are seen from a long distance. There is over a thousand acres in coffee, and the cultivation is entirely done by European colonists, Germans, Italians, and Portuguese. Each colonist family is given a solidly built house covered with tiles, and is also given pasture for cows and land, outside of the patch of coffee which is set apart for each family to treat,—to plant provisions. As this is a heavy bearing estate, seldom giving less than ten cwt. per acre, and as the colonist is paid according to the quantity of coffee picked, it is very popular amongst colonists. Judging by the number of houses one sees from the railway there cannot be less than 100 families. In good bearing coffee, a colonist family of five persons will pick from 1,200 to 1,500 boxes, of 50 litres each, in one season. The price paid to the colonist is twenty pence (1s 8d or 800 reis) for each box of 50 litres (nearly a bushel and a half) of cherry. They have also the produce of the land, which each family cultivates for growing provisions. While they make butter and cheese, which they sell in the town, they also rear fowls, fatten pigs, and indeed each in himself is a farmer on a small scale. If the mother be thrifty the family can be kept from the provision-growing and and house alone, and the £130 or so received for coffee picked and weeded is saved money. Many of the colonists on this estate are rich and have money out at interest. This year (1889) the coffee estates along here are giving a heavy crop, but as the season has been a dry one all over the country, next year's crop will be a light one, as there have not been rains to send out young wood for the October blossoming season.

The most of the estates here are in good order, but it is said they are short-handed for crops this year (1889) and a good deal of coffee will be lost and if not lost much will be gathered from under the trees and thus give an inferior quality. There are many more large coffee estates near Casabranca. From here the main line goes on to Ribeiro Preto direct west, and a branch goes north-west to Mococa, on the boundary between S. Paulo and Minas.

As our journey at present goes by the last named branch we will notice it first. Starting from Sao Paulo at 6 a.m. we arrive by train at Casabranca at 2-30 p.m., having travelled at the rate of 20 miles an hour including stoppages. I pity the traveller who has not taken something to eat with him, for there is such a confusion when changing at Campinas—from the 5ft. 3in. gauge to the 3ft. 3in.—that he has no time to eat anything there, and the Portuguese sausages which one sees for sale at some of the stations are suggestive of grease, fat pork, and garlic, a kind of food which the average Briton cannot stomach. Some of our sandwich loaf, however, remained. All the same we were glad when arriving at Casabranca to be told that there was time for the passengers going by the "Mococa" branch to have dinner. The black-beans, rice, beef steak, and fowl, the last two being the only kind of cooked food from which the strong flavouring bulb I have mentioned is excluded, were ravenously eaten by us, and our Brazilian fellow-passengers had a fair "set to" at the joint of fat pork, mixing in their black-beans a cooked farinha made of Indian corn. If I can remember I may describe the way of making this baked flour later on.

A two hours' ride on the train takes us to Sao Jose do Rio Pardo. This part of the line goes principally through far-stretching campos covered with illuk grass, and in some places studded with small stunted trees, of a kind which seems to resist the action of the yearly fires, for every dry season these campos are set on fire if not by accident then cut of pure mischief. There are however some stock farmers who believe in the yearly burning doing good, as cattle, horses and sheep greedily eat the young grass which seems to shoot up even without rain. The ground however

after this process of burning every year becomes dry and sandy, the sand being left lying between the tufts of grass, while any organic part of the soil surviving the roasting is washed away.

It is a relief now and then to come to a hilly part where coffee can be grown, and we pass on the way some very fine coffee estates, some only coming into bearing and all having large clearings of young coffee, and large villages of European colonists' houses (mostly Italians). In about two hours we reach the town of Sao Jose de Rio Pardo, having passed two small stations among coffee estates. From Casabrancia we have come in a north-easterly direction, and our journey ends here at Sao Jose as far as railway travelling goes. We have now for the rest of our route to proceed on mule-back.

Before leaving Rio we had been directed to the hotel kept by Senhor Ananias, and the proprietor was himself at the station on the outlook for "Hospedes" for his establishment: more than that, he had a conveyance called a trolley to take them, and a mule cart to carry the luggage to the hotel. I think I have on former occasions described a trolley. It is not a Brazilian invention, but was introduced by some American contractor in the days when railways were young, adapting the idea from similar vehicles used for many years in the hilly parts of the Northern States of the American Union. It consists of four wheels on the axles of which are laid two eight inch boards on the flat, these act as springs, on them are fixed seats cross-wise for holding two each seat; some have two of these seats and some three: indeed they can be made with any number of cross seats by adopting longer boards, and extending the wheel-base. The boards or (springs are of a timber called *Cabriwa*, or *Balsama* the latter name because the wood emits a strong agreeable scent, and a balsamic liquid is extracted for medicinal and surgery purposes) and are very strong: I have never heard of a case of any of them breaking. To allow for turning the boards are put closer together on the fore-axle, through which goes a strong bolt; to the fore-axle to which is also attached the pole, for two or more mules; or the shafts if for one.

You will notice that this arrangement does not give much play to the look in turning, and the unwary driver if he makes a quick turn and the inside wheel in turning catches on the board-spring, he may upset the "trap" and bring its living freight to the ground. If the trolley has to turn right round on a road the occupants must all come out, and the driver will then lift the hinder part to one side, that is to say he will himself turn it end for end, which he can easily do, as when empty the whole thing is very light; so in this way it can be turned completely round on a narrow road.

