fore, without getting the upper rolling surface free of the jacket surrounding it. In the Standard the motion was imparted to the case or jacket from the upper rolling surface while in the Excelsior and the Triple Action the principle was motion imparted to the upper rolling surface through the case or jacket, and that was the point on which they claimed that there had been an infringement. Passing on to the judgment delivered by the District Judge, counsel alluded to the fact that because certain portions of the jacket in the plaintiff's machine answered the purposes of a connecting rod, certain scientific witnesses called by defendants who had studied mechanics in the abstract declared that those parts were a connecting rod, but he submitted that the whole was a case or jacket because it confined the tea. Defendants' witnesses had said that it formed a connecting rod however, and the learned Judge appeared to have gone off on that line. Mr. Wendt then went on to refer to defendants' specification, and then, reverting to the District Judge's remarks, he said that the D. J. had stated that the motion of the plaintiff's upper rolling surface was acquired by impact whereas the defendants' rolling surface got no impact whatsoever. Plaintiff, however, contended that it received impact from the outer case by means of the bracket. Then the District Judge had said that the defendants' machine could be worked if the wooden lining was taken out. They granted that, and with their machine it was exactly the same thing; but they were only producing models and the defendants' model had been so made that it could be dissected, which was not the case with the Excelsior model, and this appeared to have impressed the Judge. Their model was made as though it was a machine for work and it was not so made that the wooden portion could be taken out. Then, too, the learned Judge said that the upper rolling surface had its rotatory and its horizontal—otherwise called its eccentric—motion entirely independent of the case or jacket. If the learned Judge meant that piece of wood that might be true, but if the hollow cylinder carried the upper rolling surface it was not true, because their lordships would see that the defendants in their own specification described this upper rolling surface as having a rotatory motion in addition to the eccentric motion imparted by the hollow cylinder. The fact that the machine worked without the lining had evidently impressed the District Judge, and he disregarded the rest of the evidence and said he saw with his own eyes that it could be taken off and this was not done with the Excelsior. But the Excelsior Roller would work on the same principle. And then came the part on which he desired to lay great stress, because it was the part that he had said should have been followed by a verdict for the plaintiff. Said the District Judge: "As the Excelsior was an improvement on the Standard, so the Triple Action Roller is an improvement on the Excelsior," and he added, "and is a decidedly far more efficient and satisfactory machine"—a thing he was not called upon to say. He desired to repeat this passage, for it was an important one. Plaintiff improved on the Standard by disconnecting the driving mechanism from the upper rolling surface and connecting it to the jacket. The learned Judge said that defendants had improved on their improvement.

The CHIEF JUSTICE said it seemed to him the whole question hinged on what was the jacket? It seemed to be time thrown away by arguing questions of motive power.

COUNSEL agreed; but pressed his last point. It was a principle that if he improved another man's machine that had been patented it did not entitle him to any right to the machine. If A had patented a tea roller and he discovered something that would add to its efficiency, all he could patent was the improvement he had discovered. Suppose he found A's machine might be bettered by fitting a surface, or by making the machine of some other material, he might patent his improvements so as to prevent the original patentee from adopting them, but he could not adopt A's machine for the purpose without obtaining his license.

Mr. Justice LAWRIE asked what cases there were in support of this assertion; but Mr. WENDT replied that this was not contested. A man could not adopt another man's patent for the purpose of bringing out his improvement. Yet, after saying the Triple Action was an improvement on the plaintiff's improvement, the learned Judge went on to give judgment in favour of the defendants. He would now like to make a short reference to some of the authorities on the subject. As he had said in opening, one had to look very closely to the specifications, as there they found what was the nature of the invention and what was patented, and, for convenience sake, if their lordships would permit him, he would refer to a text-book, namely, Johnson's Patentees' Manual, page 161, and following pages. The two cases to which he specially wished to direct attention were both cases in which the Master of the Rolls had given his opinion. One was the case of Hicks *vs.* the Safety Lighting Co. (Law Reports, 4 Chancery Division p. 670), and the other was the case of Clark *vs.* Adie (2 Appeal Cases, p. 423). In these, the remarks were directed to showing how a specification should be looked at in ascertaining what was meant by a patentee. This brought him to the specifications, and here he would suggest an adjournment for luncheon if their lordships did not object.

This was agreed to, and the Court adjourned for half-an-hour.

On resumption Mr. WENDT said there was one other case he meant to cite, namely, the action Proctor *vs.* Bennis (Law Reports, 36 Chancery Division, p. 751). He then went at some length into the plaintiff's specification, and contended that what was meant by the case was something more than the mere wooden portion to which the District Judge had restricted it. Then finally came the claim of the invention which began with a sort of disclaimer. What they considered novel and original was, first, the arrangement which was the subject of that action, and, second, the arrangement for turning over the jacket B to give ready access to the upper rolling surface. Was there any arrangement described for turning over the wooden lining simply? The words used were "turning over the jacket B." There could not be a doubt that what was intended was the whole case or jacket, as the plaintiff contended. Much had been said as to the location of the distinguishing letters in the drawings, but a careful study of the specifications showed exactly what parts were referred to. Looking at the specifications and well weighing all he had adduced, he hoped the Court would say the case or jacket was all they claimed for it, and that their principle had been adopted by the defendants, which act on their part was an infringement entitling plaintiff to a verdict on that one issue alone.

Counsel then resumed his seat, after speaking for about three hours.

THE REPLY.

In response, Mr. DODWELL BROWNE said he appeared with his friends Mr. Dornhorst and Mr. Loos on behalf of the defence, and they had now drifted so far away from the question of the pleadings with which his learned friend opened his case that it would be perhaps well for him to follow his latest line first, and, much as he admired the lucidity of the address which his learned friend had made to their lordships, he ventured to say that he had not touched upon the real point in the case. The plaintiff had come into the Court and by his counsel he had said he claimed a patent right which was the arrangement of transmitting motion to a certain thing in a certain way for a certain result. He did not think his learned friend had touched at all in his address on the transmission of motion, and yet when they came to look at his first claim of novelty they found these words:—"I claim an arrangement of transmitting motion to the top rolling surface through the case or jacket surrounding it, whereby the top rolling surface is left free as regards vertical movement from the mechanism operating it," and, naturally, there came to their minds five questions:—"What is the motion transmitted; what is the top rolling surface; what is the case or jacket;

what is the mechanism operating it, and what is your arrangement for transmitting that motion?" His learned friend had dealt with several of these, but he did think he had dealt with them all. He thought he might agree with him in saying that one of the largest was "What is the case or jacket," but, to determine that, they had to look into certain mechanical principles, and they had to search thoroughly into the plaintiff's specification and determine thereon as to what was the case or jacket, and what was not? Now, there was one point on which he agreed with the other side. It was: *qua* the plaintiff, the Court had to attend to his specification, but there was one point on which he disagreed with him, and that was, *qua* the defendant the court had to attend to his specification. The whole of the plaintiff's case against the defendants was a sporting action resting on one man's writing of a principle in defendant's specification. Mr. Wendt had rung the changes over and over again on the imparting of the motion to the upper rolling surface by the cylinder surrounding it whereas it ought to have been imparting the motion to the top rolling surface of the cylinder surrounding it. He submitted he was not to be judged by what he had written, but by what he had done. If he had made a machine that infringed the plaintiff's patent it was immaterial if he wrote a word or not and if he had only written an idea of a machine, if he had not a specification for it he had not infringed his patent. Infringing was an act, and though he believed a specification might be read against a man for the purpose of prejudice to a certain extent, it would not really affect the issue, for the issue was what had he done in fact not what had he written; what had he made; not what he had designed; what had he sent to the whole country the use of which had limited the sale of Mr. Jackson's machines?

The CHIEF JUSTICE could not accept the last remark; it was, what had defendants done; had they worked up plaintiff's machine in some other shape and served it out to his disadvantage?

Mr. BROWNE agreed. Now the plaintiff had gone into this case and he must say he was amused at one of the last arguments of counsel who had said it was a question of specification and that the judge need not have gone into the evidence. Why plaintiff called witness after witness into the box and examined them as to whether the defendant's invention constituted an infringement or not defendants also called evidence on this point and when the Court came to attend to that evidence he had no doubt it would decide that the evidence of the plaintiff and his witness must be taken with a good deal of discount after the cross-examination for that adduced on behalf of the defence was indisputably of a surperior character. Let them start at the point Mr. Withers did. Somewhere in the seventies the Standard machine came to Ceylon and was imported to Loolecondra estate, and no patent was taken out or it. The model of the machine came into the Court bearing a lid with the inscription that it was Jackson's tea rolling machine and plaintiff stood up in the District Court and swore on his oath that he had invented the machine. Then at the Court he saw on defendants' model of the same machine "Kinmond's Patent" and he went to Loolecondra and got the name plate from the machine, when it turned out that the machine was not Jackson's; it was Kinmond's with a few minor improvements made by Jackson and these improvements involved him in litigation with Kinmond which resulted in his having to get Kinmond's license; so that Mr. Jackson when he wanted to come into the Court as an inventor had to be disallowed the credit as far as that machine was concerned. The Standard was a purely rectilinear machine. Undoubtedly scientific books told them that circular motion might be always resolved into its two component parts; but the separate parts of it made two rectilinear lines. Mr. Jackson took objection to this machine, as had been stated, and so he altered his machine completely and discarded the old process. Then came the question of what was the jacket, and here the defendants claimed that the wooden lining was the jacket, in

that it was entirely a separate part from the lower portion of the machine, which was the connecting rod. The under part was a part of the mechanism of the machine and was necessary for the suppression of circular into rectilinear motion. Passing on, counsel drew the attention of the Court to the fact that the model was not in accordance with the drawing of the machine, where the bow bracket did not spring from the connecting rod as in the model but from the wooden portion; while he asked the Court to remember that in the Court below the plaintiff distinctly disclaimed the transmission of any motion whatever to the top rolling surface by means of the spindle, so that his method of transmitting motion which he patented did not include that. The next point was what motion did the plaintiff give to his top-rolling surface; it was by leaving it loose and letting it lie an inert weight inside the box. There was no motion through the spindle. It was a motion of impact; the motion of a pea in a thimble; or of a dice in a box. The Excelsior was a rectilinear machine which began with a circular motion which was afterwards suppressed to rectilinear to make a circular roll. It began with a single action which resolved itself to two to go back again to one. The Triple Action on the other hand began with three and worked out a triple quotient in the end. The machines were entirely different in design and entirely different in the arrangement of transmitting motion because in the Excelsior the motion was transmitted from the side of the jacket by impact, whereas in the Triple Action it was all transmitted through the spindle. If he made a mark with any one part of the plaintiff's machine while in working the result would be a straight line; but with defendants' machine all parts would describe a circle. This he thought brought him to the end of his argument; but he should like to say a word about the skilled evidence they had brought forward; and counsel went on to refer at some length to the evidence given by Major Day and L. Brown, reading long portions of their evidence. In the course of this the question of driving and driven machinery again came up, and the CHIEF JUSTICE got in a difficulty in regard to the subject. To help in the matter he asked whether a horse in a carriage would be described as driven or driving, viewing the whole as a machine?

Mr. BROWNE replied that the horse would be the motive power, and the wheels of the carriage part of the driving machinery.

The CHIEF JUSTICE:—I am talking about the horse.

Mr. BROWNE:—Well, take a leg off the horse. (Laughter.)

The CHIEF JUSTICE further instanced a riksha man pushing a riksha backwards, and Mr. BROWNE repeated that the man would be the motive power.

The CHIEF JUSTICE, laughingly remarked that all this was very interesting; indeed, he did not know when he had been so interested before.

Mr. BROWNE replied that the case was one that if they once went into detail there was no saying where they would end. The great thing aimed at by plaintiff, he contended, was to leave his upper surface free as regarded vertical movement from the mechanism operating it. It was so settled in his specification but was not stated so in the libel. On the other hand, defendants' machine was not free in this respect, but got all its motion that way. They had adhered to Kinmond; but plaintiff had discarded Kinmond. Jackson in trying to fasten the liability of infringement on them had left out the very pith and marrow of his claim as set forth in his specification. As regarded points of law he had left these to his friend Mr. Dornhorst who would if necessary speak to them.

The CHIEF JUSTICE said he could not hear two counsel; upon which Mr. BROWNE referred the Court to the judgment in the case of Curtis vs. Platt, and, then briefly recapitulating his points, he gave way to Mr. WENDT who briefly replied. On the point of whether there was a case against Mr. A. Brown, counsel stated that he had admitted he was receiving a benefit from the making and selling of the

Triple Action Roller. On the other points he urged Mr. Browne had not met the case plaintiff put forward. As to the motion of the machine it did not matter if it was circular or rectilinear; if the defendants acquired motion through the case or jacket they had infringed, and he urged that they did so acquire motion and that consequently they were liable. As to the fact that their machine would work if the cylinder was removed, defendants said their cylinder was supported by horns and gudgeons, but in removing the cylinder they did not remove these horns and gudgeons, but they were as much a part of the cylinder as the bearing. Defendants had also fought to amend their specification on the subject of the eccentric motion imparted by the cylinder. They said now it should be of the cylinder; but he contended that "by" was meant and was not improperly used. The case of Curtis and Platt he admitted was good law, but did not throw much light on the case.

The CHIEF JUSTICE remarked that judgment could not be given for some time, as he had to go on circuit, but he asked that the models might be sent to his house to look into them carefully with his brother Lawrie, remarking facetiously that they might induce them to alter their professions and to give up the law for engineering. The case was closed after lasting nearly five hours.

DECISION OF THE SUPREME COURT.

MR. JACKSON WINS.

In the Supreme Court on 13th September, judgment was given in the appeal in the Tea Roller patent case in favour of Mr. Jackson.

THE CHIEF JUSTICE'S VIEW.

The CHIEF JUSTICE said:—As might be expected actions of this kind for infringement of patent are of very infrequent occurrence in Ceylon, and it cannot but be a matter of consolation to us to know that whatever judgment we may arrive at is subject to appeal to the Privy Council, and if we are wrong we may be set right at the instance of either party. It is useless for us to burthen our judgment with any recital from the pleadings. The parties at the trial agreed upon the issues which the learned Judge settled as the issues between them as follows:—(1) What is the nature of the invention which it is alleged the defendant has infringed—is it the arrangement for transmitting motion to the top rolling surface through the case or jacket surrounding it? (2) Is the plaintiff the first and true inventor of that? (3) Was it new and useful? (4) Did defendants infringe it? Connected with these issues we take it that it was admitted as a fact that the plaintiff had in July 1881 obtained a patent in Ceylon for "improvement in machinery or apparatus for rolling tea leaf," and had under that patent manufactured and sold a machine or apparatus called "Jackson's Excelsior"; and it was also admitted that the second defendant had on the 4th day of October 1888 (seven years and more afterwards) obtained a patent in Ceylon of "an invention for improvements in machinery for rolling tea," and that under the patent the first defendant Company with the license and authority of the second defendant had manufactured and sold a machine or apparatus called the "Triple-action roller"; and it was with regard to this machine that it was alleged the infringement of the plaintiff's patent had taken place. The learned District Judge has given judgment for the defendant, his finding on the respective issues being, as to the second issue, that the plaintiff was the first and true inventor of the machine "Excelsior"; as to the third issue that it was a novel and useful machine; and as to that part of the first which referred to infringement, that the defendants have not infringed plaintiff's particular right to the transmitting of motion to the upper rolling surface through the case or jacket. Now as regards the first issue, it is to be observed that there is no definite finding of the learned judge as to the first part of it—

"WHAT IS THE NATURE OF THE INVENTION?"

On it must necessarily depend all the other issues, particularly the fourth—did the defendants' machine infringe the plaintiff's patent? I take it for granted that the nature of the plaintiff's invention is, by peculiar mechanical means and contrivances developed in a machine, a manner of rolling tea is secured to be substituted for, and made to resemble tea rolled by the human hands. If this is so, then it follows that we may assume that the direct findings of the District Judge involve the further finding that that was the nature of the invention of which the plaintiff was the patentee inventor. The District Judge has, as I have said, directly found that it was a new and useful invention. He also has found, as I have said, that in the particular specified in the first issue, the defendants have not infringed the plaintiff's patent. On the fourth issue Did the defendants infringe the plaintiff's patent as a whole?—the learned District Judge has either come to no distinct finding or, if I am to treat what he has said as indicating what his finding should have been, it was, as I shall hereafter show, that the defendants' machine was an infringement of the plaintiff's patent. I do not forget that under the 20th section of the Inventions Ordinance it is provided that in suits for infringements the plaintiff shall deliver particulars of the breaches complained of in the suit, and at the trial no evidence shall be given in support of any infringement which shall not be contained in the particulars. I do not understand that an infringement occurs if one machine is made on the pattern of another, or if one part of a machine is adapted to another, unless it is as well used as such to the plaintiff's damage; it is the use of the machine as well as the making of it to which the words "particulars of infringement" must relate, the acts of making and utilizing which entitle the plaintiff to damages, and not to the particular parts only of one machine which may be pirated but not utilized. Now, although in the plaintiff's particulars he asserted that the machine which the defendants imported and sold possessed

A PECULIAR ARRANGEMENT

which his machine possessed, I cannot understand that he was thereby restricted to show only in that respect that his patent had been infringed. Therefore, besides the particular issue—Was the motion transmitted in a particular way an infringement?—there was as well the general issue stated fourthly by the District Judge—Had the defendants infringed the plaintiff's patent?—Had they made and sold a machine or machines which infringed the special privileges of the plaintiff's machine? Both in the Court below and in this Court in appeal the defendants laboured this issue and endeavoured to show that their machine was an improvement upon another machine used in India known as the "Standard" but not patented in Ceylon. It is authoritatively said "that provided the particulars of breaches give the defendants a fair idea of the case to be made against him they will be sufficient if they refer to specific claims and specify certain machines of the defendant as an infringement of those claims, and it is not necessary that they should state by reference to page and lines what portion of the specification has been infringed." I don't therefore think that either party can now treat that issue as not fairly within the pleadings; they both consented to it being raised and they both dealt with it as embracing the contest between them. Where a question arises as to the infringement of a patent, the substance and not merely the form of the invention will be looked into in a Court of Justice, and where it is shown that two machines are alike in principle and that the construction of the second machine has carried the principle into effect by substituting one mechanical equivalent for another, it will be held that that is an infringement. (Thom v. Worthing Skating Rink Co., L. R. 6 Ch., D 415; Adair v. Young L. R. 12 Ch. 21.) I now proceed to deal with the issues as contested and found. I prefer taking the second and third issues first, inverting their arrangement in the Court below which

PUT THE CART BEFORE THE HORSE

—(2) Was the plaintiff the first and true inventor? (3) Was the invention new? The learned District Judge has found both these issues in plaintiffs favour, and I don't think we are prepared to say that finding was wrong. We may here revert to our Patent Ordinance again. In the interpretation clause (36) "the word inventor" when not used in conjunction with the word "actual" shall include the importer of an invention not publicly known or used in Ceylon"; or by section 17, an invention shall be deemed "a new invention within the meaning of this Ordinance if it shall not before the time of applying for leave to file the application, have been publicly used in Ceylon." In the words of an old authority "if the invention be new in England, a patent may be granted though the thing was practised beyond the sea before, for the statute speaks of new manufactures within this realm, so that if it be new here it is within the statute, for act intended to encourage new devices useful to the kingdom and whether learned by travel or by study, it is the same thing." The machine called the "Standard" had never been patented here; the necessity for such machines must necessarily have existed only in connection with

THE TEA INDUSTRY OF VERY MODERN DAYS

and there is nothing to show that any such machine had been publicly used in Ceylon before. The "Excelsior" certainly contained principles and combinations of principles of a distinct character from, but used to produce the same effect, as in the "Standard," but novel as regards the "Excelsior" and I do not doubt that the plaintiff's patent was for a new machine in Ceylon as developed in the "Excelsior," and that he was protected by his patent in the substance of his invention as well as in the particular novelty of any portion of it, and these two issues have been properly decided in the affirmative. I may pass over the issue of utility: the fact of its being in demand for the purposes for which it is intended, may be accepted as proof of its utility. Then we come to the

ALL-IMPORTANT

first issue—what is the nature of the plaintiff's invention? I cannot answer this question, other than I have already done, viz. that by a combination of mechanical appliances and apt arrangement in a machine, amongst which is a case or jacket and two corrugated surfaces, top and bottom, acting on each other horizontally, one of which is confined within the case or jacket, the driving power being by any motive force acting upon wheels and cranks, to obtain as nearly as possible, by a machine, the result on tea leaves submitted to the machine, which is obtained in China by the manual process of passing or rolling the leaves through the palms of the human hands. One of the

PRINCIPAL NOVELTIES

which the plaintiff claims in his specification is the arrangement of transmitting motion to the top rolling surface through the case or jacket surrounding it, whereby such rolling surface is left free as regards vertical movement from the mechanism operating it; and one of the issue, perhaps the issue most strongly contested was—does the defendants' machine infringe this particular novelty? The learned District Judge has, in our opinion, fallen into error on this point more perhaps from a too literal reliance on what the scientific witnesses said rather than from the actual bearing of the evidence itself. Both Major Day and Lieut. Brown refer to the plate or hand encircling the case as the connecting rod, although anything less like a rod than the bit of iron in question it would be difficult to imagine, but in the language of specialists it is easy to understand that the name is applied to it because of the function it performs, and I do not understand these witnesses to say that because this plate performs the part in mechanics which is assigned to a connecting rod, that therefore everything connected with it can only be called a connecting rod, and that it is not possible to speak of "case or jacket" as including the four-sided box from

lid to bottom and through which the upper rolling surface passes. The specification alludes to the case or jacket surrounding the upper-rolling surface. It could never have intended to mean only one side of the box or the top or bottom of the box. Is there anything in the specification to restrict those words to the mere wooden or metal lining of the case itself? We have no doubt upon this point; it would be idle and

CONTRARY TO COMMON-SENSE

to say that plaintiff called only one part of his case "the case," because that part was made of wood; but it is still more repugnant to common-sense to urge that the thin cylinder of metal which is inserted as a lining to the cylinder of the defendant's machine and which confines the upper rolling surface and which is movable at will, corresponds to the "case or jacket" of the plaintiff's machine. We hold against both these contentions, and we hold that what is called the "cylinder" in the defendant's machine is nothing more nor less than the "case or jacket" of the plaintiff's machine, from its top edge to the bottom, both inside and out. Then, has the defendant's machine infringed the principle upon which motion is transmitted to the upper rolling surface? After much and most anxious consideration I have come to the conclusion that it has, and that in this respect the one machine is the counterpart of the other. The gearing is the same, the cranks are the same, and the motive power thereby transmitted operates with the exception directly referred to, on the upper rolling surface in the same way. For the defendants it was contended that it did not operate in their machine through the lining of the cylinder which it was urged corresponded with the plaintiff's case or jacket. We repeat, the two things are manifestly distinct. We say the defendants' cylinder is the corresponding part to the plaintiff's case or jacket, and that in both machines linear motion is conveyed to the upper rolling surface by reason of its connection with the jacket in the one case, and with the cylinder in the other. The square sides of the rolling surface in the plaintiff's machine which are acted on by the jacket pushing them to give it motion, correspond to the circular surface of the vertical shaft in the defendants' machine which starts out of the upper rolling surface called the lid, and is acted on by the connecting bracket of the cylinder pushing the shaft from side to side or eccentrically to give the lid or upper rolling surface its motion. But if the model machines before us are to be relied on there is even not that difference between the two machines, because the rolling surface of the defendants' machine has as well a vertical shaft attached to it which passes through a bracket and embraces the jacket in the same way as the bracket embraces the cylinder of the defendants' machine, and by which motion is conveyed to the upper-rolling surface by the bracket in contact with the vertical shaft. What is the evidence of the defendants' own specification on this point? It says "The pulley connected with the 'lid' causes it to revolve inside the hollow cylinder while at the same time it has the eccentric motion imparted to it by the hollow cylinder." For "lid" read "upper rolling surface," and for "cylinder" read "case or jacket," and you have the defendants' machine described in precisely the same words as the plaintiff has specified his, and so important was this piece of evidence, and such was its

ADVERSE BEARING UPON DEFENDANTS' CONTENTION,

that one of the defendants wished to make it appear that it was a mere clerical error by which "by" had been written for "of." In this respect therefore we hold that as this particular result was novel in its application to the plaintiff's machine and was embraced and particularized in the specification of his invention, it was not competent to the defendants to appropriate it to any machine of their own. There is one difference as we have said between the action of the two machines, and it is this: that whereas the plaintiff's machine accomplishes but two surfacial motions that of the de-

endants' has three leading to its appellation "Triple-action roller." This super-added third motion is doubtless new to the plaintiff's machine, but it cannot exist independently of it, and cannot be regarded in any other light than as an improvement or application to the plaintiff's machine, and in that respect it might be the subject of a patent right, but the defendants could not use or apply it without the license of the plaintiff. This brings us to the last issue, one of fact, upon which we are called to perform the functions of a jury. We have already said that if we take the learned District Judge's expression of opinion upon it as indicating how it should be decided, it must lead to a finding in favour of the plaintiff. This is what the learned District Judge has said—we quote from his judgment—"As the Excelsior was an improvement on the 'Standard,' so the 'Triple-action roller' is an improvement on the 'Excelsior,' and is decidedly a far more efficient and satisfactory machine." This finding of fact would necessarily lead to judgment against the defendants, for while the plaintiff had a perfect legal right to appropriate to himself and secure by patent all the novel and useful mechanical contrivances contained in the "Standard" which had never been patented here and in which no public use had been acquired; so soon as he had done so, shut the defendants out from the appropriation of the same invention, and it was not possible for the defendants to have patented a mere improvement on his (the plaintiff's) invention, independently of the plaintiff. Looking at the two machines and working them side by side, and bearing mind the identical purpose which both are intended to secure, I am unable to come to any other conclusion than that the defendants' machine is the result of an adoption of the mechanical principles and contrivances which found practical adaptation and arrangement in the plaintiff's machine varied no more than in non-essential form, but with certain improvements made by the defendants and which are practically useful only in connection with it. The plaintiff must therefore have judgment and the case must go back in order that the District Judge may deal with the prayer for accounts and for damages.

JUSTICE LAWRIE'S OPINION.

JUSTICE LAWRIE said:—I agree. The plaintiff has by his patent an exclusive right to sell tea rolling machines in which motion is transmitted to the top rolling surface through the case or jacket. The best evidence in this case proves that the case or jacket is the sides which surround the upper roller, which form a space or box into which the tea leaf is poured and which keeps the leaf together while it is being rolled between the surfaces of the two rollers. The projections which connect this case or jacket with other parts of the machine have been called by some of the witnesses a connecting rod, and in a sense that part of the projection which joins the case to the gearing is a connecting rod; but the better part of the evidence, and I think

A REASONABLE USE OF WORDS,

leads me to the conclusion that a part of the jacket is the thickened band which passes round the case or jacket and which at once serves to connect it with the gearing and to give it strength. I do not include as part of the case or jacket, the bow bracket, spindle, &c. By "through" I understand "by means of." If this meaning were attached to the words "case or jacket" there would be but little difference of opinion between the witnesses, and I think that all would agree that in the Triple-action roller the motion is transmitted to the upper roller by means of the case or jacket if case or jacket includes as much as I hold it does. The motion is not transmitted precisely at the same place or in the same way in the defendants' machine as in the plaintiff's, though I confess I agree with those witnesses who are unable to see much difference; but the exact way in which the motion is transmitted is not the question. The question is—Is the case or jacket whether

it be made of wood or brass or iron the structure through which the motion is transmitted in the defendants' machine?—and that question I answer in the affirmative. The rotatory motion imparted to the upper rolling surface which is not in the plaintiff's machine, is transmitted by gearing above it, but that gearing rests on and is attached to the case or jacket. The defendants lay stress on the part taken by the bow brackets, but these also rest on the case or jacket. Even if in the Triple-action roller no part of the upper-rolling surface comes in contact with the jacket in any other way than that the spindle which passes into the roller is connected to that jacket by the two bows, still this communication transmits motion to the rolling surface and in the transmission the jacket plays a necessary part. The upper rolling surface has a horizontal as well as a rotatory motion and that rotatory motion is given to it by means of the jacket. The weight of evidence proves that the two machines are

ALMOST IDENTICAL.

and this evidence is consistent with the impression which a study of the models has made on my mind.

THE PLANTING ENTERPRISE IN THE DISTRICT OF MATALE.

A report from the Government Agent of the Central Province with no mention of the planting enterprise, is surely the closest of possible approximations to "the play of Hamlet, with the part of Hamlet omitted by special request." The omission may be due to the fact that Mr. P. A. Templer took charge of the Province late in the year. Not only is there nothing in the report on the Kandy district about the position and progress of planting, but the same silence in regard to the great enterprise of the colony marks the report on the Nuwara Eliya district. That we have information regarding the position of the planting enterprise in the district of Matale is due to Mr. Hugh Fraser, with whom tea on Bandarapolla has been such a marvellous success. We recently wrote of the district of Matale as fallen from its once pre-eminent state as a coffee producer, without having as yet retrieved its fortunes by means of tea. The description is essentially true, although Mr. Fraser shows that good progress has been made with tea, and that no district in the island has been more successful in the cultivation of cacao. The statistics for coffee place the poor old dethroned monarch in a far worse position than we imagined. To those who remember Matale, West and East, the Kelebobka Valley &c. in all their glory as coffee yielders, how melancholy must it be to contemplate the remains of a deceased potentate represented by such figures as 944 acres yielding 1,159 cwts. or at the rate of 1.23 cwt. per acre! But there are 70 acres out of the 944 young and not in bearing, 53 acres having been actually planted in 1891 by some enthusiast who believes that "there is life in the old dog yet." But, oh! we see it is not the old Arabian dog but the young Liberian. Let us hope that the 13,517 acres of tea, yielding 3,607,000 lb., and the 3,806 acres cacao yielding 6,272 cwt., are but harbingers of a time when the glories of the coffee era shall be excelled by that of "new products." Much of the district is so low in elevation that the climate is suitable for the cultivation not only of *Theobroma cacao* but of the coconut palm (*Cocos nucifera*), so frequently confounded with the chocolate shrub by people "at Home." With so many and varied resources there is no reason why Matale should not flourish, although the decree has gone forth and is made absolute, that railway extension northwards shall not start from the station in Matale town, but from Pol-

gahawela and Kurunegala. We can understand what Mr. Saxton says about gingelli, an oil-yielding plant, not flourishing on recently exhausted chena soil. But *per contra* to what he writes about paddy fields being injured by silt from estates, we have in another administration report a complaint by a native headman that since the abandonment of coffee estates, the paddy fields below them, failing to receive, as of old, welcome supplies of manure washed down from the estates, have failed to yield at their former rate. The portion of Mr. Saxton's report on the Matale District which deals with "CULTIVATION" is as follows:—

Mr. H. Fraser, of Bandarapolla estate, has favoured me with the remarks below about various products.

I had sent a circular to all the planters in the district with the object of obtaining accurate figures for the Blue Book return, but my efforts did not meet with universal response, although I had promised to treat the individual returns as confidential. Mr. Fraser has been more successful, and the result of his inquiry is embodied in the statement annexed to his remarks. It contains more accurate figures than those I sent in for the Blue Book return.

As I have previously stated, a good deal more paddy land has been cultivated this year than in preceding years. I have issued several esweddun licenses, most of them for lands which have been out of cultivation for a considerable time. There are also a few applications for the restoration of more tanks, as people see the benefits derived from those already restored.

There is hardly any tea cultivated by natives, the only piece I know of being a small garden on the Elkaduwa road planted by an estate kangani.

It is impossible to say how much cacao has been planted, but there is immediate application for the seed as soon as I receive a parcel from the Peradeniya Gardens. There has been a good deal of gingelly (tala) cultivation, which is somewhat of a novelty; but the general impression is that it requires new soil, and does not give a good return on chena land recently cultivated.

The cultivation of garden produce must have declined in some places where the owners of land have been selling their properties to planters, as at Ukkuwela, Warakamura, and other places. Frequently they sell right down to the edge of their fields, leading to their paddy being covered up with silt from the new clearings.

Jak and mango and other trees are being ruthlessly cut down for estate purposes, and no one takes the trouble to replant any. I tried to get rid of a large number of jak seedlings from my own grounds, but no one thought the offer worth accepting.

Mr. Fraser writes as follows:—

TEA.—Although not all equally well grown in all the divisions of the district, yet in most localities near and far apart, it has become thoroughly established, and there are well authenticated figures of yields in old coffee and chena lands, in third and fourth year of plucking, of from 450 to 750 lb. an acre.

The total area under tea, young and old, in the Revenue District of Matale, is approximately 13,517 acres, producing 3,607,346 lb., averaging 266 lb. per acre.

Deducting 1,540 acres young tea from the total area, 13,517=11,977 acres plucked, averaging 301 lb. per acre.

Six hundred and fifty-seven acres have been added during 1891 to the area under cultivation in tea, divided over all the districts, but principally in Laggala, Matale East, Matale North, and Ukkuwela.

It is quite apparent, should tea continue to be the important staple it is at present, that the Matale Districts have as long a lease of prosperity before them as any quarter of the Island.

Cacao is another product which has helped Matale to compete successfully during recent years in the struggle for existence, and there are magnificent expenses of this cultivation in several portions of the district. The area under it is approximately 3,806 acres, producing 6,272 cwt., averaging 1.65 cwt per acre.

Deducting 726 acres young cacao from the total area, 3,806=3,080 acres, averaging 2'04 cwt. per acre. The total quantity is about one-third of the whole annual export from the Island.

Five hundred and twenty-two acres have been added during 1891 to the previous area, principally in the Ukkuwela District.

In its youth cacao, like many other useful products, requires and deserves a good deal of care and attention, and this may be one of the causes of its not being more adopted by the villagers; but seeing the troubles are not unsurmountable, that good seed is procurable at reasonable rates, occasionally given gratis from the Kachcheri, that the arts of successful cultivation are now well understood, and that good prices (R60 a cwt.) are obtainable at their doors for quite inexpensively and primitively cured produce, it is well worth the increased attention of the villagers, who invariably have, in even the poorest localities, suitable space enough for small gardens of it.

Tea they do not at all, so far as is known to me, affect. This is not I think, to be regretted; on the contrary it is well it is so.

The original expenditure necessary is in most cases prohibitory, and even when this is got over the leaf might not be well enough manufactured to keep up the reputation of Ceylon tea; and I anticipate that after a time there would be no sale for the green leaf at large factories, as their owners would soon tire of buying their own leaf mixed with that of the villagers, which would almost certainly be the case.

The villagers, however, male and female, I am glad to say, to the mutual benefit of themselves and the planters come much more readily than formerly to pluck, prune, hole, weed, and do all other estate work on the same footing, at the same rates, and same tasks as the Tamils.

I am aware of a recent instance where a rather intelligent, elderly man, owner of some cattle, proprietors of some acres of land, and shareholder in some small gardens, was most anxious to succeed a Tamil man as tappal and beef-box cooly, saying that the constant employment and regular pay which enabled the Tamil to "eat" (live) better was having a great effect on the modern Sinhalese, who have begun to appreciate the opportunity of "eating" (living) like the Tamils on estates. On some estates the Sinhalese are paid daily, weekly payments being, however, more common at a fixed rate per lb. for tea plucking, which is the fairest mode for all concerned.

They sometimes come by themselves, singly or in families, but generally they are brought by a kangany of their own class, which is an unavoidable necessity under the circumstances.

Were they not so poor they would probably be better off without kanganies, but as it is, the kanganies know them, collect them, and advance them small sums (for "selavu" or "viyadam"), which are fully repaid, they, not unfrequently, being so poor that they have to be advanced money the previous day to procure the meal of the following day, otherwise they are unable to come to work.

COCONUT cultivation does well in Matale, and can be profitably encouraged and extended. It is almost a native cultivation at present, but it is being adopted in suitable situations on several estates. Cotton and tobacco may be said to have become a blank for the present. There are some fine fields of tea in Matale from which heavy crops of tobacco have been taken.

COFFEE (Liberian, Arabian, and Coorg) is cultivated, but on a very reduced scale. The acreage has, however, been added to in 1891 by 53 acres.

The total area is 944 acres, yielding 1,159 cwt., averaging 1'23 cwt. per acre.

Deducting 70 acres young coffee from the total area, 944 acres = 874 acres, averaging 1'32 cwt. per acre.

The cultivation will most probably pay in suitable positions and conditions of soil at present rates.

CARDAMOMS.—This cultivation is decreasing rather than extending, all suitable land for it having been fully planted years ago. The acreage under this spice

is 671 acres, yielding 57,875 lb., averaging 86 lb. per acre.

There are 140 acres cinchona, 350 acres anatto, and 30 acres arecanuts under cultivation in various portions of Matale East.

The cultivation statistics are compiled from returns obligingly supplied by fourteen planters residing in different portions of the district.

PADDY.—The rainfall of 1891 is said to have been too much for the paddy crops. Paddy land has shared in the general depreciation of property in recent years. I am aware of a sale of 5 acres for R1,000. A dozen years ago the same land would have fetched R2,000.

TIMBER.—This is becoming a serious question in Matale, accessible places being almost denuded of large trees. A deal of money must have reached native hands by the sale of timber in recent years. Not a seed or plant is being put into the ground for future needs, and this source of income will very soon utterly fail them. They have few others to fall back upon.

GENERAL.—By this time the beneficial results of the Agri-Horticultural Shows of a few years ago, if such are to accure, should be becoming apparent. There is undoubtedly an increased demand from outside for fruits, vegetables, fowls, and eggs, but I am not aware that the people of Matale have risen to the occasion in trying to produce either increased quantities or improved qualities to any appreciable extent.

It might be worth inexpensive experiment in the interest of the natives were good eggs and fowls occasionally distributed from the Kachcheri, gratis, for breeding purposes, and were the natives occasionally encouraged by remunerative rates to bring to the Kachcheries sample lots of their best efforts in fruit and vegetable growing and fowl rearing.

CEYLON TEA IN AUSTRALIA.

The Sydney Daily Telegraph of 24th August records a little business in Ceylon teas at from 10½d to 12d; and the same paper in its issue of 27th August announces the sale of 40 chests Ceylon at 8½d to 9d. The Melbourne Argus of 29th August says:—

Ceylons have had steady attention at late rates. The Custom-house statement of receipts and deliveries of tea at the bonds for the last week, together with the stocks in bond at the close of the week, is as follows:—

	Receipts into Bond.	For Home consumption.	For Export.	Stocks on Aug. 20.

CONSULAR REPORTS.

MACAO.

Mr. H. B. Joly writes the British Consular Report on the trade of Macao for the year 1891, which Mr. Watters forwards. Mr. Joly writes:—

The year 1891 has been, so far as trade is concerned, a very uneventful one, business having continued in the same groove, presumably with some falling-off, as the export of tea and rice was below former years. As regards imports, the usual average must have been attained, as the supplies necessary for the consumption of the colony and neighbouring districts continued to arrive.

EXPORTS.

Tea.—Tea appears from year to year to lose ground and to feel more and more the competition from India and Ceylon. Lower prices than heretofore ruled during the last year, but none the less, no great profits seem to have been realised. Indeed, heavily handicapped as the teas exported from Macao are, not by duties here, as this colony is a free port, but by inland imports levied by the Chinese authorities, they can with difficulty hold their own, and would seem to be doomed to a heavy shrinkage. The quantity exported during 1891 amounts to about 155,000 chests, and falls short of that of 1890, so that this branch of trade, which was once the most important here, gradually becomes more and more insignificant.—L. and C. Express, Aug. 19th.

NOTES ON PRODUCE AND FINANCE.

TEA PLANTING IN WYNAAD.—A writer in the Madras Times takes a very favourable view of the outlook for tea planting in the Wynaad, and he winds up by saying:—"Wynaad has, unfortunately, an evil name in the London money market. So much capital was collected and squandered in the gold mania of a previous decade, that it is thought that no good thing can come out of it. But this prejudice is being gradually overcome, and we may hope to see the district rise again before long to something of its former success. New blood and new capital will again flow in, to the encouragement of the old planters who have survived the many vicissitudes of the past, and of whom the planting community of Wynaad mostly consists." He is quite right about the prejudice. The sons and daughters of Mammon, when they have a prejudice, show considerable persistency in holding on to it. That unfortunate gold business created an unfavourable impression in London, and the mention of the Wynaad even now provokes strong language in certain circles, who are quite ignorant of the fact that tea is grown there, but associate it only with mining speculation. The district will live down its bad name, no doubt, and we hope that tea will flourish and renew confidence.

PURE TEA.—The Grocer calls attention to the care taken by the Customs authorities that only pure tea is sold to grocers and the public. It says:—"If the article be not pure it is not permitted to enter into consumption in this country. Under Section 30 of the Sale of Food and Drugs Act, tea is analysed at the Custom House, so as to ensure that there is nothing in the shape of adulteration in the imports; and if the same plan were practised in regard to one or two other commodities that might be named, retailers certainly would not feel disposed to complain. We subjoin a table showing the results of the analysis of tea conducted at the London Custom House, in accordance with the statute above mentioned, during each of the last ten financial years:—

Importations represented by these samples thus disposed of.

Submitted for board's directions with following results.

Year ended March 31.	Samples analysed.	De-livered on certificate of analyst.	Allowed to be admitted for home use.	Allowed to be delivered for exportation only, but not for use as ships' stores.	Admission refused.

PLANTING IN NORTH BORNEO.—The prospect in North Borneo seems more cheerful. Pineapples are for sale in abundance at two cents each, if anyone likes to start a pineapple jelly factory. Pepper and coffee growing by the Dyaks is receiving the attention of the Raja, who is parcelling out land in the Lundi district, where tobacco has been grown. Ten piculs of coffee grown in gardens in Sandakan and another shipment of North Borneo coffee have also been sent home. The trial shipment of ten piculs of Liberian coffee grown in gardens at the back of Sandakan and shipped by the Development Corporation has been very well reported upon in London, and valued at 93s per cwt. if properly dried. Coffee, sugar, copra, tanning material, Manila hemp, and paddy are all products of world-wide demand and likely to afford material for export; and now a start has been made in the right direction. Cocoa, pepper, indiarubber, gambier, and other things are being tried, and experiments are being made with three descriptions of cotton—Shanghai, Sea Island received direct, and Sea Island already acclimatised in a tropical country. Of these the acclimatised Sea Island is doing the best.—H. and C. Mail, Aug. 26.

BRAZILIAN COFFEE.

Brazil has just broken her own record with regard to the production of coffee. The crop of the season just closed is declared to be the largest yet known. The total shipments during the twelve months, including the stocks left over at Rio and Santos on June 30, are estimated by Messrs. Alexander von Glehn & Co. at 7,530,000 bags, as compared with 6,705,200 bags for the year ended June 30, 1889—the previous largest crop on record. Favoured by the big crop and lower prices, consumption has nearly kept pace with the increased production, deliveries showing an advance of about 1,000,000 bags during the year, so that stocks in European ports at the beginning of the present month were not more than 87,285 tons, against 64,526 tons on August 1, 1891.—Colonies and India,

INDIAN TRADE PRODUCTS.

Referring to the catalogue of the articles of Indian commerce by Dr. George Watt, Professor of Botany in Calcutta, *The Times* says:—"We have thus at last obtained an exhaustive account of the economic products of India, done with scientific accuracy and a fair amount of local knowledge, arranged in the simple alphabetical order. The task proved of too great magnitude for a single worker, and since the appearance of his third volume in 1890 Dr. Watt has had the assistance of Mr. Dunthie, director of the Botanical Department of Northern India, together with two other experts belonging to the Indian Medical Service. The leading impression left by an examination of this Encyclopædia, or, as Dr. Watt modestly terms it, Dictionary of the Economic Products of India, is the large number of valuable articles of local Indian trade which still remain to be utilised by European commerce.

"That the work has, so far as the materials permit, been done with care and completeness is attested by every volume. For example, an idea of the information given under the camellia, or tea-plant, may be formed from the fact that the mere references to the works consulted almost fill three closely-printed pages. The articles on cochineal, the cocoa-nut, coffee, and the jute plant (*corchorus*) are each of them admirable for their wideness of research and valuable for their commercial information and statistics. The elaborate notice of cotton (*gossypium*, Vol. IV.), runs to 173 pages. It clears up several obscure and disputed questions of the past, while it affords a clue to practical methods for improvement in the quality and length of the Indian staple in the future. The immense importance of this product may be estimated from the fact that the total value of the cotton trade to India works out at sixty millions sterling per annum.

"Two other articles of capital importance deal with indiarubber and indigo. The former narrates the series of experiments at acclimatizing the tree in India, and the success obtained. The notice of indigo is particularly instructive. It shows that the weak points in the present system of manufacture in Bengal are to a large extent due to ignorance of the chemistry of the substance and to unacquaintance with the chemical principles which underlie the isolation and preparation of the colouring matter. A suggestive article in the same volume, under the heading of 'Introduced Plants,' will repay careful perusal alike from its scientific and its commercial aspects. The elaborate account of flax (*linum*, Vol. V.) has a special economic value, as it deals with the old standing failure of India, while abundantly growing a linseed rich in oil, to enter the world's markets as a producer of flax-fibre. Under the collective title of narcotics is given a detailed list of the articles used in India to produce narcotism or intoxication, and the extent of the traffic in each. A reference to the separate headings will convince any person who is still unconvinced, yet open to conviction, that one of the greatest immoralities which we could perpetrate upon the Indian peoples would be to prohibit the use of the comparatively innocuous opium and to force them back on the more baneful alternative drugs. The article on the opium plant (*papaver*, Vol. VI.) has already attained the dignity of a Parliamentary paper, and was noticed in our columns last October.

"The great mercantile questions involved in the Indian sugar trade are dealt with in the most elaborate exposition which has ever yet appeared of the subject (Vol. VI., Part II.) The article traces the history of sugar in India from remote times, and narrates the various unsuccessful efforts, arranged in three separate periods to establish sugar planting as a European industry in that country. The lesson which Dr. Watt desires to convey is that those failures were not a matter of necessity, but mainly the result of a disregard of the conditions of India and of the capabilities of the native sorts of cane. Vast sums were spent in vainly trying to acclimatize exotic races of the plant, and in unwise endeavours to introduce foreign systems of cultivation and refining unsuitable to India. This, in-

deed, is a subject in regard to which Dr. Watt's volumes are pregnant of instruction on other matters besides the manufacture of sugar. Too many of our efforts to improve the agriculture of India have been based on the false assumption that progress must come from without. Dr. Watt holds, on the other hand, that the careful cultivation of well-selected indigenous stocks would, in the case of sugar at any rate, develop a cane as rich in crystallized sugar as any that can be found in the world. The conclusion is forced on us that the acclimatizing system has had a long enough opportunity of doing what it can for India, and that a systematic survey of the existing resources of India should now be undertaken with a view to improvement of the native plants and fibres.

"Meanwhile, it is important to obtain a clear view of the effect of European competition on the Indian sugar industry. From the very elaborate statements reviewed by Dr. Watt it appears that the cheapest foreign sugars imported into India have been unable to undersell the article in common use among the people. The Indian refineries have, indeed, keenly felt the competition of foreign sugars. But the Indian cane-growers have not suffered. Owing to fall in the price of *gur*, the raw sugar used by the bulk of the people, consumption has increased and the area under the crop has largely extended. Dr. Watt estimates the value to India of her sugar industries, including the palms cultivated for this purpose, at 20 millions sterling a year, and the annual output at 2½ million tons of coarse sugar. The import from foreign countries brings up the total to three million tons. This represents a quantity of the refined article equal to more than one-half the total consumption of the continent of Europe, excluding the British Islands."—*H. and C. Mail*, Aug. 26th

ORCHID TEA.

One would not look to the *Kew Bulletin* for a hint upon French customs. But some who have been thinking themselves familiar with the ways of Gaul may be surprised to learn from that recondite periodical that a tea of orchid leaves has long been popular across the Channel. There is record of it fifty years ago as a beverage fairly well established, and of late consumption has increased. The sagacious and enterprising people of this country are always glad to hear of something new for the tea-table, and acquaintance with this boon should not be confined to the readers of the *Kew Bulletin*—a peculiarly estimable class, but limited. The mere name of orchid tea has something lordly and impressive in its sound. We fancy a millionaire consigning plants worth their weight in gold to the housekeeper's room, there to be stewed and served up for royal guests. It seems a revival of the luxury of old Rome. Vitellius should have drunk Orchid Tea at his feasts. Cleopatra should have dissolved her pearl therein. It is a theme for the invective of those guileless moralists who denounce the unparalleled extravagance of the Upper Classes.

Looking more closely, however, we fail to see anything really wicked in the fashion of orchid tea. The article is genuine enough. It is not compounded of some homely weed which botanists alone identify as akin to the gorgeous *Cattleyas* and the stately *Dendrobis* of the Tropics. The orchid from which this tea is made is a member of one of the handsomest and most expensive families—the *Angraecum*,—and a very pretty member too. It grows in the forests of Bourbon and Mauritius and the scientific know it as *Angraecum fragrans*. Probably the natives have been using it for ages. Incidentally we may remark that those who fear the extermination of the nobler orchids may find solace here. If a small species, occupying a very narrow area, of which flowers and leaves alike are eagerly stipped, can hold its own for generations, there is not much cause to dread that the most ruthless of collectors can do worse than retard for a little while the increase of more showy species which are quite as prolific.

The commercial virtue of *Angraecum fragrans* lies in the strong perfume of its leaves. The genus is allied to vanilla—also an orchid, of course

—and in this instance the kinship displays itself. It is enough, we read, "to touch the fresh leaves for the fingers to remain impregnated with the aroma," which remains when the leaves are dried. This process is as simple as could be, apparently. No heat is applied, no colouring matter. Describing samples at Kew, the *Bulletin* observes that they are unshrivelled and as "flat as we should find them in any herbarium." And the decoction is equally simple. You just lay the leaves and stalks in cold water, about one gramme to a tea-cup—more or less according to taste—close the vessel tight and boil for ten minutes. It may be sweetened; milk and rum bring out the flavour of the vanilla more strongly. It is as good cold as hot and may be warmed up without deterioration. Finally, we are told that material enough for fifty cups is sold in Paris for 2 fr. 50c., 105 cups 5 fr. It is called Faham, as in Mauritius.

The uses of orchids make an interesting theme for speculation. The list of those identified by European science is strangely brief at present. No large family of plants has so few members which serve a visible purpose; and if we regard the question proportionately this uselessness becomes far more striking. Not fewer than 10,000 species of orchids are known among which only twenty at the outside are credited with any virtue besides beauty. Some people hold in truth that this is all-sufficient. The enthusiast who thanked God—prematurely—that "those fiends the hybridizers" could do nothing with orchids, would ask no other merit. But a larger view may tempt one to suspect that flowers so conspicuous, so fitted in every way to draw attention, have more significance in nature's scheme. It is to be observed that Europe was not so much acquainted by sight with any epiphytall orchid a hundred years ago. Sixty years ago one could count the species grown upon one's fingers. Has any savant, chemist, or doctor made a study of these plants? We never heard of his labours. Out of three thousand species or so in cultivation have so much as a score been analyzed? It is suggestive to remark that the commonest of those which are found in the Temperate Zone—our field varieties of orchids—are highly esteemed from the Atlantic to the Pacific; more than that, the root of a North American species, one of the *Habenaria*, which proves to have very nearly the same constituents, was and is equally esteemed among the Indians. Our own forefathers reckoned *Orchis mascula* as one of their most important drugs. We have forgotten it; but from Poland to the Bosphorus, and again to the China Seas, it is still a panacea. Those who have visited Constantinople do not forget the droning cry "Saleep—saleep!" which pedlars of that milky substance raise the whole day through. If, discarding the tropic species, we take those plants of which our forefathers learned the use during countless generations, the great orchid family holds its own with any of them. We have reason to believe that the natives of India, and more especially of Africa and tropical America, could tell our scientific men some properties of orchids which would astonish them. But no one asks; perhaps he would not learn much if he did. There are so many ugly secrets in native medicine that the professors do not willingly communicate their lore.

Orchid tea is not accredited with vigorous properties of any kind. In Mauritius and Bourbon they esteem it as a digestive, and it is prescribed in diseases of the organs of respiration. Vanilla has the same merits in a higher degree, and many more. It is one of the most powerful restoratives known in cases of weakened vitality, when a large dose is given. South America in general shows a much lighter tendency to madness than any of the countries which may be called civilized. Statistical authorities attribute this fact to the ignorance and thoughtlessness of the population, but they themselves give the credit to vanilla. At the first sign of mental disturbance they ply the sufferer therewith. We are afraid to daunt the reader with a string of s-squipedalian names if we go further into a most interesting subject, the importance of which will be recognized on day. But for that consideration it

would be easy to name the species of orchid which are admitted to the pharmacopœia, though rarely, if ever, used in Europe. It would occupy but little space. Briefly, however, to cite the most conspicuous, a *Goodyera* is used in cases of scrofula, an *Epipactis* for inflammation of the joints, a *Gymnadenia* for dysentery, an *Arethusa* for toothache, a *Cypripedium* (American) for spasms. We venture to predict that when, if ever, the medical uses of orchids are investigated, this list will be prolonged indefinitely. And the additions will be startling.—*St. James's Budget* Aug. 26.

TEA—COFFEE—CHICORY—TOBACCO IMPORTED TO THE UNITED KINGDOM.

The Commissioners of Customs present a report for the past financial year which is satisfactory, if not indicative of exuberant national prosperity. The gross receipts for 1891-2 show an increase of £343,257, which might have been accounted considerable had not public opinion been habituated to leaps and bounds in revenue. Of late, however, British trade has manifestly not been in a condition to justify anticipations of indefinite fiscal expansion. The wonder rather, is after the melancholy tone adopted by many representatives of national industry, that the country has been able to consume goods liable to duty to the enormous amount implied in the receipt by the Custom-house of more than twenty million sterling. To a certain extent, no doubt, the payment in a particular year of vast sums in Customs does not prove the existence of the industrial activity which means that the kingdom is maintaining its ancient rank in the world. Men will not consent to starve, so long as they have a reserve of savings. Though British trade were afflicted with sudden decrepitude, the gross receipts of the Custom-house would continue for some time to be large. At present it is possible that the working classes, which contribute very much to the revenue from Customs as from Excise, may, out of their wages, have kept it at a level beyond that it could have preserved had it been dependent on the profits of capital. Wages are slower to feel the effects of a dwindling commerce than capital, and might go on feeding the revenue after capital had lost not a little of its vitality. At the same time, that is merely a matter of a year or two at most. Within no long period wages could not but obey the downward impulse; if it were of a permanent and serious character. The interval has been more than enough, since lamentations for depression in trade began to be heard, for the effect to be very visible in the receipts from Customs all around. The country has a right to infer, from the testimony of the Commissioners of Her Majesty's Customs to the persistency, and even increase, of the revenue from imports, that the spending capacity of the people cannot have as yet diminished. Practically this signifies that industry remains positively fruitful, though, it may be, not profitable at some former rate of increase.

One fact in the history of the past financial year the Commissioners mention as a reason, it seems, why the period does not call for exceptional attention which in reality distinguishes it emphatically. "No alteration," they record, "was made in the Tariff." Probably in not one of the thirty-five previous reports of the Department can such an assertion be found. That the statement is made nowadays much for the discretion of the outgoing Chancellor of the Exchequer, and much also for the simplicity to which the Tariff has been reduced. Fiscal changes which are not necessary are noxious. When publicly and commercially beneficial they are sure

to cause a good deal of personal inconvenience, and often hardship. If they be superfluous, the vexatiousness to individuals has no compensation. The absence recently of any clear demand for modification arises from the thoroughness with which relief to the subject has already been granted. For a succession of Administrations the Tariff has been submitted to the severest inspection, for the discovery of imposts which trouble consumers without material advantage to the State. Gradually one after another has been eliminated till virtually none remain which the Treasury, in the absence of some sudden new breeze of prosperity could relinquish in whole or part. There are but three main sources of Customs revenue left. Tobacco yielded last year in duties £10,135,666 being more than half of the entire amount. Tea gave £3,424,830 and spirits, foreign and colonial, £4,642,638. Thus less than two millions sterling have to be put to the account of all the other items still contained in the British Tariff. The only appreciable benefit to consumers which could be derived from further concessions in Customs must come if at all from additional curtailments, or from the total abolition, of the duties on spirits, tea, and tobacco. At present it is evident that the State needs the money. If it surrendered a portion or all of the income it raises from them, or one of them it would have to recoup itself elsewhere. On a review of possible heads of taxation it is difficult to see how it could equitably choose a substitute without flagrant violation of the principle that all classes of a community are bound to aid in the pecuniary support of their Government and institutions. Unless by the payment of duties on the tobacco they smoke, and the tea and spirits they drink, the masses of the people contribute nothing from their pockets. They ought to contribute; and it is not easy to perceive how their *quota* could be more equitably assessed than by the actual distribution of the load over the heads we have named. For the general good of the nation, and, in particular, of the consumers themselves, it might be wished that the smokers and imbibers of strong liquors should consent to a transfer of the value of the duties on tea and analogous imports to the articles they favour. The impediment to the realization of that agreeable and remote prospect is that, should it ever be attained, it would only be through the acceptance by the self-denying patrons of alcohol and smoke of tea instead, which must leave the Exchequer as much at a loss as before for an alternative to its present millions from the tea drinkers.

The Commissioners do not profess to have curious or remarkable incidents to relate of the past year. Still, no Customs report can be without subjects of interest. It is a mirror at once of the world outside and of the national life. A climatic disturbance in Asia Minor a twelvemonth ago was felt in English kitchens in the shape of a dearth of sultanias. A more even temperature there has now replenished the supply. Though the Exchequer has gained by an increase of home-made spirit, the Custom-house sympathizes not the less with the sufferers by the famine in Russia, which has interloped for human food the usual imports of cheap alcohol distilled from surplus grain. Similarly the Department has to lament the irruption of phyloxera into the Marne heightening the price of champagne and lessening the duty-paying imports. Of domestic phenomena reflected in the Customs statistics the chief are connected with tobacco and tea. The gross revenue from tobacco, which was never so high, exceeds that for the year before by £417,882 and 1890-1 had itself outstripped 1889-90 by £503,157. The Commissioners are informed by experts that the receipts would have been yet

more had not influenza checked consumption in the last months of the financial year. For anti-tobaccoists the results are even more dismal than the figures suggest. According to the Commissioners, who speak in a congratulatory tone, the increased revenue has been drawn mainly from Western American tobacco. Being drier, it is smoked faster; so that more leaf is consumed, and less water. In tea the most observable phenomenon of the twelvemonth has been the rapid rise in the imports from Ceylon. It is forty-eight per cent, the increase being gained at the expense alike of Indian tea and of Chinese. For the first time Ceylon tea has exceeded China tea in quantity. Year by year China tea declines, and it is impossible to say where the decadence will stop. To a certain extent China planters and merchants might arrest the tendency by more care in cultivation, preparation of the leaf, and attention to European tastes. In general, though the best Chinese will always please delicate palates, the India and Ceylon kinds are certain to predominate popularly on account of their strength. To tea altogether, whatever the particular sort, the supremacy among non-alcoholic beverages is at all events destined. Once upon a time it would have appeared absurd to dispute the ascendancy of coffee; and for generations the conflict between it and tea proceeded on even terms. There is no sort of rivalry any longer; and the admirers of the elder beverage will not attempt to pretend to equality for it. They are at least entitled to remark with surprise as well as concern the periodical symptoms in successive Customs reports that it has not yet reached the bottom in its fall. For 1890-1 there was an increase in the receipt, which inspired a hope of a rally. The Commissioners were sceptical of a revival; and they have proved to be correct. Last year the revenue fell from £185,906 to £181,287. That is only double the receipt from cocoa, and but three times that from chicory. Perhaps the juxtaposition of the figures for chicory may help to explain the extraordinary disrepute of a beverage in some respects unequalled. The one real explanation is that the preparation of tea is among the easiest of culinary processes, and that coffee, though anybody might acquire the art needs intelligence. That, however, is a matter about which Commissioners of Customs have no sensibility. They betray a little human feeling for cocoa, which they express some confidence, will become, when better known for its wholesome nutritiousness, a more valuable milk cow to them than it has hitherto been. Coffee they dismiss as useless for any purposes of revenue. It is a sombre point in a document which otherwise contains not a few pleasant features.—*London Times*, Aug. 17.

THE AMSTERDAM CINCHONA SALES.

(Telegram from our Correspondent.)

AMSTERDAM, Thursday night.

Of about 5,100 packages Java cinchona offered here today, 3,274 packages sold (the rest being held for too high limits) at 6½c. (= 1½d per lb.), a price which very nearly corresponds with that obtained at the London auctions of this week. The following prices were paid: Manufacturing barks, in quills, broken quills, and chips, from 8c. to 174c. (= 1¼d to 2s 1½d per lb.); ditto root, from 18c. to 35c. (= 3¼d to 6½d per lb.). Druggists' barks, in quills, broken quills, and chips, from 5c. to 35c. (= 1d to 6½d per lb.); and ditto root 18c. to 19c. (= 1¼d to 3½d per lb.). The principal buyers were the Brunswick works, the Auer's works, and the Amsterdam factory.—*Chemist and Druggist*, Aug. 26.

INDIAN TEA COMPANIES IN 1891.

The figures in Mr. Tye's table are very interesting. The acreages in cultivation vary from 812 to nearly 10,000, the latter in the case of the great Assam Company. The yield per acre runs from 325 to 672 lb. The profit on each pound of tea varied from 2d to 3d, and the dividends, where declared, from 2½ to 17 per cent. Only in one case was there no profit made.

SIAM AS A SCENE OF PLANTING ENTERPRISE.

A former tobacco planter in Deli (Sumatra) writes to us as follows:—

"Singora, Siam, Aug. 4th.

"Will you kindly send me your books 'A. I. about Tobacco' and 'Liberian Coffee.' I saw a copy of the former and was exceedingly surprised to find you had compressed so much matter into so small a volume. I take the liberty of enclosing a photograph of a leaf taken from a Liberian coffee plant about 3 feet high and 10 months old, it was only transplanted May 20th, I believe the leaves are unusually large; hence my reason for sending this photo of one to you. It measures 14½ x 6½ inches. Will you oblige by your comments on same.

"On the hills* in Jenna there are a number of Arabian coffee plants in great vigour, giving big crops without any signs of leaf disease on a low elevation of only about a hundred and twenty feet planted by natives. The Jenna hills are close to the Keddah and Singora road in about latitude N 7° 20', are well sheltered and are not subject to violent winds. The soil is a brownish yellow loam of great depth, and there are lime stone hills in the vicinity. The surveying engineers

* These hills run to 2,000 feet in height.

are hard at work planning out the line of railway from Singora to Province Wellesley, Penang, from which these hills are only two or three miles distant. I have given you this information, as with the high prices of coffee and cheap Siamese labour with land ready to be given away some of your energetic planters who visited Perak last year may find it suit them far better to try the soil here." The photo of the big coffee leaf, which is very well taken, can be seen at our office.

A HERESY IN THE MANUFACTURE OF TEA is broached by Mr. Arthur Sinclair in a narrative of his Peruvian travels. After stating that the leaves of *Erythroxylon Coca* are plucked when well matured, dried in the sun and simply packed in bundles for use or export, he goes on to write:—"Probably tea might be treated in the same way, and its real virtues conserved in the natural vessels of the leaf till drawn out in the teapot; the fermenting and elaborate manipulation introduced by Chinamen are of doubtful utility." If so, what needless expense have planters incurred in rollers, driers, &c. Who has tried or will try the experiment of simply drying the flush in the sun?

VEGETABLE PRODUCTIONS OF KOREA.

Mr. C. W. Campbell (of H.M.'s Consular Service in China) read a paper before the Geographical Section of the British Association on Aug. 9th, at Edinburgh. The subject was the journey undertaken by him through the northern half of Korea to the Manchurian frontier in the autumn of 1889, which has already been mentioned once or twice in our columns.

Starting from Söul, the capital of Korea, on Aug. 31st, Mr. Campbell crossed the Peninsula by a north-easterly route to Wön-san, the treaty port on the east coast. The interesting portion of this traverse was the Keum Kang San, or Diamond Mountains, which had not previously been visited by a European. They are a notably irregular section of the principal Korean range which descends from the Ch'ang-pai Shan (Ever-White Mountains) of Manchuria, are the *chef-lieu* of Korean Buddhism, and possess some striking scenery which attracts numbers of native tourists every year in spring and autumn.

From Wön-san the route followed the coast to Ham-heung and Puk-ch'öng, where it broke inland to Kap-san and the Yalu River. At Po-ch'ön, a village on a branch of the Yalu, Mr. Campbell procured guides and bearers, and continuing northwards through an uninhabited forest, made an attempt to ascend the now extinct volcano of Peik-tu San (White-Head Mountain), better known as the "Long White Mountain," which is an erroneous translation of the Chinese *Ch'ang-pai Shan*, or Ever-White Mountain. It was first authentically visited in 1886 by Mr. James and his party, who approached it from the Manchurian side. Besides being the centre of much legend and fable in both Manchu and Korean history, the White Mountain is remarkable physically by reason of an Alpine lake which has formed in the extinct crater at 7,000 or 8,000 feet above sea-level. Mr. Campbell just failed to reach this lake in consequence of heavy falls of snow and the illness of his principal guide. The return journey to Söul was varied by recrossing the Peninsula to P'ing-yang. Altogether the ground covered was 1,300 miles, a good deal of which was unknown to geography.

Mr. Campbell interspersed his descriptions with some fresh observations on the economic products of the country. The following extracts bearing on the field of agriculture are interesting:—"As to the extent of land under cultivation I have no information, nor do I believe that any reliable data exist. Some rough conception, which is perhaps better than none at all, may be found by a comparison with Japan, where official investigations have furnished tolerably correct estimates of the proportion of tilled to untilled and forest land. In the Japanese islands, including Yezo, about 12 per cent of the whole area is devoted to agriculture, and Korea being almost to a certainty less widely cultivated than its more populous neighbour, we may surmise that probably not a tenth of its surface is farmed. Rice, of course, is the great food plant of Korea: there are many varieties, a remarkable one, upland rice (*Oryza montana*), which thrives without irrigation, being only occasionally met with. It is grown throughout the southern and central provinces, but in Ham-kyöng it is confined to the sea-coast, and in P'öng-yang to warm, low-lying valleys. Barley and wheat are common winter crops wherever rice can be grown, and in the mountainous regions one may see them as summer crops. Oats, however, are much more frequently cultivated in the highlands of the north. The pretty white flowers of the buckwheat (*Polygonum fagopyrum*) are met with everywhere: it is usually planted in small fields where the soil is comparatively poor or sandy. Italian millet (*Panicum italicum*), punice millet (*Panicum miliaceum*), and *su-su*, or tall millet (*Holcus sorghum*) are, after rice, the important cereals. Indeed, in the interior of Ham-kyöng and P'öng-yang Italian millet takes the place of rice in the peasant economy. Maize is not largely grown, at any rate in the centre of Korea: the peasant seldom cultivates more than a few score of plants in the garden near his hut."

"Of leguminous plants the soy-bean (*Glycine hispida*) is most prominent, and the ready market found for it in Japan tends to increase its cultivation. Kidney

beans (*Phaseolus vulgaris* and *P. radiatus*?) and peas are ordinary summer growths.

"The potato is not uncommon in mountain districts, but it does not find much favour as a food. Like tobacco, it seems to have been introduced from Japan within the last three centuries. Small ponds of lotus (*Nelumbo nucifera*), grown partly for its seeds and partly for its starchy rhizomes, occur near Söul, and, I am told, in the south of Korea. The radish-turnip (*Raphanus sativus*) and "Chinese cabbage" (*Brassica chinensis*) are abundant crops everywhere. Brijjal (*Solanum melongena*), garlic (*Allium sativum*), onion (*Allium cepa*), and ginger (*Zingiber officinale*) also find place in gardens, but not to such an extent as chilli (*Capsicum frutescens*), which is the condiment *par excellence* of the Korean nation. Melons (*Citrullus edulis* and *Cucumis melo* amongst others), pumpkin (*Cucurbita pepo*), cucumber (*Cucumis sativus*), and gourd (*Lagenaria vulgaris*) are cultivated universally in the centre and south, as well as in the warm valley of the north of Korea.

"The principal textile plants in their order of importance are cotton (*Gossypium herbaceum*), hemp (*Cannabis sativa*), and China-grass (*Boehmeria nivea*). Cotton is grown little or not at all above the 39th parallel, and I do not think that *Boehmeria* succeeds so far north. Hemp is the sole cloth-plant to be found in the greater part of the two northern provinces, where it flourishes exceedingly well. The progress of foreign trade, bringing with it cheap Manchester goods, seems destined to reduce cotton cultivation to a low ebb, but the production of hemp is not so likely to decrease for that reason—at any rate, so long as hemp is used for mourning clothes.

"The white mulberry (*Morus alba*) and the paper mulberry (*Broussonetia papyrifera*) are included in the list of cultivated trees. Plantations of *morus* were established at Söul (where an old disused palace and grounds were given up for the purpose), and near Chemulpo, some years ago, by the Korean Government, acting under foreign advice, the object being the advancement of silk culture. The scheme has proved abortive, purely in consequence of lack of funds, coupled with a near-sighted opposition from officials. In no case that came under my observation was I more struck by the want of perseverance and enterprise which too frequently marks the national character. The failure was regrettable, for there was little doubt that a moderate outlay and careful management must have made these mulberry plantations a considerable benefit to the silk industry in Korea. The paper and white mulberries are generally found in hedges and gardens, singly or alternating with other shrubs, and do not occur in plantations.

"As with rice and cotton, tobacco thrives everywhere, except in the interior of Ham-kyöng and P'öng-yang. The best leaf is said to come from the eastern provinces, Kang-won and Kyöng-sang. According to the annals of the present dynasty* tobacco was introduced some three centuries ago by a Korean envoy on his return from a mission to the Japanese Court. Sesame (*Sesamum indicum*), castor-bean (*Ricinus communis*), and rape (*Brassica chinensis*), are grown for the oil which is expressed from their seeds, that of sesame being considered the purest and most palatable. A knotweed (*Polygonum tinctorium*) furnishes a well-known indigo dye, for which it is cultivated. Other dye plants are safflower (*Carthamus tinctorius*) and stone-crop (*Lithospermum officinale*), used for colouring red and violet.

"Many edible fruits common to the temperate regions of the earth, and a few which are peculiar to the Far East, are widely distributed in Korea. In comparison with the European fruits they are all sadly inferior in size and flavour. Whether or not, as some say, the soil and climate of Eastern Asia is unfavourable to fruit culture—an assertion to some extent borne out by the well-known deterioration of European species which have been transplanted to China and Japan—it scarcely admits of a doubt that the woful inferiority of Korean fruits is due to the slight attention devoted to them. The trees are neither pruned nor manured, no serious endeavours are made to prevent the ravages of insects, and the improvement of species by propagating

select varieties has rarely occurred. Apples are small and acid or bitter. Pears (*Pyrus sinensis?*) are usually round, like apple, juicy and sweet, but hard and coarse. The Ham-heung pears are exceptionally good. A few that I bought on the road between Puk-ch'ng and Ham-heung were shaped like English 'William' pears and almost equalled them in flavour; they were the only evidence I noticed in the country of a fruit being improved to anything approaching a European form by selection and cultivation.

"A dwarf variety of orange grows, the Koreans say, on Quelpart Island, but not on the mainland. Grapes (*Vitis vinifera*) are small, thick-skinned, and harsh in taste. The vine grows readily in warm situations as far north as Soul, yet very little seems to be cultivated. Peaches, apricots, plums of two or three kinds, cherries, and 'jubes' *Zizyphus vulgaris*, are common stone-fruit. Berries rarely appear to be grown for food. The fruit of brambles (*Rubus*), the gooseberry-like product of an *Actinidia*, the Cape gooseberry and mulberries are eaten; and walnuts, chestnuts, and seeds of pine, lotus, and *Salsburia adiantifolia*, are always exposed for sale in the markets.—*L. and C. Express*, Aug. 19th.

THE COFFEE-PLANTING ENTERPRISE IN SELANGOR.

The Collector of Land Revenue (Mr. L. P. Ebdon) reports as follows:—

The most encouraging feature in the progress of the District during the past year is to be seen in the development of coffee-planting enterprise. Particulars are shewn in the following table:—

Situation	Name of Estate	Proprietors	Managers	Average Total Acreage Under Cultivation

I have recently received complaints from various planters who hold their land under the Land Regulations 1882, respecting the cutting of timber on their estates by the holders of ordinary timber passes. It was, I believe, formerly held that special permission was required for the felling of timber on alienated land in accordance with the provisions of Section 3, Sub-section 2, of the old Regulations. The Court however, has decided

otherwise. This is a source of great inconvenience to the coffee planter, not only because it is desirable for the sake of the soil that the timber should be where it falls, but also on account of the difficulty of eradicating the brushwood which springs up immediately after the clearing of the jungle. I think it desirable that the Government should reserve the power to confer the right of timber felling on alienated land uncultivated, but this right should be allowed to be exercised only in virtue of special permission. Coffee planting under European supervision is an industry which it is most expedient to encourage, and while planters comply with the conditions of their grants they should be encouraged in every possible way. If they fail to do so, it is better to forfeit their land altogether than to punish them by allowing indiscriminate timber cutting thereon.

I may mention that a Ceylon planter, Mr. E. V. Oarey, has applied for 1,000 acres of land for planting coffee, which there seems to be every prospect of his taking up, and that a permit has already been prepared for the same.

999 pikuls 84 cattles of coffee were exported from Klang during the past year, the total value of the same being \$24,424 '85.—*Selangor Gazette*.

CONSULAR REPORTS.

SHANGHAI.

EXPORTS.

In order to show the changes that have taken place among the various consumers of Chinese produce, I append a comparative table of the distribution of the export trade for 1881 and 1891:—

Exported to	1881.	1891.
Great Britain .. Hk. Tls.	12,670,300	9,169,021
India	484,171	1,560,111
Singapore	562,559	313,636
Australia	30,185	28,865
Continent of Europe ..	9,782,446	14,746,572
United States	7,507,574	6,285,463
British America	17,271	471,832
Russian Manchuria	315,027	825,084
Japan	1,127,017	4,606,276
Other countries	948,011	2,002,407

Total 33,444,461 40,009,267

It will be observed that there have been considerable changes during the ten years. In particular the Continent of Europe takes a great deal more directly, and great Britain takes a great deal less.

This is principally due to the fact that ever since the opening of the Suez Canal, the tendency of trade has been to divert that portion of it meant for Continental markets to one or other of the Mediterranean ports, instead of going, as it used to do, first to London for re-distribution. When all the cargoes went round the Cape, London lay practically on the direct geographical route, between the East and the Continent.

But that is no longer so, and the Mediterranean ports, such as Marseilles and Genoa, must necessarily attract all cargo destined for the southern half of Europe. The several new lines of steamers, which within recent years have begun to run between China and the Continental ports, still further enhance this tendency.

India has trebled her requirements, and is now a customer of Chinese produce to the extent of 100,500,000,* but her purchases are but a sorry set off against the large bill which she has against China for opium and cotton yarn, the former being some 12,500,000 taels, and the latter nearly 10,000,000 taels.

Japan has increased her requirements from 1,227,000 taels to 4,606,000 taels, the greater part of which is for Chinese cotton supply her mills in Osaka. Her debtor and creditor about balances.

* ? See figures above.—*Ed. L. & C. Ex.*

The increase to British North America is also noticeable, that being due, no doubt, to the direct line of steamers placed by the Canadian Pacific Railway between China and Vancouver.

SILK.—The export of silk given in the yearly returns shows a large increase over last year, the total of raw silk, white and yellow, being 60,000 piculs, as against 40,000 piculs in 1890. This, however, is accidental, as the silk season extends from June to June, and it is therefore a question of market, and not of production, how much of the crop is exported before and how much after Dec. 31st.

As regards the season 1891-92, business has been on the whole steady and fairly satisfactory. The total export for the season up to date has been about 61,000 bales, with a stock on the local market of some 8,000 bales, more. This is rather over the average of previous years. The export of China silk is, on the whole, increasing, but at no very rapid rate, nor does the quality improve to any appreciable extent.

The filatures in Shanghai, belonging to foreign firms, continue to be kept fully employed. Of the total export some 1,500 bales is reeled and prepared in the foreign flatnres. But notwithstanding the use of foreign reeling machinery, the production of these filatures, either through carelessness or for want of efficient foreign supervision, is not free from fault, and compares, I am informed, very unfavourably with the silk sent out from the filatures in Japan.

China silk is intrinsically the best silk in the world, but from ignorance or lack of energy on the part of the producers, it continues from year to year to be prepared in the old faulty method, while Japan silk, by nature much inferior, is beating it in the market, simply by the care and attention bestowed on its preparation, and by the fostering provision of the Japanese Government, who provide the means of educating their people in the most approved methods in vogue in Europe.

The export of silk piece goods is increasing, having risen from 3,500 piculs in 1881, costing 3,900,000 Haikwan taels, to 6,500 piculs in 1891, costing 9,300,000 Haikwan taels. The great proportion of this export is for France.

BLACK TEA.—For the following information I am indebted to a gentleman of long experience in the tea trade:—In the early part of the season a very active business was done in Hankow first crop teas, three-fourths of it being for the Russian market, which now takes more than the half of the black tea exported from North China. The Chinese had bestowed special care in the preparation of the crop, with a view to meeting the demand of the Russian buyers, and sent to market some remarkably fine teas, equalling the best of former years. Handsome profits were realised by the native dealers, as much as 86 taels a picul (3s 5½d per lb.) being paid by Russian buyers for choice Ningchow. But the Russian demand being satisfied prices fell off, and the dealers lost severely, especially on second and third crops. Shippers to England realised more or less heavy losses, profits being quite the exception. Some rash buyers who shipped five teas to London, costing about 2s, lost over 1s per lb. while losses of 4d to 6d per lb. were quite common. The only kinds which are said to have covered cost were common grades, costing about 5½d per lb.

This disastrous result was in no way due to the quality sent forward. The export to England for the season 1891-92 being only 26,750,000 lb. In 1880-81 the amount sent forward was 74,500,000 lb.

The real mischief which is driving China teas out of the market is the heavy local taxation, which makes it impossible to compete with the untaxed produce of India and Ceylon. Duty and lekin together come to about 6 taels per picul, which, considering that the average price of Shanghai bought teas is 13 taels to 14 taels per picul, represents a taxation of some 36 per cent. On the commonest sorts it is as much as 53 per cent of the cost.

These facts have been urged on the attention of the Chinese Government again and again, but they seem indifferent to the threatened ruin of the once great

national industry. At the present moment Russia is the best customer for China, and if the Russian taste were changing to India, which is always possible, the China tea trade would soon be a thing of the past.

It is a delusion to suppose that China tea has deteriorated; the apparent deterioration of late years in teas sent to England has been due to the low prices paid by English buyers, at which they could naturally only get inferior teas. The Russian buyers who pay good prices get teas of the former excellence. If the onerous burden of taxation were brought down to something like what it was originally meant to be, viz., 5 per cent ad valorem, instead of 20 per cent to 50 per cent as it now is, there would be a good chance for China teas yet. For the time being, India and Ceylon teas are the most popular, no doubt, but there is a large consensus of medical and expert opinion in favour of the view that China tea is more wholesome, and in its method of preparation freer of tanning and other deleterious elements.

GREEN TEA.—The business in this kind holds its own with difficulty, and has this season been a losing trade for native dealers, and an unremunerative one for foreign buyers. Japan teas, being untaxed except to the extent of \$1 per picul, can undersell Shanghai green teas in America, which is the principal market for this class. It is not, perhaps, too much to hope that the Chinese Government will yet follow the example of the Japanese in the matter of both tea and silk.

Comparing the exports of 1891 generally so far as they are destined for foreign consumption with those of the years 1879-81 the following changes may be noted:—The export of silk has increased by some 3,000,000 taels, and that of tea has fallen off by nearly 2,000,000, and general exports have increased by some 5,500,000 taels. The combined effects of cheap tea transit and cheap silver have brought into the market a vast quantity of raw material, most of which goes to England. The principal items (not counting straw-braid which has long been exported), are hides, goat skin rugs, camel and sheeps' wool, hemp, feathers, &c.—*L. and C. Express*, Aug. 19.

THE GOVERNMENT COFFEE CROP IN JAVA has been taxed upon 586,477 piculs for the month of July last, this being an increase of 79,582 piculs on the preceding month. The population of Palembang are discontented, owing, it is said, to the liberal grants which have been made by Government of uncultivated land.—*S.F. Press*, Sept. 3rd.

COFFEE IN WEST AFRICA.—Information respecting railway progress in South-West Africa has a bearing on coffee production. One line is now open for 220 kilometres, and we read in the *Manchester Guardian*, that

It is hoped that a few months will bring it to Casengo where all the coffee plantations are. Great efforts are being brought to bear for this end, and the works on the more distant sections have been greatly reduced for the present, the staff employed on them being added to that between kilometre 220 and Ceiras, all work being concentrated on that one section. The constructors have had many difficulties to contend with, not the least being the scarcity of labour. Heavy rains have also done a great deal of damage; in December, 1891, the loss was enormous. In one part the line was washed away in 18 different places in as many kilometres, the gaps varying from 10 to 150 metres in width, rails, sleepers, embankment, and culverts being washed completely away. This damage was not caused by local rains, although they were considerable, but by an enormous body of water suddenly coming down from the higher lands further in the interior. The receipts though small, have been increasing steadily from the commencement; but no really great difference can be looked for until Casengo is reached and the coffee brought down by train, instead of, as now, taken by carriers to Dondo, and shipped thence by steamer via the Quanza River to Loanda.

MR. JACKSON ON TEA IN INDIA AND CEYLON AND ON HIS PROJECTED TEA WITHERER.

The representative of the "Times" has regularly "interviewed" Mr. Jackson (see extract below) regarding his projected witherer. Mr. Jackson told us that, when in India, he had seen some patented machines, the principle of which he regarded as good although the machines themselves were imperfect in execution and action. Believing that he could improve upon the principle and the action of the machines, he pursued the honourable course of purchasing the patents at some considerable cost. Mr. Jackson, it will be seen, was "reticent;" but the witherer which is in course of trial on Great Western, we now feel justified in saying, will combine the use of Blackman's fans with trolleys by which the tea leaves to be withered will be carried forward through the space on which the fans are acting. We believe Mr. Jackson does not anticipate the entire supersession of withering lefts by the machine which he hopes to perfect, but rather that it should be a valuable adjunct to such lofts, especially in weather unfavourable for the ordinary withering process. Pending the production of a really effective withering machine, it must not be forgotten that Mr. Jackson's "Britannia" and other driers are to a large extent useful in the withering of green leaf. We suppose that Mr. Jackson is correct in stating that what is considered inferior jät tea cannot be got to flush in Assam as it can be in Ceylon. On the higher Ceylon estates especially we have noticed that tea bushes which in large leafage appealed to the eye as of high class and nearly approaching Assam indigenous, does not flush so plentifully as a lower looking jät does, while we have not discovered compensation in better quality. On mountain estates a medium jät does better than what is deemed first class.—If Mr. Jackson correctly judges that the superiority in Assam tea is due to the opening up of new gardens on superior virgin soil, the old, even when yielding as Mariawatte does, being abandoned, then indeed Ceylon cannot possibly compete with Assam. But Assam is a very comprehensive term, embracing not only the valleys of Assam proper (Brahmaputra, Surma, &c.) but the specially moist district of Sylhet, the teas from which do not share in the high prices realized by the teas of Assam proper. We cannot help thinking, therefore, that not merely soil but meteorological conditions affect the problem. In the very wet districts of Ceylon and in very wet weather in other districts, we know there is much difficulty in producing good tea. It becomes Ceylon planters, therefore, to see if they cannot by the judicious use of fertilizers improve their soil, while such appliances as Mr. Jackson's withering machine may enable them to overcome the inimical influences of a damp climate.