When the writer came first to Brazil there were not many of these conveyances, and they looked very rudely made articles; any paint they had was engrained with mud or dust. But now, in the country-towns, trolley-making is a profession, and professional painters "do them up" with paint and varnish in a sort of artistic manner, and the trolleys give a good washing every day it is used. A nicely done-up trolley with seats for four will cost £10. My estate carpenter—a Scotchman—made me one to my own design, and I paid for the ironwork alone to a professional trolley maker £15.

In the trolley in which we were conveyed to the hotel there was yoked to it a large horse, a sort of kangaroo breed. All its action seemed to be in the hinder quarters, and as the only pace the animal had was a gallop, he took us through the steep streets by genuine "leaps and bounds." And such streets—laid out on the face of a hill! About a hundred yards near the railway was flat, and a large square on which were situated the church and the jail was nearly so, but all the rest of the streets were at a gradient of one in three, or not to exaggerate they were like what "Willie Gordon" of Oodasgeria would call the "good old one in five." This was not the greatest objection to them, they were innocent of paving—although any quantity of workable

granite peeped through the sides of the hills near the town—and the heavy rains had made them full of ditches, ruts would be a mild name. Sometimes the axle of the forewheels of the trolley would be at 35 degrees with the horizon while the hind wheels would be nearly on a level. Although they have not got farther in Sao Jose than a one-horse trolley, the citizens would be very much offended if a stranger called it "a one-horse town," for here is a centre of republicanism, and discussions go so high some times as to defy the authorities to keep the peace, and now (Sept. 1889) there is a detachment of soldiers, which had been sent up not long ago to keep the outrageous spirits within legal bounds. We learned through conversations with "mine host" and others, that the same Ananias who was driving the kangaroo horse was a rank republican and more so a decided socialist. He good-naturedly stated his opinion, and with a prophetic inspiration declared the monarchy doomed.

Senr. Ananias made us very comfortable at his hotel, gave us clean rooms and good food, but laughed at the idea of our thinking it possible to hire mules to continue our journey the next day. "No, no, senhores, we are an advanced people, but we must not be hurried. There are mules to be hired, but you must wait a day and then start at five next morning."

Next day we had an opportunity of noticing that Sao Jose was really advancing, new houses were springing up in all directions. The railway has been opened only for one year, and before it was projected there very few houses and population could not be counted above 300. I should say there were now 3,000 inhabitants. The bulk of the population is Italian, and the storekeepers, a great many of whom in addition to their *Casas de negocio* (retail shops) add that of *Mascatto* or podlar, many of them had large stores, and send goods on mule packs to the far interior, for at present this is the *ultimo thulo* of this branch of the Mogyana. It is to be feared however that the opening of this branch as far as Moceca—near the boundary of Minas—Sao Jose will get a check in its advancing career as far as the last mentioned branch of trade is concerned.

The day was not lost, for as our mode of travelling was to be on mule-back, and as we were to use our own accoutrements, some additions had to be made to our accoutrements, in the shape of extra cruppers, girths, saddle-cloths, and, above all, a breast belt for the saddle must not be forgotten, for the roads we had to go over were described by Ananias as steep and stony in some places, and having mud-holes in others that would try the best *graith* and the pluck of the best mules to get through them. We had guns and a fair supply of ammunition, but the country was described as so full of game; some extra shot suitable for what we were likely to meet had to be procured. Cartridge cases we had enough of, and knowing from past experience the wretched powder procurable in the interior I had brought from Rio a fair stock of Curtis & Harvey's powder, note this as the powder to be bought here has more smoke than penetration small shot for *snipe* and *codorno* (a small partridge) we bought 800 reis—(1s 8d) per kilo: and the small bullets, of which you put three in your gun, if you meet an *Ouaca*, (a small tiger) we got for 600 reis (1s 4d) per kilo. All our luggage had to be arranged to go conveniently on the pack-mules, and many details, which many of your readers as old travellers, well understand had to be attended to.

The evening was agreeably spent, for with dusk came an advent of some three or four "Comets." In country hotels they generally make their appearance for the first time about dinner time; they are observable for perhaps a single day and two nights, and they continue their eccentric orbits, some having Sao Paulo as their centre, and some Rio de Janeiro, after short visits, to these little worlds in the interior. They disappear and return some months after. I do not know if your commercial travellers would feel honoured by such a name being applied to them, but those of that class here are proud of it. These gentlemen scour the country with samples carried on pack-mules, and take

orders from the traders in the towns, for the houses they represent in Rio de Janeiro, Sao Paulo, or Santos. They are intelligent, energetic fellows, sociable, and jolly in the evenings, and to the traveller visiting these parts for the first time, they are living encyclopedias from which a great many notes of a very useful character, regarding the country one has to pass through, can be taken.

O Ananias! your name since my early infancy is connected with one who did not object to suppress the truth, and now that five o'clock has struck and daylight is breaking in sparkling golden lines away behind these high hills, there is no appearance of the mules which you said would be waiting before we could get out of bed. We were so anxious to catch the cool of the morning that night shirt, pijamas and slippers were put in the saddle-bags the night before in case the packing of these should cause delay.