A CHAT WITH MR. W. JACKSON.

TEA IN CEYLON AND INDIA: TEA WITHERERS.

Mr. Wm. Jackson, who has just won his case in the Supreme Court against the Colombo Commercial Company with regard to their alleged infringement of his tea-roller patent, leaves Ceylon today (Sept. 15th) by the P. & O. steamer "Rome" for London. The case, Mr. Jackson is aware, will be carried to the Privy Council, and he returns not only to watch his own interests in London, but also to carry out several improvements in tea machinery which he has already projected. He returned from Calcutta about four months ago having, whilst away, visited most of the Indian tea districts. Mr. Jackson, in reply to an inquiry from our representative as to how it was that Assam

gardens were getting such high prices for their tea at this time, remarked, with a smile: "Well, you see, in the olden days, when I was a planter in India, we did not care very much about seed or soil; but pitched upon spots to open gardens where transport was easy and labor fairly abundant. But, nowadays, with Ceylon competition so keen it is necessary to pay attention to other matters, and every care is taken to obtain good seed and good soil, resulting in fine prices. Why, I have seen 500 acres of as fine tea as Mariawatte abandoned because it would not pay, for poor jät will not flush in India as it does here. Nowadays only the finest plots of land—and there are magnificent blocks of forest there—are planted with tea, and Assam planters are gradually abandoning their old fields and opening new land. This is why they secure good prices."

THE COST OF PRODUCTION.

What about cost of production? Well, perhaps, they are not so well off as you are in Ceylon. They have not such good roads or such excellent means of communication, which cheapen production. But their expenses are being rapidly reduced, and some gardens compare favourably even with Ceylon. Take the Borjuli garden for instance—one of the finest in Assam. It gave 15 maunds all over, and the tea is laid down in London at 3½d. a lb.! Ceylon can do the same I know, for many Kelani Valley places can lay down their tea in London for this, but they don't get 15 maunds regularly over a large acreage. I have seen stems of trees as thick as my leg, and every tree the same, due to the fine soil and to the system of plucking which allows the trees to grow more. In Ceylon this style of plucking cannot be followed.

MR. JACKSON'S NEW WITHERER.

Asked regarding the new witherer he is bringing out, Mr. Jackson was somewhat reticent, but said that it was an improvement on Turton's machine brought out in India, the patent of which he has purchased for a large sum. Several of these machines are at work in India, the Jhansi Association having withered the whole of their leaf for the last two years, no matter whether the weather were favourable or not, in the witherer. An improvement on the original patent has been elected by Mr. Jackson on Great Western estate, excellent results having been obtained by Mr. Mackie, who will, it is hoped, make them public as soon as convenient. The machine is, we believe, very simple, being in reality the better application of the principle of Blackman's fan. Mr. Jackson is confident, with a little more time, of being able to so improve the machine as to give us one which will enable planters to wither quite independently of the weather, and how great a boon that will be, only those situated in districts where a good wither is almost impossible to obtain in certain seasons, can appreciate.

Mr. Jackson will be back some time next year,* and he has our best wishes, for no one has done more for tea planters than he has.—Local "Times."

THE experimental farm established by the Government of Victoria for the purpose of ascertaining the suitability of the soil and the climate for numerous kinds of crops, and for the instruction of students in agriculture, now extends to nearly five thousand acres. It is situated at Dookie, in the north-eastern districts of the Colony, and has been in practical operation for the last seventeen or eighteen years. A small portion of the land is under vines, another portion is devoted to Zante currants, and various medicinal plants are also cultivated. The Dookie experimental farm, however, represents but a small part of what is being done for agriculture by the Government of Victoria. The Agricultural College Act provides for the permanent reservation from sale of 150,000 acres of Crown and by way of endowment of State Agricultural colleges and experimental farms.—*Indian Agriculturist* July 23.

* Mr. Jackson told us that he would not be back in Ceylon for some years.—*Ed. T.A.*

WHAT IS OUR STOCK OF QUININE?

Sir,—With reference to your interesting note of August 27 under the heading "What is our Stock of Quinine?" supposing the number of cases to be correct, the net weight is considerably over-estimated. The weight of a case of 10 tins of 100 oz. each B & S. for Aderbach quinine is as near as possible 1 cwt. 1 qr., more often a few pounds over than less, while 2 cases of five 100-oz. tins each of Brnswick go about 145 lb. gross total. The contents of 2,550 cases should therefore not be estimated at over 1,750,000 oz., and would probably weigh less, as we have to make a reduction for smaller packages, such as 25-oz. tins and 1-oz. vials. There must be a fair amount of the latter (Howards' and Pelletier's), and the tare of a case of 100 oz. net weighs probably nearer 56 lb. than 28 lb.

The stocks at Smiths's warehouses have decreased for years, and if we add, for safety's sake, 1,250,000 oz. for Smith's & Bull wharves—a figure, in my opinion, very considerably in excess of the actual stocks there—we get at a total stock of 3,000,000 oz. in London. We have very little stock of suitable barks to fall back upon should the regular supplies be interrupted, and a stock of 3,000,000 oz. of quinine is just enough to protect the trade against very violent fluctuations. In any case it should not frighten the most timid holder, and your statement that stocks have actually decreased during the biggest years of production shows that quinine is slowly working into a very sound position indeed.—Yours faithfully,

H. BUCHLER.

Dunster House, Mincing Lane, E.C., Aug. 30.

WHAT IS OUR STOCK OF QUININE?

In our correspondence columns will be found a letter from a well-known operator in quinine, who states it as his opinion that our estimate of 3,500,000 oz. as the net weight of our stock of quinine in the Dock Company's warehouses is much too high. With regard to our correspondent's estimate of the stock of quinine at Smith's warehouses and Bull Wharf (the two other chief points of storage in London) at 1,250,000 oz., we should think that that is much in excess of the actual fact. Very little quinine, so far as we are aware, has been imported into either of these two warehouses since 1887 or 1888, while, on the other hand, the old stocks there have been constantly drained by deliveries to consumers. Our correspondent himself, we believe, has not entered a single package of quinine at Smith's warehouse for the last five years, and, so far as we can gather, the only quinine importers who are regularly in the habit of consigning their imports to Bull Wharf are the agents for a brand which has practically been out of the market ever since the German makers began to undersell one another. It is doubtful, therefore, whether the total stocks outside the dock warehouses would do more than account for the difference between the figures mentioned by ourselves—viz., 3,500,000 oz.—and Mr. Buchler's estimate of 3,000,000 oz.—*Chemist and Druggist*, Sept. 3.

FIBRE INDUSTRY AT THE BAHAMAS.

(Agave rigida, var. Sisalana.)

The development of an important fibre industry at the Bahamas has already been the subject of notes in the *Kew Bulletin* (see March 1889, p. 57, and October 1889, p. 254.)

As indicating the character of the industry from an American point of view the following Report prepared by the United States Consul at Nassau at the beginning of this year will be read with interest. This Report is reproduced exactly as it appears in the "Reports from the Consuls of the United States," No. 114, March 1890:—

CONDITION OF THE SISAL INDUSTRY IN THE BAHAMAS.
REPORT BY CONSUL MCLAIN, OF NASSAU.

One year ago I made a report to the Department upon the culture of Sisal hemp in this colony, calling attention to it as a new industry just being introduced, and which promised to bring substantial prosperity to these islands in the near future.

During the year, and especially within the last few months, so many letters have been received at this Consulate from various parts of the United States, making inquiries upon the subject, that I am satisfied a statement touching the present condition of the industry would interest many of our people, and I therefore submit the following:—

The progress made in the development of Sisal culture in the Bahamas during the past twelve months is marvellous. One year ago there was scarcely a dollar of foreign capital, and very little local, invested in this business in the colony, while to day parties from Great Britain, Canada, and Newfoundland, representing large resources, are interested in Sisal, have bought tens of thousands of acres of Government land, and are industriously engaged in clearing and planting the same to the full measure of their ability to procure the material. A local stock company, styled the Bahama Hemp Company, organised and managed by Nassau capitalists exclusively, has also purchased a large tract of land and is developing the same, whilst thousands of acres are being planted in every direction by individual owners of smaller pieces. American capital up to this date, I regret to say, for it is to its own disadvantage, has been conspicuous by its absence. One company, however, styled the Inagua Hemp Company, organised under the laws of the State of New Jersey, with D. D. Sargent, United States Consular Agent at Inagua, as manager, has lately procured about 1,200 acres at Inagua, and has begun operations.

Messrs. Munro & Co., of St. John's, Newfoundland, have obtained a grant of 18,000 acres of Crown land at Abaco, and are planting the same. Another tract of 20,000 acres has been allotted to a London company on the same island. Mr. Alex. Keith, of Edinburgh, Scotland, has taken 2,000 acres on Andros Island, and is working upon it. But the largest demand has been made lately by two London companies, who are said to be applying for not less than 200,000 acres between them.

Many applications for land have not been reached at all as yet on the files, the Surveyor-General's Department being hard pushed in the matter of surveys and locations, whilst applications are being constantly received, and have to wait their turn of consideration. So much land has been taken up that the Governor, a short time ago, advanced the price of Crown land from \$1.25 per acre, the ordinary price, to \$4 per acre, withholding also the benefit of the bounty. And lately it has been decided to sell no more large allotments of Crown land at present, the quantity already allotted with a view to cultivation being as great as the condition of labour in the colony will justify. The number of acres of Crown land already disposed of is about 120,000 acres, whilst pending applications on file, and not yet reached, will amount to at least 200,000 more.

This substantial withdrawal of Crown lands is creating some movement in real estate—as is natural under the circumstances—between private parties, some old properties changing hands at prices double and treble their supposed values two years ago. Persons buying private lands and cultivating them will share in the bounty of 1 per cent. per pound provided by law on all fibre raised and exported. Private lands in New Providence can be bought, unimproved, for from \$8 to \$12 per acre, and for less on the out-islands.

The employment given to labourers in clearing land and in setting out plants has already put considerable money into circulation, the beneficial effects of which are being felt in various quarters. There has been no special advance in the price of labour, field hands commanding from 40 to 60 cents per day, and finding themselves. Each month, however, witnesses a large increase in the number of those who find remunerative employment, and pleasant relations obtain between employers and employed. The labour question has been and is one that here, as elsewhere, requires delicate treatment; but it has been skillfully met by Sir Ambrose Shea, the Governor, who long ago perceiving that to permit investors to locate upon adjoining lands would induce sharp competition in

wages in thinly settled districts, adopted the plan of scattering the allotments about the different islands, or in localities remote from each other on the same island, so that each settlement should have its share of the benefits of the new industry, by obtaining, at fair wages, employment for its local labour. In this way, also, a surplus of labour at one point and a scarcity at some other has been avoided. When the entire labouring population becomes employed, as will happen before long at the present rate of development, a new phase of the labour question will arise; but that time is yet in the future, and the remedy can be applied when the situation demands it.

Small shipments of fibre continue to be made by nearly every steamer, a few old plantings furnishing the material. It is not likely that shipments in any quantity will be possible under two years, but after that time an enormous increase may begin to be looked for, increasing steadily as new fields come into bearing, until the annual exports of the colony, which now average about \$600,000 will leap well up into the millions, as a moment's reflection will show.

It is a very low estimate to expect half a ton of fibre per acre, and a very low estimate to call it worth \$100 per ton, for it is worth over \$200 per ton in the world's markets today. When even the present quantity of land sold and applied for, to wit, 300,000 acres, is bearing, which ought to happen within five or six years, it will produce 150,000 tons a year, worth \$15,000,000, an increase of prosperity that sounds more like a fairy tale than a strong probability deducted from reasonable figures. And yet 300,000 acres is but a small portion of the uncultivated lands within the limits of the Bahamas.

It is estimated that about 6,000 acres of land have already been planted in Sisal (a plantation once started needs no replanting for many years), and that many additional ones have been cleared and made ready for the plants, the obtaining of which has been almost impossible, the industry being seriously retarded thereby. The prices paid for plants have risen from 6 cents per dozen to 36 cents, so great has been the demand; but the price will now decline rapidly, since the supply of plants is developing enormously, about 2,000,000 being now available for planting, and others coming on speedily. The Pita plant is being found on all the islands growing wild, and the stock of old plants is very great. From the centre of the old plant rises a pole about 16 feet in length, on the branches of which small plants grow, averaging a thousand to each pole, and from these poles a vast supply is coming into market, creating a profitable business; for what were two years ago only noxious weeds have all at once become worth \$20 apiece for pole plants alone. Quantities of old plants have lately been discovered growing on the cays along the Florida coast, and small schooners are already buying these up and bringing them here for sale. This fact suggests the question whether this new hemp industry, which is about to revolutionise the condition of the Bahamas, may not also be developed in the southern portion of Florida. The plants are found there growing wild just as they are in these islands, and they flourish best in dry sandy soils, fit for little else. I would earnestly call the attention of the Department of Agriculture to this matter, and suggest the propriety of looking into it, and of calling the notice of the people of Florida to this possible source of wealth and prosperity. The conditions of soil, climate, &c., which make its culture a success here may not obtain there, but the simple fact that the plant is found growing wild in Florida is of itself a consideration that should warrant an investigation at the hands of the Department.

The unexampled success of the Sisal industry, in so brief a period, in this colony is entirely attributable to the business-like, systematic manner in which it has been managed by the present Governor, Sir Ambrose Shea, who has all long taken a most earnest interest in the matter. He is a man of large experience in affairs, and has practical knowledge of the proper way to manage industrial enterprises.

From the start he realised that this industry would be the salvation of the Bahamas, and, setting his heart upon it, he pushed it forward with great energy and prudence, overcoming numerous difficulties, surmounting obstacles, encouraging the faint-hearted, until now the people are touched with his own enthusiasm, and the industry is fairly afloat. He visited England, and by personal effort enlisted capitalists and procured large investments. To Sir Ambrose Shea the colonists owe a large debt of gratitude; and when the signal prosperity which is already hanging over the islands shall have been developed to its full measure, they will more perfectly realise how not only their individual interests, but those of outside investors, have been wisely and prudently promoted and guarded from the very inception of the industry by the practical, discreet, and conservative action of their Governor.

There can be no doubt or question as to the success of Sisal culture in this colony. It has passed far beyond the experimental stage, and is giving daily evidence that it will become a source of wealth to all concerned. The combined conditions of soil and climate especially adapted to the growth of first-class fibre giving this colony a marked advantage over other West Indian islands, where the plant may grow luxuriantly enough, but will be found deficient in good strong fibre. The poorer and more sterile the soil the better the result, and here the plant flourishes where ordinary vegetation seems almost impossible. It is a plant of unfailing growth, it will live without rain to moisten the soil, you can scarcely exterminate it if you try, it requires but little cultivation, and at an expense below that of almost any other agricultural product, and its value is substantial.

As two-thirds of the trade of the Bahamas is now with the United States; as their only steam communication with the outside world is by a subsidised line of American steamships running between Nassau and New York; as their increased wealth and prosperity means a larger and more profitable commercial intercourse with our own country, we should view this coming development of their material interests with pleasure, and with the warmest wishes for its complete success.

In conclusion, I would add that I have sent by this mail four samples of the Bahama fibre for the information and satisfaction of the State Department, believing that the same would be of sufficient interest to justify me in so doing. These specimens were not specially selected, but are only fair samples of the average fibre which is now being grown and shipped from the colony. Two of them have still attached a stub, or portion of the butt end of the leaf, which was purposely not passed through the machine, showing the character of the Sisal plant when extracted.

THOS. J. McLAIN, jr.,
United States Consul, Nassau, Consul,
January 20th, 1890.—*Kew Bulletin*.

SYLHET NOTES.

A couple of years ago there was quite a little sensation amongst the *cognoscenti* in tea—a little tempest in a teapot—over a mysterious

NEW PROCESS OF TEA MANUFACTURE.

It seemed to be on a par with Schrotky's discovery of some wonderful process connected with indigo, of which, I regret to say, I am densely ignorant, even as to whether Schrotky's idea ever came to anything, or ever amounted to much to begin with. My knowledge of the processes of indigo manufacture is derived from "Ali Baba's" instructive pages, which although immensely interesting, are scarcely quite accurate in detail. There were several brilliant (and otherwise) "skits" in your columns from Dooar correspondents about the secrecy and mystery enshrouding this new process. The tea houses wherein it was carried on were *tabu* and no one might enter therein save the duly initiated. Fantastic rumours as to bottled essence of

tea and other marvels were rife; and nobody seemed to know exactly what was being done.

But in South Sylhet I think I came upon the track, alas, it was a defaced and abandoned track, of the mystery. The new process which, even now, is more or less of a secret, was an attempt to make tea on some new and scientific system, on the part of

MR. JAS. DAVIDSON,

whose success in the machinery line, and in sale of tea in packets, has made him so well-known in the tea world. Carried away by his reputation as a successful and "level-headed" man, the South Sylhet Tea Company gave him *carte blanche* to conduct his experiments in their factories, regardless of expense. Existing machinery was altered, moved about, and generally turned end for end and upside down; new machines and new "fakes" of various sorts were indented for; and the whole system of manufacture reorganised throughout all the big factories of the Company. Such thorough confidence was felt by Davidson himself in the new system; and by the Company in him, that the experiment was tried, not in one factory only as one would have thought advisable in introducing an entire revolution in manufacture, but throughout all the factories. Davidson himself remained up in Sylhet throughout the greater portion of the manufacturing season last year, superintending the operations, and working himself, early and late, in the tea house, with all the ardour of a young and energetic assistant just out; having to be extracted forcibly for his meals and necessary rest. But, alas! "the best laid plans o' men and mice;"—you know the rest. Whatever the mysterious process was, it was by no means a brilliant success. The market was not educated up to the tea of the future probably. Anyhow

THE RESULTS WERE ALMOST DISASTROUS;

and a drop of a penny or more per pound on all the teas manufactured under the new process added to the expense of moving machinery, getting up new machines, and so on, made a big hole in the profits of the Company for the year. Davidson went home, disheartened—but only for the time—at his failure, financially speaking, to improve prices; and the machinery has had to be all moved back again, and the old style of manufacture reverted to. But it is said Davidson is still full of the hope of yet revolutionizing the process of tea making by his new system, further thought out and perfected: and more than one of the planters who worked on his system, believe in it, and declare that, notwithstanding sale results on the market, the process produced the finest drinking tea they have ever tasted. So we may yet educate the tea market up to scientifically manufactured teas. The *profanum vulgus* has to be educated up to many new ideas, and the process takes time. It is said that even beer-drinking is an acquired taste: but the British public—and the planter too—have thoroughly acquired it. Meanwhile we have Mr. Bamber carrying on a series of careful chemical experiments on the various processes employed in the present "common or garden" method: testing the temperatures, the time necessary for each process, the gases evolved during fermentation or "oxidation" and various other things I don't pretend to understand, up at the Jhanzi Associations estates, with a view to crystallizing

A FIXED SYSTEM OF MAKING GOOD TEA

into a certainty, and evolving a knowledge of how to produce with scientific accuracy any particular qualities which the market for the time being may demand. This is undoubtedly a step in the right direction: tea manufacture hitherto has hardly emerged from the "rule of thumb" stage, resulting from the practical experience of individual planters; and is dependent to a far greater extent than it ought to be on that very uncertain factor, the weather. It is far behind the scientific accuracy of most other manufactures, and it is unquestionable that the marks which command the highest prices (I am not speaking of those absurd "fancy" thirty guinea Ceylon teas, the outcome of advertising dodges and a ring of bidders, but of steady high averages at reasonable prices) are the production of exceptionally careful men who give

an unusual amount of attention to their leaf, from the time that it is to be taken off the bushes, right through the tea house, into the boxes; and who endeavour to reduce their manufacture to an unvarying and most carefully supervised system.

THE GEOGRAPHY OF SOUTH SYLHET

is somewhat peculiar. The district is divided into a number of valleys by parallel spurs running out almost due north from the Lushai hills; each valley drained by its own main stream, flowing into the Barak or its tributary, the Moan River. These spurs between the different valleys are of varying height, and are traversed by roads of more or less pretensions, called *pharis*, locally;—short cuts from valley to valley. A longer and better road round from one valley to the other is generally available by going right out of the valley and round the end of the separating spur into the next one; but the *pharis* are much shorter routes; and, except after unusually heavy rain, when bridges, and sometimes whole bits of road "carry away," are more generally used. A ride through one of these *pharis*, winding up the minor valleys in the spurs, through forest and bamboo of every variety across an almost imperceptible watershed, and down again into the other valley, is by no means an unpleasant experience in good weather. The road is very pretty in places; you come round a corner now and then on quite picturesque little nooks. But crossing a *phari* after heavy rain is, well, it may be picturesque, but it is not pleasant. Bridges conspicuous by their absence, leaving yawning chasms,—just round a corner as a rule, so that you come on them unexpectedly; slips, by which portions of the road have retired down to the bottom of the valley to spend the rest of the season, and what is left of the road either cut up, or rendered intensely slippery, so that your pony's legs go all abroad as if they didn't belong to him; these things keep your interest in the road from flagging, and attract your attention undoubtedly, but they are hardly cheerful or exhilarating experiences. I heard one or two

HEARTRENDING STORIES

of parties crossing from the Balisera Valley to the Dhulai Valley by the Kamalganj *phari*; how a couple of young ladies and one of the men went perfectly astounding "croppers;" how their horses either went dead lame or bolted (while the riders had retired temporarily down the *khud*). I forget the exact details of the cause of the catastrophe, but remember the result; that these unfortunate dismounted ones had to sit pensively on the edge of the road for hours while one of the cavaliers rode back (or forward was it?) to the nearest garden to procure chairs, or *dhulis*, or ponies, or some means of conveyance. Of course it was raining, as it knows how to rain in Sylhet, all the time; and those young ladies—one of whom was rather badly hurt by her spill, got slightly damp. N. B.—The breed of leeches in these *pharis* is an extremely thirsty, insinuating and energetic one.

The Sylheti is a gentleman I confess I do not like. To my mind, he is the worst type of about the worst class in India,—the Eastern Bengali Mahammadan,—and under the fostering influences of a permanent settlement, and a ready access to minor local courts wherein he has sharpened his already naturally fine talents for litigation, with its concomitant luxuries of perjury, forgery, and subornation of evidence—he has developed into

THE MOST OBJECTIONABLE KIND OF NATIVE

I have met in my wanderings. Very probably I have only seen the worst side of him. He may have many virtues I am unacquainted with. I have generally come in contact with him in connection with boundary disputes,—or in trying to get him to do something in the way of work or assistance (for reasonable payment of course), and I have invariably found him untrustworthy, "cheeky," lazy, and withal truculent. He is hardly plucky; but, in numbers, he has been known to go for a *sahib* occasionally,—and to get him, too. During the first settlement of the Balisera lands, there was more than one *murpiti* case in which a *sahib* got a broken head. There is all eyes trouble about land questions in Sylhet. The

wretched permanent settlement; and the still more wretched *thakbast* survey of 1860 odd, which was supposed to define the limits of the permanent settlement; combined with some vague and ill-defined rights of the Maharajah of Tipperah, who claims nearly all the land outside the permanent settlement, holds lands within it, and exercises certain surface rights of cultivation and jungle cutting—*jhum* and *gurkhatti* over the lands he doesn't own;—all these mixtures of tenures and claims result in a fruitless and endless crop of litigation, which the average Sylhetti seems to revel in.

Another of the propensities of this specimen of the people we sacrifice ourselves and govern India for, is a matter one can hardly write calmly about. They are ghouls, these brutes; they

DIG UP GRAVES,

pour s'amuser, I suppose, for their plea, or rather the plea advanced for the culprits (who have never been caught) by their brethren when questioned as to the reason of this ghastly practice,—that the *sahibs* are supposed to have a lot of treasure buried with them, is too transparent to be accepted. Whatever the reason, there is the fact. Not a European has ever been buried in South Sylhet but has had his grave desecrated, his body dug up, and his bones scattered abroad, unless most extraordinary precautions have been observed to guard and watch the grave. Time is no object to these loathsome villains: if they can't dig you up fresh, they'll wait weeks and months for you. More than one man has sat up night after night with a rifle or shot gun over a friend's grave, only to find that, the first night precautions were relaxed—the deed had been done. Which is one of the reasons I don't like the Sylhetti.—*Indian Planters' Gazette*, Aug. 27.

WEST AFRICAN ANNATTO.

(*Bica Orellana, L.*)

The cultivation and preparation of the colouring substance known as Annatto were fully discussed in the *Kew Bulletin* for the months of July and Sept. 1887. Since that time attention has been given to Annatto in West Africa, where the plant has apparently become widely naturalised. From the correspondence with follows, it will be gathered that the Annatto seed so far received from West Africa does not possess the qualities of Jamaica Annatto; but this may be due to the fact that the seeds had been gathered before they were fully ripe, or that they had been packed in a damp condition. There is apparently only a limited demand for Annatto in commerce, and it would be undesirable in any case to embark upon the industry on a large scale. Where, however, plants are found in a semi-wild state, as in some parts of West Africa, it might be possible to establish a small trade in preparing "flag" and "roll" Annatto. These consist of the colouring matter washed from the seeds and made up into rolls or paste. There is a steady demand for good Annatto made up into this form, and as the freight and other charges would be less on paste than on seeds, there is a distinct inducement to adopt the preparation of paste. While the price of seeds varies from 1½d. to 3d. per pound, the price of paste ranges from 6d. to 1s. 8d. per pound, according to quality.

From the correspondence which follows we make an extract.

Messrs. Fullwood and Bland writes:—

We have received the parcel of Annatto seed from Lagos, and inasmuch as they are not a good sample, being small, and their colour not so bright as it should be, evidently having been gathered before they were quite ripe, we think that the present market value of such a quality would not be worth more than 2d. per lb. We, in fact, bought 70 barrels of about the same quality at 1½d. per pound. The value is, of course, regulated by the quality and the quantity in the market. The highest price obtained in the London market last year was 3d. per pound, but when there was a scarcity in previous years they have realised

as much as 6d. per pound. We think that before they send the seeds to London for sale they should send a sample first, and ascertain the market value, which we shall at all times be pleased to obtain for them. The Ceylon people made a great mistake in 1888 in sending one consignment of 150 barrels; the consequence of so large a quantity being thrown on the market was that they were sold for less than cost of freight, dock charges, &c.—*Kew Bulletin*.

THE CINCHONA SYNDICATE.

Baron J. von Rosenberg writes as follows from Manalé, Devikulam, Madras, to the *Chemist and Druggist*:—

Some weeks ago I read in your columns a notice and prospectus of a proposed cinchona "Association." It was not the first I had heard of it, but the details were interesting—the more so as I was the first, some years ago, to propose a union of planters and merchants, with a view to giving a "fillip" to the bark market. As to the attitude of the planters towards the scheme, I need only refer you to my former letter. At the present prices these gentlemen cannot live, much less keep up their estates. My figures have been confirmed by those issued by the Java Government. An output of 260 lb. per acre, with 4½ per cent., average analysis and 1d. unit, means starvation to a proprietor or "no dividends" to a company. It must be further noted that this item of 260 lb. per acre includes a considerable vanishing-point in the future, and for this reason a very considerable portion of the bark exported from Java has been root-bark, and no root-bark can be taken unless trees are uprooted. But in order to emphasise yet further the present untenable position of the cinchona-producer and his ultimate supply of bark, I venture to give you a few figures with regard to our own small District. Out of, say, 1,700 acres planted with cinchona, 373 acres (nearly 20 per cent.) are being, or have during last season been, coppiced; and this in spite of the fact of our average analysis being higher than that of the Java planters, and the mark of our District being the well-known "Elephant" brand. Then, again, our return per acre is above that of our Java *confreres*, an average of 500 lb., of shaving per acre being not uncommon, and 800 lb. per acre having just been realised on this and an adjoining estate. It will be apparent to you that if, with all these circumstances in our favour, estates here are sold for a song, and a very old one at that, or coppiced, the cinchona-planter is reduced to his last legs. Only the capitalist can hold out, and even he will prefer to put his "eggs into other baskets," if some remedy is not shortly found to give a "quinine" tonic to the market. And I believe that the planter has at last awakened to the necessity of co-operation with merchants and others, subject to an equitable arrangement with the merchant being arrived at. And, with regard to this latter question, it will be necessary for the founders and merchants to issue an estimate of the "office and general costs" of working the Association, and they should sign an agreement to keep within these estimated costs, subject to heavy damages, just as the planters sign, agreeing to sell their produce on the stated agreement, with the penalty of being heavily mulcted if they don't adhere to their word. It will be evident to my brother planters that, with 800 lb. per acre of well-known "Elephant" bark, I have not advised them selfishly. It would certainly have paid me better to say, "Those who cannot do as I do, let them go to the deuce with a low unit; my time will come the sooner and the stronger." But since I have never said this, I hope and believe that my letters will have the more

effect in convincing my brother planters of India and Java of the value of my advice—"Work together, and co-operate with the merchants and brokers." Shortly such co-operation must be and will be effected, and I am certain it will not harm either the retail chemist, the wholesale druggist, or the manufacturer. The purchasing public will have to pay more for their ounce of quinine, but, considering the amount of manual and brain work an ounce of quinine represents, and the immense benefit the public derives from a judicious use of the drug, there is no hardship in the consumer having to pay a shilling or two more for the many doses contained in an ounce of quinine. While upon this latter subject—*i. e.* the consumer's point of view—I would advise your constituents, if they wish to increase their sale of quinine, to suggest its being taken in ginger wine—say 3 grs. to a wineglassful. Taken in this way it is agreeable, and quite equal to a sherry and bitters.

COLOMBIAN INDIARUBBER.

(*Sapium biglandulosum*, Muell. Arg.)

The United States of Colombia have long been recognised as a subsidiary source of Indiarubber. Colombian rubber has been generally known in commerce from the place of export as "Carthagena." It has been supposed to be the produce of a species of *Castilloa*, and this may to some extent have been actually the case. The larger proportion of the export found its way to the United States.

In the following correspondence Mr. Robert Thomson, formerly in charge of the Cinchona plantations, Jamaica, and now settled at Bogota, gives an interesting account of a tree which yields the indiarubber, known in commerce as "Colombia Virgen." This has the peculiarity, unlike all other known sources of this substance, of growing at high elevations, and therefore in a comparatively cool climate.

From the indications furnished by Mr. Robert B. White, and subsequently by Mr. Thomson, there can be little doubt that the tree is one of the multi-form varieties of *Sapium biglandulosum*, a member of the family *Euphorbiaceae*, to which the trees yielding the Para and Ceara rubbers also belong. This widely spread and extremely variable species extends from Mexico and Panama to Colombia, Venezuela, Guiana, and Brazil. The variations which it presents in habit are probably as extreme as are to be met with in the vegetable kingdom. And it is probable that its rubber-producing qualities may be equally, variable. In the West Indies it exists in forms which are probably conspecific. But though recognised as abounding in a milky juice it has never been regarded in that region as a source of caoutchouc, at any rate in appreciable quantities.

In British Guiana the species occurs in two forms, which have been carefully studied by Mr. G. S. Jenman, F.L.S., Government Botanist. The form which occurs on the Pomerou River is known in Carib as *Touckpong*, in Arawack as *Cunakaballi*. The examination of the caoutchouc-like product of this tree, conducted at the works of the Indiarubber, Gutta Percha, and Telegraph Works Co., Limited, at Silvertown, through the courtesy of Mr. S. W. Silver, F.L.S., were, on the whole, unsatisfactory as regards its utilisation for any commercial purpose. This was due to the presence of a resinous substance, which seriously deteriorates its characteristic properties. There can, however, be no sort of doubt as to the value of the Colombian rubber yielded from the same species, and this would make it desirable to give the Guiana trees a fresh trial. M. Sagot, the well known Guianan botanist, to whom Mr. Jenman's specimens were submitted, knew nothing of the caoutchouc-producing properties of the species beyond the fact that the aborigines of the West Indies used the sap as a bird-lime for catching birds.

Mr. Thomson in his letter states:—

I have established in this country during the last five years a plantation of this rubber consisting of about 70,000 trees, this being, I believe, as yet the only plantation made of this sort. Under cultivation this tree thrives admirably, growing with great rapidity, and averaging about five feet a year.

Crops are obtainable in from six to eight years, but a tree five years old yields as much as 1 lb. of rubber. It is a large forest tree, the trunks attaining six and seven feet in circumference. Four arrotas (100 lbs.) of rubber have been extracted from a single tree, but the average yield is far less.

I would undertake to convey to India a supply of plants and seeds, the germination of the latter to be ensured on the spot, and to deliver the same in Sikkim, the Nilgiris, or Ceylon. The supply of plants thus to number from 10,000 to 50,000, which I would deliver for the sum of 1,000l.—*Kew Bulletin*.

TEA TRADERS' TALK.

CHINA TEA AND TEA TRADE.

(By Consul Bedloe, of Amoy.)

Tea culture is assuming large proportions outside of the Chinese boundaries. The Spanish authorities have tried to raise it in the Philippines; the Dutch in Sumatra, Java and Borneo; the English in the Straits Settlements, and the French in Cochinchina. Nearly all these experiments have been failures; the only successes reported being from mountain countries, where there was moisture, good soil, and not an excess of warmth. The Dutch have turned this discovery to account, and now confine their efforts to the high mountainous districts with which their colonial possessions abound. While good tea has been produced in a number of places under these auspices, the quality has been very inferior to the fine growths of Formosa and Foochow.

The reports from other tea districts of China are all assuring. The Congous, which come from north of Amoy, are certainly equal in quantity and quality to those of last year, and probably a trifle better. The Pekoes, from the south, are up to the average. The northern teas are reported as better than ever. This will not affect the American market, as they are bought up in advance by the Russian merchants and command prices that seem the height of extravagance. Chops running from \$100 to \$300 per picul are not uncommon, while now and then extra fine pickings find customers who pay from \$10 to \$50 a pound. In Russia and Japan, and above all in China, there are epicures more dainty as to their daily tea than wealthy connoisseurs are over their Madeira and Burgundy. The Governor of Formosa pays from \$10 to \$20 per pound for his tea. When I dined with him I justified the extravagance. The perfume of the tea filled the palace, and the exquisite, incomparable flavor lingered upon my palate hours after the meal was over. After drinking such tea the finest comet-growth of Burgundy seems coarse and savage.

Tea drinkers at home may revel in the fact that they will have better tea in 1891-92 than they have had for a long time. They are the only Americans who derive any benefit from the tea industry. At one time it poured a stream of wealth into our land, but somehow or another we grew careless and allowed the channel to be diverted to other nations. The spectacle is very painful to a patriot. The heavy capital with which the crops are raised, the experts who taste, and the dealers who buy the leaf, the lead in which it is cased, the steamers in which it is carried, the companies which insure it, and the banks which attend to the financing are all foreign, chiefly British. When we pay for it in money, we send the amount to be shaved in London; and when we pay in kerosene, flour and manufactures, we pass them through almost the same line of hands from New York to Amoy.

The American people will spend over \$11,000,000 for Chinese tea in 1891-92. Of this vast sum the planters will receive \$3,000,000, the tradesmen and home dealers \$2,500,000, and foreigners, with no

interest in America or China, the handsome balance of \$5,500,000! Why cannot we have some of it? There is the same field here today as in the time of Low, Grinnell, Howland and Train, when we were the owners of the China trade. Why do not our business men take advantage of the opportunity?

A few words of advice to tea-drinkers may not be *malapropos*. When I left the United States I was considered a fair judge of tea. Now, after having visited Ceylon, Formosa and the Amoy district, I find I knew nothing of tea. We Americans don't know the first principles of making tea. The delicate leaf should never touch metal. It should be kept in paper, wood, glass or porcelain. To make it, put a small quantity in a porcelain cup, fill the latter with boiling water, cover it up with a porcelain saucer and let it stand three minutes.

Then, if you desire to be an epicure, drink only the upper layer of the golden liquid, throw the rest away, rinse the cup, and begin drawing *de novo*. Never use sugar any more than you would sweeten Chamberlain or pour molasses into Mumm's extra dry. Do not use milk. It ruins the flavor of the tea, and the combination ruins the stomach. The cloudiness produced by adding milk to tea arises from the action of the tannin upon the casein, and is, chemically speaking, pure leather.

Above all things, do not boil tea. The heat drives off the perfume, spoils the flavor, and extracts the tannin, the astringent principle. If the boiling is done in a tin or iron pot the tannin attacks the metal and makes the liquid black. This fluid is simply diluted ink.

Never let the tea stand except in a tightly closed porcelain pot. Standing changes it from a delicious, wholesome beverage into an ill-tasting and bitter liquor. Better make it in small quantities, and make it often. In summer, when you want to cool off quickly, sip the tea boiling hot, with a slice of previously-peeled lemon, or nicer still, of orange without the rind, floating in it. In winter, especially when you have a cold and require a sudorific, add a wineglass-full of arrack to it and drink it down as hot as you can stand it. It will bring out a profuse perspiration when punch or hot Scotch fails to thaw you out.

Beware of green tea! It is an abomination and a fraud. In the first place it is the unripe leaf and bears the same relation to the real article that the green does to the ripe peach. The green tea of commerce derives its rare color from being cured, or rather killed, on dirty copper pans, from being mixed with weeds and shrubs, from being stained with indigo and chrome-yellow, from being colored with verdigris, grass juice, or chlorophyll. Every green dye known to commerce has been used to produce that much admired but death-dealing color, excepting it may be Paris green. As soon as the use of that poisonous substance will give a profit of a cent a pound, no doubt it will be liberally used by the mercenary Mongolian merchant and the much more mercenary cultured European tea trader.

I will venture the statement that there is no fine tea in the United States. What goes to our country is the cheap stuff used here by the coolies and jail inmates.

When an American housekeeper pays \$1 per pound for her Oolong or English Breakfast, she is buying what is sold here for 25 cents. No really good tea is sold here for less than \$1 per pound by the wholesale. If laid down in the market at home it could not be sold for less than \$1 75.

The tea-plant is very sensitive. It flourishes best on a mountain side, where it is neither very warm nor cool; where the soil is dry, but the rains and dews are frequent; where the force of the wind is broken by adjacent woods or hill; where there is a maximum of sunlight, and according to the Celestials, of moonlight; and where the surrounding ground is kept free from weeds or other vegetable growths.

There are farms in Formosa, Fo-Kien, and other tea districts where these conditions exist unchangingly, whose tea crop is as famous and distinctly known in the Eastern world as the various chataux of France

are to the wine experts of Europe. Just as the millionaires of Europe control certain vineyards, so do the millionaires of the flowery kingdom control tea plantations, whose annual output is worth a king's ransom.

Another point of the many we have to learn from the Chinese is the proper mode of packing the leaf. That which goes to America is dumped as soon as it is "fired," burning hot into a lead-lined box, the lead is soldered, and the airtight coffin is sent around the globe in the hot hold of a steamer. The tea sweats and undergoes many changes, which alter its flavor altogether, and vitiate its quality.

The Mongolian packs the poorest kind in strong paper packages, and these in turn in mortuary lead; the better kind in soft tin paper covered boxes; still better ones in silver foil inside of 1-pound cases, made of spirit, sun-dried bamboo, and the best in porcelain jars and vases. He packs in eighths and quarters of a pound, so that if a few leaves are improperly treated or not cured they will not contaminate much surrounding tea.

The Russians compress the tea into bricks, or cover it with silver foil and many paper wrappings, or else put it into glazed jars.

The principle is the same—the subdivision of the tea and the prevention of risks attending larger packages or in bigger bulk, such as heating, sweating and moulding.

This principle we have yet to learn and apply, and will be fully rewarded by the exquisite pleasure to be found in a cup of truly fine tea. The color is a delicate gold; each leaf unfolds into a perfect olive oval: its fragrance, delicate and yet penetrating, dainty but distinguishable above all other perfumes.—*American Grocer*, April 13.

THE RED CEYLON PEACH.

Editor, Farmer and Fruit Grower.

I am sending you today by express a few Red Ceylon Peaches. All my trees were loaded again this year. I have been here four years and every year the trees have had to be propped up to prevent the branches from breaking. In this part of Florida, at any rate, the Red Ceylon is a sure crop; it is very strong growing and seems to be free from all disease, but I do not think it is long lived, and it is best to keep up a succession by raising new seedlings every year. All the seedlings I have seen came quite true.

The oldest trees I have are about eight years old, and they are fine big trees; they branch out low from the ground and don't form a single stem like many peaches. Some of the branches are about fifteen feet long and never grow straight up, as the fruit bends them so that they always remain arched. Of course if I had thinned the fruit the peaches I send you would be larger, but I didn't have time to do it. The Red Ceylon Peach, though not the finest to eat raw, preserves and cans better than any other I know, and, being a freestone, is less trouble to put up than a cling. It should prove a valuable peach to cross with other varieties. It ripens about the same time as the Peento.

Trusting the peaches will arrive in good condition, believe me yours truly,
LOUIS BOSANQUET,
Fruitland Park, Fla.

The peaches were received in excellent condition. Most of them were evidently picked before they were quite ripe. The mature specimens were of a fairly good size for this dry season—shape, roundish oblong compressed, a conspicuous suture on one side at the stem end, a bulge on the same side at the blossom end; with the peculiar recurved point like the Honey, but not so long and sharp; skin yellow and green, washed with dull red; flesh white, red next to the stone, moderately juicy and of a pronounced acid; perfect freestone.—*Florida Dispatch*, June 16.

["The Red Ceylon Peach" is, we presume, a fancy name, for there is certainly no peach indigenous to Ceylon.—Ed. T.A.]

DID YOU EVER TRY

A mixture of alum, glycerine, vinegar and water for mosquito bites?

Salt or ashes for removing discolorations from coffee cups or other dishes?

Cleaning the lint from a clothes wringer with a cloth saturated in kerosene?

Alcohol to remove grass stains from the children's white aprons, skirts, etc?

Pulverized chalk and ammonia for removing stains from marble basins and closet bowls?

To clean a gilt picture frame by using a sponge wet with hot spirits of wine or oil of turpentine, then leaving it to dry?

To cook onions, cabbage or turnips without having the odor escape to all parts of the house? If you have, then you probably failed, even if you had a dish of vinegar on the stove.

To do over the much-used baby carriage, staining with equal parts of solution of extract of log-wood and solution of saffron in diluted spirits of wine, with a solution of tin thrown in for tone?—*Good Housekeeping.*

HELP FROM MEMBERS OF THE CITRUS FAMILY.

PRESERVED LEMON PEEL.—Make a thick syrup of white sugar; grate off the yellow portion of the peel and boil it in syrup ten minutes. Put in glass jars and paste paper over. A teaspoonful of this flavors a loaf of cake or dish of sauce very acceptably.

ORANGE AND LEMON TARTS.—Cream two tablespoonfuls of butter and a cupful of sugar; add the grated rind and soft pulp of two oranges. Beat separately the yolks and whites of three eggs; mix all together with half a cupful of milk and two tablespoonfuls of rolled cracker crumbs. Fill shells made of puff paste. Lemon tarts are made in the same way, substituting for the oranges one large or two small lemons. A twisted strip of paste may be put on like a handle, converting these tarts into tasty baskets.

ORANGE JELLY.—One-half box of gelatine, one-half cup of cold water, one cup of boiling water, juice of one lemon, one cup of sugar, one pint of orange juice. Soak the gelatine in cold water half an hour and add the boiling water, lemon juice, sugar and orange juice; stir till the sugar is dissolved, then strain. Lemon jelly is equally nice, substituting a half cup of lemon juice instead of the orange juice and steeping the grated yellow rind in hot water ten minutes. Make a day before you wish to use it.

ORANGE SHORTCAKE.—Take a dozen juicy oranges, peel and put in a cool place. Make a shortcake of a pint of prepared flour, a tablespoonful of lard and the same of butter rubbed well together and made into a dough with a cup of rich sweet milk. Roll out about an inch thick into a sheet, put it into a well buttered pan and bake in a quick oven a light brown. Take out of the pan, and pull apart and dot with butter. When it has melted spread the sliced oranges on half the cake, sprinkling well with sugar, put the rest on top, cover with sugar just before sending to the table. Occasionally a person prefers this shortcake served with sauce made from the juice of three oranges and two lemons boiled in a pint of water with sugar and nutmeg to taste. When the sauce is used the butter is omitted.

LEMON SYRUP.—Roll the lemons, then press the juice into a bowl or any deep earthen dish, take all the seeds out as they give a bitter taste. Remove the pulp from the peels and cover with water and boil a few minutes, then strain the water with the juice of the lemons. Allow a pound of white sugar to every pint of juice, boil ten minutes and then bottle and seal. A tablespoonful or two of this in a glass of water with cracked ice furnishes a delicious drink on a July day.—*Florida Dispatch*, May 26.

GENERAL NOTES.

CREAM TOMATO.—One-half can of tomato, boiled and seasoned with salt, sugar, butter, and thickened slightly with flour. Just before turning on to slices of hot buttered toast, add one cupful of cream (the

richer the better), into which has been stirred a small pinch of soda. Serve immediately. This makes a nice supper dish.

TOMATO DRESSING FOR FISH.—One can of tomato, one small onion, one-half spoonful of celery seed, two cloves, a small slice of turnip and carrot, a sprig of parsley. Cook twenty minutes. Three tablespoonfuls of flour mixed with butter (size of an egg) added after the tomato is strained. This is especially nice with fried cod and halibut.—*Good Housekeeping.*

PINEAPPLE CAKE.—Use any nice recipe for layer cake. Spread each layer with boiled icing, then with grated pineapple, finishing the top with a plain icing.

PINEAPPLE FRITTERS.—Make a batter of one pint of sweet milk, three eggs, one pint flour, one teaspoonful good baking powder, a scant half teaspoonful salt; divide slices of pineapple into pieces of a suitable size, dip each piece into pulverized sugar, then in the batter and fry in boiling lard to a golden brown color. Dish them on a folded napkin, sprinkle lightly with pulverized sugar, and serve as quickly as possible, with plenty of sugar. Another way is to cut the pine into dice and add a pint of such bits to the batter.

These are equally good made with peaches.

PINEAPPLE RICE PUDDING.—Prepare a quantity of plain boiled rice. To a quart of it, while hot, add a tablespoonful of butter, half a cup of white sugar and three well-beaten eggs. Butter a plain pudding mold or basin and strew it with bread crumbs. Meantime the pine should be prepared by cutting it into dice and stewing gently in a little sugar and water till tender, then draining it from the syrup. Fill the mold with alternate layers of rice and fruit and bake it about fifteen minutes. When done turn out of the mold and serve with a boiled custard sauce flavored with the syrup in which the pine was stewed.

BAVARIAN CREAM WITH PINEAPPLE.—Cut a pineapple into small pieces, boil it with half a pound of white sugar till reduced to pulp. Rub this through a colander, drain off part of the juice. Add half a package of gelatine dissolved in half a cup of water. Stir well and when cold add a pint of cream which has been well whipped and more sugar if needed. Put in a mold and set on ice to harden.

PINEAPPLE ICE CREAM.—One and a half pints of rich milk, two cupfuls of granulated sugar and the yolks of three eggs well beaten should be scalded together in a double boiler till slightly thickened (too much cooking will curdle it). When cold add a pound of pineapple grated fine, and when it begins to set in the freezer add a half pint of cream (whipped). If cream cannot be obtained, however, a half pint of milk should be added to the quantity given above.—*Florida Agriculturist.*

PLANTING IN NETHERLANDS INDIA.—The Amsterdam correspondent of the *L. & C. Express*, writes:—

Aug. 3.—*** The Sourabaya Bank and Trading Company, de Rijk, Gros-kamp and Co., held its annual meeting on the 29th July. The agricultural undertakings were considerably extended, and the contracts for consignments of produce increased from 29 to 34 contracts. The total production of the undertakings was 26,126 piculs prepared coffee, and 20,764 piculs coffee in parchment. Of many coffee estates it may be said that the cultivation is only commencing, so that larger quantities may be expected in the forthcoming years. The prices went from 48 to 53 guilders for parchment coffee, and from 60 to 65 guilders for prepared c.f.f.e. Of the new crop there were sold already on delivery 12,500 piculs parchment coffee, and 1,500 piculs prepared at average prices of 51½ and 63 guilders. * *

The profit and loss account of the Soerabaya office exhibits a net profit of f. 222,984. Reserve fund receives f. 50,000, and after writing off there is an amount of f. 1,01,521 available, from which 7 per cent. will be paid to shareholders, while bond-holders will receive f. 7-50 per bond. Within a short time shareholders will be again convoked to a meeting, at which a plan of reorganization will be discussed.

The Cinchona Company "Gooroet" has declared a dividend of 5 per cent.

Correspondence.

To the Editor.

VANILLA PREPARATION AND TRANSPORT.

London, E.C., Aug. 10th.

SIR,—You do so much to try and bring up any facts to the latest date as they are discovered that I feel bound to send you any information of a reliable nature which comes before me. I have just received from France some vanilla beans that have been sent over in spirit. Of course I am unable to give the whole details of the treatment, but the spirit was thoroughly impregnated with the flavor and the beans arrived in a full meaty state, without having lost very much of their flavor. I am told that the vanilla in this form has been found very acceptable to the chocolate and the cream makers in France. I need hardly say that by preparing the vanillas in this way great risk is avoided of the beans becoming mouldy, also when they are sold there is a great difference in price between a crystallised bean and one that has not been perfectly dried. No such discrepancy will arise with the vanilla beans sent home in spirit. They are packed as tightly as possible into the vessel and then spirit poured upon them.—Yours truly,

THOS. CHRISTY.

SEEDS WANTED IN JAVA.

Soerabaya, 22nd Aug.

DEAR SIR,—Would any reader of the *Tropical Agriculturist* kindly inform me where I can buy the following seeds or, if better, young plants of the best of the (1) Criollo and Forastero types of Cacao; (2) Mountain Papaw (*Carica Candamercensis*); (3) *Carica* (*Vasconcellia*) *Centiflora*; (4) Chocho; (5) Arracacha; (6) Cherimoyer (*Anona Cherimolia*); (7) Mahwah (*Bassia Latifolia*). They need not, of course, all be from one place or person. I wrote more than a year ago to Messrs. J. P. William & Bros. about them, but got no reply.—Yours faithfully,

THOS. G. WILSON.

[J. P. William & Bros. have been advertising the last-named, and could have got or could now get all the others (except, perhaps, the cherimoyer) from Mr. Nock.—ED. T. A.]

"AN OLD COFFEE STUMP."

DEAR SIR,—Doubtless, if we give this writer time enough, and rope enough, we shall get, indirectly, at the meaning of the statements he so freely asserts, yet is so shy to explain. His last dictum is: "What little good there is in Ceylon soil is being pumped out of it by fine plucking." This implication is by no means original: we have all heard it before. But what we have not yet been told is: how the law, thus laid down, operates. When we understand that clearly we shall know what to do. "An Old Coffee Stump" must know this "law" as he so forcibly insists upon it; and it is the height of selfishness to keep to himself whilst twitting us with it abuse. It, most likely (in his opinion), has something to do with the "atmosphere"; but what? If we did not pluck "so fine" we should give the atmosphere more chance, he as good as says. And in this there is a sparkle of truth, for "the larger the weight of the produce, the more the carbon and its compounds; and, the coarser we pluck, the more produce we get." Is this what he means? But the more we produce the less coin we get

for it. How then? As regards this *nom de plume*, it also is not original. It will, sir, be in your recollection that it was appended to a series of letters in the *Observer* seven or eight years ago by a very different pen. Memory though latent, is tenacious, and it is as well to note this now to prevent a confusion of epitaphs hereafter.

ANOTHER PROPRIETOR.

[We suspect that "An Old Coffee Stump" does not answer because he is "stumped." That carbon is derived from the atmosphere every tyro knows, but what planters hoped to learn from the man who seemed so confident and well informed, was how to attract nitrogen from the same source. We doubt if "An Old Coffee Stump" has any secret to tell in regard to this important question. Has any experiment in growing leguminous plants between rows of tea and turning such leguminous plants down green, or when dried, into the ground? —ED. T. A.]

AN AGRICULTURAL DEPARTMENT.

Colombo, 15th Sept.

SIR,—Your suggestion that the Central Irrigation Board should be developed into a Central Agricultural Department or Board, and worked on the lines of the Agricultural Society of Jamaica, is an admirable one. This is I think the second time the reform has been suggested by you, and I trust you will continue to urge the advisability of such a measure till it is carried out. There is a tendency amongst us, in making innovations, to be content with merely nominal appointments and half measures. The result of such action is even worse than if no innovation was sought to be introduced, for it tends to bring discredit on the movement itself and those who are connected with it. This has been the case in more than one instance of late, where those who have been appointed are given no facilities for performing their duties with that freedom which they should in justice have so as to render the maximum amount of service in the cause which they are supposed to be working for. The hampering of persons who are acknowledged to know and are willing to conscientiously perform their duty has been the cause of much evil in our midst. The blame for "omissions and commissions" and the ridicule by the supercilious who are ever ready to throw contempt on every attempt at reform always come down in the head of the nominally responsible, while the *deus ex machina* hides behind his cloud. If agricultural, veterinary, or technical work is to do any good it should be left to the direction of those who are qualified to control in such matters and help in its development and progress. Let an agricultural department or board such as you suggest be established, and then will follow, as it should, the consummation of the objects you have indicated—the collection of useful information, correspondence with other societies, the encouragement and improvement of certain processes in agriculture, the discovery of new varieties of the staples and other plants useful for man and animals, the enlightenment of the cultivator, the improvement of stock, the development of old products and the introduction of new, the amelioration of unfavourable conditions for culture, &c. This can only result from free intercourse, mutual advice and consultation of such qualified men as should be urged to co-operate in these important matters. Here we are still stagnating while other colonies are doing everything in their powers to advance the interests of agriculture, veterinary and technical education. We must drop our make-believe schemes

and go in for honest thorough methods; for if these branches are to be conducted on the present hollow system, the results must be defective and ridiculous, disappointing to those who look for their advantages and discouraging to the workers.—I am, yours,
X.

COFFEE TEA.

SIR,—I do not know if many of your readers are aware that a large quantity of tea is made from coffee leaves, and that some 2,000,000 persons are said to drink this coffee tea. It has been estimated that the percentage of theine in the leaves of coffee was 1.26 against 1.00 in the berry. It is a question whether it would not be an advantage to pick its leaves, and if so, as long as it did no harm to the berry it would greatly enhance the value of coffee estates to be able to get this double crop; certainly I think the experiment would be worth a trial.

H. H.

[Certainly not; planters would, by depriving the bushes of their leaves, be imitating leaf-disease, and with a like evil effect on crop.—Ed. T.A.]

WEEDS AS MANURE FOR TEA.

Marakona, Sept. 15th.

DEAR SIR,—I have read with interest the conversation between Tom and Placid Joe in your issue of 13th inst. The latter is on the right track: green weed and turf worked into the soil is the best food for plants of all descriptions; if we have the seed in the ground let it grow, if not scratch your soil between every second line same as in hales do for their kurakkan. Sow kurakkan or other weeds, hack them down when grown up six inches, new shoots will come up; roots in ground will spread; when again six inches high, if ground is not well covered again repeat the cutting down; but if well covered then turn the soil (weeds under) with mamoties, give a top dressing of stiff soil with lime (even in tea); if light soil with wood ash, smoothing surface if on steep land and sow the seed of small creepers a grasses* we have in Ceylon which do not grow high but cover the land like a green sheet to protect moisture in soil,—absorb more of our rain and save wash.

The first time you prune after that make trenches in your other line, cut up the prunings small, mix with a little soil and put in trenches, cover and give a top dressing of lime or ash or any other manure you are able to add as may be required. This treatment will give more crop, strength in tea, if carefully fermented flavour in cup, estate more valuable, and save tons of soil at a moderate expense. I know clean estates, good crops and cheap work is what proprietors want and therefore visiting agents try for it; but what about long life to your trees or bushes, future outturn and value of estate? You can run a willing horse to death, same has been the case with many coffee, cinchona, cacao and tea estates already. I know estates in the front rank which eventually had to give way to others that were despised but which came on at great speed and are now far ahead of their former leaders and giving handsome returns. The soil is so grateful if you only treat it properly (assist it) that you can grow almost anything with success in Ceylon.—Yours faithfully, J. HOLLOWAY.

P. S.—I know of fair cacao being condemned some years ago near Wattegama; cacao and shade was cut down and tea planted where, a little extra assistance had then been given and proper work done that cacao would now have given good

* Names of grass or samples I will give to anyone writing for it.

profits. Now the tea (also without help) never came on and does not pay; holes are again cut for cacao after so much soil has been washed away and shade lost. What a waste of time and money!—doing things in haste and repenting at leisure, while adjoining estates near it with same soil, carefully nourished at the proper time when young, now give good crops and paying handsome profit, worked when young as I describe above.

[As we understand Mr. Holloway, he fully carries out the system he describes. In that case full accounts of results would be valuable.—Ed. T.A.]

TEA CULTURE: THE BURYING OF WEEDS AND PRUNINGS.

SIR,—The following satirical conversation between two old planters was held in an upcountry bungalow.

DEBILITATED TEA BUSH.

Placid Joe.—Good morning Tom, have a smoke?

Tom.—(Just in, and dashing his hat on the table.) Smoke?!—be blowed!—That's all you think of! Why, that wretched tea maker of mine has not only smoked but burnt about a thousand lb of leaf last night: if this sort of thing continues I shall be ruined before my time!

P. J.—“Keep your hair on” old man, take things philosophically, better let him burn some more, you are the gainer by it—

T.—Gainer! how?

P. J.—You can't put your tea in the Colombo market under 46c., the average price there, by last sales was 40c., ergo you've saved a clear 6c., a pound by it!!!

T.—Hum!—well—but how is one to produce it for less?

P. J.—“Old Coffee Stump” in the *Observer* has thrown out a hint or two, why don't you act up to it?

T.—“Old Coffee Stump”?! some Indian planter, I expect, come over here to try and teach his grandmother how to suck eggs; why does he not give us a reason for his absurdities?

P. J.—Likely! but you'll admit that the Indian planter is taking the wind out of our sails, and probably “Old Coffee Stump” is not paid to give his reasons.

T.—Yes! but the Indian men have the soil, which we lack.

P. J.—All the more reason why we should make, the most of the little we have. Scientists have proved that the principal constituents necessary for the production of good tea are “potash” and “nitrogen,” from the analysis of the soil on your own “totum,” shows that it is woefully deficient of both.

T.—Granted, but how am I to make more of the wretched soil than I do? I can't run to manure, that's flat!

P. J.—Why keep your “totum” so free of weeds?

T.—Good Heavens! surely you would not be so idiotic as to suggest allowing any to grow? There is hardly sufficient nutriment left in the soil as it is to help put a little flush on the bushes, yet you would have me grow weeds to exhaust the soil still more! to say nothing of spoiling the look of my estate.

P. J.—If you buried the weeds in green you would return far more to the soil than they took out, you would return what has been taken from the soil, plus those chemicals (nitrogen, &c.) that the weeds have absorbed from the atmosphere, leaving aside the saving of wash. Supposing I were to clear an acre of jungle, keep it free from weeds and drain it carefully without growing anything upon it, do you mean to say that by the end of ten years that land will have improved? Why, the sun and air combined continually acting on the soil would tend to evaporate those chemical constituents that tea soils owe their fertility to; tea 4x4 does not use all the soil round it, but only a little, and the remainder lying idle, I say, becomes barren. I thought profits was what you were working for, not looks.

T.—That's all skittles! no one does it in the island

P. J.—Well they do it in India, and it has been found to pay there, and where the rainfall is far

heavier than we ever get here. Besides; why do you prune "down to the ground" and so religiously pull off every leaf of the pruned bush? Surely you must know that the leaves are the *very lungs* of a plant! and by that terribly severe butchering, you do more harm than good, were you to prune lightly leaving as many leaves as possible they would (after doing their duty) fall off of their own accord and the bushes would winter (?) just as well, exhaust the soil less, and yield better; why not bury the green prunings?

T.—It's the custom, and everyone does it here, I can't afford to bury the prunings, it's cheaper to rake them down into the river, when I want the fields to look clean, besides they do no good.

P. J.—Oh! custom!!! were it the *custom* for every planter to drown himself after five years' hard work, would you consider it necessary to follow suit? Prunings if buried green would add to the soil, a weeding and burying of prunings could be combined, the digging *alone* necessary for it would enable the fresh soil to take in a little of the atmospheric chemicals.

T.—Now Placid Joe! you are talking "rot"; you know perfectly well no one ever does it here, our main object is to get as much out of the places as we can and in as short a time as possible at the least cost.

P. J.—Steady old man! Sit tight!! How about present prices hardly allowing the places to pay expenses *with the small flushes you now get*, what will you do if they go down still lower?

T.—Do! why I trust it will never come to that, however, I hope to sell out before me!

P. J.—Ah!—well—I won't be the buyer!!! I admit you have as good a chance of selling as you have of drawing the winner of the St. Leger, the odds are heavy! However, I think it very stupid of you, you evidently want a "short and merry" life; you are certainly going the proper way about it, but where the merriness comes in I fail to see, "slow but sure" I should have thought the best. No plant life can possibly go on for ever in the *same way* of cultivation, they like change as well as we do.

T.—Now "dry up" Placid Joe, why on earth don't you carry out your ideas on your own totum or better still cut your throat?

P. J.—My dear fellow! I'm only paid to *do what I am told*; if my "boss" would guarantee to support for life those I would have to leave behind I would gladly do the latter!

THE CINCHONA AND OLEANDER MOTHS.

New Cornwall, Nuwara Eliya, Sept. 23rd.

DEAR SIR,—Will you kindly tell me if the cinchona moth is the same as the death's head hawk moth of England—and whether the larva feeding on oleander is called the cinchona larva.

I should say the cinchona and oleander moth are quite different species. "Newman," one of our greatest entomologists, gives a plate in his book of the oleander moth and larva how. Can you tell me if this is what is called in Ceylon the cinchona moth—or are the cinchona and death's head the same and the oleander a different species? Sorry to trouble you, but this is worth knowing.—Yours faithfully,
F. H. A. FOSTER.

P. S.—I have not found any larva feeding on cinchona so cannot give an opinion as to difference.

[If our recollection serves us aright the cinchona moth is a hawk moth. We do not know the oleander moth, but we should think it improbable that it was identical with the cinchona insect. On reference to our entomological authority he states that the cinchona and death's head hawk moths are two distinct species. He has never heard the oleander larva called the cinchona larva; and cannot say if the cinchona and oleander moths are different species, never having compared them; they may be only varieties. The oleander moth, he says, is also a hawk moth.—ED. T.A.]

THE CINCHONA MOTHS.

Colombo, Sept. 27th.

DEAR SIR,—In regard to Mr. Foster's query in your last night's paper, it may be of interest to know that there are in Ceylon two species of the cinchona moth:—

1. That known as *Daphnis nerii*, identical with the oleander moth of Europe, and the larva of which feeds on the oleander as well as cinchona.

2. *Daphnis hypothous*, slightly more robust than the former, and very similar in markings on the wings and body, the light green of *nerii* being replaced by a blackish or deep purple green. The larva of this moth feeds only on cinchona so far as I know.

The death's head moth is quite different to the two foregoing, and of it there are also two species in Ceylon:—

1. The large death's head, *Acherontia lachesis*, with wide curved black bands on hind wings and blue and black markings on the upper surface of abdomen.

2. The smaller one, *Acherontia styx*, distinguished by its ochreous yellow hind wings and abdomen with narrow black markings.—Yours faithfully,
M.

A VALUABLE DISCOVERY.

Col. M. B. Wever, of this county, has discovered a process by which the orange may be perfectly preserved for an indefinite time. He has been experimenting for some years, feeling assured that it was within the range of human possibilities to discover some process whereby the orange might be kept from decay and the loss of those properties which render it so delicious. In the early part of this year he perfected, as he believed and hoped, his process. He began at once to subject his oranges to treatment and placed them in store to await results. He brought to Dade City a few days since several oranges, which he treated on the 20th day of February last. These were inspected and critically examined by several of our most prominent citizens, who were surprised at the perfect state of preservation of the fruit. It was natural in color, weight, juices, flavor and every other property. When cut and eaten the orange was in every respect just as if plucked from the tree during the proper season. Col. Wever is an intelligent man of sound judgment and strong practical common sense, who is not likely to be led astray by visionary schemes, and he feels assured that he has solved the problem which will revolutionize the orange business and take the growers out of the clutches of commission men. He is now preparing to secure letters patent to protect his process, which he claims will not only preserve all kinds of citrus fruits, but all other fruits and vegetables that have traces of silica in their covering or peel. We trust that his faith is well founded and that he may realize his fondest hopes.—Pasco County Democrat.—*Florida Agriculturist.*

COFFEE IN JOHORE.—A few days ago we announced the sale of Loonchoo Coffee Estate in Johore; and we now hear that an offer has been made to the proprietor of Drumduan Estate to lease his property for a term of years. As Loonchoo has been purchased by a practical planter, and the offer for Drumduan has also been made by another planter of long and varied experience, it looks as if coffee planters, at least, believed in the future of "Liberrian" in the "State and Territory." Coffee prices are still healthy, not to say handsome; and though such a product is always liable to fluctuation, we do not think that there is any danger whatever of overproduction causing a collapse in price, such as has occurred in Tea and Pepper.—S. F. Press, Sept. 12.

CONSULAR REPORT.

CANTON.

Mr. T. Watters reports to the Marquis of Salisbury on the trade of Canton for 1891 as follows:—

TEA.—The customs returns give the following as the export of all tea, including dust and stalks, for 1891, viz:—Canton, 10,611,867 lb.; Kowloon, 4,428,933 lb.; Lappa, 3,422,400 lb.; total, 18,463,200 lb. Of tea proper the total export was 17,533,333 lb., being 3,000,000 lb. above 1890, and larger than the export for several years before. Still the tea merchants have represented the year as unsatisfactory alike to foreigners and natives. One of them, to whose kindness I am indebted for information on the subject, states that “congous were in small supply, but sold in London at lower rates than have ever been known previously.” He adds: “Scented capers have been in over-supply, and the export by the end of the season reached a figure much in excess of the most liberal estimates previously formed. This was brought about partly by a large increase of the supplies of the lower grades, caused in a great measure by the addition to them of leaf from inferior districts, partly by the native shipping on their own account to an unusually large extent, and partly by a reduction in the duty on tea passed through the natives customs. The consequence has been a most depressed market in London, where teas are now selling at 2½d. to 3d. under rates ruling at this time last year.”—*L. & C. Express.*

COCONUT BRUSHES.

The manufacture of brushes of coir, one of the industries of Rhode Island, is carried on at East Greenwich, by Messrs. Pierce and Wadleigh. This material for brushes, says the “Providence Journal,” is obtained from the husk of the cocout, which at first sight would be considered very unpromising, but by macerating in water and fermentation all the gelatinous substance is washed out, leaving the fibres in a state to be spun into a coarse yarn. The natives spin the fiber by rolling it on the knee by the hand until there is twist enough to form it into a coarse thread, somewhat like rope yarn, which is then made up into bales for exportation. The best is obtained from coconuts grown on some of the Islands on the India coast—Islands that are mere coral circles, on which a fringe of the trees grows, with the salt water on both the inner side and the outer side; while that produced by the trees on the mainland, for lack of the salt water, apparently, is much inferior, and many arts are used by the natives to make this fibre simulate that of the Islands, and obtain a corresponding price in the market. It is imported in bales weighing about 250 pounds, in the form of small skeins, very tightly packed. The first process in manufacture of the brush consists in reeling the skeins in spools. These are placed on a very ingenious machine invented by John Earnshaw, of East Greenwich. The brushes come from the machine in couples, like the two webs of a double-pile fabric of plush, for instance, face to face, which is separated by cutting apart. The next process is putting the binding, which is made from the same material on a heavy braiding machine. This is secured by stitching through and through the brush and is also done on a machine. Then the brushes are finished by trimming and shearing, like the pile fabrics before referred to, to give them a smooth, uniform face. The brush is semiflexible, as it consists almost wholly of the fibre. A few light strips of wood are inclosed in the back to give it some stiffness. They are made in quite a variety, from the common scrubbing brush up to the neat clothes brush and brush for the bath. This coir fibre, owing, probably, to the tannin contained in it is found to be almost indestructible by decay, as shown by an incident that occurred early in its manufacture. Mr. Earnshaw used some of the tangled fibre for bedding in his stable, from whence it went into the rubbish heap and after remaining there all winter it was used with the fertilizer in raising potatoes, and when the potatoes were dug

to Mr. Earnshaw's great surprise the fibre was found unchanged. So he had some of it cleaned out and manufactured, as it was evidently as good as ever and as useless for a fertilizer as are scraps of leather. This property of the fibre of resisting decay makes the brushes invaluable for use in markets, as they never become foul, as the bristle brushes do in a very short time. The coir fibre is also used in making mats, for which purpose Mr. Earnshaw invented a loom.—*Scientific American*, Aug. 20.

THE WEEDING OF COFFEE ESTATES.*

SIR,—I invariably peruse with interest the excellent letters from your Coorg correspondent and venture to consider them of the greatest assistance to the planting community. He has evidently such favourable opportunities for making extended and careful observations relative to routine cultivation, that his remarks and suggestions are most valuable. He will, however, I feel sure, be the first to regret that by quoting my writings from memory he has misinterpreted my statement that “burying in weeds sours the soil.” My views were expressed in 1879, and did not refer in any way to the approved system of digging or stirring in small weeds in a well-worked soil, but to a pernicious method adopted in olden days of scraping together with a mammoth vast quantities of rank grass and weeds off land in faulty condition at the end of the monsoon, and burying them deeply in closed pits, in which, after undergoing fermentation, they were converted into what may be termed very bad ensilage. My remarks relative to stacking large weeds on the surface or in renovation pits were pointedly directed to the necessity for hand weeding or grass-knifing before a general digging. As the matter is one of great importance I may be permitted to quote what was really written by me:—

“The soil assisted by the atmosphere must, as it were, cook the food for the plant, and must do so thoroughly, otherwise the proximity of semi-decomposed vegetable matter must be as hurtful to the living plants as a festering corpse is to a human being. Land that has been superficially worked and long exposed to atmosphere action always gets covered with moss and creeping weeds, loses its granular form and becomes clogged. The soil after a time becomes cold and surcharged; with all sorts of acidity and noxious gases. Decomposition of organic matter is checked. . . . and the plant has to eke out a wretched existence surrounded by a clammy mess of soil and organic matter in a form alone favourable for the formation of pernicious combinations. . . . If weeds and rubbish are to be buried, such should not be done merely to get rid of them, but to benefit the condition of the soil, and every means must be adopted to insure their becoming useful as they are not ornamental. They must not be hermetically sealed up in a small hole cut cheese-like in a cold retentive soil, but should be mixed generally with the soil, an operation which will make the land friable and rich; at the same time decomposition will not be checked and the trees will be generally benefited. A sample of partially decomposed vegetable matter found during digging in a cold, sour, retentive soil after 80 inches of rainfall, clearly shows what sort of food the plants have in their proximity. This substance is composed of leaves of forest trees, twigs and general debris and is found to be completely bound together with fungoid filaments. Immediately it is broken up, exposed to the air and generally mixed with the soil it changes its appearance and the fungus disappears. Does this prove that the food for the fungus has passed into a more advanced stage and has become food for a higher order of plant? “The ground must be deeply worked. Digging, draining and the burial of surface matter and green weeds are indispensable, but each operation must be systematically performed with the objects of maintaining the texture and condition of the soil in a proper state,

* And the disposal of weeds generally.—*Ed. T. 4.*

rendering its properties available, and of making its temperature more uniform. . . . If weeds and debris are abundant, such should on no account be buried deeply, but should be allowed to decay in heaps on the surface or in renovation pits and be utilised subsequently as manure. 'Scraping and burying' in is a most objectionable process and should be discontinued. The 'turning in' of weeds is a very different operation and one much to be recommended being adopted by gardeners in England and elsewhere. It consists of digging the surface to the extent of a few inches, each spadeful being completely upset; thus the weeds are superficially buried and the soil improved. The old system consisted in scraping all weeds and debris into a deep trench which was then covered up and the surplus soil from the pit scattered over the surface. No good can possibly result from such an operation. The weeds thus deeply buried pass through a tedious process of fermentation, but ultimate decomposition is seriously retarded. The continual burial of surface debris in this way robs the upper layer of soil of all the valuable organic elements of plant-food and the feeder roots are unable to support the plant in vigour. The operation, moreover, seriously affects the physical condition of the soil, which gradually becomes compact, retentive and unmanageable. The land rapidly loses its hygrometric properties and during the monsoon becomes quickly sodden or saturated."

In conclusion, allow me to point out that the ravages of the borer were far greater in the days when the operation of "scraping and burying in" was in fashion. The great object which must never be lost sight of in the matter of making arrangements to lessen the effects of this pest, is to reduce the temperature of the plantation during the hot weather. Properly selected and well-arranged shade is of course a first essential, but the maintenance of the surface of the soil in a finely pulverised condition is equally important, and this is best effected by summer stirring, which, be it marked, is a very different operation from hot weather digging, being in fact a secondary operation performed after the ordinary digging of the estate, and one that does not interfere with the roots. A field turned up into large clods loses more moisture and becomes far more heated during sunny weather than one that has the first few inches of the surface well pulverised. The great object is to maintain a fine, open surface and a free, deep and rich feeding ground for the fibrous roots. Captain Thomason, in an Essay written in 1871, pointed out several most important facts which are well deserving of the closest study by all planters in arranging their shade and when endeavouring to checkmate the borer. Whatever the heat may be that is necessary for the successful hatching of the insect's eggs, it must be remembered that the cooler the plantation be kept, the fewer eggs will come to maturity. Of course rain or thunder occurring before the eggs are hatched are of the greatest benefit to the planter; but as the insect probably lays several different batches of eggs, artificial arrangements must not be neglected, and in this respect Captain Thomason's remarks are extremely valuable. In general, the most dense bodies are the best conductors of heat; probably because the denser the body the more the number of points that come into contact with caloric. The faculty of absorption seems to be a great deal influenced by colour. The amount of refraction for the same medium varies with the obliquity with which the rays strike the surface. When perpendicular to the latter it passes without change of direction at all; and in other positions the refraction increases with the obliquity. The plane of refraction coincides with that of incidence. Generally speaking, the densest substances refract the most. Bodies that absorb the most light, and of course radiate heat, are heated the most when exposed to solar rays. Of all known constituents of soils, dry quartz sand absorbs heat most rapidly. I venture to think that the above clearly proves why the borer is worse in some soils and situations than in others: but a few thermometers placed in different

fields will readily show what I mean. It is well to remember that in shallow soils mulching must be associated with surface stirring. No amount of surface stirring, however, can ever compensate for deficient depth of working, which should have attention bestowed upon it at a season which must be chosen most carefully with due regard to the condition of the coffee plants, as it is self-evident that the cutting of roots while the trees are bearing a heavy crop, or just before the blossoming time, is certain to have anything but a desirable effect. Too frequent digging may be safely said to decrease fibrous roots near the surface, which all gardeners preserve as essential in crop time and for the development of fertile blossom.

GRAHAM ANDERSON.

Barguai, Munzerabad, 28th August.

—*M. Mail*, Sept. 3.

THE AUSTRALIAN TEA SEASON 1891-1892.

The Australasian tea season closed on the 30th June and the following is a review of the various changes in the markets of production, and the course of the Australasian trade during the year.

CHINA.

The principal supply still comes from China, from whence we received—From Foochow, 16,038,000 lb., from Hongkong, 1,500,000 lb.; the receipts from the former port including a small quantity of Northern teas and from the latter Macao and Canton sorts. Foochow has again failed to supply the demand for common Congou, and consequently the latter half of the season has seen very high prices for the small quantity that was available. But so small was this quantity that towards the close there have been no marked transactions at all for any of the lower grade China descriptions, whilst for any that previously remained upon the market 6½d was obtained for even coarse descriptions. Better kinds have had a gradually falling market in sympathy with the markets of production, and the fall in the value of silver. Choicest kinds, however, brought very full prices at the opening, and have remained firm throughout, owing entirely to the very limited supply. Fine grades down to good medium, for which there is a large consumption, were gradually forced down, until fine teas showed a fall from 1s 2d to 10d and good mediums from 1s down to 7½d. Fair mediums and flavoury sorts also participated in the fall, but recovered somewhat, and in sympathy with common kinds closed strong. All fancy teas, such as scented (which show a rapid falling off from Foochow, but a small increase from Hongkong), and Kaisow buds have had but little interest taken in them, which in itself is a certain indication that other growths are displacing them. Amoy now sends us nothing at all, Macao only a small quantity of new makes, Tayshan congous and scented (except kooloo kinds) are gradually disappearing. Hankow sends but a few thousand pounds' weight, and Shanghai greens are almost unknown, so that for all practical purposes we received all our congous from Foochow, and our scented teas from Canton.

The financial result of the China shipments has not, however, been unfavourable, supplies upon the whole being well regulated. The existence of a good, steady demand enabled sales to be effected, and so prevented accumulation of stocks. Where, therefore, at times small losses were made, at others considerable profits resulted. Bearing in mind the volume of stock disposed of at each period, we incline to the opinion that for once importers of Foochow congous have made a small profit upon their season's trading, and also that the distributing trade have enjoyed a steady but profitable business throughout the extraordinary value shown in all the useful medium flavoury sorts during the latter half of the season, helping materially to swell the profits of the year.

INDIA

comes next in importance, over 5,160,000 lb. having been shipped from Calcutta to the colonies. This supply would have been far below our requirements had the pressure not been relieved from another

quarter, and consequently we are of opinion that taken throughout the past season has shown importers a small loss. Prices opened high but while there has been a very limited supply of good class pekoes and pekoe souchongs, common kinds were in over-supply, and thus a range of prices existed for many months in these grades that must have proved very satisfactory to shippers. Good pekoes had also an unsatisfactory result upon the whole, owing mainly to the London demand forcing rates above our idea of relative value which contrast became more marked when compared with the prices ruling locally for lower grades that had been forced below their relative value. Choice teas can hardly yet be said to have a market, the quantities being so small, and that this is so is because the public demand is limited for "straight" Indian teas, almost every pound sold passing through the blenders.

CEYLON,

With shipments of 3,500,000lb., completes the list of the important sources of the Australasian tea supply. Although today its position is apparently rather low, there can be no question that a considerable improvement is close at hand. "Straight" consumption is not only admitted, but is of considerable moment, and the public now ask for Ceylon tea, consequently choice kinds are more freely taken than is the case with Indian. Shipments that commenced with 150,000 lb. per month now reach 300,000 lb. to 500,000 lb. per month, and the demand has continued so strong for the value offering, that dealers have had to live up frequently to get even a chance of bidding. Prices at which these teas could be profitably sold have for several months past been very low, and it was this in part that made the trade less dependent upon Foochow for low cost stocks.

So far buyers do not take kindly to small leaf. Broken pekoes and dusty teas have almost throughout shown an unsatisfactory result to sellers. Good rates are readily paid for all true Ceylon character kinds. Even dust has friends if the liquor is distinctive. All fannings and broken leaf pekoe souchong kinds have had strong support, and fine liquoring orange pekoes show a much-improved demand. Fanly liquoring kinds of all descriptions have always been difficult to place, but, taken as a whole, the trade has throughout proved satisfactory to dealers, and although for the first half of the season shippers complained about the prices their teas realised, the rapidly-increasing shipments towards the end of the season indicated a very satisfactory trade.

TRADE GENERALLY.

In the face of the depression that has existed, it has been somewhat surprising that the tea trade has continued so sound. Shippers, importers, and dealers all appear to have enjoyed a fairly successful season and owing to the very low prices ruling, the public were also satisfied. The shipping interest shows signs of increasing, and the importing strength diminishing. Dealers now almost all devote their energies to blending, and so are enabled to hold much smaller stocks, and with this frequent buying in smaller quantities the long terms once so necessary to induce sales of quantities are now disappearing, and the great bulk of the trade is done upon a cash basis.

Of the total shipments, 26,200,000 lb., from the three principal ports as shown above, Melbourne provided a market for 15,000,000 lb., or over one-half of the entire trade of the Australasian colonies.—*Indian Agriculturist*, Aug. 13.

THE INFLUENCE OF TEA, COFFEE, AND COCOA ON DIGESTION.

Dr. James W. Fraser, in a recent number of the *Journal of Anatomy and Physiology*, has recorded the results of an interesting series of experiments on the action of our common beverages on stomachic and intestinal digestion. The experiments have been most carefully arranged from a physical standpoint, and give us some valuable hints on the digestion of the chief alimentary principles, but they have no bearing, it should be mentioned, on individual variations of

human digestion, or on the influence of the various glands in preparing the gastric or intestinal juices. They are, however, of much value in showing how standard preparations of the peptic and pancreatic ferments are modified in action when our ordinary daily beverages are allowed their free action on the digestion of various articles of food. The digestive processes were carefully investigated, and absorption was imitated by a proper dialyzing arrangement. An artificial peptic juice, and afterwards an artificial pancreatic juice, were employed, and the amount of nitrogenous matter dialyzed was most carefully estimated. The food stuffs experimented on were raw and cooked serum and egg albumens, raw and cooked myosin, syntonin, alkali albumen, casein, gluten, starch, and oleine. The results obtained from an exhaustive series of experiments and analyses show that all the three typical infused beverages—tea, coffee, and cocoa—retard the digestion and absorption of all the nitrogenized proximate principles of dietetic substances when peptic and pancreatic digestion was taken together, and that they uniformly retard peptic digestion, although tea may assist the diffusion of peptones from the stomach. Pancreatic digestion is also uniformly retarded, and diffusion thereafter is but rarely assisted, so that neither of them compares advantageously with water as a standard beverage for experimental investigations. A summary of dietetic advice is added to Dr. Fraser's observations, which will, in the main, agree with that which is now given by our best authorities in cases of dyspepsia; and we are glad that experimental inquiries afford so strong a basis of support to empirical clinical observations:

"1. That it is better not to eat most albuminoid food stuffs at the same time as infused beverages are taken, for it has been shown that their digestion will in most cases be retarded, though there are possibly exceptions. Absorption may be rendered more rapid, but there is a loss of nutritive substance. On the other hand, the digestion of starchy food appears to be assisted by tea and coffee; and gluten, the albuminoid of flour, has been seen to be the principle least retarded in digestion by tea, and it only comes third with cocoa, while coffee has apparently a much greater retarding action on it. From this it appears that bread is the natural accompaniment of tea and cocoa when used as the beverage at a meal. Perhaps the action of coffee is the reason why in this country, it is usually drunk alone or at breakfast, a meal which consists much of meat, and of meats (eggs and salt meats) which are not much retarded in digestion of coffee.

2. That eggs are the best form of animal food to be taken along with infused beverages, and that apparently they are best lightly boiled if tea, hard boiled if coffee or cocoa is the beverage.

3. That the casein of the milk and cream taken with the beverages is probably absorbed in a large degree from the stomach.

4. That the butter used with bread undergoes digestion more slowly in the presence of tea, but more quickly in the presence of coffee or cocoa; that is, if the fats of butter are influenced in a similar way to oleine.

5. That the use of coffee or cocoa as excipients for codliver oil, etc., appears not only to depend on their pronounced tastes, but also on their action in assisting the digestion of fats."

COFFEE AND TEA GROWING IN PERAK.

Mr. Butler, the Collector and Magistrate, at Kuala Kangsar, in his annual report for 1891 published in the *Perak Government Gazette* of the 26th August thus describes the progress of coffee planting there last year:—

Sir Graeme Elphinstone informs me that he is much pleased with the character and promise of the young coffee on the Waterloo Estate, and that his favourable opinion is shared by others who have had many years experience in Ceylon coffee. In referring to the labour question, he writes: "I have now 80 Mala

working, and hope to have over 100 next week. I pay them weekly, and find them capital 'workmen,' The following is a report on the estate for 1891 with which he has kindly furnished me :

Acreage of coffee :-

	Acres.
Old coffee...	67
Young coffee ...	159
Grass ...	8
Total planted ..	234
In course of planting	48½
	282½

Owing to the illness and death of the late able manager, Mr. Thomas Fraser, the clearing work was for 1891 unavoidably delayed.

Crop for 1891 :-

	Bushels.
Parchment ...	1,188
Cberry dried ...	564
	1,752

Equal to 330 cwt. clean coffee.

PROSPECTS FOR 1892 CROP.—It is as yet too early to give an estimate; there is a very fine blossom in sight but no blossom of importance will be out till the end of February or March.

ESTIMATED WORK FOR 1892.—Completing 48½ acres now in hand. Felling and roading another 50 acres of jungle. The most favourable time to commence felling is, I believe, in September. Prior to felling, however, in view of successfully planting the estimated 50 acres, roads through the jungle must be cut, boundaries cleared out, and a good nursery completed. The Kamuning Liberian Coffee Estate is working very well, and has been greatly extended during the year. There are now 265 acres under cultivation, 252 of these being planted with coffee and 13 with pepper. The latter and about 120 of the coffee are now in bearing. Picking was commenced in March, when 1½ boxes were obtained. The quantity of crop gradually increased, and in December 296 boxes were gathered, the total quantity picked during the year being a little over 100 piculs. About 12 piculs were cured from the dry cherry and sent to Singapore, where the price realised was \$37 a picul. The estimated crop for the current year is 360 piculs. Cleaning is at present performed by drying and pounding, but a pulping machine is expected shortly, and the building for it is in course of erection. The estate has about three miles road frontage, that portion of it to the north of the road having a depth of about two miles, and that on the southern side about half a mile. A block of 5,800 acres was surveyed during the year. The remainder of Mr. Hill's concession of 10,000 acres has been selected and is being cut out. It adjoins the present block, and extends up to the left bank of the Plus river. The estate will thus be particularly well situated as regards transport and means of communication, having a cart-road on one side of it and a deep and easily navigated river, flowing into the Perak river, on the other. The total number of coolies employed on the estate is 135 the daily out-turn being from 110 to 115. The last of the contracts of the statute immigrants expired in June, and now, with the exception of eight female coolies lately arrived from India, the estate is worked entirely with free Tamil labour. The health of the coolies has much improved. During the last three months of the year the daily average number of coolies in hospital has been only four, whereas in 1890 it was between 30 and 40. The manager attributes this to the new water supply, well water being used instead of water from the stream. The total expenditure on the estate for 1891 was, I am informed, \$12,890.

The Cicely and Hermitage Estates have been greatly improved during the year. They were let to a Chinese company in 1890, but for some months afterwards were much neglected, in consequence of which, and bad

pruning, the trees were considerably damaged. In March last an experienced tea planter, Mr. F. Watson, was put in charge, and the monthly output of tea, which was then only 600 lb. and produced at a cost of 30 cents per lb. has now, with a small increase of labour and judicious penning, been increased to 1,500 lb. at the reduced cost of 21 cents per lb. The climate and soil appear to be in every way favourable to the growth of tea. Eight months' seedlings, planted in April last, are now four feet high, and will, I am informed, be picked in April next. The average local price of tea is 60 cents per lb. and there is sufficient demand to warrant a far larger cultivation of it.

INVENTION OF A NEW WOOD CONCRETE.—A new wood concrete, according to the *Bau technische Zeitschrift*, has been invented in Germany. Shavings and planing mill chips, either of common or fancy woods, which may be stained before use if desired, are mixed with cheese or, rather, casein, calcined magnesian limestone, glycerine, silicate of soda and a little linseed oil, and this queer mess is forced by hydraulic pressure into moulds, where it is allowed to harden. When dry, the composition is strong and solid, and can be sawed, planed, polished and varnished. It is expected that it will be found useful as an "ornament" in the shape of panels, or as a covering for entire wall surfaces.—*Indian Engineer.*

THE TROPICAL AGRICULTURIST MONTHLY.

Vol. XII.]

COLOMBO, NOVEMBER 1ST, 1892.

[No. 5.]

THE CEYLON FOREST CONSERVANCY : REPORT OF 1891.

HERE are some droll features in this grave official report. It bears on its title-page that it is the "Report of Mr. A. M. Walker, acting Conservator of Forests," it is signed by him, and in a portion of it

he expresses gratitude for a personal allowance of R2,000 per annum added to his salary of R6,000. And yet Captain Walker is repeatedly mentioned in the third person as acting for Mr. Broun, or giving over charge to the latter, who is really the "I" of the report. The explanation is that the report which has been only now produced in a complete form was prepared by Mr. Broun before he went on leave six months ago, all but a portion which he was unable to complete because of the culpable delay in the sending in of reports by some of his subordinates, whose conduct is severely reprehended. The voice is the voice of Mr. Broun though the hand which signs may be that of Captain Walker. Another amusing statement, although to Mr. Broun himself it was no joke, relates to the slowness with which Government forests are demarcated. At the present rate of procedure he calculates it will take four centuries to complete the work. Then we do not know whether Mr. Broun was "kinder sarkastic" when he indicated that the members of his department had not done heavy work during 1891; but he was certainly serious enough and correct enough in stating that "there is no department in the island which has to work at all times in more unhealthy localities." But incalubry will be modified, and it is to be hoped ultimately banished as boundaries, roads and paths are cut by the officers and areas of forest cleared of creepers and parasitical growths and thinned of superfluous trees,—although in many cases these latter have long ago disappeared under the destructive systems which prevailed prior to the establishment of a regular forest conservancy department. During 1891 only one reserve forest of 782 acres was proclaimed in the Kurunegala district including which the acreage of reserved forest was at the end of the year 26,580 acres. It is on these unsatisfactory figures that Mr. Broun found

his estimate of 400 years as necessary for the completion of the work. The number of forests taken in hand during the last three years, but not proclaimed, was 53. Details are given; and from the report of the Assistant Conservator of Sabaragamuwa we quote a few significant paragraphs:—

The Weywilla forest was the subject of some litigation in 1891, with results so far quite unsatisfactory. It will be remembered that one Jayasundara Kirelle Menika claimed upon a sattu certain lands in the village of Weywilla, and that she objected to the finding of the Forest Settlement Officer and carried her appeal to the Supreme Court, with the result that the Forest Settlement Officer's proceedings were quashed.

Later, a case was brought against her for felling certain trees in Weywilla in primeval forest, and the lower court found in favour of the Crown, but upon an appeal being made to the Supreme Court the case was again reversed in favour of the claimant, with the distinct implication that no proof of trespass was disclosed by the prosecution.

The result of so unfavourable a finding by the Supreme Court, added to its first finding upon the judgment of the Forest Settlement Officer, tends to strengthen the claimant's claim upon Weywilla as a whole, while her rights to a part is only admitted.

The crown is deprived by this of one of the best pieces of forest in the Kuruwiti korale, at a place where not only is forest scarce, but highly important as being part of the reserves situated round the Labugama reservoir that, I need hardly remark, demand the greatest care and preservation.

The proposed reserve at Weoja, in the Kegalla District mentioned in the annual report for the Province of Sabaragamuwa for 1890, remains still unsettled, as no further surveys have been made with this end in view.

The importance of establishing a reserve here is very great as the tea industry in the Kelani Valley will in time bring a large demand upon the Forest Department to supply fuel, upon which it depends entirely for its existence.

A rough estimate of the extent of forest in the island which it will be necessary to reserve is represented by the figures for square miles, 2,974, but as no information came from Uva we may safely increase the area to over 3,000 miles. This seems a small proportion out of a total of 25,000 square miles for the surface of the whole island. Multiplied by 640 for acres, however, the area looks respectable. Mr. Broun contends that

In order to show some marked progress in the reservation of forests, it will be necessary to take in hand large stretches of forest in which there are not large numbers of claims to stay the work of the Settlement Officer. Excepting in the densely populated Provinces, and within easy reach of the railway, it will as a rule not be desirable to take in hand small

forest areas which would be costly to demarcate and to supervise, and which, moreover, might with advantage be utilised as village forests. In the forest Provinces, such as the Northern, the North-Central and Eastern Provinces, and a large portion of the North-Western Province, the cost of reserving thousands of acres and of demarcating and supervising them will not be greater than on one-tenth of the area in Sabaragamuwa and portions of the Western Province.

The length of boundaries cut by the Survey Department in connection with forest surveys has been 116,788 chains and the boundary pillars erected have been 321.

The area surveyed during the year amounts to 63 square miles and 232 acres, and the total area of forest surveys amounts to 359 square miles and 216 acres. The cost to the Survey Department amounts to Rs.25,760.25 for the year, but to the Forest Department it only comes to Rs.1,84.50, which was disbursed on cooly pay, chiefly in the Western Province.

The completion of the survey of lands taken up for railway fuel plantations at Galboda was urgently required,—we say was, because we presume the work was completed before the report was issued in the middle of September 1892. We quote what is said about working plans (for thinning and replanting natural forest) and Enumeration Surveys:—

WORKING PLANS.—The work in the Nanuoya forest has been carried out on the strip system, as described in the annual report for 1889. Plots Nos. 14 to 29, amounting to 25 acres, were felled, and plots 14 to 22, amounting to 15 acres, were replanted with blue gum. *Eucalyptus robusta*, *Citriodora amygdalina* and *diversicolor*, *Acacia decurrens* and *Melanoxylon*. No working plan has, however, yet been drawn up. At Nanuoya system of working has merely been adopted, but the possibility and rotation have not yet been properly fixed. Some of the Assistant Conservators have also adopted special systems in their forests. It is hoped, however, that before long working plans for the railway fuel reserves at Mirigama and Nanuoya will be submitted for the sanction of Government.

ENUMERATION SURVEYS.—On his return from Dehra Dun Forest School Mr. J. St. L. Hansard was deputed to Mirigama to report on and make enumeration surveys in the forests set apart for the railway fuel supply. After a stay of about three months he was permitted to exchange duties with Mr. Ferguson, who carried on the work until he took over the duties of Superintendent, Railway Fuel Supply, at the end of November. The work is not yet completed, but enough has been done to show that the forests have been cut into in a most extensive manner, and that at present the average yield per acre is very low, and that a larger extent will be required to satisfy the yearly requirements of the Railway Department.

The following paragraph is one of a series in which the Government Agent of the Western Province is represented as ignoring or placing himself in dead opposition to the officers of the Forest Department:—

For some unaccountable reason the 200 acre block referred to in my annual report for 1890 has not yet been taken in hand. I have drawn the attention of the Hon. the Government Agent to this, but hitherto without success, and it appears as if it would be even too late to do anything in 1892. The orders of Government as regards this experiment were issued more than a couple of years ago, and it is strange that, although the land has been subdivided into plots for different villages, they should not be allowed to begin.

An enumeration by Mr. Huddleston at Trincomalee of trees per acre in Government forest was disappointing, the totals being 30.81 sound trees and 5.54 unsound. The prevalent timbers were *palai* or *palu*, satinwood, ebony, *ranai*, with very little *halmill* and *milla*, while "other good species" not described were about one-third of the whole. Between thirty and forty years ago, the Trinco-

malee forests were subjected to a barbarous system of destruction from which it will take them long to recover. On 10 acres of what Mr. Tocke called "good ordinary forest" in the Northern Province, he enumerated 18-10 trees of satin, ebony, palai, and *ranai* per acre,—a "beggarly account" surely. Mr. Broun in view of his Indian experience remarks:—

This table is useful for comparison with the table given above for Trincomalee forests, for it shows 0.6 satin tree per acre above 6 ft. in girth against 0.01 in Trincomalee, 0.3 ebony against 0.02 in Trincomalee. The palai is, however, somewhat less abundant—a fact which rather surprises me, as the Northern Province forests usually team with palu of large girth. Still, taking the four species—satin, ebony, palu, and *ranai*—there are in the Northern Province sample area 1.5 trees per acre above 6 ft., while in Trincomalee there are only 0.89. The other girth classes not being the same, it is difficult to make comparisons between trees of smaller girth. There are, however, in the Northern Province 5.8 trees of the same four species per acre between 4 and 6 ft. in girth, while in the Trincomalee District there are only 6.81 between 3 and 6 ft. in girth. To a Forester who has been accustomed to work in gregarious forests neither of these results appear good, and if Mr. Tocke's enumeration is a good sample of a fairly good forest, it helps in explaining why the working of our forests is so expensive compared with that of good Indian forests, and it shows that we require large areas of supplying the same requirements in good timbers.

It seems hard that Mr. Broun should have to tell the public which pays, in regard to "sample plots":—

Notwithstanding my remarks in paragraph 19 of my last annual report little zeal has been displayed by the large number of the Assistant Conservators in establishing sample plots in natural forests. Every year wasted means one year's delay in the progress of the Department. The sample plot near Anuradhapura has not yet been measured—indeed it had a narrow escape from being sold—and the only officers who have taken active measures are the Assistant Conservators of the Central and North-Western Provinces. Near Diambulla two sample plots have been started, and in Narigama forest in the Chilaw District a sample plot among kumbuk trees was started in 1890 by Mr. Tatham. Measurements were again taken in 1891. In this sample plot there are 20 trees ranging in 1890 from 2 ft. 7 in. to 7 ft. 10½ in.. The average girth increment of these trees is 1.37 in., but if they are taken girth class by girth class the mean annual girth increment is, for—

1 tree, VIth girth class (paragraph 23)	1.00 in.
10 trees, IIIRD	do .. 1.35 "
7 trees, IIRD	do .. 1.43 "
2 trees, ISt	do .. 1.50 "

If this sample plot is a fair example it accounts for the large girth which the kumbuk attains, for it attains its highest mean annual increment only when it gets well above 6 ft. in girth. Another sample plot for palu and tammana was started in the Kulnaga forest, Kurunegala District.

Sample areas were also chosen in plantations in the Eastern, North-Western, and Uva Provinces. These will be referred to under the head "Artificial Reproduction."

Under the heading "protection and improvement" it is stated by Mr. Broun:—

In six of the Provinces the dealings between Government Agents and the Assistant Conservators have on the whole been satisfactory, notwithstanding occasional friction. The Government Agents consider the Assistant Conservators as their Assistants in forest matters, and entrust them largely with the forest administration of their respective Provinces. Where this co-operation exists the administration is by far the most successful, and the headmen knowing that the forest officers have the Government Agent's support are much more willing to help them. The Eastern Province and Sabaragamuwa can be quoted as examples in point. On the other hand, in the

Western and Northern Provinces there is no such co-operation. The Government Agents give orders to subordinates without referring to the Assistant Conservators, who are in the same cases left in ignorance of forest work which has been carried out, and of expenditure disbursed during the year. This has in the case of the Western Province led to confusion in the accounts and to an expenditure larger than the vote allotted. In the Central Province the Government Agent declined to have any responsibility with respect to forest business, and as I received no orders from Government to take over the responsibility, the Assistant Conservator was more or less independent of all control.

We take it for granted that the Governor, who read this report before it was printed, took immediate and stringent measures to correct a state of things so injurious to the public interests as is above represented. Mr. Broun complains, too, of discouragement from the judicial officers of Government:—

Altogether 1,364 cases were taken up, and resulted in 799 convictions implicating 1,294 persons, and 459 acquittals concerning 916 persons. The proportion of acquittals to convictions is somewhat large, but it is not to be wondered at when Magistrates take so little trouble to deal severely with cases of chena and of timber theft. The Assistant Conservator, Sabiragamuwa, complained to me that it was of little use his bringing any cases in Kegalla and Rajanapura courts, as the Judge in the latter court gave such slight punishments when convictions were obtained, that they were rather an encouragement than a prevention to offenders. At Kegalla the District Judge ill conceals his sympathy with the accused. Only recently in a case brought against an estate for cutting down a stream reservation he stated that Government had received in exchange land covered with tea, and that it had therefore not suffered, but obtained improved value.

At Vavuniya two men were caught by the Assistant Government Agent cutting branches of palai trees for fruit. Notwithstanding that this is a practice which has been grossly abused for years, the men were discharged with a caution.

A man was prosecuted by the Assistant Agent in the Tangalla Court for clearing a chena in Palla Rota, where he felled a number of large trees. The Magistrate fined the defendant Rs50. On appeal to the Supreme Court the judgment was quashed, because the proceedings had been irregularly taken. Another case was entered against him on precisely the same evidence and before the same Magistrate, who, however, this time acquitted the accused! In both cases the latter produced a "labima," not registered. This "labima" only showed one boundary, "the river." On the strength of the judgment the man now claims a large extent of country, including a portion of Palla Rota, always looked upon as Crown forest. He appeared with a large knife at a place where 15 palu trees had been felled by the Assistant Conservator, and threatened to use it against anybody who touched the trees.

A case was brought by the Forest Ranger, Kalmunai, against a man for offering him a bribe to induce him not to report a theft of timber from Crown forest. The Police Magistrate held that the timber theft being compoundable, section 211 of the Penal Code does not apply to it. The consequence is that almost all forest offences being compoundable, no man can be punished for offering bribes for concealing them and that, conversely, no forest officer can be punished for accepting bribes for concealing offences other than those under sections 66 and 67 of the Ordinance! I represented the matter to Government, and stated that the officer in question was not empowered to receive compensation, but to no effect, and the Hon. the Attorney-General expressed a doubt as to the possibility of altering either the Penal Code or the Ordinance, because ordinary people cannot be expected to know what officers are empowered and who are not.

The case in Kegalla court mentioned in paragraph 29

of my last report has, for some unaccountable reason not yet been finally dealt with. In another case known as the Mitipola case, the Superintendent of "Fairfield" estate was fined for cutting timber out on adjoining Crown forest to build his bungalow, but, notwithstanding that the Magistrate visited the spot himself to satisfy himself as to its being forest or not, his finding was set aside by the Supreme Court.

The above examples show how disheartening it is for forest officers who attempt to preserve the forests under their charge to try and bring cases against people who go in for systematic pilfering and destruction.

In dealing with forest fires Mr. Broun starts the theory that the upland patanas originated with them! He writes:—

Fire protection is happily not as important in Ceylon as in India, as the shrubby evergreen undergrowth and the dense leaf canopy as a rule prevent any fires reaching far into the forest. In Tamankaduwa, however, where large herds of cattle graze in the open plains near the Mahaweli-ganga and around Kandela, Topari, Giritulla, and Minneri, the graziers set fire to the withered grass so as to obtain a green and succulent crop for their cattle. These fires gather strength until they reach the forest, where they kill most of the trees or at least saplings within some distance from the edge. Thus, year by year the grass lands encroach upon the forest, and it is necessary that steps be taken to save them from further damage. Very possibly the patanas of Uva and elsewhere in the island originated in this very manner. The hills which are now covered with grass were probably covered with park-like forest, such as is now found near Ekiriyankumbura and Bibile resembling in many respects, as well in species as in grassy undergrowth, the sub-Himalayan forests. The annual recurrence of fires must have stripped the hills of all their woody covering except in cool sheltered hollows and ravines where fringes of trees are still to be seen.

Some of the patanas may have been due to fire and that "devouring element" may have extended others, but the received geological opinion is that most of the grassy prairies of Nuwara Eliya, the Horton and Elk Plains and Uva are due to ancient water floods of great extent and violence.

What is said about natural and artificial reproduction is so interesting generally and calculated to be so useful to planters and others who may be trying experiments in arboriculture that we will quote those portions of the report in full on the completion of this notice. We submit that special attention should be paid to the careful collection of well-ripened seeds of such valuable trees as satinwood, pslu, kumbuk, &c., and that full information should be tabulated and published regarding the success, or otherwise, at different altitudes and in differing climates of experiments with the Australian eucalypti and acacias, *Grevillea robusta* and other foreign trees as well as those indigenous to the island. It seems to us that special attention ought to be paid to the cultivation of jak. It is one of the few valuable timber trees which grows rapidly, and which during its life yields large supplies of fruit for human food, while the spare portions of its luxuriant foliage affords an excellent forage for animals. A young man planting from 30 to 500 acres of jak in a good position with reference to carriage and demand for timber, would at middle age be possessed of a fortune. Of the introduced trees *Eucalyptus robusta* and *E. diversicolor* seem amongst the best. After reference to roads and buildings, we are told under "other works" that

The most important addition was the arrival of a circular saw and steam engine from England. The saw mill was sent to Batticaloa, where it was expected to be of most use. It was put up, but owing to the site being unwholesome and objectionable to the police, it is to be shifted to another ground which is to be

purchased by Government for a depôt and site for the Assistant Conservator's bungalow.

In the Central Province two wire shoots, each a quarter of a mile long, were purchased at a cost of a R330 for the railway fuel operations at Nannu-oya. New sling carts were obtained for the North-Central Province and North-Western Province, which, it is expected will considerably reduce the cost of transport.

The Paswelli-oya in the Barawa forest in the Western Province was cleared of snags and overhanging trees at a cost of R2,363.92. Of the wood obtained in this manner 541 cubic yards were sent to Kelaniya depôt and 500 are lying in the forest awaiting a public sale.

The very wet weather which has prevailed during the year has greatly impeded operations, and much stock which should have been brought out of the forest had to be kept. Cholera, which appeared during the year, had also its effect in scaring away sawyers in the Central and Eastern Provinces especially. The result has been that a large unexpected balance of funds had to lapse to revenue at the end of the year.

The total value of timber and other produce sold during the year amounted to R377,562.77, against R371,215.03 in 1890 and R337,120.84 during 1889.

As we read what follows about timber for sleepers and telegraph posts, we feel inclined to ask if much of the failure of certain timbers was not due to imperfect seasoning?

SLEEPER OPERATIONS.—The Railway Extension Department indented for 5,700 railway sleepers, which were to be supplied at Hatton, Matale, and Polgahawela respectively. Of these, the Assistant Conservator, Sabaragamuwa, delivered 1,906 sleepers at Hatton, the Assistant Conservator, Central Province, 644 sleepers at Watterama and Matale, and the Assistant Conservator, North-Western Province, 563 sleepers at Polgahawela. The Assistant Conservator, Central Province, attributes his delay to cholera, which caused his sawyers to bolt.

Experimental sleepers of alubo (*Eugenia Sylvestris*) etaheraliya (*Kurrimia zeylanica*), and dawata (*Carllia integerrima*), were supplied to the Railway by the Assistant Conservator of Forests, Western Province, during the year, but, excepting the alubo, which stood fairly well, the sleepers made no stand against damp, and rotted away quickly. Dawata had the additional fault of being liable to attacks of white-ants. No reports have been as yet received as to the behaviour of other Island sleepers, although the low country dun sleepers supplied to the Kalutara-Bentota extension do not appear to have done very well.

TELEGRAPH POSTS.—The pandikasa posts supplied from the North-Western Province have not done well at all: a large proportion rotted flush with the ground and broke down, and towards the end of the year the Postmaster-General applied to have them renewed by the Department. Instructions for a new supply of posts made of good wood were issued shortly after the close of the year. I have informed the Postmaster-General that in future no species would be guaranteed, and that if he wanted posts made of the cheaper woods he must take the risk of premature decay himself. If attempts are made to do a large quantity of work for a small outlay, accidents must be allowed for. The Postmaster-General attempted to obtain posts for the Tangalla-Hambantota extension at so low a price that neither the Southern Province nor Sabaragamuwa were able to undertake the job.

How white-ants could find a lodgement in sleepers subject to the reverberations of several trains daily, puzzles us. But perhaps the sleepers were merely buried in earth. Could not what are called inferior timbers, such as *hora*, be profitably utilized by being subjected to some cheap preservative process, such as the application of kerosene which renders naturally poor pinewood so useful? As regards satinwood, we are told that

The demand for this timber in the log has increased largely during the year, and inquiries have been made by several firms for large quantities for export to India and Europe; and if the Central Depôt can be kept

supplied by the Provinces at a fairly regular rate, a steady trade can be made in this timber.

Restrictive measures of an apparently vexatious character have affected injuriously the

RAILWAY FUEL SUPPLY.—Although it had been estimated that about 93,000 cubic yards would be required by the Railway Department, this year only 82,079 cubic yards of Crown and private wood were delivered by the Department. The cause of this has been the strict enforcement on the part of the Hon. the Government Agent, Western Province, of the system of passes for all firewood brought to the line. The contractors complained of being subjected to much hardship owing to their being sent about from headman to korala and from korala to Mudaliyar, in a way to make them lose time and money. The Government Agent thought that it was merely a trick on the part of the contractors to get better price out of Government, but the system has had sufficient effect on the public generally. The Director of a mill in Colombo informed me that since the enforcement of the stricter system of passes the prices of firewood for his mill had risen from R3 to R5 per ton. Anyhow the supply to the railway materially diminished, and at last the running engines on the railway—*i.e.* those which did not, like mail trains, take the wood supply for a whole section at Colombo, but filled in again at Henaratgoda, Veyangoda, or Mirigama—had to give up wood altogether and had to burn coal. This has caused a considerable extra expenditure to the Railway and a noticeable falling off in the revenue to us.

Of the 82,079 cubic yards, 26,710 came from Crown forests. The expenditure on them was R29,502.07, or R1.10 49-100th per cubic yard.

Then as to

FUEL SUPPLY TO THE PUBLIC.—Jaffna is the only town in which a large traffic in firewood goes on. The sale of firewood at Jaffna produced a revenue of R12,676, which is by R855 larger than that of last year. At Trincomalee an attempt was made towards taking the firewood supply under the management of the Department, and a stock to start with was being collected towards the end of the year. It is now time for Galle and Anuradhapura to begin to adopt some system for the firewood supply. At Badulla and Nuwara Eliya a good stack of firewood is being kept in the depôt, the sales to private purchasers at the latter place amounting to 1,169 cubic yards, worth R2,155.75. Kandy is utterly unprovided for, and it may become necessary to start plantations for the fuel supply of the town.

The largest sales of standing timber were in the planting districts, Sabaragamuwa selling timber to the value of R13,676.51, while the Central Province and Uva show sales amounting to R8,552.56 and to R8,806.76 respectively. The Assistant Conservator, Central Province, however, reports that there have been few extensions of factories, and that demand has consequently been somewhat low. Exclusive of the Western Province, for which no returns can be obtained the sales of timber on payment of royalty amounted to—

Total number of trees	25,183
Number of waricheches	43,000
Number of shingles	5,200
Number of cubic feet	109,754
Value	R34,866.07

The Assistant Conservator, Northern Province, says that the number of permits to fell on payment of royalty has increased during the year, and represents that it is not proper policy, as with the very imperfect protection the forest have it is very easy for license holders to commit timber thefts.

OTHER PRODUCE.—Like last year Uva leads the list on account of its revenue on the lease of gallnut (*Terminalia chebula*), which this year fetched even higher prices than usual. There is no reason why the Eastern Province should not make almost as good a revenue over the same product.

In the Northern Province R480.50 were obtained from licenses to lop green leaves for manure. The Assistant Conservator observes that, notwithstanding his complaints, care has not been taken to restrict

the species to be lopped. The operation is a very exhausting one to the forest, and gives only small returns, and should be restricted. In the Southern Province the kitul rent has only obtained R203-02. The headmen in the villages usually bid for the lease of all the kitul trees in a forest, and make a profit by re-renting single trees to separate people. When they bid of course the other people in the village do not like to outbid them and the revenue is as yet small. The total value of minor produce taken from the forests by purchasers amounts to R6,980-55.

EXPORTS OF FOREST PRODUCE.—The Hon. the Principal Collector of Customs has kindly furnished me with a table showing the exports of timber and other forest produce sent from Ceylon. The table will be found in appendix D. The exports of ebony and halmilla have considerably diminished during the year, but those of satin have risen from 306 to 1,409 cwt. The export of ironwood, which I expect must be palu, have nearly doubled. The export of palmirah laths and rafters fell off by about half during the year. This may be due to the attention of the Jaffna people being diverted to the collection of palmirah fibre for Messrs. Vavasour & Co. Amongst the officers mentioned with special approbation by Mr. Broun is the Assistant Conservator of Sabaragamuwa, Mr. Lewis. While dilatoriness was complained of in regard to many, Mr. Lewis

was the first to send in his annual report, which reached me on 7th March. He sent a very full report, accompanied by a map showing very clearly the distribution of different classes of forests, the mountain ranges, and the catchment areas of the Kalu and Walawe gangas. The Assistant Conservator, Sabaragamuwa, has also annexed a map to his report showing the areas which, in his opinion, should be reserved.

As regards probationers at Dehra Dun forest school, we learn that

Mr. W. Ferguson obtained the Ranger's certificate at Dehra Dun, while Mr. J. St. L. Hansard failed to obtain the necessary certificate. The illness which he contracted after being mauled by a man-eating tiger interfered with his studies, notwithstanding that he was given one year extra at the school, and he was unable to get pass marks. Mr. A. M. Walker was the only student left at Dehra during the rest of the year. He passed the final examinations after completion of the year.

The concluding paragraphs of this interesting report are as follows:—

AGRI-HORTICULTURAL SHOW IN COLOMBO.—All Assistant Conservators, except the Assistant Conservator North-Central Province, sent specimens of timber and forest produce to this Show. The collection was really a very good one, that from the North-Western Province calling for special remark on account of the handsome timber specimens exhibited, while the Eastern Province sent in a capital collection of minor forest produce. Uva also sent a very good collection, but it was broken up, and the fibres, dyes, &c., were exhibited in another section.

The following silver medals were awarded:—

For the best collection of cabinet woods—Assistant Conservator, North-Western Province.

For the best collection of forest produce—Assistant Conservator, Eastern Province.

For the best collection of timber—Assistant Conservator, Central Province, Assistant Conservator, Sabaragamuwa.

For the best collection of jungle fruit—Assistant Conservator, Uva.

For the best collection of jungle roots, &c.—Assistant Conservator, Western Province.

GAME LAWS.—A law for the protection of elephants and buffaloes has at last been passed, and a law for raising an export duty on hides and horns. It is hoped that these measures will have some effect in stopping indiscriminate slaughter. There has been a great deal of grumbling on account of the license for shooting elephants being raised to R100. I cannot see much cause for this grumbling. To a person who has never

shot an elephant and who is desirous of killing one an elephant should be well worth R100, and one animal of this kind should satisfy most men. Those who are not satisfied should, if they are not willing to pay the money, confine themselves to proscribed rogues which the Government Agents will gladly allow them to kill without paying for licences. The export duty on hides and horns will no doubt have some effect in checking wholesale slaughter of game, but it will not put a stop to the *battues* organised by gypsies and by estate coolies, who go to the low-country for the sake of the meat of deer and pig, which they dry and take up for sale to the estates.

The Assistant Conservator of Uva reports a case of this sort and suggests that Forest Officers be empowered by Government to arrest any person killing game or shooting out of his division without a license.

ELEPHANT ESTABLISHMENT IN THE EASTERN PROVINCE.—An elephant was captured, but received a fall when it was caught, from the effects of which it ultimately died. Another was found in the jungle, but having lost its mother and being still very young it died before it could be taken out of the jungle. Another, a cow-elephant, was caught and is doing well. She was found stuck in the mud at Labugalla tank and was rescued and brought in. The elephant caught in 1890 is doing well and growing fast. He is now very fairly trained for depot work.

COLLECTION OF PALMIRAH FIBRE.—Dr. Trimen, in his annual report, has already referred to the trade in palmirah fibre which has sprung up in the Jaffna peninsula. What is sought for is the base of the petiole of the leaf, and only the ends of old leaves which have already dropped off should be pulled from the trees. But the people in their greed for money pull off stalks which have not died off completely, and thus the naked stems of the palms are exposed prematurely, and many trees die off. It is to be hoped that in Crown lands at least a check is given to this new trade, and that only trees which would any how be felled for their timber will be stripped of their leaves.

We now quote the section on natural and artificial reproduction:—

NATURAL REPRODUCTION.

Most of the Assistant Conservators' reports speak more about the sending than about the reproduction. On the whole the year seems to have been fairly good, although the Assistant Conservator, Central Province, complains that the excess of wet in the wet part of his Province killed the seed, while the Assistant Conservator, Northern Province, blames the dry weather in his Province for causing much of the seed to be sterile. The Assistant Conservator, Sabaragamuwa, who has evidently studied the natural reproduction of his forests with great care, and who gives in his report the result of his remarks, reports that the abnormal rainfall has caused a large increase of seedlings in his forests.

The reports on all species are shown in table in appendix A, and I shall here only make special mention of the more important species.

Na (Mesua ferrea): in the Kadawatu and Atakalan korales of the Ratnapura District the seed crop of the year was not quite so large as in previous years, but a good supply of plant was produced.

Red Dun (*Doona zeylanica*) flowered abundantly and germinated very freely in the Morahella forests in the Ratnapura District. I noticed that the white dun (*Doona trapezifolia*) also seeded freely, but the seeding of not only the duns but of other Dipterocarps, such as *Shorea*s and *Hopeas*, appears to be very uncertain, or only recurred at intervals of several years. I have thus for the last two years been unable to get the seed of several species which are yet unidentified.

Halmilla (*Berrya ammonilla*). In the Matala District of the Central Province this tree is springing up in favourable localities wherever light is admitted by the felling of other trees. In the Eastern Province seedlings are also abundant and fill up gaps in the forests, and in the Manuwangama forest of the Chilaw District, North-Western Province, and in the Kolonna korale of the Province of Sabaragamuwa there is a plentiful crop. In

the North-Central Province it seeded freely towards the end of the year.

Satinwood (*Chloroxylon Swietenia*). During my inspection of the Eastern Province in May last the forests were white with the blossom of satinwood, the trees of which could thus be recognised miles away. A plentiful supply of seed and a very fair crop of seedlings followed. The seed appears to have been plentiful and reproduction fair in the dry forests of the Central, Northern, North-Western and North-Central Provinces, and in the Kolonna and Atakalan korales of Sabaragamuwa.

Nedun (*Pericopsis Mooniana*). Seed crop large along the banks of the Hangomuwa and Kurnwiti ganges in Sabaragamuwa.

Kumbuk (*Terminalia glabra*). This magnificent tree which grows in abundance along the banks of most streams and tanks in the dry zone, generally seeded in profusion. A large proportion of the seed is carried out to the sea during floods: portion is stranded on the banks and germinates, and it depends on the moisture which the young plant gets during its first year whether it lives.

Palu or Palai (*Mimusops hexandra*). This tree seeded profusely in the Northern, Eastern, and North-Western Provinces, and fairly well in the Central and North-Central Provinces. There is a general complaint as to the way palu trees are mutilated for the sake of their fruit. It is a pity that the custom cannot be restricted to the scrub palu which grows in the low forests near the sea, as not only are the trees themselves ruined, but the chances of natural reproduction are very much impaired. A glance at the table furnished by the Assistant Conservator, Northern Province, and given in paragraph 24 above, shows that of all valuable species palu is the one which shows the smallest number of seedlings.

Ebony (*Diospyros ebenum*). Reports from the Northern, North-Western, and Sabaragamuwa Provinces show a fairly good crop of seed, but only little is said about a natural reproduction. This species require a careful study.

Milla (*Vitex altissima*). There was a moderate fall of seed in Matale, North-Central Province, and the Assistant Conservator, North-Western Province, reports that a large number of seedlings have sprung up in the Kalugalla forest, where the palu fellings have been made.

Wewerana (Ranai or Yawarana), *Persea semicarpifolia*. Good falls of seed are reported from the Central and Eastern Provinces, and fair crops from the Northern and North-Central Provinces.

Observations made in the forest tend to show that for na, kina, dun, hora, mendora, tumpalai, halmilla, and domba, moderate fellings are sufficient to encourage natural production, while satin, palu, ebony, milla, and wewerana require fairly heavy preparatory fellings, either by the removal or girdling of trees of inferior species in the neighbourhood of the seed bearers.

ARTIFICIAL REPRODUCTION.—During the year 475.5 acres were added. Form No. 5. in the appendix will show that the increase is due chiefly to the starting of railway fuel plantations at Galboda.

WESTERN PROVINCE.—No change.

CENTRAL PROVINCE.—Plots Nos. 14 to 22, amounting to 15 acres, were planted with *Eucalyptus robusta*, *citriodora*, *amygdalina*, and *diversicolor*, and with *Acacia melanoxylon* and *decurrens*. These plantations of the year are very successful. The plots planted in 1890, were supplied with the same species as mentioned above, and are now doing well, and those planted during 1889, and which had to be largely supplied during 1890, are now showing up, some of the trees being 14 to 15 ft. in height and 15 in. in girth, at breast height. The number of standards left standing on the strips varies a great deal, and is much greater in the earlier coupes. It will now be interesting to see how Australian trees behave with different degrees of shelter. At Nuwara Eliya the plants now show above the young trees of spontaneous growth which had been left when the clearing was made; a number of young trees of worthless species and with low spreading crowns had however been left standing, and were impeding the growth of many young *Eucalypti*. It

became necessary therefore to remove these, which was done but after the close of the year.

The nursery and small plantation near Gallwey's land were extended by about 4 acres. The nursery has been used for rearing plants for all the plantations in the Central Province. The system appears costly, and I do not much approve of it, but it had the advantage of constant supervision on the part of the Forester. It appears also that some of the species spring up more readily at Nuwara Eliya than in local nurseries. At Galboda four fields of patana land, known as Blackwater, Dekinda, Mapakanda, and Penbros, were taken in hand. It was intended to plant 600 acres, but, as is usual in the first year, there were a great many difficulties to overcome, the chief of which were an uncertain and irregular supply of labour, an unusually wet and destructive rainy season and the want of surveys showing the actual boundaries of our land. As a result only 320 acres were planted. Of the four fields the Blackwater field, situated close to Blackwater estate, has been the least successful. The land is exposed to the full force of both monsoons, and the soil is gravelly and poor. In the most exposed places only *Acacia melanoxylon* seems to be able to stand the strong wind, and *Casuarina* also does fairly well. *Eucalyptus robusta* does well in sheltered places, but I noticed that some had been attacked by white-ants, musk rats, and by pigs. *Grevillea* looked sickly on Blackwater, as it could not stand the wind properly; it was moreover much attacked by a locust which nipped the head of many tender seedlings.

In the other fields the results are far more promising, although the violent rain which came on steadily through the greater part of the year washed a lot of the top soil off and caused immense quantities of weed to spring up. *Eucalyptus marginata*, *amygdalina*, and *citriodora* are doing fairly well, and *hal* and *hora* are doing well near the streams at the bottom of the slopes. *Jak* also did well at the lower elevations, but was rooted up by pigs. *Grevillea* has been slow. It seemed to get too much wet. The plants which did best had their roots dipped in liquid manure just before they were put in. The plantations were at first under the direct supervision of an overseer, then on his return from the Dehra Dun Forest School. The latter officer, however, soon after exchanged duties with Mr. Hansard, about whose work the Assistant Conservator reports very favourably.

NORTHERN PROVINCE.—Nothing has as yet been done towards starting palmirah plantations. In existing palmirah forests it will, however, I think be sufficient to close them to grazing to ensure abundant natural reproduction.

EASTERN PROVINCE.—A clearing was sown at stake with teak seed, behind the Tumplancholai resthouse, but it failed. The Acting Assistant Conservator advises to follow the plan which has been successful at Puttalam, of making nurseries close to the plantations.

The growth in the teak chenas has progressed favourably, and a table showing measurements corresponding to those shown in appendix A of last year's report are now shown in appendix B.

It is curious to note that the mean annual increment has considerably improved in all the Paulkanawa plantations, while it has fallen off in all but the youngest plantations of Divilane.

Mr. Tatham reports that in some of the chenas he saw natural seedlings from five-year old trees.

A plantation started at Divilane in 1890-91, consisting of satin, halmilla, and teak, is doing well.

NORTH-WESTERN PROVINCE.—The plantations in the North-Western Province give great satisfaction, and are quite a success. The Puttalam teak plantation, which was started in 1879, consists now of 99 acres fully planted with teak, 56 acres having been added during the year. Of these 56 acres, 8 were planted on the old system, the plants being put in 5 ft. by 5 ft., and were a success. The remainder were planted on a new system which was advocated by Sir D. Brandis when Inspector-General of Forests in India. It consists in parallel strips $\frac{1}{2}$ chain long being cut through the jungle, leaving belts of standing jungle $\frac{1}{2}$ chain broad standing in between; each strip

is half a mile long and runs in a direction to escape as much as possible the effect of the strong wind and to afford shelter against the sun. This system promises to be a success, as it will afford shelter to the young plants and later on a mixture of species, which is favourable to teak.

The whole block No. 5 planted in 1890 had to be re-supplied in consequence of a large number of plants having died owing to a severe drought which came on just after they were put out, and owing to weeds suppressing most of the survivors. It took 17,000 plants to replace vacancies in this one block, which is now doing well. A number of self-sown satinwood seedlings have sprung up, and will mix well with teak. The nurseries were a great success, and Mr. Armitage deserves credit for the manner in which he kept them up. Teak seed was obtained through the courtesy of the Conservator of Forests, Quilon. The seed was spread in trenches 2 in. deep and watered constantly. After seven days it commenced to germinate, and the number of sterile seeds proved to be very small. Palu seed also came up very readily, being watered twice a day.

The older plantations are also doing well notwithstanding the somewhat rough treatment which some of the blocks have received. The gaps in the oldest plantations have in many places been filled with a spontaneous growth of satin, which mixes well with teak. The Assistant Conservator submits with his report the measurements of two lots of twenty trees each taken in the plantations of 1879 and 1881, and of ten satin poles measured in the plantation of 1890. The teak poles in the block of 1879 were measured shortly after the close of the year: on an average 25.85 in. in girth at 4 ft. from the ground, the average girth increment for the last year being 1.7 in. and the mean annual increment 2.11 in. The 1881 lot measured on an average 19.54 in., showing an increment during the year of 1.49 in. and a mean annual increment of 1.95 in. These girth measurements are on the whole as good as those taken in the Eastern Province, although the trees in the latter Province are as a rule picked trees taken here and there, and frequently standing isolated. The ten satinwood trees which grew up spontaneously in the plantation of 1880 have attained an average girth of 18.6 in. Their mean increment during the last year has been 1 in. and the mean annual increment 1.69 in.

During my inspection tour through the North-Western Province the Assistant Conservator, the Forester, and I marked a thinning in the plantations older than that of 1886. 532 poles were removed and portion sold for R370. A large quantity of firewood which was sold from off the last plantation should have been credited to the plantation, but this has not been done.

The Kumbalpole plantation of ten acres, started near Kurunegala in 1890 as stated in the last report, suffered at first a good deal from drought, rats, and cattle, and a large number of vacancies had to be filled in during the north-east monsoon of 1890. The growth of the plantation is in consequence somewhat irregular, but is now doing very well, the tea saplings being now from 8 to 20 ft. in height and from 3 to 7 in. in girth. Jak, which has been most ill-treated by cattle, is now 6 to 15 feet in height, and halmilla has a very uniform height of 4½ feet.

The Sandapola plantation, also near Kurunegala, is also a very great success, and consists of jak, teak, na, satin, mahogany (*S. macrophylla*), and bora. The plantation was at first made under partial shelter, the creepers and undergrowth being cleared and useless trees girdled. It appeared to me that the seedlings required a little more light, and subsequently the Assistant Conservator adopted a system similar to the one adopted at Pattalam, by clearing strips 15 ft. wide and leaving alternate belts of forest 40 ft. broad. Twenty-eight strips were thus cleared, covering about fifteen acres. The growth of all species of plants on this plantation is excellent, and Mr. Fyers can be congratulated on the success of all the plantations in the North-Western Province.

PROVINCE OF UVA.—Judge's Hill plantation of twenty-four acres. The portions which have been kept clear of weeds are doing very well, but the un-

weeded portions are somewhat stunted. The sapu plants put in 1888 have formed complete leaf canopy, and no grass can grow underneath them. It is to be hoped that weeding will not much longer be necessary in the plantations of 1888 and 1889.

Elladuwa Plantation of thirteen acres close to Badulla. The plants are coming on well, and there are few vacancies. A road, 6½ chains long, was cut right through the clearing.

Haputale Plantation. The *Eucalyptus robusta* and *Acacia melanoxylon* put in 1889 are doing very well. There is hardly a vacancy. One and a half acre has been added during the year.

Bandarawela Plantation. There is not much of a success. A good deal of the *Pinus longifolia* has come up, but made little progress. Some *Eucalyptus robusta* which was put in have also a stunted appearance. The Assistant Conservator attributes this to the whole land not having been cleared of weeds.

Appendix C shows the measurement taken in the Uva plantations by the Assistant Conservator.

PROVINCE OF SABARAGAMUWA.—Para Rubber plantations. During 1891 a fresh plantation of this species was made at Yetipona, in the Medapattu of the Kuruwiti korale, of some 16 acres in extent, beside adding another acre to the older plantation at Edangoda. The old plants at Edangoda are now from 15 to 18 ft. high, and look as healthy as possible. No branches were formed up to the end of 1891 by any of the Edangoda trees. The Yetipona plantation being well above flood-level is the most even in growth, while the plants show an equal robustness, though the soil of Edangoda is superior to that of Yetipona.

The teak plantation at Gabella is a failure. Defective seeds in the first instance and poor soil appear to have been the causes of failure.

In order to make up as much for the loss of the teak the Assistant Conservator planted 500 jak plants, besides hal and bora, that appear to succeed moderately well. The hal seeds planted along the sides of a small stream in the Gabella plantation have proved a success, and on this experiment Mr. Lewis planted more at Edangoda at the flood line, with equally favourable results, still following up the experiments at Yetipona, where there is a piece of swampy or damp ground, making 1,000 plants in all.

Of mendora he planted 700 seeds within the flooded area of the rubber plantation at Edangoda, the greater number of which have succeeded. A few nedun seedlings have been tried at Edangoda with success.

On the whole, I think that the Department has made very marked progress in its plantations during the year under report, and the work has been well carried out by the Assistant Conservators.

IMPROVEMENT FELLINGS AND CREEPER CUTTINGS.—Small improvement fellings of various kinds have been made in some of the Provinces. In the Central Province three small areas were taken up, in which the inferior species were removed and the better classes left standing. It depends on the manner in which this was done whether the operation can be called an "improvement" felling. Similar operations which I have inspected in the North-Central Province near Anuradhapura and Alut-oya can hardly deserve that name, young saplings of valuable species having been left to stand unsupported, exposed on all sides to sun and wind. I propose during my next inspection tours to make a few improvement fellings and clearings together with Assistant Conservators, and to see this useful work started in earnest. I have shown the Assistant Conservator, Northern Province, how to make clearings in halmilla forest, but nothing seems as yet to have been done.

Creeper and climber cutting was carried out in the Kalugalla forest by the Assistant Conservator, North-Western Province, and in the Gabella forest by the Assistant Conservator, Sabaragamuwa. The operation has had a very beneficial effect on the standing trees, poles, and saplings, and in Sabaragamuwa has caused the springing up of a large number of seedlings.

EXPERIMENTS IN EXOTICS.—The plantations in the Central Province, in which exotics have chiefly

been planted, can in some respects be said to have passed the experimental stage. In the Galboda plantations, however, some species were tried about which little was known at that elevation. Such were *Pithecolobium dulce* at Blackwater, which did not succeed at all, while *Pithecolobium saman* and *Pterocarpus indicus* at Dekinda have made somewhat slow progress.

The conifers, the seed of which was obtained from India, have not done well: *Pinus excelsa* dying out while *Pinus longifolia* is making only slow progress. This tree is however somewhat slow at starting, and may make better progress in a year or two. The deciduous plants are looking very sickly, and I fear that the Nuwara Eliya climate does not suit them.

POULTRY KEEPING.

OVERCROWDING THE HENS.—The greatest of all temptations to resist, is that of overcrowding. The majority of poultrymen, in order to save expense of buildings and yards, usually put too many hens together in one flock. It is false economy, for what is gained in space is lost in product. The smaller the number of hens together the larger the number of eggs obtained, proportionately, although we do not advise having the flocks smaller than ten hens and a cock. The size of the flock should depend upon what may be the object of the breeder. If eggs only are desired, as many as thirty hens may be kept together in a building 10×20, and they will lay well if rightly managed, while no cocks at all will be necessary. The eggs from hens not in company with cocks, will keep twice as long as will those that are fertile. If the eggs are intended for hatching purposes, ten or twelve hens and a cock may be kept in a building 10×10 feet. If a larger number of hens are used, they will require more than one cock, and such mode will occasion strife and combats.

There is another difficulty in the evil of overcrowding, which is that, in all flocks, there are "boss" hens, and they compel the more timid ones to keep at a respectful distance to the rear, the consequence being that when feed is given, some of the hens will secure more than their share, while others will not have enough. Disease often results from overcrowding also, and in summer the animal heat renders the poultry-house uncomfortable, while lice will certainly appear, unless the sanitary regulations, in regard to cleanliness, are strictly observed.

INVIGORATORS AND EGG FOODS.—The majority of egg foods are composed of those elements that enter into the composition of an egg, and their success depends upon the fact that they supply material which is often overlooked by those who keep poultry. For instance, ground bone, ground meat, salt and charcoal, are ingredients—the first, to supply the phosphates; the second, the albumen; the third, that which is often not supplied, and the fourth as a corrective. Hence, two pounds of ground bones, two pounds of ground meat, half a pound of salt, a pound of charcoal, a pound of fenugreek (used as a tonic, and assistant to digestion) with an ounce each of sulphur, bread soda and ginger, makes a very good egg-food, which may be given to six fowls daily, using a tablespoonful. We have given other egg-foods, but mention the above as very cheap.

WHITEWASHING MADE EASY.—In whitewashing the poultry-house use a forcepump. There are forcing contrivances by which the contents of a bucket can be forced from a nozzle. Make thin whitewash, and then force it against the walls, roof, on the floor, and over every part of the poultry-house. By so doing the work can be performed in a few minutes, while by the old method of using a whitewash brush it sometimes takes a whole day. Anything can be pumped over the house. A solution of copperas, carbolic acid, or soapsuds, can be used as well as whitewash. A great saving of labor will be effected while the work can be done much better than in any other manner.

When chicks droop, and appear sick without cause especially in summer, look for lice—not the little red mites, but the *large grey body lice* on the heads and necks.—*Poultry Keeper.*

USEFUL NOTES.

It takes many years, and often many generations, to develop a fruit or vegetable with the best edible qualities from its original wild state. It was the opinion of Dr. Gray that if modern civilization had begun in America our Ground Nut (*Apios tuberosa*) would have been the earliest developed esculent tuber, and would probably have held its place among the first, along with Potatoes and Sweet-Potatoes.—*Garden and Forest.*

CINNAMON IN JAMAICA.—Mr. Allan Eric, in a recent number of the *Drug Reporter*, writes:—

Cinnamomum zeylanicum, or cinnamon, is cultivated extensively in Jamaica, where it was introduced from Ceylon about 1782. There is also a species of wild cinnamon which grows plentifully in Jamaica, but possesses scarcely any commercial value. The first-named grows to a height of from twenty to thirty feet, and has a trunk about eighteen inches in thickness. Its bark is of a grayish brown colour, and the inside of the bark is yellowish red. The leaves are oval, from four to six inches long, and have blunt points. The flowers are silky-gray on the outside, and of a pale yellow colour internally. The fruit is somewhat like an acorn in shape, and is brown when ripe. In gathering cinnamon bark the branches of from three to five years' growth are cut down, the epidermis is scraped away, the bark is then ripped up longitudinally with a knife, and gradually loosened until it can be removed. The slices are then exposed to the hot tropical sun, when they curl up into "quills," in which form they are familiar to commerce. The smaller of these quills are inserted into the larger, after which the bark is tied up into bundles of about eighty-five pounds each, in which form it is ready for export.

A GREAT INDIAN TEA "CONCERN" is thus described by a correspondent of the *Indian Planters' Gazette*:—

The South Sylhet Tea Company is a Big Thing. Figures hardly give one an idea of it: you want to ride round the property to get an idea of the size of it. They have some 24,000 acres of land lying round a big *bhil*, the "Hael Hanr" they call this *bhil* locally, and it isn't a bad name for it. I was "shipwrecked" (in a country boat) and nearly drowned in it some seven years ago,—so it nearly introduced me to its namesake where I've been in the paying line so long. There are four divisions, comprising some 8,000 acres under tea; including another concern sandwiched in between two of the divisions, in the same agency, 10,000 acres of tea would be nearer the mark. All these gardens, sixteen of them, lie between the foot of a sort of horseshoe range of hills and the big *bhil*; the gardens all touch; and you can ride for over 20 miles through tea and a good deal further if you count in a few adjacent gardens not belonging to the same company, without a break in the continuity of the stretch of bushes yielding the "cup which cheers but not inebriates." From the Superintendent's bungalow on the hill at Kalighat you can see 12 or 13 bungalows, and five or six huge central factories; there are forty Europeans employed in the concern; eighteen miles of horse-tramway laid down and regularly worked; a sort of co-operative store which supplies whisky and other necessities of life to the employés; and the annual outturn of tea shipped on that *bhil* is something I am afraid to put into figures. But as the average outturn of full-bearing tea there is from 8 to 10 maunds an acre, it might safely be put at between four and five million pounds without any unpleasant references to Ananias. Of course they have their own Doctor and their own "boss" engineer, the latter of whom I had the pleasure of meeting again recently up at Darjeeling, recruiting—his health, not coolies. But they further indulge in a luxury not common to most concerns, however big; they have their own *padre*. The Doctor and the Engineer may be classed, from a tea planter's point of view, as necessities of life, but the *padre*, from the same point of view, is distinctly a luxury; and a well appreciated one too, may be added in this case.

THE NEW INDUSTRY IN PALMIRA
STEM FIBRES.
DANGER OF THE EXTIRPATION OF THE
PALMS.

Ever since the peninsula of Jaffna was peopled, —and the population of the Northern end of the island is exceedingly dense (280,000 in the district) —there has been an extensive export trade in the products of the palmira palm (*Borassus flabelliformis*) apart from the use of those products locally by the people themselves. The nuts yield nutritious matter, the wax-like juice being inspissated and preserved under the name of *panato*; the seedlings are rich in farinaceous matter; jaggery, a coarse kind of sugar, is made from the saccharine juice of the flower-spathe; and there can be no better timber for the rafters and reapers of houses than sections of old palmira trees. There are palmira rafters and reapers in houses built by the Dutch at Jaffna two centuries ago, which are still undecayed. Next in importance to tobacco in products exported from the Northern Province beyond sea, (mainly to Southern India) have been palmira timber and jaggery. While all who have the well-being of the people of the Northern Province at heart have been urging the extended cultivation of this valuable palm—which flourishes where the coconut palm will not grow, with fully four times as many trees to the acre—we have noticed with concern a serious lessening of the exports of palmira produce. As it is not at all likely that the demand in the Madras Presidency for the valuable timber and the jaggery for mixing with mortar or for refining purposes has abated, there can be little doubt that a reckless destruction of trees to secure immediate returns has been the cause of the diminution of exports. And now it looks as if the discovery that the leaf-stems yield a valuable fibre were likely to prove fatal to the remaining portion of the groves of straight-growing, round-headed stiff-leaved palmira palms which impart so special a character to the scenery of much of the Jaffna Peninsula, so different to that produced by the long, graceful drooping foliage of the coconut. One curious effect of the new fibre industry and the employment of the people in its preparation is, according to Mr. Twynam, that votes for metalling the North-Central Road for a couple of years back could not be spent, from the impossibility of obtaining labour. We suspect, however, that the repeated cholera scare frightened away labourers who would have otherwise worked on the road. If the information Mr. Twynam has collected is correct, it would seem as if in this case, as in that of so many other agricultural products which become articles of commerce, the middlemen take the lion's share of the profits, the owners of the trees which are so ruthlessly deprived of the leaves on which their continued vitality depends having to be contented with—we mean no pun—the *leavings*. How seriously the industry initiated by Messrs. Vavasour & Co. of Colombo has affected the export trade in palmira products, the figures for the past two years shew. The piece of palmira timber exported in 1891 were only 177,047 value at R44,146, against 262,315 pieces and R60,000 in 1890. In jaggery the fall was nearly one half, 3,325 cwt. valued at R11,846 in 1891 against 6,426 cwt. and R22,457 in 1890. Meantime fibre prepared from the leaf-stems was prepared and shipped to Colombo, for export thence to Europe, equal to 450 tons in weight and R122,559 in value. Of the sum for value less than half, it is believed has gone into the hands of the poor people who extracted the fibre. Mr. Broun, in his report on the Forest Department, noticed the injury which the large deprivation of leaves would inflict on the

palmira palms; and Mr. Twynam mentions 1,000 fatalities from this cause amongst young trees in one locality, the trees bleeding to death from the wounds inflicted in the process of tearing away the leaves. The case is so serious as to demand the attention of Government; although we suppose the policy of killing the goose that lays the golden egg can only be met with "moral suasion." No amount of money paid to and distributed amongst the people at present can compensate for the impending disappearance of one of the chief supplies of THE FOOD OF THE PEOPLE, apart from the destruction of the timber. Mr. Twynam has but performed his duty in requesting the attention of the Government to the danger of extirpation which threatens the palm which for ages has been so important a food and timber yielder to the people of Jaffna, and well may he say, "It would be a bad day for the Northern Province when the palmira palm is killed out, as its African (I believe) palm from which fibre was extracted has apparently been cleared out by the process." What is so awkwardly stated about an African palm destroyed by similar means and for similar purposes is new to us. There are palms which, like our own kitul (*Caryota urens*), produce masses of fibre at the junction of the leaf-stem to the trunks of the trees, but until Meers, Vavasour & Co. started the industry which has attained such large proportions, we never heard of useful fibres being extracted from the leaf-stems of palms. Previously to the enterprise which has given such new and we fear baleful value to the short stiff stems of the palmira leaves, the older leaves, as they were gradually cut from the trees, were used for fences and thatch and largely as manure for tobacco and other culture. We now quote what Mr. Twynam states in his report on the Northern Province for 1891, regarding the

PALMIRAH FIBRE INDUSTRY.

A new industry, called the "palmirah fibre industry," was started in the beginning of the year by a Mr. Appleby, agent of the firm of Messrs. Vavasour & Co. of Colombo.

The industry has no doubt brought a large sum of money into the Province and benefited the poorer classes, the middlemen, and those who have acted as agents of the firm in Colombo. The fibre is extracted from the stalks, and there is no doubt that the trees are being injured by the manner in which the stalks are torn off. It was reported to me that over 1,000 young trees had been killed in Eluvativu by the stalks having been torn off.

The following are extracts from my diary regarding the destruction of the trees in Eluvativu, and the process carried on in the factory at Point Pedro:—

Kays, January 30, 1892.—After appointing headmen went in the afternoon to Eluvativu to judge for myself what truth there is in the reports that the palmirah trees were being destroyed in consequence of the stalks being torn off for the purpose of extracting the fibre now being bought up in large quantities by Messrs. Vavasour & Co. of Colombo. Found that the statements made to me were perfectly true. I saw about 100 young trees that had been killed out by the process, the trees having bled as it were to death. The Acting Maniakar informed me in September that over 1,000 trees had been killed out in Eluvativu alone. The sap appears to have oozed out where the stalks were removed in a thick black gummy fluid.

Complaints are numerous now of the destruction of palmirah trees consequent on the new fibre industry. I have reported the matter to Government, and can take no further action in the matter. It would be a bad day for the Northern Province when the palmirah palm is killed out as its African (I believe) palm from which fibre was extracted has apparently been cleared out by the process.

Jaffna, February 9, 1892.—Returned to Jaffna last night after making an inspection of a part of the town of Point Pedro which is being cleaned up and cleared of the mess left by the late floods, Mr. Strong's fibre factory, and extending the warrants of the police-vitanais. Mr. Strong is agent for Messrs. Vavasseur & Co., who introduced the new palmirah fibre industry, which no doubt has given the people of the peninsula and islands about R100,000—300* tons of fibre having been exported last year. At the same time it cannot be denied that the trees are being injured by the manner in which the stalks are torn off.

Mr. Strong's factory is well worth a visit. It is very interesting to see the processes gone through in cleaning, sorting, and packing the fibre; most of the work appears to be done by women, of whom a large force is employed by Mr. Strong. Messrs. Vavasseur & Co. paid at first 16 cents a pound for the fibre; they now only pay 11 cents. The fibre is now purchased up in the bazaars and villages by petty traders and hawkers, chiefly Moors, who bring it to the agents of the firm in Jaffna and Point Pedro; they pay from 6 to 9 cents a lb. for it.

The following is the quantity and value of palmirah fibre shipped from the different ports of the Province for Colombo in 1891:—

	Quantity.		Value.	
	Cwt.	qr. lb.	R.	c.
Jaffna ..	1,942	0 17	19,629	20
Kayts ..	150	3 8	2,070	0
Kankasanturai..	3,129	3 1	51,380	0
Point Pedro ..	3,806	1 0	49,480	0
Total..	9,028	3 26	122,559	20†

NATAL TEA INDUSTRY. LIST OF ESTATES.

How the tea industry is satisfactorily progressing in this colony is well illustrated by the particulars given below. The total estimated acreage is 1,900 acres; out-turn for 1891-2, 360,000lb., being a short crop owing to the long drought. The estimated out-turn for 1892-3 is 560,000lb., of course, assuming that the planters have a good season. It will probably not be known to many, even in Natal, that there are so many growers of tea, or so many tea-gardens, in the colony as the subjoined list shows. Those opposite whose name an asterisk appears make their own tea:—

*Kearsney—J. Liege Hulett, M. L.C.	} Kearsney Central Factory.
Kirly Vale— Ditto	
Island Farm—W. Clayton	
Michelham—B. Balcombe	
Glenwood—G. Clayton	
Sprouston—T. Peachey	
Merindol—Capt. Malan	
Isivundu—H. Balcombe	
Highlands—Schram	
Balgownie—Sime	
Ashley Hill—F. Tbring	} Teas made at Bulwer; but sorted, sifted, and packed at Kearsney.
Ocean Lodge—Bebrmann	
*Bulwer, Jas. Hulett, junior	} Aroma, C. F
Orwell—Capt. Barker	
*Aroma—Ladyhoer	}
Hermelo—Colenbrander	
*Clifton—W. R. Hindson.	
*Cobham—Ditto.	
*Nonoti—Ditto.	
*Simton—Ritchie.	
*Bonnie Doon—Davis (changed hands—now Mr. Flower).	

* I have since ascertained that the quantity exported is 450 tons, and its value over R122,000.

† Of this R62,000, at least, has gone into the hands of the poor people who extracted the fibre, and the rest into the hands of the middlemen, hawkers, and agents. All those bringing fibre for sale whom I have questioned on the subject have informed me that they received 9 cents a lb. I am told, however, that 7 and 8 cents only have been paid by Moorish traders in the more distant villages.

*Upton Park—Robbins.

*Prospect—Brickhill.

*Barrow Green, Bisset.

*Ruthville—Aiken.

*Bozaino—P. Wilson (not started manufacturing yet).

TEA INDUSTRY IN NATAL.

A SUCCESSFUL CONCERN. PRIVATE COMPANY FLOATED.

Mr. Hindson, whose name is so familiar in connection with tea-growing in this country, returned to the colony yesterday, after a visit to England. While there he succeeded easily in floating a private company, with a capital of £50,000 in £10 shares, to carry on the business of tea and coffee merchants and planters, and the style adopted is that of W. R. Hindson & Co. The concern is not a speculative one, the whole of the capital being privately subscribed, with, in addition, £12,000 in debentures, and none of the shares can be sold for seven years. The object of the company is, of course, to promote extension of the enterprise, and that there is ample scope is sufficiently apparent from the following facts. There are three estates, viz., Clifton, Cobham, and Nonoti, on which there are 450 acres under tea, 16 under coffee, and with other products the total cultivated area is 500 acres. The whole area of the estates is 3300 acres. The output of tea for the past year totalled 80,000 lb., and it is expected the yield for the season 1892-93 will be 100,000 lb. Mr. Hindson (through Mr. R. W. Evans, of West Street, the company's agent) has been singularly successful in disposing of his tea in the local market. Indeed, it is very doubtful whether the supplies will last till the new season's teas come in. One reason for the growing popularity of this Natal tea is doubtless due to the fact that none is sent to the market until it has matured for three or four months. As colonists, taking an interest in our colonic products, it is exceedingly gratifying to note the favour with which Natal tea has been received both in the colony and by the neighbouring states. Mr. Hindson had further proof of the excellent quality of his own growth while in London. He took with him about 170 lb. of tea of different qualities, which were put on to the Mincing Lane market, with the result that the commonest kind was valued at 7d, and the highest at 14d, brokers' prices—this in a market where the average quotations for teas from Ceylon and India was not above 9½d. It will, therefore, be seen that the newly-formed company has good prospects. The first subscribers are:—Messrs. J. W. Arrowsmith, J. P. Browth, J. Brown, J. Adams, and J. R. Pascoe, and there are to be not less than three or more than seven directors. The first are the gentlemen above named, who are permanent directors, their qualification being £5,000 each. Subsequent directors' qualification is £510. Remuneration is to be fixed by the company in general meeting.

NATAL TEAS.

In our references to the formation of a company to work Clifton and other tea estates we omitted to mention that Mr. W. R. Hindson, the original owner, is in the list of subscribers, and that he is the managing director, a post he undertakes to retain for seven years.—*Natal Mercury*, Ang. 17th.

NOTES ON PRODUCE AND FINANCE.

IT CAN BE DONE.—Indian tea planters have good reason to know that the retailer plays a very important part, not only as a distributor of produce, but in pushing certain articles, if he be so minded. At one time the grocer, having decided that tea should come from China, and that it was very wrong of the consumer to desire the teas of India, preferred to sell Indian tea blended with China. Later on, when the consumer insisted on having his Indian tea pure, the grocer kindly gave way, and the result is that, owing to the magnitude of the trade in Indian and Ceylon teas, China is practically out of

the field. There is no doubt that if grocers decided be given to chicory mixture. The *Grocer* mentions the case of a correspondent who took a special interest in selling pure coffee as opposed to chicory mixtures:—
 'He began to sell coffee 'fresh ground and pure'—that is, without the sophistication of chicory—and how the results have come up to his most sanguine expectation. During the last six months his trade in this branch alone has risen from 7 lb. per month in January last to 40 lb. in July (he is not in a very large way of business), and the profit realised has been thoroughly satisfactory. He has not been specially favored by circumstances in any respect, and has been able to push the trade entirely on its merits.'

DRYING COCOA.—In his report on the trade of Paramaribo for the past year, Consul Wyndham says with reference to drying cocoa:—Four different systems of cocoa drying are in use or have been tried. 1. Sun-drying on large trays on trams run out from under sheds when the weather is favourable, and brought under cover in rainy weather. 2. Drying on brick floors under which furnaces are placed. 3. Fruit-drying machines of various sizes. 4. A system of drying by steam outside an enclosed cylinder has been tried, and another of drying by hot air in a revolving cylinder is about to be tried. Of the first, it may be said that it is unsatisfactory as it is dependent on the season, and a wet season may cause much loss of good cocoa by its becoming sour before it is properly dried. Of the second, that it is apt to shrivel up the beans and to discolour them. Of the third, that fruit driers, even the best and most expensive as yet introduced, have only served to partially dry the bean and saves it until it can be sun-dried ready for sacking. Of the fourth, that the machine requires some alterations; as it stands it appears rather to cook than to dry the bean. And, lastly, the revolving cylinder has not yet had a fair trial. An English firm has patented a cocoa-drier called, I believe, the "sirocco," which was lately tried at Trinidad before the Governor of the colony and several officials and planters with satisfactory results. Details of the trial, however, are not yet to hand, but if on receipt they prove the machine to be a success, I think the member of the firm who visited this colony and invited the planters and the Government to send some one to represent the colony at the public trial of the "sirocco," at Trinidad, even offering to pay all the expenses, will have no cause to regret his trip, and that orders for the drier will reach him from Surinam.—*H. and C. Mail*, Sept. 2.

A CHEERFUL NOTE.—At this dead season of the year it is quite a boon to be able to chronicle a meeting of tea shareholders, and though the gathering was merely a statutory one, the note of cheerfulness sounded was in pleasant relief to the general financial gloom. Mr. J. Berry White is an excellent chairman at a meeting of shareholders, and he may be reckoned upon at all times to take a clear and open view of the situation. He is a firm believer in the resources of Assam, and the province is under no little obligation to him for an advocacy which has done it some substantial service in the commercial world. His remarks upon the prospects of the Assam tea industry, founded as they are upon practical and up to date knowledge, are well worth the attention they always command.

CAN LOOK ON AND SMILE.—At the statutory meeting held on Monday of the Makum Assam Tea Company, Limited, Mr. J. Berry White emphasised the fact that the depreciated rupee was a matter that the proprietors could regard complacently. The fall of 12½ per cent in silver, which has depressed the importer of merchandise in India and caused the Government of India, the officials, and other classes serious trouble, enables the directors of a concern like the Makum Tea Company to get one-eighth more work done for the sterling capital now than they did when the company was first started. Under these circumstances, the dark cloud of a depreciated rupee has a silver lining indeed to some eyes.

A NICE POINT.—Tea dealers, who pride themselves on selling tea direct from their own gardens, and who endeavour to persuade their customers that this is a great advantage, are not allowed to have all the fun to themselves. Large grocery firms, who do not grow their own tea, endeavour to impress upon their customers that the advantage lies in buying teas blended from many gardens. One firm has issued a circular in which this is pointed out, so that in any case the dealer who buys in the market from the very best growths offered, and judiciously blends the different kinds, can produce and supply a much more uniform and cheaper tea than any so-called grower can possibly do. This is a nice point, and would afford a good subject for debate at a Grocers' Association meeting.

PRODUCE IN BOND.—According to the B Bill of Entry showing the quantity of bonded goods remaining in the Customs and Excise Warehouses of the United Kingdom on the 31st ult., the stock of tea was 84,139,211 lb., against 81,089,221 lb. at the corresponding date of last year, and 80,756,666 lb. in 1890; coffee, 149,645 cwt., against 160,323 and 236,678 cwt.; cocoa, 13,095,203 lb., against 14,214,829 and 12,518,148 lb.

THE TRADE BAROMETER.—The Board of Trade returns for the month ended August 31st, just published, are more favourable. They show that the imports for the month amounted £34,844,365, showing an increase of £2,098,086 as compared with the corresponding month last year. The exports for the month were £20,051,330, being a decrease of £619,159. The imports for the eight months ended August 31st amounted to £281,019,613, or an increase of £3,302,683, compared with the corresponding period last year; while the exports for the same time were £151,375,929, showing a decrease of £15,305,924 compared with the first eight months of 1891. The imports of tea were 2,238,351 lb. more than in August last year, but most of that increase is due to China having sent more; the value of the larger total, however, is declared to be £32,102 less.

CINNAMON.—At the quarterly sales of cinnamon held last week the auctions passed off at better prices. As against 4,240 packages in 1891, the landings of Ceylon cinnamon in London for the last thirty-four weeks have not exceeded 3,220 packages, and whilst the deliveries have been 750 packages heavier than in the preceding year, the stock remaining on hand on the 27th inst. was the lightest that has been known for years past, being reduced to 2,615 packages in comparison with 4,390 packages in 1891. Therefore it followed that of the 900 bales Ceylon offered nearly the whole was cleared off, excepting a small portion really fine which was withdrawn at extreme rates, and, confirming the improvement in value recently observed privately, the rates obtained were mostly 3d to 1d per lb. above those current in May last, viz., ordinary to fine firsts at 7d to 11d; seconds at 6d to 8½d; thirds at 6d to 10d; fourths at 5½d to 7d; and broken (in nine boxes) at 5½d to 6½d per lb.—*H. and C. Mail*, Sept. 9.

THE RICE TRADE FOR 1891.

Messrs. Fraser and Co.'s annual review states:—The trade of the past twelve months does not afford very much scope for an interesting review. Indeed, for the first seven months of the year, nothing of importance arose to cloud the horizon, and there was a minimum fluctuation in prices, thereby allowing purchases and sales to proceed on the even tenour of their way without any extraneous excitement. There appeared to be the prospect of rice enough and to spare, notwithstanding that the expected surplus available for shipment of 400,000 tons from Japan turned out to be over 300,000 tons short, and the "good prospects" cabled from Saigon resulted only in 33,565 tons! A larger quantity from Burmah, however, had to be reckoned with, and an extra amount from Bengal, while even Persia sent a few thousand bags more than in the previous year to swell the list. Still the rice trade had its little flutter, as most traders have just to relieve the monotony of register-

ing what had almost come to be considered as standard quotations. According to the published statistics from certain European ports, it was evident that consumption had wonderfully increased in several districts, and with the end of July came a breath of suspicion that this increased demand might exceed the probable supply, and before summer was over prices were 1s. per cwt., dearer! The August boom was not so short lived, as such sudden advances generally are; miners had rushed in where even speculators feared to tread, and, consequently, a level of rates above 8s for Rangoon rice was maintained to the end of the year. Once more steamer shipments have increased in comparison with the quantity taken by sailing ships. 100,000 tons over last year is a large increase, the actual figures being 677,700 tons against 566,800 in 1890, 466,480 tons in 1889, and 378,390 tons in 1888. Freights fluctuated between 32s 6d and 40 during the year, and similar rates have been paid for the coming season. Cleaned Rice: speaking generally, we think we may describe the trade of the past year as very satisfactory; both to millers and dealers, and it must be noticed that so far as London and Liverpool are concerned, millers are fast adopting the position of dealers, there being in face of continued and increasing shipments from Burmah, but few opportunities left to them to mill rough rice to advantage. They therefore meet their altered circumstances by purchasing the cleaned instead of the rough article, as formerly from Burmah in large quantities, and so to speak become distributors and retailers to provide the requirements of their buyers. Although the shipments, to Europe and America have increased to the extent of some 50,000 tons, the shipments to the Far East Straits, China and Japan have fallen off to the extent of about double this quantity, which is almost entirely due to the absence of demand from Japan, which drew so largely on Burmah in the previous year, in consequence of the partial failure of the crop in that country. The course of prices has been generally a steady rise throughout the year, embracing an advance of about 1s 3d per cwt on shipping quantities of Rangoon while cleaned broken rice and rice meal showed at one time an improvement of 2s to 2s 3d per cwt from the lowest point. Values ranged as follows say, fair shipping qualities of Rangoon and Bassein and Neeransie 8s 7½d to 10, Patna 10s to 13s 9d. Japan 12s 9d to 14s. Japan: Contrary to general expectations shipments were on a much smaller scale than foretold in our last review. Although the crop of 1890-91 was undoubtedly very abundant the troubles consequent on the failure of the previous crop seem to have created a feeling of anxiety throughout the country which had the effect of maintaining values at such a high level that exports were necessarily curtailed. We had the highest authority for stating in our last year's review that quantity available for export would be some 400,000 tons, but as a matter of fact the actual shipments did not amount to more than about 25 per cent of that quantity, and were distributed as under:—Shipments to Europe 80,000 tons, America 14,000 tons, Australia 4,000 tons. The quality and condition were extremely satisfactory as a whole, and the deliveries of the rough grain were without exception, quite up to the selling standards. Some of the cleaned shipments were, on the other hand, most disastrous, and in some cases as much as 3s to 3s 6d per cwt, was awarded to buyers for difference in sample. It is only fair to state, however, that these great differences were due to damage by either sea or fresh water as also to the presence of worms which infested some parcels. We attribute these troubles to the fact of the damage having taken place previous to shipment, most probably from being kept a long time in stock in Japan, and not from any fault in the actual cleaning. Prices ranged from 10s 3d to 11s 9d for rough and the cleaned, which was chiefly sold on a fine standard, at about 14s per cwt. For the coming season only about 8,000 tons have been sold at from 11s to 11s 9d, delivered terms. The crop is said to be a fair average one, but the recent disastrous earthquake has so unsettled the country that it is extremely difficult to say what may

be the result. All that is known is that prices remain very high, and the speculative element is quite master of the situation. In a country where this feeling is so rife, it is quite possible the present range of values may be maintained as last year, in spite of ample supplies, though the typhoon in the month of September is said to have reduced the available quantity of export quality very considerably; at the same time the Northern rice, which is not suitable for export and is entirely consumed in the country is said to be very abundant. Java shipments continue on a comparatively large scale, and exceeded those of the previous year by about 3,000 tons. The quality was fairly good, though some parcels shipped to London were found to be considerably under the standard of sale being chiefly deficient in colour and containing too great a percentage of broken. As usual, the bulk of the imports were landed in Holland and prices are difficult to trace. The values of shipments to London ranged from about 11s to 14s 3d. per cwt. Siam and Saigon (Cochin China): shipments of both descriptions were less than the previous year, especially from Siam, where the crop suffered very considerably from drought and the quantity directed to Europe was some 70,000 tons less than in 1890. Saigon, on the other hand, contributed within about 4,000 tons of the total of the previous year. The qualities were fairly good and the Saigon shipments were nearly all taken by France where the protective system favours this grain to a very marked degree, coming, as it does, from a French possession. The rates obtained for cargoes ranged from about 7s. c. i. f. for Siam, to 7s. 1½d. to 7s 2½d. for Saigon.

The total-shipment of Siam to Europe were 9,950, against 80,500 tons in 1890, and 59,000 tons in 1889, and 110,000 tons in 1888, and from Saigon 33,565, against 37,000 in 1890, 17,400 in 1889, and 71,500 tons in 1888.

New crop prospects in Siam are less promising than last year at this time, when a partial failure was predicted. The reports so far seem to point to there being no available supplies for Europe, but on the contrary it would appear the crop has suffered to such an extent, that there may not be sufficient for the internal requirements of the country. The crop reports from Saigon are good, and already over 40,000 tons steam-milled, including some 4,000 tons pneumatic shelled, have been sold for shipment to Europe during February, March, April and May, at about 7s. 4½d. and 7s. 3d. c.i.f., shipping weights.

—L. and C. Express.

THE CINCHONA INDUSTRY IN BENGAL.

The annual Report of the Government Cinchona Plantation and Cinchona Factory in Bengal for the year 1891-92 is submitted by Mr. J. A. Gammie, Acting Superintendent. In marked contrast with the heavy rainfall in 1890-91, the year under review witnessed the scantiest fall at the plantation since its formation being 81 inches against an average 126. Fortunately it was well distributed and proved sufficient for the requirements of the plants. Flights of locusts visited the cinchona reserves, but caused no material injury to the cinchona trees, which they passed by for the leaves of the acacias and the worm-wood which abounds in these parts. The number of cinchona plants in the plantation on the 1st April, 1892 was 4,369,971, of which 3,149,971 were quinine-yielders. The cultivation of the *Calisaya Verde* and *Morada* species, of which great hopes were at first entertained, is being gradually abandoned, their yield of quinine being scanty as compared with that of *Calisaya Ledgeriana* which must occupy the first place on the plantation as a quinine-yielder. The statistics given at the end of the report show that no red bark trees were

planted out during the year, while the number of such plants up-rooted was 200,000. This is in accordance with the policy steadily observed for years past of gradually reducing the red bark trees, which, though rich in the inferior alkaloids, are poor in quinine. The complete exhaustion of these plants is only a question of time, the object being to gradually convert the Government Plantation into a source of quinine rather than of cinchona febrifuge.

The crop collected amounted to 285,500 lb. of dry bark against 293,972 lb. in the previous year, of which 80,430 lb. were of red bark, 114,540 of *Ledgeriana*, 70,870 of hybrid, 19,170 of *Verde* and *Morada*, and 550 of Crown or *Officinalis* bark. In other words, the crop was composed of 205,130 lb. of the quinine yielding, and 80,430 lb. of the febrifuge-yielding bark*. The whole of this crop, with the exception of a small quantity supplied on indent or sold to Government institutions, was made over to the Febrifuge Factory for disposal.

The output of the factory, which is regulated by the demand, was 4,500 lb. of sulphate of quinine, and 4,190 lb. of febrifuge, against 4,010 and 4,031, respectively, in 1890-91. The entire quantity was manufactured by the fusel oil process, which continues to work satisfactorily. The issues from the factory were as follows:—Sulphate of quinine 3,714 lb., cinchona febrifuge 4,726 lb., the corresponding amounts in 1890-91 being 3,789 and 3,857 lb.

It is not explained why the medical depôt at Bombay has ceased to indent for the drug. In 1890-91 the demand from Bombay was no less than 400 lb. of sulphate of quinine, and 1,000 lb. of the cinchona febrifuge. The report also fails to distinguish clearly the supply to dispensaries; this should be separately shown in future reports.

The revenue derived from the sale of sulphate of quinine, cinchona febrifuge, cinchona bark, and other products of the plantation amounted to R1,09,321 against R1,18,576 in the previous year. The net profit on the working of the estate amounts to R7,962 12 8, against R17,040 2 in 1890-91. The decline is attributed to the unusually low market rates, above which the Government quinine is not sold. The profit, small as it is, is sufficient. As explained in last year's Resolution, the Government does not aim at a profit, the sole object in establishing the cinchona plantations being to secure for the people a cheap remedy for fever. In pursuance of this principle the question of reducing the price of Government quinine lately engaged the attention of Government. Under the orders of the Government of India, the rate for locally manufactured quinine supplied to Government should be the rate in England of Messrs. Howard and Son's quinine on the 1st January each year converted into Indian Currency at the official rate of Exchange. The price of the quinine supplied to Government officers and local authorities is, however, slightly higher than that charged to medical depôts, and the question is under consideration whether the former should not be placed in the same position as the latter. Another important scheme is now being matured by which pure Government quinine will be placed within the easy reach of the poorer classes in Bengal. The quinine will be made up into packets containing five grains each and sold for a pice apiece. The sales will be conducted at all public offices in the interior, such as thanas and police outposts, dispensaries, offices of managers of Ward's estates, etc., and also through the more effective agency of the village post office.

The Lieutenant-Governor again acknowledges the efficient management of the Department by Dr. King and Mr. Gammie.—*Madras Times*, Sept. 12.

AGRICULTURE.

MANURES AND MANURING.

III.

I see that *A Wanderer* in your columns, while expressing the opinion that the compost suggested by me is deserving of trial, falls into the common error of supposing that bones are suitable only for a seed-producing crop, and therefore by inference unsuit-

able for tea. It must not be forgotten however that though the dominant constituent of bones is phosphate of lime, yet it contains an appreciable quantity of ammonia. In a very useful little publication "McCConnell's Agricultural Note Book," dissolved, boiled and finely ground bones appear both as a nitrogenous (or forcing) and phosphatic (or seed forming) manure. It must also be borne in mind that phosphoric acid in some cases in appreciable quantities, enters into the composition of leaves. Hughes in a letter to your columns in 1886 wrote: "Coffee leaves are really far more exhausting to the soil than parchment coffee, and if the trees can produce plenty of leaf naturally, no manure should be necessary in order to produce the coffee bean, which is certainly not an exhausting crop." It is necessary to bear this in mind in view of the thoughtless suggestion recently made in your columns by a correspondent, that coffee bushes might be made to yield handsome profits by converting the leaves into tea in addition to harvesting the berries.* In an analysis of Assam Hybrid tea leaves by Schrotky we find phosphoric acid represented as composing 16.214 per cent. of their ashes. It may be of use to reproduce the analysis:

Chloride of Sodium	2.247
Soda	8.941
Potash	36.514
Magnesia...	10.089
Lime	8.517
Oxide of Iron and Manganese	3.966
Phosphoric Acid	16.214
Sulphuric	13.017
Silica	0.439

†99-924

An *Old Coffee Stump* has recently relieved itself by the delivery of enigmatical dicta. These have raised the ire of a few planters who have evidently thought them deserving of refutation. Of course the Stump has been asked to demonstrate how the unlimited resources of the atmosphere can be more freely drawn upon them at present and equally of course sphinx-like he preserves a discreet silence. We have been made acquainted with the possibility of conducting the nitrogen of the atmosphere to the soil by the artificial aid of electricity, and the most recent investigations of agricultural science point to the possibility of a certain class of plants absorbing the free nitrogen of the atmosphere through the infection of their roots with bacteroids. These researches after all point to the possibility of our being able to draw on the atmosphere for only one of the constituents of plant food.† How for the rest and for the important mineral constituents?

It may be within your recollection and that of your planting readers that not very long ago a Mr. Reeves startled the world of science by the very original discovery that plants obtain water and mineral food through their leaves from the atmosphere, while the roots absorb most of the gases required for their growth. This fossilized *Coffee Stump* is evidently a disciple of Reeves' but he surely out-Reeves' Reeves when he sapiently counsels us to draw more from the atmosphere than from the soil. How are we to lessen the action of the roots and to increase that of the leaves?

After a period of suspended animation *An Old Coffee Stump* displays signs of vitality by the not very original remark that "what little good there is in the Ceylon soil is being pumped out of it by fine plucking." He has common sense on his side this time, though *Another Proprietor* attempts to combat it. This latter

* Which we denounced.—Ed. T.A.

† As a matter of fact, much the same constituents of a manure which are good for coffee are good for tea and good also for wheat.—Ed. T.A.

‡ But one of the most important and most costly to purchase.—Ed. T.A.

gentleman I would designate as an agricultural agnostic. Before he accepts *Old Coffee Stump's* statement he wishes to know how the "law" laid down by him operates. As it is unlikely that the *Coffee Stump* will break his rule of speaking in enigmas and then keeping silence, I will attempt to point out how the "law" operates. The leaves of plants perform the functions of the lungs and stomach. The crude sap travels up to the leaves (apologising to Mr. Reeves), is elaborated there by the aid of the chlorophyl and sunlight and descends to nourish and build up every part of the plant. These functions are performed by leaves only during a certain period of their existence, after which they harden and are not of very much use. The tea bushes that are constantly picked, are constantly throwing out new shoots or flushes to lessen the injury done them and to have sufficient foliage to support them. If we are not perverts to Mr. Reeves' theory, then we must believe that the mineral matter for the formation of the flushes is drawn from the soil. It may be urged that this is true of plucking generally whether coarse or fine. Yes to a certain extent; but if fine plucking means more, frequent plucking, then it follows that fine plucking draws more from the soil than coarse. It also impoverishes the bushes more than coarse plucking, because it allows less time for the leaves to perform their all-important work of assimilation. Why tender leaves and twigs contain more potash than those of older growth becomes apparent from the preceding.

The reviewer of Reeves' theory says "cultivated trees that are pruned and deprived of their life-giving foliage, decrease in strength and fall easier victims to disease than the heavily foliaged trees in their natural state." If this be true of trees that are pruned and deprived of their foliage once a year, how much more true is this of a plant that, if I mistake not, stands alone amongst cultivated plants for the exceptional treatment it receives. It is deprived of its foliage 3 or 4 times a month, and when nature is no longer able to replace what has been removed, is cut down and is called pruned, an operation with no pretension to Science.

It stands to reason that plants so exceptionally treated as regards the crop gathered from them, require to be more than ordinarily liberally treated as regards manuring and aids to root development. It is no answer to say that because Tea continues to flush freely on certain situations without the aid of manure, therefore the preceding conclusions are falsified. These experiences only prove that Tea is a more than ordinary hardy plant and is able to adapt itself to very adverse circumstances. The length of time it will be able to do this will be dependent on circumstances, chiefly of soil and climate; but the day of reckoning must surely come. Mr. Shand, to whose interest it cannot surely be said it is to decry Tea, found the bushes enfeebled when visiting the Island after an absence of a few years. Mr. Hawes said, and said truly, that the quality of Ceylon Tea deteriorates as estates age. It may be to the interests of planters to combat this and as chivalrously as Mr. John Ferguson has. But the conclusions of an outsider like myself who has not the slightest interest in Tea, but who carefully watches events, were precisely those of Mr. Owen. In private conversation I always instanced in support of this belief those estates whose averages dazzled Tea Planters and promoted emulation a few years ago, but have now subsided to the level of the multitude. These are facts and not opinions. How can these be accounted for? Can it be that the makers of all the leading brands of a few years ago have entered into a conspiracy never to make good Tea hereafter? Since the above was written I have seen the statement credited to Mr. Jackson, that Assam keeps up its quality of Tea by abandoning old estates and opening new ones. We have not the land nor the necessity to do that; but I submit we can maintain the quality of our Tea by judicious manuring after consultation with experts.

B.

* Many who plucked very fine found the system did not pay and abandoned it.—*Ed. T.A.*

THE BRAZIL COFFEE CROP.

The receipts of coffee in Rio and Santos, for the trade year ending June 30, compare with preceding years, as follows:

	Rio bags.	Santos bags.	Total bags.
1891-92	3,722,000	3,675,000	7,397,000
1890-91	2,413,000	2,945,000	5,358,000
1889-90	2,389,000	1,871,000	4,260,000
1888-89	4,189,000	2,638,000	6,827,000
1887-88	1,912,000	1,121,000	3,033,000
1886-87	3,497,000	2,581,000	6,078,000

The exports from Rio and Santos for the year ending June 30 and the preceding five years were as follows:

	To U. S.	To Europe.	Total Exports.
1891-92—Rio ..	2,556,000	1,148,000	7,267,000
Santos ..	997,000	2,556,000	
1890-91—Rio ..	1,556,000	750,000	5,537,000
Santos ..	798,000	2,253,000	
1889-90—Rio ..	1,767,000	724,000	4,570,000
Santos ..	512,000	1,567,000	
1888-89—Rio ..	2,332,000	1,542,000	6,431,000
Santos ..	533,000	2,024,000	
1887-88—Rio ..	1,337,298	541,876	3,189,383
Santos ..	427,750	822,459	
1886-87—Rio ..	2,121,000	1,835,353	5,949,581
Santos ..	554,954	1,938,274	

The arrivals of Brazil coffee in the United States in 1891-92, were 3,451,689 bags of Rio and Santos; 1,165,330 bags of other kinds, making a total of 4,617,019 bags. In eight principal ports of Europe, 6,715,935 bags; a grand total for the United States and Europe of 11,432,954 bags. The total visible supply in both countries July 1st, 1892, was 2,955,023 bags, against 1,909,120 bags, July 1st, 1891.

The exports from Rio and Santos for the year ending June 30th, 1892, were larger than any previous year on record. During the six years ending June 30th, 1892, the exports from the two ports to the United States and Europe, aggregated 32,763,964 bags, or an average annual export of 5,460,661 bags, or 321,215 tons. The exports for the past year were 427,470 tons, being 127,506 tons above the annual average of five preceding years, and 106,255 tons as the average for the last six years.

Prices have been remunerative to the planter, making the industry one of the most profitable on the globe.

The total sales for future delivery on the New York Coffee Exchange amounted to 6,949,000 bags for the year ended June 30, 1892, compared with 7,700,750 bags in 1890-91 and 13,014,500 bags in 1889-90. The largest transactions for any one month were in September, when they reached 1,057,000 bags, and for the quarter ending November 30, 3,595,250 bags. More than one-half of the year's business was done at this time. The highest price paid was 17-25 cents for July delivery in July 1891, and the lowest was 10-35 cents for January and February delivery in October last.—*American Grocer*, July 20.

CINCHONA IN JAVA.

The report for the second quarter of 1892 by the acting director of the Government cinchona enterprise in Java says:—

The weather during the quarter was not unfavourable for the growth of the plants, owing to an alternation of dry weather and rain. In the first half of the quarter there was an exceptionally heavy fall of rain, whilst the latter half was pretty dry, intermitted by a few showers. No commencement was yet made with the working of the soil in the old plantations; in the younger fields, on the other hand, the upkeep cost a good deal of manual labour, owing to the vigorous growth of the weeds. Of the crop of this year already some 150,000 half-kilograms of bark have been obtained, of which by the end of the quarter about 100,000 half-kilograms had been despatched to Landjong Priok. This product was ob-

tained by the digging out of sickly trees, and by the removal of branches, which had become sickly from scraping. Of the branches scraped about a year ago many were apparently still healthy after that operation, and the mass of leaves, where such existed, had retained their green color; but a closer examination showed that at the union of branch and stem and somewhat above, the bark had died off and had acquired a black hue. In order to prevent further loss of bark and alkaloid all these sickly branches were removed, and the still living bark was harvested. Without exception the phenomenon was presented, that all the trees whose branches were scraped blossomed very profusely; whilst this was much less the case with those which had not undergone this operation. On the Tjibeureum establishment a couple of old plantations suffered greatly from stem and branch canker. The trees affected by this disease were dug out, and where it was only the branches, these were removed, after which the healthy bark was harvested, and the diseased was burnt. Several old plantations at Tjibeureum, and on the other hand the young plants at Tjibitoeng and Tirtasari still suffered much from the *Helopeltis Antonii*; whilst on the Nagrak establishment will pigs caused great damage by the destruction of terrace walls and the uprooting of the ground in the young plantations. The grafting of *Cinchona pitayensis* on *Cinchona succirubra*, begun in 1888, was stopped. Having in view the result of the examination of 7-year-old grafts of this variety of cinchona, and the high quantity of quinine, found a short while ago in *Cinchona officinalis*, further cultivation of this variety cannot be recommended. The analyses 1-10 in appendix B give the yield of the ten trees of *C. pitayensis* which are to be found on the Tjinjirean establishment; whilst analysis No. 11 gives the yield of 150 grafts, all offshoots of these ten mother-trees. The grafts examined were three years old and had a height of 1½ meter. In consequence of the working at the *saravahs* and the large coffee crop, the supply of labour was small, both on the neighbouring private estates as well as on the Government estates, so that operations suffered much therefrom. On 5th May and 9th June sales of cinchona bark of the crop of 1891 were held in Amsterdam. The unit price of manufacturers' bark was at both sales 6 cents.

Appendix A gives the number of plants in the Government gardens at the end of the second quarter, viz.:—In the nurseries—267,000 ledgeriana (including 27,000 grafts) and 702,000 succirubra—total 969,000. In the open—2,118,000 ledgeriana (including 300,000 cuttings and grafts, and exclusive of the more or less 3,000 original ledgerianas), 2,200 calissya and hasskarliana 620, 00 succirubra and caloptera, 46,900 officinalis, and 2,000 lancifolia—total 2,789,100. Grand total of plants 3,758,100. Appendix B is as follows:—

No.	Variety.	Place of growth.	Quinine.	Cinchonidine.	Quinidine.	Cinchonine + Amorph. Alkaloid.	Total
1..	C. Pitayensis.	Tjinjirean.	6.75	1.00	—	1.80	9.55
2..	id.	id.	3.31	1.81	—	1.34	6.46
3..	id.	id.	3.37	2.40	—	0.59	6.36
4..	id.	id.	3.50	0.80	—	2.70	7.00
5..	id.	id.	6.06	1.25	—	2.39	9.70
6..	id.	id.	2.30	1.43	—	0.82	5.10
7..	id.	id.	4.03	1.10	—	0.37	5.50
8..	id.	id.	3.60	1.21	—	1.42	6.23
9..	id.	id.	4.10	0.90	—	0.87	5.87
10..	id.	id.	2.71	2.90	—	2.51	8.12
11..	id.	id.	2.31	0.90	—	1.64	4.85

The analyses are calculated on absolutely dry bark.

MAKUM (ASSAM) TEA COMPANY.

The statutory meeting of the Makum (Assam) Tea Company, Limited, was held on Monday, at the offices, Blomfield House, London Wall. The Chairman, Mr.

J. Berry White, said the list of applications was opened on May 7th and closed on May 10th, the whole of the shares being over-applied for. They were allotted to 191 persons, and one-third of these were either planters or residents in Assam, which indicated that experts on the spot held a high opinion of the value of the property and of the good opinion entertained in the Assam district. This season, since the company was formed, had been a very rainy one; but, notwithstanding that disadvantage, their local resident reported that very good progress had been made on the estates. Upper Assam was the natural home of the tea plant, and many attempts had been made to dispute its supremacy, but this year it stood head and shoulders above any other district, whether in India or Ceylon. This country had been educated to drink Indian tea, and now remained to educate the world. There was no doubt, notwithstanding what medical journals said, that Assam tea was a most wholesome and nourishing beverage. Referring to the silver question, he remarked that since the company was projected silver had fallen about 12½ per cent. Now, all their expenditure was in silver, and this fall, which had so disastrously affected the officials and the Government of India itself, meant to this company that they would get one-eighth more work done for their sterling capital than they did when they projected the company. With regard to the finances, the money paid on application and allotment would be sufficient to carry on the company for this year. Another call of 5s. would be made in December, to be payable in February, and that, he anticipated, would carry them on for more than a year. Next year they would be making some tea, although the amount would be infinitesimal, and the following year he hoped they would be making a considerable amount. In reply to a shareholder, the Chairman said that after the holidays a formal application would be made for a Stock Exchange quotation, and he had no doubt it would be granted. A vote of thanks to the Chairman concluded the proceedings.—H. and C. Masl, Sept. 9.

ANALYSIS OF TEA.

In regard to the purity of tea, both the grocers and the public are protected in a special manner. If the article be not pure, it is not permitted to enter into consumption in this country. Under Section 30 of the Sale of Food and Drugs Act, tea is analysed at the Custom House, so as to ensure that there is nothing in the shape of adulteration in the imports: and if the plan were practised in regard to one or two other commodities that might be named, retailers certainly would not feel disposed to complain. We subjoin a table showing the results of the analysis of tea conducted at the London Custom House, in accordance with the statute above mentioned, during each of the last ten financial years:—

Importations represented by these samples thus disposed of. Submitted for board's directions with following results.

Year ended March 31st.	Samples analysed.	Delivered on certificate of analyst.	Allowed to be admitted for home use.	Allowed to be delivered for exportation only, but no for use a ships' stores.	Admission refused.

—Indian Planters' Gazette, Sept. 17.

INDIAN TEA.

Our friends at home, as was recently shown, have great difficulty in procuring Indian tea, pure and simple. This is, of course, vastly in favour of the middleman, the skilled taster and blender of tea, the grocer who likes to sell apparently cheap tea and yet net his profit. These are powerful interests, and they practically rule the tea trade. Indian planters are taxed with a want of enterprise, they are charged with not realising the virtues, of advertisement. But what is the good of advertising wares which rarely if ever make their appearance in an undisguised form in the market? Before this can be done, we must have unmixed Indian tea introduced by competent persons to drinkers at home. We cannot doubt that the pure tea will prove as pleasant to British palates as it does to us here. Probably the great Mr. Lipton's enterprise in Ceylon tends in this direction. That eminent purveyor of breakfast table foods and drinks has bought gardens of his own, and will no doubt place their produce on the English market in a pure and unmixed state. This will help towards a right appreciation of Indian tea. The consumer will be content to pay a little more for his tea, partly because it is stronger and will go further than the mixtures now in vogue, partly because he will in time realise that the flavour of the Indian product is pleasanter more stimulating to the duly educated palate. We may yet see the English purchaser taking an intelligent interest in discriminating between the produce of different Districts, and the geography of the Terai, of Darjiling, of Assam, and Sylhet, and Cachar may become as fascinating a subject to the educated tea-drinker as that of the winegrowing countries is to men who are experts in vintages. An educated taste in tea should surely be as much respected as an appreciation of the flavours of wine, in view of the prevalent tendency to adjure alcohol in all its seductive forms. The drinking of tea is held to be a harmless luxury, whether by washerwomen or bishops. The difficulty is to make men realise how many varieties and niceties of flavour and fragrance our Indian tea-gardens afford. The way of education would seem to lie in the sale,—and the judicious advertisement,—of pure and unmixed brands of Indian tea.—*Englishman.*

CEYLON AND CHINA TEA.

To the Editor of the "North-China Daily News."
SIR,—I was interested in reading in your issue of this morning a copy of the circular of Messrs. Gow, Wilson, and Stanton. Though not in the tea trade, but being personally acquainted with some of the tea growing districts, it has always been a puzzle to me to understand why the first crop of tea, which can be bought at or near the place of growth for 3d per catty, or even less, should be sold at Hankow for 40 or more taels per picul. This no doubt explains why Ceylon can be laid down in London so much cheaper than Chinese tea.—I am, etc.,
C. J. E.
Sept. 6th.

SOUTH WYNAAD NOTES.

We are rejoicing in a complete change in the weather, and not before it was needed. For seventy consecutive days there was not one wholly free from rain, and on this estate, which has a very medium rainfall as a rule, we registered over 100 inches in that time. It was becoming a serious anxiety to us as the continual damps and lack of sunshine, brought out a tolerably sharp attack of leaf disease and leaf rot, and a good deal of crop has fallen in consequence. I am glad to notice, however that leaf seems to be passing off again, and that the coffee is making a brave struggle to recover itself. No doubt this is due to the long rest from disease, during the hot weather drought. There is a steady increasing demand for Liberian seedlings, and even those who hitherto have set their faces most determinedly against the introduction of anything but Arabica, are now putting Liberian wherever there is room for it. Those who planted it some years ago, are proving by experience, that it must become exceedingly valuable to

us for its hardness, strong cropping and immunity from leaf disease. I hear that it is intended to try some experiments on hybridising Liberian with a view to producing a variety which will crop at a more convenient season, and have softer pulp. Of course it is rather a nuisance having to pick crop in June.

Tea prospects have advanced considerably since I last wrote. There have been about 1,000 acres sanctioned for opening on different estates, which certainly looks like business. But opinions differ considerably, as to the advisability of planting tea in Wynaad, and there are those who consider it a great mistake because they say that even now the tea market is becoming overstocked. Of course it can only be done by companies or very well-todo proprietors. Those of us who can just screw out our bread and cheese with nothing or very little over, cannot think of attempting the outlay necessary for the opening and working of a tea estate, but we all of us have excellent land for sale, and a few good purchases, with money to carry things on would simply be the making of Wynaad. But I suppose we must wait patiently until the present openings come into bearing, and prove practically that tea will pay; no doubt there will then be a good time coming for our rising generation. Coochoda, I am sorry to say, is not flourishing, and it is very disgusting to see our fine ledgers dying out, for we had hitherto hoped that they were impervious to causer.—*Madras Times, Sept. 23.*

BARK AND DRUG REPORT.

(From *Chemist and Druggist.*)

London, Sept. 1.

ARECA NUTS.—Fifty bags of fair quality, which have been bought in on several occasions previously, were again taken out today at 32s 6d per cwt. A bid of 27s per cwt. was declined.

CALUMBA suffered an almost unprecedented downfall today, a considerable quantity selling at a decline of from 10s to 15s, which is equal to from 50 to 75 per cent. Of 420 bags, 264 sold at 24s to 26s for fine medium to bold brownish and yellow mixed natural sorts, 20s to 22s for rather darker ditto, and 19s for rather ordinary grey mixed.

COCA-LEAVES.—Four small boxes from Ceylon nice green leaf, good flavour, but rather broken, were bought in at 2s to 2s 6d per lb. today.

QUININE is dearer, and yesterday some business was done in second-hand German bulk at 9½d on the spot, while for January delivery we hear 9½d was refused. Today the owners' quotation may be called 9½d, at which, however, there are buyers and sellers. "This," said a dealer to us yesterday, "is the first occasion I can remember upon which quinine has gone up in price without any speculative action to cause the advance."

OTHER USES FOR GRAPHITE.—A correspondent says:—I have read an article on graphite taken from the *American Machinist*. Let me say that I have used graphite for many purposes, some that the correspondent did not name, which I will give, as it may benefit some of my brother engineers, who perhaps have not experimented to any great extent with the article. I have used handhole and manhole gaskets eight or times by carefully smearing the surface next boiler shell, taken out at periods of three to four weeks, using steam pressure as high as 100 pounds. In packing water glasses, by putting a little graphite and oil on the gasket they would vulcanize as soft as lamp wick and retain their elasticity until the glass was changed, when the old rubber could be removed without trouble, while by the old way I have spent much time in digging out the rubber, baked as hard as vulcanite. Another thing I used it for was after putting back my handhole plate or plugs in back connection, I carefully brush all the soot and ashes, then with a small brush paint a good coat of graphite over flange, stud and nuts. After running boiler from three to six months, and using coke for fuel, with forced draft, the nuts can be removed without trouble, as the heat has not been enough to burn the lead.—*Louisiana Planter.*

THE AGRICULTURAL PESTS OF INDIA.

Considerable attention has been directed lately to agricultural pests of all kinds, and especially to insect pests, in various countries, because the injuries occasioned to crops by their agency have greatly increased, and in some instances altogether new disorders and diseases attributable to them have appeared. The universal international exchange of agricultural produce and other commodities has tended and must tend to distribute insects, fungi, and other sources of evil to mankind, animals, and plants, throughout the world. Thus the terrible scourge of the vine, the *Phylloxera vastatrix*, was first introduced into the French vineyards with plants, or cuttings, of vines imported from the United States. Very many insects most noxious to agricultural, fruit, and garden crops in the United States were brought there with plants, cuttings, fruits, and seeds. The elm-leaf beetle, *Galeruca xanthomelana*, which is now seriously damaging elm trees, was not known in the United States until 1837, and came probably from France, or Germany, where it had been a troublesome pest long before that date. The hop fly, *Aphis humuli*, called the "barometer of poverty," by a Kentish historian of hop culture, has only recently visited the hop plantations of America; yet it caused almost a total blight last year in those of the Eastern States, upon an area of nearly 40,000 acres. Without any doubt this insect was conveyed from England in "hop sets." The Hessian fly has been conveyed to Great Britain by some means or other not yet discovered, during the last year, and bids fair to be a dangerous and permanent scourge to the wheat and oat crops of this country.

It is the same with moulds, or mildews, or "blights," occasioned by fungi. The vine mildew, *Oidium tuckeri*, was not dreamed of in France until 1845. The potato mould, *Peronospora infestans*, had shown no important sign in Great Britain until 1844. The coffee mildew, *Hemileia vastatrix*, did not serious harm in the coffee plantations of Ceylon until after 1870; but during the last ten years it has enormously decreased their yield.

Diseases of animals have also been greatly intensified during the past thirty years in Great Britain and in other countries. In India, as we gather from this little book of Surgeon-General Balfour, anthrax, pleuro-pneumonia, rinderpest, foot-and-mouth disease, are so rampant that the Madras Government has recently appointed an inspector of cattle diseases with a sufficient staff under him.

There is no doubt that the attacks of certain insects and parasitic fungi are more frequent and more fatal than formerly. Hop blights from aphides and mildew, *Spæctheca castanei*, are far more common and destructive in England than they were fifty years back; and the orange-growers of Florida, California, and other places where oranges are cultivated, are at their wits' end to combat the ravages of scale insects, Coccidæ, which have greatly increased since 1870.

It is a moot point as to whether this is due, or not, to modern and more artificial systems of cultivation, which may be more favourable to the spread of insects and parasitic fungi. Or it may be that these new systems interfere with the balance of Nature by decreasing parasitic and other insects, and birds and other animals, which are the natural foes of injurious insects. It has been discovered by Prof. Forbes, of Illinois, that several species of the Carabidæ and Coccinellidæ eat the spores of fungi; therefore an unusual increase in the number of birds, or other foes of these insects, might occasion a serious spread of mildews.

The importance of the subject of agricultural pests cannot be overrated. It is now fully recognized by the Government of the United States who have a distinguished entomologist upon the staff of the National Agricultural Department. Besides this, many of the States have their own entomologists, who furnish frequent and valuable reports and advice as to methods of treatment. In England the Agricultural Department of the Privy Council have lately issued a series of reports upon insects injurious

to crops, written by Mr. Charles Whitehead; and Miss Ormerod, the entomologist of the Royal Agricultural Society, has published annual reports for upwards of ten years, which have been of the utmost value and practical benefit to agriculturists. And in India, as Surgeon-General Balfour tells us in this work, the serious injuries caused by insects and other animals, fungi, and bacilli, to mankind, animals and plants, have at last attracted the attention of the Government of India, and it is proposed to invite communications from those engaged in agriculture, forestry, and horticulture in that country, to furnish matter for periodical reports like those issued from time to time by Miss Ormerod. These would of course be published in the vernacular and should be illustrated by woodcuts, as Miss Ormerod suggests in her comprehensive letter in the preface of "Agricultural Pests of India." It is much to be hoped that a competent entomologist may be appointed in India to direct this work.

Surgeon-General Balfour, so far back as 1880, recommended the Secretary of State for India to obtain reports on the diseases of cattle and plants, and on creatures noxious to mankind and vegetation. In his admirable "Cyclopædia of India and of Eastern and Southern Asia," published in 1885, he gave a general view of the entomology of these regions, and described the losses sustained by agriculturists from these and similar causes. He has followed this up with the work now under review.

Though a small book, the "Agricultural Pests of India" is very ambitious in design, as it treats not only of insects and fungi and animals injurious to mankind and agricultural crops, but of all manner of birds, beasts, and fishes. Several of these cannot, even by the greatest stretch of the imagination, be classified as pests to agriculture, and seem to be altogether out of place in this category. Under the heading "Fish," sharks and silurids are described, though it is not by any means clear in what way they are agricultural pests, except, perhaps, that they might bite off the limbs of unwary agriculturists disporting in the sea. The book should have been styled the "Natural History of India," or "A Manual of the Natural History of India," rather than the "Agricultural Pests of India." But the fact that rather too many subjects are dealt with cannot be held to be a very serious fault in a compilation containing an immense amount of serviceable information arranged alphabetically, together with a good index; so that any head can be quickly found. The author had great opportunities of acquiring knowledge of the branches of natural history he has here discussed while he was engaged in forming the Government Central Museum at Madras, and other Museums in various parts of India as well as in the preparation of "The Cyclopædia of India" and his work on "The Timber Trees of India." He was therefore very well qualified to prepare this manual or dictionary of natural history, which will serve to show Indian agriculturists what are the principal foes of their crops and herds. No remedies or methods of prevention are given in detail. Some general instructions appear in the introductory chapters, such as to farm cleanly, and to use certain washes and powders in case of the attack of some insects. These, however, have evidently been taken from lists of remedies prescribed by American and English practical entomologists, and have not been actually tried in India. Now that Surgeon-General Balfour has demonstrated the dangers, and indicated general remedies which have been found advantageous in other climes, the farmers, the foresters, and fruit-growers of India should at once make experiments, and prove for themselves whether these are as efficacious in the fiery heat of the East as in the temperate climates of Great Britain and America.

This notice cannot be concluded without an allusion to some of the errors which have been carelessly allowed to remain in the book, having evidently escaped the notice of the eminent scientific man who "revised nearly the whole in manuscript, and the proofs as they passed through the press." It is not to be expected that Surgeon-General Balfour should be a skilled entomologist, but it is very unfortunate for

him that those on whom he relied for assistance should have so signally failed him. He says that the *Cecidomyia tritici* is the Hessian fly of Europe and America. In reality the Hessian fly of Europe and America is *Cecidomyia destructor*, named so by Say long ago, and is completely and specifically distinct from *Cecidomyia tritici*, which is the true wheat midge of Great Britain. This is a mistake which appears unpardonable in a scientific reviser. On p. 45 it is stated that "the species of *Necrophorus* and *Silpha* are useful; they feed on carrion and by scratching the ground from under dead animals they partially bury them." As a fact the *Silpha opaca*, and another species the *Silpha atrata*, eat and seriously injure plants of beet and mangelwurzel as, has been shown by Curtis and Miss Ormerod in England, by Guélin Méneville in France, and Taschenberg in Germany. It need hardly be said that correct information as to the habits of insects is as necessary as accurate nomenclature at least to agriculturists.

Again, under the heading *Buprestidae* and *Elaterridae* (click beetles) it is remarked that the larvæ feed on living wood and are more or less injurious. The wire-worm, the larva of *Elaterr lineatus* is fearfully destructive to the roots of crops of all kinds. In the description of *Elaterridae* further on, this kind of mischief is attributed to their larvæ; so that there are two utterly conflicting accounts of the habits of these insects calculated to puzzle the inquiring Indian farmers.

A sweeping statement that "all the weevil family insert their eggs in the stigma of the flower" cannot be supported, and is utterly opposed to the experience of observers. A few species do this, but others deposit their eggs in a variety of places. Of weevils it is also said that they "attack principally in their larval stage every part of vegetable tissues." As a fact, many weevils do incredible harm to vegetation in their perfect or weevil form, and it would be difficult for the larvæ—mere maggots—to hold on to leaves.

Sitonas, described as attacking stored grain and seed, have been evidently mistaken for species of *Bruchi*.

These and other mistakes ought to be corrected before the work is put into the hands of the agriculturists of India as a text-book for their guidance.—*Nature*.

PLUMBAGO MINING IN TRAVANCORE.

We print in another column a letter addressed by a London correspondent to a Ceylon contemporary on the above subject, which has evidently exercised considerably the minds of those in Ceylon who are interested in the plumbago industry. From information which we have been able to gather we are inclined to think that our neighbours are not entirely wrong in supposing that the monopoly which they have hitherto looked upon as theirs is theirs no longer. But that the competition which has now arisen is as serious as the London correspondent would lead them to believe we are not as yet quite satisfied. It is nearly two years since mining operations for plumbago were started in Travancore by Messrs. Parry & Co., who, we may say at once, are the Madras concessionaires whose enterprise has so seriously disturbed the mind of the Ceylon miners. That plumbago existed in large quantities in various Districts of Travancore territory has been known for some years, and it was indeed the existence of old workings which led Messrs. Parry & Co. to consider whether under a more modern system of mining, and with the newest machinery, this valuable mineral could be extracted at a cost likely to prove remunerative. The trial has apparently been a thorough one, and if the results so far obtained fall somewhat short of the description contained in the letter to which we have referred, at least they have been so far satisfactory as to decide Messrs. Parry and Co. to continue their operations, which are, we believe, still in an experimental stage, in the hope that as the workings extend and the ore obtained improves in quality, the value may be so increased as to put them on a more level footing with their Ceylon competitors.

Under the old methods of working, which methods still obtain in most of the Ceylon mines, the extraction of plumbago in Travancore was found to be unremunerative, as proved by the abandoned workings to which we have already referred; but Messrs. Parry & Co. have gone to very considerable expense in laying down the latest machinery, and it is hoped that in spite of many disadvantages with which they have to contend the eventual output of the mines, both as to quantity and quality, will justify the outlay. Messrs. Parry & Co. have had every facility afforded them by the Travancore Government, which has wisely determined to foster the development of this new and valuable industry by every means in its power, and they have received such assistance in the matter of concessions as will effectually protect the industry from premature competition. It may be interesting to the Ceylon plumbago miners to learn that in the early state of the operations a small parcel of Travancore plumbago was shipped to Ceylon for valuation. The report obtained was that the quality was far below even the most inferior of that shipped from the Ceylon mines, and that it was in fact unsaleable. This report was hardly justified, however, for the parcel afterwards realised in the London Market £9 per ton, or about the equivalent of £7 per ton, f.o.b. From a Ceylon point of view, no doubt, this price was not encouraging, but it would appear from Messrs. Marshall and Trench's (we presume the well-known firm of Messrs. Marshall and French is meant) remarks quoted in the London correspondent's letter, that the quality has since steadily improved and is presumably now worth a better price. As to this, however, we understand that the concessionaires have not heard anything before. On the other hand, the fears expressed in Ceylon that Travancore plumbago will improve in quality as a greater depth is attained would appear to be unfounded, since the Travancore deposits are already being worked at a depth of 150 feet, and not only 50 feet as stated. We believe that very few of the Ceylon workings exceed this depth.

In commenting on its London correspondent's letter our Ceylon contemporary remarks that while the Travancore mines can possibly be worked at a cheaper labour rate than those of Ceylon, the advantage in cost of transport should rest with the latter. Of this we think there can be little doubt, and it was chiefly this question of transport which was in our mind when we spoke of the disadvantages with which Messrs. Parry and Co. have to contend. Our Ceylon contemporary's London correspondent was unable to furnish any information as to the distance from the coast at which the mines now being worked in Travancore are situated, or of the means of transport available for traversing it. The mines are, we understand, situated at a distance of about one hundred and fifty miles from the port of shipment, and transport is both difficult and expensive. At present the plumbago is carried part of the distance by cart, and part by boat, and the time occupied is considerable. The disadvantage as regards transport is not, however, limited to the journey between the mines and port of shipment, for ocean freights are both high and uncertain, as compared with those obtainable from Ceylon. At present a portion of the labour employed in the Travancore mines is imported from Ceylon, and is expensive; but this will no doubt be dispensed with in favour of local labour after a time. One of the difficulties of working lies in the fact that the climate is extremely feverish, and it may be found impossible to continue working without interruption during the unhealthy season. This in itself would be a very serious disadvantage. But, as we have already said, hopes are entertained that, in spite of the disadvantages named, the undertaking will prove a sound commercial enterprise, and justify the large outlay made in its experimental stages. This has as yet hardly been ascertained, but there seems to be no doubt that the demand for plumbago is at present considerable and even should the Travancore plumbago prove decidedly inferior to that obtained in Ceylon, there still appears to be an outlet for the

inferior quality, and we trust that a large, and valuable industry may be established in Southern India.—*M. Mail*, Sept. 22.

CALIFORNIA COFFEE.

A coffee planter from Guatemala has recently been investigating the climate and soil of the Alessandro Valley, San Bernardino county, with a view to the introduction of coffee growing in that section. The conditions there, it is stated, he regards as favorable, and he has offered to invest capital in a company to be organized to carry on the business. It is proposed to put two acres in nursery which would yield 80,000 sprouts per year, worth 25 cents each, and to set thirty-eight acres to coffee trees. This would require 30,400 trees, and the estimated yield on the third year is 91,200 pounds, valued at 20 cents per pound, or a total of \$18,240. The fourth year after planting the yield, it is estimated, would be \$34,340, figuring four pounds to the tree. This is a good exhibit, but like others in regard to the profits to be derived from the introduction of tropical or semi-tropical products in this State, it should be carefully considered before capital is invested. In regard to the cultivation of coffee, even if the climate and soil are found favorable here, the fact should not be lost sight of that in countries where this staple is largely grown, labor an important element in its cost, is to be had at a very low rate. On this coast, conditions are quite the contrary, a fact that precludes the introduction of many new industries which otherwise might prove remunerative and successful.—*S.F. Grocer*.

REMARKS.—The estimate given above for the yield of coffee is a long way off. An average of one pound per tree is a fair yield at three years old. And one and a half to two pounds per tree, when five years old; and if this average is maintained in future years, the plantation will do well. In Ceylon, a crop in full healthy bearing formerly averaged about 700 pounds of cleaned coffee per acre, though exceptional yields may have reached 2,000 or even 3,000 pounds per acre.—*Editor Planter*.—*Planters' Monthly*.

THE TEA PLANTERS AND THE CURRENCY QUESTION.

The following is the memorial of the Darjiling and Terai Planters' Association to the Viceroy upon the Currency Question:—That your memorialists are an association representative not only of the European and Indian capital which for the last thirty years has been so largely invested in the development of the staple industry, viz., the tea industry, carried on in the hill districts of Darjiling and Kurseong and in the district of the Terai, but also of the important resident community of skilled Europeans who for a like period have been similarly engaged. To that capital and to the efforts of that community is almost entirely attributable the degree of prosperity at present enjoyed by the districts named. Your memorialists have read with concern the petition of the Indian Currency Association addressed to the Honourable the House of Commons, praying that the Government of India be fully empowered to take such immediate measures as to it may seem fit for the purpose of remedying the evils attending on the present condition of the Indian currency system; for instance, by the prohibition of the free coinage of silver and by the adoption of gold as the monetary standard of value.

Your memorialists submit that if that prayer be granted and acted upon there is every probability that the Indian tea industry will collapse. In clause 20 of the petition above referred to it is stated that, under the present conditions of the currency system "the exporter is no gainer, for each fall in exchange is followed by an equivalent fall in the gold price of the commodities he exports." Your memorialists submit that this statement, besides being an insuffi-

cient representation of the facts, is one which it is extremely difficult, if not impossible, to verify. On the other hand it is a fact well within the experience of your memorialists that the fall in gold prices at home, which has been going on steadily for the last twenty years, is attributable to *over production of tea*. That it has nothing to do with the fluctuations of exchange is obvious from the fact that within recent years, whenever the gold value of the silver rupee has risen in England, that rise has not been followed by an equivalent rise in gold prices. In clause 22 of the same petition it is stated that "the investment of English capital in the development of the material resources of the Empire is discouraged, for both as regards the remittance of interest and the final transfer of invested profits and economies the continuous fall in exchange imparts to the investment of capital in this country a speculative character and a risk which the capitalist is unwilling to face." Your memorialists submit that, apart from the fact that many of the capitalists engaged in the development of the Indian tea industry are resident in India, thus eliminating to a great extent the question of remitting interest home, and also apart from the fact that the idea of finality is a very indeterminate one to attach to the operations of the English capitalist, which are continuous operations, and therefore postulate the return to India, under advantageous conditions of exchange, and in the shape of further capital, of the interest previously remitted home; it is within the experience of your memorialists that whatever difficulties they meet with in procuring financial assistance from capitalists resident in England, are also, like the fall in gold prices at home, attributable to *over production of tea* and not to any deterrent effects produced upon English capitalists by the fluctuations in exchange.

Those countries which still retain silver as their monetary standard of value have hitherto entered into no international agreement under which they shall all combine (1) to check the present continuous fall in the value of silver, or (2) to impart a character of stability to any rate of exchange upon which they may fix for the rupee or dollar, or (3) to adopt gold as the common monetary standard of value. China is a country with a silver standard, and the rise and fall of the price of her silver *tael* is regulated by the same conditions that govern the fluctuations in the price of India's silver rupee. She is also a tea producing country and thus enters into competition with the community who are engaged in developing the tea industry of this country. In days gone by, China exported as much as 170 millions of pounds of tea to the London market. Since then, however, the superior quality of the tea exported to the same market from India has precluded China from exporting more than 50 millions of pounds, and thus the ascendancy in this respect once belonging to China has been transferred to and now rests with India. Your memorialists submit that any interference, such as that prayed for in the petition of the Indian Currency Association, with the natural course of exchange between India and the country where both she and China find a market for their teas, would inevitably cause the price of the Indian rupee either to be stationary or to rise gradually or suddenly, whilst at the same time the price of the Chinese *tael* would be falling; and your memorialists are therefore apprehensive not only lest China should, in consequence of that interference, regain the ascendancy which has been wrested from her, but even lest the tea industry of India should be entirely and irretrievably ruined.

Your memorialists, therefore, pray that, until such time as an international agreement is entered into by all countries having a silver standard, the Government of India, even if empowered by Her Majesty's Government in the way prayed for in the petition of the Indian Currency Association, will stay its hand and not interfere with the present condition of the currency system; for under it those engaged in the Indian tea industry enjoy a considerable degree of prosperity, and this to the best of their ability they endeavour to share with all with whom they are con-

nected, thus making the surrounding regions what they are, a happy district for the natives, with busy factories and an enormous population, of industrious, contented coolies—a prospect which will immediately vanish should the prayer of the petition above alluded to be granted, and your Excellency's Government act upon the powers conferred on it. And your memorialists, &c.—*M. Times*, Sept. 27.

A GREAT BANANA FARM.

The banana trade of the United States is enormous. Among the most attractive features to those passing along the lower portion of New York city's water front are the East River piers, occupied by tropical fruiterers, where the steamers lie discharging cargoes of delicious bananas. From one side of a steamer gangs of men carry the bananas to the waiting truckmen on the pier, while on the opposite side of the fruiter lies a large float, on the deck of which receiving their loads are railroad cars especially constructed for carrying bananas in good condition to different parts of the United States. Four years ago Messrs. H. Dumois and Co. purchased thirty-five square miles of land in Banos, Cuba, which at that time was a dense forest and there were only ten inhabitants in the whole district. With indomitable energy and enterprise, and a sufficient amount of capital, they began the arduous work of clearing away the forest and putting the land into a proper state for agricultural purposes and making improvements. Level roads, ranging from 60 ft. to 100 ft. in width, have been laid out so that carriages can be driven over the entire plantation. The company have built a 3 ft. gauge railroad ten miles long, and an extension of eight miles is now in progress. They have also built a pier 300 ft. long from the hard native woods, and have a saw-mill and water-works. One thousand five hundred men are employed on the plantation during crop time, and Banos had in May last a population of 3,500 which shows the rapid progress that has been made, and it bids fair to be one of the finest and most thrifty portions of Cuba, besides the most important fruit centre in the world. The company has about one-half the entire land cleared, and 9,600 acres planted with bananas—2,400,000 fruit-bearing trees. There are twenty-six steamers in the banana trade plying between Cuba and New York all the year round. Between the months of April and July a steamer arrives at New York almost daily, and during the busy season each steamer will discharge her cargo, which averages 12,000 bunches, and depart the same day in ballast. The demand for bananas has reached such large proportions that this year the export from Banos to the United States will be about 1,500,000 bunches.—*Indian Agriculturist*, Sept. 3.

COCOA ADULTERANTS.

REPORT OF THE GOVERNMENT CHEMIST.

The raw material from which the cocoas and chocolates of commerce are manufactured is the "cocoa bean," the seed of the cocoa, or cocoa tree (*Theobroma cacao*). While this tree has been successfully introduced into various warm countries, tropical America, its native land, still furnishes the larger and more highly valued portion of the world's supply of cocoa. From Mexico to Peru on the west coast, Mexico to Bahla, Brazil, on the east coast, and on the West India Islands, the most favorable conditions for its cultivation are met. After removal from the fruit two processes are used for the preparation of the seeds for market. For the production of "unfermented cocoa," they are freed from adhering fruit pulp and are at once dried in the sun. For the production of "fermented cocoa," the beans are placed in piles in sheds or are buried in trenches and allowed to ferment for a time before being completely dried in the sun. When buried the beans are now placed in casks or other coverings; hence, the earthy coating is no longer a mark for determining the process of preparation. Much of the

acridity and bitterness disappears in this process of fermentation; the beans so prepared have a mildly oleaginous, pleasant, slightly bitter taste, and are more or less aromatic. The value of the product therefore greatly depends upon the care bestowed upon this operation. On account of the peculiar properties of the cocoa bean, its preparations merit a place on our tables for two reasons. In addition to being, like tea and coffee, the material for the preparation of a pleasant and exhilarating beverage, it is a valuable food material. Not only is it much richer in nutritive substances than tea or coffee, but both the soluble and insoluble portions become a part of the beverage, while only the constituents soluble in hot water are obtained in the beverages prepared from tea and coffee.

The investigations of Stutzer and others clearly prove, however, that the food value of cocoa preparations has been greatly overestimated, and that many of the present modes of preparation do not develop in the highest possible degree the pleasing aroma and flavor. The inventive energy of many manufacturers seems to be spent on the production of a highly nutritive and easily digestible preparation; the valuable fat is removed and the delicious aroma and flavor destroyed by chemicals for the ostensible purpose of rendering more digestible a residue of doubtful food value. The more important constituents of the husked cocoa bean are fat, theobromine, the nonalkaloidal nitrogenous substances, starch, the coloring matter called cocoa red, and the mineral matter. The fat, cocoa or cacao butter, in consequence of its quantity and peculiar excellence, is unquestionably the constituent of the cocoa bean possessing the highest food value. It usually forms 45 to 55 per cent of the husked bean, rarely falls below 45 per cent, and only one recent analysis shows as low as 36 per cent. At ordinary temperatures it is a white, or slightly yellowish, brittle solid, having a pleasing taste and odor and showing but little tendency to become rancid. The preparations of cocoa are so numerous that more or less confusion of terms naturally arises. Most American manufacturers prepare a plain chocolate (known in Europe as cacao-masse), made by reducing the roasted and husked beans to a paste and pressing into the form of cakes. When this is combined with much or little sugar (generally much), vanilla and spices, the various "sweet," "vanilla sweet," "vanilla," "spiced," etc., chocolates are produced. These are also usually met in the form of cakes, but are sometimes pulverized and sold as "powdered chocolates." The high percentage of fat renders a permanent powder impossible without its partial removal or the addition of some diluent, as sugar, starch or flour. The preparations in powder, known as "cocoas," "bromas," etc., are prepared in accordance with one or the other, or a combination of these methods.

No cocoa in the market contains a very considerable percentage of matter soluble in water, unless the material so dissolved is foreign soluble material that has been added during the process of preparation. The term seems to be used to denote a preparation that allows none of the insoluble matter to deposit from the beverage prepared from it. This purpose may be accomplished in two ways—the material may be so finely divided that a very long time will be required for its deposition, or foreign substances (as starch or sugar) may be added to render the liquid of so high a specific gravity, or so pasty, that the insoluble matter will not deposit. The removal of the fat is not considered to be an adulteration when it is acknowledged. It seems important, however, that the public have a means of accurately knowing to what extent it has been removed. Perhaps no food material offers conditions so favorable for profitable adulteration and so well utilized by its manufacturers as do cocoa preparations.

Here were given the results of analyses of cocoa preparations made in the laboratory of the United States Department of Agriculture, of nearly forty different samples procured in open market of the makes well known, most of which contained stock, flour or arrowroot. The amount of sugar ranged from 25 to 65 per cent.

Beef tea was once considered to be a very concentrated and easily digested food, and was given to invalids in small quantities with full confidence in its great, almost miraculous, nourishing power. It has long since been degraded very nearly to the rank of a mere stimulant and is never intelligently administered except when accompanied by an ample amount of nourishing food. As a concentrated and easily digestible food for invalids cocoa preparations are already beginning to share the same fate; as material for the preparation of pleasant, exhilarating and slightly nutritive beverages for both weak and strong, the career of cocoa preparations is just begun. Moreover, their progress in popular favor will keep pace with the manufacturers' appreciation of this fact.

The results of these investigations emphasize in many ways the many pleas that have been made for the establishment of standards of purity, strength and quality for foods—for some certain means of enabling the public to know the strength, quality and degree of purity of the food materials on the market.—*Oil, Paint and Drug Reporter.*

TEA, COFFEE AND COCOA ADULTERATIONS.

The Chemical Division of the Department of Agriculture has for some time been engaged in making analyses of tea, coffee and cocoa preparations as sold by retailers in leading cities. There were sixty-three analyses of tea bought in Washington, New York and Baltimore, covering all grades, including India and Ceylon tea of special brands. The report says of

TEA.

As nearly as possible all the grades of tea on the market are represented in this work.

Many of these samples are of very inferior quality, but neither the analytical nor microscopical data give positive evidence of the addition of spent or foreign leaves.

A large number of the samples examined by the writer were faced. With the present ideas in regard to this practice, it cannot be considered a form of adulteration, but facing should be condemned on account of its use in making inferior teas appear to be of a superior quality.

The analytical and other work indicates that there are few if any spurious teas on the market. The range in quality is undoubtedly very great, many samples deserving to be termed "tea" simply because they are composed of the leaves of the *Thea*, and not through the many pleasant qualities which we usually associate with the beverage of this name.

With the strict enforcement of the United States adulteration act, the consumer is reasonably well protected, so far as securing the genuine leaf is concerned, but of course has no protection from the sale of inferior teas.

COFFEE.

Of course, 112 samples were analyzed, of which thirty were ground, sixty of whole roasted beans, three coffee extracts, eighteen of green coffee, one coffee substitute.

But three of the samples of whole roasted coffees were adulterated. Knowing the large amount of imitation coffee that is on the markets, this result was unexpected. Three samples each contained imitation coffee.

The imitation coffee in one case was introduced by the roaster. It is very probable that roasted coffees are adulterated to a very much greater extent for sale in packages in districts not readily accessible to a roaster. Large quantities of package coffees are sold in Kansas. One sample was roasted with a large amount of a glazing material.

Coffees are sometimes treated with sugar or syrup, then roasted. When the caramel formed on roasting amounts to an appreciable weight, it should be considered an adulterant.

A—Coffee Roasted With Sugar.

	I. Per cent.	II. Per cent.	III. Per cent.
Moisture	9.91	10.46	4.41
Calculated on the dry substance:			
Soluble matter adhering to the beans ...	7.72	7.59	5.91
Reducing sugar, calculated as dextrose ..	1.49	1.49	.91
Total water soluble matter ...	28.12	27.71	26.07
Fat (volatile oil, ether extract) ...	12.62	12.34	9.45

B.—Coffee Roasted With Sugar.

	I. Per cent.	II. Per cent.	III. Per cent.
Moisture	3.14	2.73	2.79
Calculated on the dry substance:			
Soluble matter adhering to the beans ...	4.77	4.15	4.43
Reducing sugar present calculated as dextrose ..	.44	.34	.19
Total water soluble matter ...	24.09	21.81	25.97
Fat (volatile oil, ether extract) ..	16.29	13.44	12.06

The large percentage of moisture retained by the glazed coffee and the decided increase in the soluble matters adhering to the beans must certainly prove of considerable profit to the roaster without advantage to the consumer.

It is probable that the retail dealer is not usually directly to blame in foisting imitation coffee upon the market, though he must in many cases know that he cannot obtain a good merchantable coffee for the price he is paying. In most cases the imitation coffee is probably introduced by the roaster. The price paid for roasting coffees is usually very small and the competition is very sharp. A dishonest roaster can so easily increase his profits by the addition of imitation coffee, and with so little fear of detection, that he is often tempted and probably as often yields to temptation.

GREEN COFFEES.

A large number of green coffees, bought on the open market, were examined, all of which were genuine. It was impossible to detect cases where coffee of one grade was sold for that of another. There were undoubtedly many such samples.

GROUND COFFEES.

Ground coffees afford a very wide field for adulterations. This class of coffee is sold largely by the smaller dealers. The large stores usually grind the coffee to order, but in the latter case the presence of the purchaser does not always insure pure coffee.

The result of the examination of thirty samples of ground coffee show that twenty-six samples, or 86 2/3 per cent. of the samples examined, were adulterated. One sample, sold as ground Rio, contained no coffee at all. The price paid for some of the samples was certainly high enough to have insured a pure coffee.

SUBSTITUTES.

This number of coffee substitutes on the market is large. Many of these are sold under this name and others are simply designated as substitutes. One sample was sold as a coffee substitute. It is composed largely of chicory (50 to 75 per cent.), with wheat and peas or beans.

There is no objection to the so-called coffee substitutes, provided they are sold as such and do not contain harmful ingredients. All substitutes should be sold in packages, bearing labels distinctly stating their composition.

The report says the examination of the coffees and coffee preparations on our markets shows that the

consumers, and especially the poor, are being grossly deceived. Very little pure ground coffee is sold, and even whole coffee does not escape sophistication. The purchase of green coffee for home roasting does not insure a pure product, since even the green coffee is imitated. Stringent laws are certainly needed to suppress these frauds.

That there is a large demand for imitation coffee is evidenced by the fact of its importation from Germany. The manufacture of these coffees in imitation of the form of the genuine bean should be interdicted, even if the product is said to be sold as a substitute.

Of greater interest than the analyses of tea and coffee is the report on cocoa preparations. Sixty-four samples, including leading foreign and domestic brands, were examined. This report is of so much importance that we reproduce the main table, with copious extracts from the report, as follows:

On account of the peculiar properties of the cocoa bean, its preparations merit a place on our tables for two reasons: In addition to being like tea and coffee, the material for the preparation of a pleasant and exhilarating beverage, it is a valuable food material. Not only is it much richer in nutritive substances than tea or coffee, but both the soluble and insoluble portions become a part of the beverage, while only the constituents soluble in hot water are obtained in the beverages prepared from tea and coffee. The investigations of Stutzer and others clearly prove, however, that the food value of cocoa preparations has been greatly overestimated and that many of the present modes of preparation do not develop in the highest possible degree the pleasing aroma and flavor. The inventive energy of many manufacturers seems to be spent on the production of a highly nutritive and easily digestible preparation; the valuable fat is removed and the delicious aroma and flavor destroyed by chemicals for the ostensible purpose of rendering more digestible a residue of doubtful food value.

The more important constituents of the husked cocoa bean are fat, theobromine, the non-alkaloidal nitrogenous substances, starch, the coloring matter called cocoa red, and the mineral matter.

The fat, cocoa or cacao butter, in consequence of its quantity and peculiar excellence, is unquestionably the constituent of the cocoa bean possessing highest food value. It usually forms 45 to 55 per cent of the husked bean, rarely falls below 45 per cent, and only one recent analysis shows as low as 36 per cent.

The commercial importance of theobromine at present offers no temptation to remove it from cocoa preparations before placing them on the market.

Small percentages of caffeine have been found in cocoa beans, especially in the shells. It is separated from the theobromine by solution in cold benzol, in which the theobromine is practically insoluble.

The aroma of cocoa is considered to be due to the presence of minute quantities of an aromatic volatile oil. Bousin gault proves its presence by distillation of the roasted grains with water.

The preparations of cocoa are so numerous that more or less confusion of terms naturally arise. Most American manufacturers prepare a plain chocolate (known in Europe as cacao masse), made by reducing the roasted and husked beans to a paste and pressing into the form of cakes. When this is combined with much or little sugar (generally much), vanilla and spices, the various "sweet," "vanilla sweet," "vanilla," "spiced," etc., chocolates are produced. These are also usually met in the form of cakes, but are sometimes pulverized and sold as "powdered chocolates." The high percentage of fat renders a permanent powder impossible without its partial removal or the addition of some diluent, as sugar, starch or flour. The preparations in powder, known as "cocoas," "bromas," etc., are prepared in accordance with once or the other, or a combination of these methods.

The chemist Stutzer, who has made a careful study of the effect of different processes of manu-

facture on the chemical constituents of cocoa, the quality of the product, etc., states that many roasting processes hitherto used are faulty, the duration of the roasting being too long. The faults disappear when new double roasting apparatus is used. He regards it—

For the interest of the public and of the manufacturers that the artificial perfuming of cocoas be abandoned in future, and that only such preparations be brought into the market as contain the natural cocoa aroma in pure unadulterated condition. The technical arrangement of roasting apparatus and the methods of preparation heretofore in use seem to render this artificial perfuming necessary. This, as well as the addition of alkalis or ammonia, becomes unnecessary when Salomon's apparatus is used.

The value of cocoa as a mere pleasant addition to the table depends entirely upon the content of the natural aroma. The finer it is the higher the price that will be paid for the product. The manner of preparation, especially the manner of roasting, in a marked degree influences the development and maintaining of the aroma.

The quantity of the physiologically important constituent appears to vary only slightly with the different kinds of cocoa and different methods of preparation.

The value of cocoa as a nutritive material is essentially dependent on the content of the cocoa powder in digestible albumen. The amount of cocoa butter should not exceed 30 per cent. as a rule. The digestible albumen can easily be rendered ingestible by too high a temperature in roasting. By examination of a well-prepared cocoa powder, we found the relation of the quantity of digestible albumen to the quantity of indigestible nitrogenous substances to be nearly 4:3. If too high a temperature be used, this relation rises to 4:4, or even to 4:5. In the four samples investigated, No. 1, which was roasted in C. Salomon's apparatus, shows in this regard the most favourable and the Holland cocoa the most unfavourable relation.

There is probably no more misleading or more abused term in the English language than the term "soluble cocoa." No cocoa in the market contains a very considerable percentage of matter soluble in water, unless the material so dissolved is foreign soluble material that has been added during the process of preparation. The term seems to be used to denote a preparation that allows none of the insoluble matter to deposit from the beverage prepared from it. This purpose may be accomplished in two ways—the material may be so finely divided that a very long time will be required for its deposition, or foreign substances (as starch or sugar) may be added to render the liquid of so high a specific gravity, or so pasty, that the insoluble matter will not deposit. The first method is decidedly to be preferred; it accomplishes the object in view and puts the preparation in better condition for the action of the digestive juices—all this without the addition of a cheap diluent that is always at hand in every kitchen, should its use be desired. Any additions of this kind should be considered adulterations unless their nature and quantity are accurately stated.

The husk, because of its coarse nature and consequent tendency to act as an irritating substance in the alimentary canal, and in consequence of its poverty in the constituents that render cocoa valuable, is regarded as an adulterant when not removed or when added to increase the weight or bulk of the preparation.

Of sixty-four samples, twenty-seven contained large additions of starch and flour; fourteen contained large amount cocoa husks. This was true of eight out of thirty samples of sweet chocolate and six out of twenty-eight samples of cocoas, bromas, etc.

Determinations to show the solubility of cocoa and its constituents in water show great variation. Of seven samples, the total ash varies from 3.17 per cent., the lowest, to 8.64, the highest, the former an American brand, the latter, European. The total matter soluble in water varies from 11.28 per cent. for American made to 19.84 for foreign, these latter all running high. One American made rises to 18.27 per cent.

The amount of fat was not sufficiently inconsistent with the amount of the other ingredients to attract suspicion to any one of the samples.

"Sugar and starch are used to a most deplorable extent." In adding "phosphates, as found in wheat," the manufacturers of Digestible cocoa "overlooked the fact that the husked cocoa bean is fully as rich in phosphoric acid as is wheat."

Beef tea was once considered to be a very concentrated and easily digestible food, and was given to invalids in small quantities with full confidence in its great, almost miraculous, nourishing power. It has long since been degraded very nearly to the rank of a mere stimulant and is never intelligently administered except when accompanied by an ample amount of nourishing food.

As a concentrated and easily digestible food for invalids cocoa preparations are already beginning to share the same fate; as material for the preparation of pleasant, exhilarating and slightly nutritive beverages for both weak and strong, the career of cocoa preparations is only just begun. Moreover, their progress in popular favor will keep pace with the manufacturers' appreciation of this fact.

In conclusion the report says: The results of these investigations emphasize in many ways the many plans that have been made for the establishment of standards of purity, strength and quality for foods—for some certain means of enabling the public to know the strength, quality and degree of purity of the food materials on the markets. The question of economy alone is sufficiently important to justify serious consideration of this need, for no question can be of more importance to a great part of our nation than questions of economy in food, drink and clothing.—*American Grocer*, June 29.

PLANTATIONS AT MAHANORO.

ALMOST ALL BELONGING TO BRITISH SUBJECTS.

I send you a list of the plantations of Mahanoro and its neighbourhood. We reckon in the Mahanoro district, 43 plantations of Vanilla, and in the district of Vatomandry, close to Mahanoro, 8 plantations. The planting of vanilla is increasing gradually, and is now very important. Almost all these plantations (with a few exceptions) belong to British subjects. It will also be remarked that the cultivation of Cocoa, Tea and Liberian Coffee has commenced. As regards the sugar cane, which would succeed very well, when judged from specimens of those cultivated by the natives who, however, do not take the least care of their plantations, its cultivation has not yet been undertaken, owing to the scare French pretensions have placed on all of us, every one fearing to engage much money at once in such critical times.

80,000 Vanilla Vines.

The number of Vines on the above-mentioned estates are approximate.—*Madagascar News*, July 9.

AGRICULTURE AND HORTICULTURE IN PERAK.

Mr. Oliver Marks, Superintendent Government Plantations, has made the following report regarding the District of Taiping in 1891:—

The year has hardly been a successful one in regard to agriculture. No coffee planting has been done, to any large extent; and in spite of the very favourable terms offered by Government to pioneer planters, the results have been disappointing. Several applications have been made for coffee land, and large grants have been given to approved applicants, but up to date nothing has been done to open up the land.

The natives, and the Sumatra Malays now in Perak, have planted several small blocks of land with Liberian coffee and fruit trees, and the demand for seed increases as the success of Liberian coffee becomes known. Raja Mahmud, of Batu Gajah, and Imam Prang, of Gopeng, have already large tracts of land under cultivation and are adding to their estates, and have been supplied with seed and plants from the Government nurseries. Several thousand pepper cuttings have been sold and distributed to native planters, principally in the Kuala Kangsar district, where the cultivation of pepper is daily on the increase. Kong Ling's estate and that of Syed Musa are both doing excellently, and should both give fair crops this year. Pepper cultivation is admirably suited to the Malays, the easy and idle work of tending the vines requiring very little exertion, and the small profit satisfying their ambition.

The Government pepper gardens at Pandang Rengas have been kept in good order during the

year. The young vines from which the unripe crop was pulled look exceedingly well, and will be allowed to yield this year. The nurseries have been well tended by Mat Saleh, and kept well stocked with strong healthy cuttings. All the Liberian coffee plants in the nurseries here have been disposed of, and more nurseries are being prepared. An experimental nursery of native fruit trees was also successfully tried on a small scale, and arrangements are being made to supply the applicants who were too late to obtain plants from these nurseries.

A large number of coconuts have been planted by Haji Mat Saman in the Kinta district, and by others in the small native kampongs in the various districts. The planting of coconuts should be encouraged as much as possible, as it is one of the most paying enterprises, and the trees flourish equally well inland as on the sea coast in this State, and experienced judges have said that the old trees at Kuala Kangsar are more than equal to those on the best Ceylon plantations.

The tea on the Cicely and Hermitage Estates has greatly improved under the able supervision of Mr. F. J. Watson, and has given a yield of over 240 lb. per acre for the year; this is very creditable, as all the fields had to be pruned during the year and considering the large percentage of vacancies, the tea never having been supplied until Mr. Watson took over charge. The young tea planted in April has come on remarkably well, and the plants are now very vigorous and healthy. The made tea has been very favourably reported on by both London and Calcutta brokers, and has realised a good profit in local markets. Mr. Watson deserves great credit for the manner in which he has managed the estates for the lessee, Mr. Li Chin Ho, and for his hard work in pushing the sale of the tea.

* * *

The fruit gardens at Kuala Kangsar have been slightly enlarged, and are now in thorough order. All the fruit trees have been manured and bore heavy crops, and give every promise of doing well again this year. The pines have been separated and replanted after the ground had been manured. The field of Indian mango trees is not very successful, the young branches blackening back and dying before properly matured; this is hard to account for, as the native variety thrives well in the same soil and under the same treatment. The cattle establishment at Kuala Kangsar is also doing well.

Waterloo and Kamuning estates are doing exceedingly well respectively in Arabian and Liberian coffee. The former estate has some young coffee equal to any seen on Ceylon estates in their most prosperous days. This estate suffered a great loss by the death of Mr. T. Fraser, a planter whose wide experience was invaluable in a new country like Perak. Kamuning estate is a great credit to the manager, Mr. Darby; nothing could look better than the Liberian coffee, which is bearing an estimated crop of 5½ cwt. per acre. The managers of both these estates find it more satisfactory to work them with free labour instead of Statute Immigrant coolies, who occasionally are quite useless for agricultural work, having been recruited from towns, and in consequence are unable to stand the exposure to sun and rain when working on estates.

NOTES ON PRODUCE AND FINANCE.

INDIAN TEA COMPANIES.—It is satisfactory to find the *Economist*, the leading financial weekly journal, devoting one of its paragraphs to the Indian tea industry. The following appeared in a recent issue of that paper, and ought to be of service in directing the attention of the highest class of investors and financiers to tea companies' shares:—"We have received a copy of a very complete and exhaustive table, compiled by Mr. George Seaton, showing the results of the working in 1891 of thirty-five joint stock Indian tea companies having their headquarters in London. The inference to be drawn from this statement is that, notwithstanding an adverse market for the produce, and the recent very great competition

of the Ceylon plantations, the Indian tea industry, as a whole, still holds a flourishing position, and yields pretty good results to capitalists. The statement deals with concerns having an aggregate capital of nearly £3,500,000 sterling, owning lands extending to about 300,000 acres, of which 80,000 are planted with tea, and produced last year 30,000,000 lb. of tea. After allowing for losses made by seven of the companies, which are over-capitalised, and pay no dividend, the profits amounted to fully 6 per cent upon the entire capital invested, while the dividend varied from 2 per cent (the smallest) up to 17 per cent, the largest earned. It may be noted, however, that these thirty-five companies only represent about one quarter of the entire Indian tea industry, which, it has been computed, has a capital of from ten to fifteen millions sterling and a total cultivated area of over 300,000 acres, expected to produce in 1892 about 125,000,000 lb. of tea. From another statement we learn that while the home consumption of China tea fell off in the twelve months ending July last by 23,000,000 lb., that of Indian tea increased 11,000,000 lb., and of Ceylon 14,000,000 lb.; while the total consumption of all kinds increased from 193,000,000 lb. in 1890-1, to over 205,000,000 lb. in 1891-2, or about 90,000 tons weight in the United Kingdom alone.

THE CHINESE GOVERNMENT AND INDIAN TEA.—One of the causes of the delay in the conclusion of the negotiations between China and Great Britain in regard to Tibet is said to be the difficulty of coming to an arrangement as to the import of Indian tea to Tibet. At present Chinese tea only is consumed in that country, and it is generally believed that it is a monopoly in the hands of certain important personages in Lhasa, the capital. The import of the cheap Indian tea, which is grown close to the Tibetan frontier, would, it is thought, interfere with this monopoly, and hence the opposition of the Chinese to allowing Indian tea to enter Tibet.

THE COFFEE AND CHICORY QUESTION.—This question is continually cropping up, and analysts and the police magistrates are often in dispute as to what constitutes adulteration of coffee. Mr. A. W. Stokes reports to the Vestry of St. Luke's that in one instance where 85 per cent of chicory was present and there was no "mixture label" on the package, the vendor swore he verbally stated that the article was a mixture; the inspector swore that no such statement was made. On this the magistrate dismissed the case. "Hence," says Mr. Stokes, "it appears that a dealer may sell any amount of chicory to a buyer who asks for coffee without even pretending to label it. Certainly the tetteral has a worse time of it than the others; the law protects the purchaser from having his beer or spirits watered, but winks at any amount of coffee adulteration." In another case a sample of coffee was found to contain 70 per cent of chicory. Here Mr. Bros, the magistrate, ruled that because on a part of the packet occurred the words "this is sold as a mixture" the case must be dismissed. Other magistrates, Mr. Stokes says, have held that if "coffee" is asked for the vendor commits an offence if he substitutes any mixture, however labelled. We believe the law at present provides for a label, but says nothing about the proportion of chicory and coffee to be used. Until this is done, and vendors of chicory and coffee required to state plainly what they are selling, magisterial decisions will be at variance.

HOLLAND AND JAVA.—An important Bill has been brought into the Netherlands Parliament. It is proposed that in future the Dutch East Indies shall be made self-dependent. Their revenue, instead of being made a source of income for the mother country, is, according to this Bill, to be devoted entirely to the service of the several colonies. All grants at present made to them from Holland are to be abolished, and the colonies are, in fact, to be made self-dependent. This proposal involves, of course, many important alterations in the trade of the Dutch East Indies, which is at present largely under the control of the Home Government.—*H. & C. Mail*, Sept. 16.

PALMIRA FIBRE, COIR AND DESICCATED COCONUT.

With reference to Mr. Twynam's report, which we recently published and commented on, Mr. Figg, as the agent of Messrs. Vavasseur & Co., very naturally wished to explain that the Firm were no parties to the alleged destruction of trees by the tearing away of immature leaves. Accordingly in a very interesting visit to the mills yesterday we were assured that fibre from immature leaves was most undesirable, as sure to be weak and inferior. What the conductors of the enterprise desiderate are the old leaves, or rather portions of leaves which the old trees can well spare, and which, indeed, must be removed before the trees can be climbed to procure either fruits or the saccharine juice from the flower spathes known as "toddy" (*tari*) used in the manufacture of "jaggery." It is the fibres from fully matured and withered leaves which possess the necessary thickness and strength. It is not, we find, from the stem proper that the fibre is obtained, but from its broadened base, that portion which clasps the trunk of the tree for the larger portion of its circumference. The outer edges of these are trimmed away, and the superfluous matter in which the fibres are embedded got rid of in the localities where the leaf-bases are collected, by such means as wooden mallets and water. The unsorted fibres are then shipped to Colombo; and the processes which we saw yesterday conducted at the mills consisted in sorting the fibres into various lengths cutting the ends of bundles straight, dyeing the fibres of a uniform dark colour, making up quantities of different lengths equal to $\frac{1}{2}$ cwt. in each case, subjecting the parcels to the action of a screw press, hooping and covering with gunny cloth. As far as Messrs. Figg and Heinekey know, the only uses to which the fibres are put are for the manufacture of brooms and brushes, the expenditure per annum of which must be enormous, judging from the large and increasing demand for the raw substance. The demand was previously met principally by imports of a similar substance from Brazil, the *piassava* fibre, which seems now to have given out or to be too expensive. The advantages of the enterprise in Ceylon are abundance of the material in the Jaffna Peninsula in the vicinity of cheap labour. We should think the same conditions must largely prevail in the Shanar regions of Tinnevely and Madura. The calculation we have seen gave five millions of palmira trees to the former district, but in Southern India it is the jaggery enterprise which is principally encouraged by the European firms of Madras and Cochin. The tree is known in India as the *brab*, and is widely distributed there and in Burma; and when we were editing the late Mr. Wm Ferguson's monograph, we were able to quote Livingstone's notices of the existence of *Borassus flabelliformis* on the borders of the African lakes. The palmira is, in tropical regions of the earth, one of the most plentiful of palms, but it is seldom that cheap labour is so closely associated with the trees as it is in the Northern Province of Ceylon. An enterprise which has distributed a deal of much needed money amongst the poor peasantry of Jaffna, would be regarded with unqualified pleasure and approval, but for the danger indicated by Mr. Twynam, that the greed of the owners of young palmira trees may lead them to sacrifice such trees. But, as we have shown, it is the interest of Messrs. Vavasseur's agents to discourage such reckless destruction, by rejecting or paying greatly lowered prices for fibre from immature leaves, so that, we trust, the undesirable process resorted to on a small scale and

exceptionally may not continue. We also trust that Government as well as individuals will slacken no efforts in extending the growth of this valuable food as well as fibre-yielding palm.

Besides palmira fibres, Messrs. Vavasseur & Co. are large exporters of coir, the fibre which surrounds the coconut. This, we should say, is the cheapest fibre which enters into commerce, the price in London being only £5 per ton, while £3 of this sum is absorbed by freight. It is only the very large transactions which Messrs. Vavasseur & Co., and other firms conduct, that leave any profit to them and the portion which accrues to the poor natives who prepare it more or less in a finished state must, we fear, be very small. Much of the work of steeping in water, cleaning, drying, &c., is done by women and children, however. The use of coir mats in Europe and America is very extensive; and Messrs. Treloar have manufactured many fancy articles from this substance, including a lady's bonnet!

The coir industry is an old one, but the main enterprise conducted at the Mills we visited yesterday, that in desiccated coconut, is, like the fibre industry, a new one, and exceedingly interesting. As our readers are, most of them, aware, the juice and meat in the interior of a coconut shell are in young coconuts deliciously saccharine. In the copra (dried kernels) of fully ripe coconuts, the saccharine matter has been converted into an oleaginous substance, and the oil expressed from the ground copra has a very pronounced flavour, which we cannot honestly describe as agreeable. The nuts used in the desiccating process must be mature though not over-ripe. A very large force of labourers, much machinery and great heat were all employed yesterday in the various operations of opening the shells, taking out the kernels, slicing them into films and threads, and in some cases grinding them to the consistence of very fine arrow-root. This latter preparation, we were told, was used in biscuit-making, the other forms entering largely into confectionary, dear to the juveniles of Britain, the United States and everywhere. A *soupeon* of the peculiar coconut odour seems only to add zest to appetite in regard to these preparations. What greatly excited our admiration was the snow-white hue preserved in all the forms into which the kernels were prepared. The process of desiccation was conducted in a number of Brown's Tea Desiccators, which required but slight adaptation to suit them to this purpose and which may ultimately be employed in drying plantains for export? The coconut kernel preparations finished off in tea desiccators are packed and hermetically closed in lead-lined tea-chests, long rows of which, to our mystification at first, we found ready for filling and soldering in the factory. As finally packed for export the desiccated coconut contains about 4 per cent of saccharine matter and only 2 per cent of moisture, the latter about the smallest proportion which any substance, however prepared, can show. The result is that no injurious chemical action takes place *en route*, and the pure and wholesome substances reach purchasers and users, with their snowy hue as clear and untainted as when they left the shores over which the palms which yield this and so many other products bend. The Tamil writer, by the way, who enumerated the "Thousand Uses of the Palmira Palm" never in his wildest dreams contemplated the additional use which is at the root of Messrs. Vavasseur's interesting enterprise. We very naturally asked if experiments had been tried with the bases of coconut leaves with reference to fibre. The answer was in the affirmative, but that the resulting fibre, and also the *eckels* from the leaf

midribs which the natives use for brooms and whisks, had been found too weak and brittle to be of use. The reason is supposed to lie in the fact that the coconut palm flourished only where moisture in the soil was abundant, while the palmira palms grow in dry and even arid situations. The timber, too, of the palmira vies with ebony in denseness and hardness, while the trunks of all save very old coconut palms are composed of soft fibre.

Since writing the above, we have read the following notices of the palmira fibre and allied substances in the *Kew Bulletin* for May and June, which we quote for the information of our readers:—

PALMYRA BASS FIBRE.

(*Borassus flabelliformis*, L.)

Owing to the scarcity of the Bass fibres hitherto obtained from two Brazilian palms, *Attalea funifera* (*Kew Bulletin*, 1889, p. 237) and *Leopoldinia Piassaba*, inquiry has been made in most tropical countries for palms likely to yield fibres of a similar character. A bass fibre has been obtained in Madagascar from a species of *Dyopsis*; and more recently Lagos or West African bass has been obtained from *Raphia vinifera* (*Kew Bulletin*, 1891, p. 1). A fibre almost identical has still more recently been prepared in Ceylon from the Palmyra palm (*Borassus flabelliformis*). The following information has been obtained on this subject.

DIRECTOR OF NAVY CONTRACTS TO ROYAL GARDENS, KEW.

Admiralty, Whitehall, S.W., June 1, 1892.

Sir,—I shall be much obliged if you will be good enough to inform the Department whether anything is known of a material called "Bassine" said to be grown in India and dressed for the English market at Colombo, as to its value as a substitute for Brazilian Bass, and whether it is likely to displace bass on account of its quality or price.—I am, &c., (Signed) C. M. HEATH, for Director of Navy Contracts.

The Director, Royal Gardens, Kew.

ROYAL GARDENS, KEW, TO DIRECTOR OF NAVY CONTRACTS.

Royal Gardens, Kew, June 8, 1892.

Sir,—I am desired by Mr. Thiselton-Dyer to acknowledge the receipt of your letter of the 1st instant on the subject of fibre prepared from the Palmyra palm as a substitute for Brazilian Bass.

As shown in the enclosed extract from the Report of the Director of the Botanical Gardens, Ceylon, the fibre from the Palmyra palm is being prepared in small quantities in the north of the island. The quantity available is evidently limited, and as the palm is an important source of food supply to the people it would be impossible to develop the industry to any very large extent without affecting that supply.

As regards the value of the fibre in European markets it may be useful to communicate to you a copy of a letter received from Messrs. Ide and Christie, a firm of fibre brokers in the City, giving particulars of the prices recently obtained for the fibre. A small quantity of the fibre as received today is forwarded to your address in a separate parcel.

This fibre is apparently not so good as the West African Bass (*Kew Bulletin*, 1891, p. 1), and it is decidedly inferior in length and flexibility to the Bahia Piassaba (*Kew Bulletin*, 1889, p. 237). Its chief use would probably be to adulterate these fibres and not to be used alone.—I am, &c. (Signed) D. MORRIS.

The Director of Navy Contracts,
Admiralty, Whitehall, S.W.

EXTRACT FROM THE REPORT OF THE DIRECTOR OF THE ROYAL BOTANIC GARDENS, CEYLON, 1891, p. 15.

PALMYRA FIBRE.—The sheathing leaf-stalks of the palmyra, as of many other palms, contains a stiff thick fibre, and a new industry in the collection of this has sprung up, under the auspices of a Colombo firm, in the north of the island. These fibres or

bristle are much like the "Piassaba" so largely exported from Brazil (the produce of the palms *Attalea funifera* and *Leopoldinia Piassaba*) for brush-making and are doubtless exported hence for the same purpose. Immense numbers of the palmyra exist in the Jaffna peninsula and the islands near, and it is in the latter especially that the business of collecting the leaf-stalks for sale has been carried on by the inhabitants. In Elavaitivu the value thus collected in six months was about R3,000, a great addition to the means of the people. Unfortunately, in their eagerness for this easy method of money-getting, they have treated the trees so badly that it is reported that in that island alone 1,000 young palmyras have been destroyed. As this palm is the principal permanent source of food in the country, and is besides of immense utility for timber, fences, &c., it became obviously necessary to put a stop to this reckless destruction, and I understand that steps have been taken to regulate the fibre industry, which, properly conducted, should become a valuable addition to the means of living for the inhabitants.

MESSRS. IDE AND CHRISTIE TO ROYAL GARDENS, KEW.
72, Mark Lane, London, E.C., June 7, 1892.

Sir,—We duly received your favour of the 2nd instant and have pleasure in sending you a sample of Palmyra fibre as offered on this market. This is of average quality and valued today at 28l. per ton in London.

The first arrivals of this fibre took place about a year ago, the scarcity and high values of Brazilian Piassaba having induced the production and shipment of substitutes. The early imports realized from 36l. to 42l. per ton, against West Coast African Piassaba 55l. to 65l., but with fuller supplies of these brush-making fibres (including split bamboo) market values have receded, and Palmyra ranges to day from 22l. to 33l.

The chief objection to Palmyra by manufacturers is that it lacks straightness, but experiments are being made in this country to overcome this defect, and should they prove successful it is claimed by importers and dressers that Palmyra should, for wear then, be found equal to the best Brazilian.

We are, &c. (Signed) IDE AND CHRISTIE.
D. Morris, Esq., M.A., F.L.S., Royal Gardens, Kew.

FROM THE METROPOLIS.

LONDON, Sept. 16th 1892.

ESTIMATE OF CEYLON TEA CROPS FOR 1892.

In reducing from 85 to 72 million lb. the estimate of exports for the current year, you have surely gone from one extreme to the other—and I should judge that the actual result will be some way in the middle, say from 77,000,000 lb. to 78,000,000 lb. Supposing that only the same proportion is kept up, we have 48 million lb. shipped up to middle of August in 7½ months, and at that rate we would get in the remaining 4½ months about 29 million lb., or 77 millions in all. The London Brokers in their circulars as a rule only take cognizance of the estimated exports from Ceylon to London—so that to their estimate of 70 millions will have to be added 6 or 7 millions for what is sent to Australasia, America, &c. No clear light has yet been shown on the big discrepancy between the Customs and Chamber's figures. For myself I shall be disappointed if our total outturn of tea in 1892 does not approximate nearer to 80 millions lb. than to 77 millions lb. As for the tea market and prices, alterations in the estimates can have little or no effect. Tea dealers judge by the immediate stocks and their own requirements mainly; but the great factor in respect of estimates early in the season for India and Ceylon is undoubtedly found in the encouragement, or discouragement, offered to the China trade, and no doubt exports in the early months were increased from China to London owing to the exportation of short supplies from India and Ceylon,

CEYLON PRODUCTS BEFORE THE LONDON CHAMBER.

I have not yet seen the *Chamber of Commerce Journal* with the second portion of my paper. Dr. Trimen who has read it all in "proof" gives me one or two important corrections and is good enough to write:—"I have enjoyed reading your lecture, which gives an excellent review of the present position of our 'planting' industries. I am glad you speak up for cacao and Liberian coffee. As to rubber, I do not expect it ever to become an article for private cultivation, and still less can guttapercha be so, as the trees are of little value till 80 years old, and then the yield is small. As to the introduction to Ceylon of some of our leading products. *Coffee* was certainly unknown in Tropical Asia till the Dutch introduced it to Java in 1690; it was brought thence by them to Ceylon, probably about the same year. I have not my books and notes here to refer to, but I am pretty sure that the following are the known facts as regards tea. Bennett gives a figure (a good one) of the real tea plant which he says was collected near Batticaloa (I think in 1826), but from the text he clearly confused it with our 'Matara tea,' the leaves of the 'Ranawara' (*Cassia auriculata*). Still I think true tea may have been grown in some gardens in Ceylon, as it was certainly in the Botanic Gardens at Kalutara before 1824, the date of Moon's 'Catalogue.' This is the earliest date I have met with for it, and I have no reason to suppose it was in Ceylon in Dutch times. Assam tea was sent from Calcutta as early as 1839 and planted at Nuwara Eliya. As to cacao, the history is somewhat the same. The first certain record is Moon's 'Catalogue' (1824), and as the plant is not mentioned in a list of useful things introduced in 1804 (given I think in Percival's History) I put its introduction somewhere between these dates, and am inclined to think we owe it to Moon himself. It may, of course, have been somewhere else, but the date must be about that indicated above, and therefore after the Dutch periods."

I am disappointed to learn that Dr. Trimen does not favour private cultivation of rubber trees: I was quite hopeful that the later experience gained in Dumbara and Hewa Eliya would show that it was worth going in for the quicker-growing rubber-yielding trees and creepers. The information as to the beginnings of coffee, tea and cacao in Ceylon from Dr. Trimen is, of course, the most reliable extant. My term "shrewd," as applied to our worthy Director, has been challenged as scarcely so applicable as "cautious", but I should certainly insist that he is both or at any rate keenly observant as well as scientifically exact, and withal as truly modest as the great Darwin himself. By the way Dr. Trimen tells me that "Grains of Paradise" are quite a different product from cardamoms, though they are certainly given as synonymous in Porter's and other works on tropical products. Among others present at the lecture whom I missed was Mr. T. C. Owen who says it excited great interest, though some dissatisfaction over the allusions to West Indian planters and cacao. By the way I am reminded that Mr. Owen's remarks on the difference in "flavour" of Ceylon teas referred to high estates of which it is the characteristic in their teas; while "strength," the characteristic of the lowcountry, was not referred to by him.—Another old friend (Mr. T. Wright), after reading the lecture, sends me the following interesting and suggestive remarks:—

"Your London lecture ought to have a wide circulation and you should send a copy to the editor of each leading London and Provincial newspaper. Many of them want enlightening on coffee, tea and cocoa questions. For instance only the other day

the editor of *Manchester Guardian*, in an editorial note, called attention to the enormous figures representing 1891-2 (financial year) clearances of tea for home consumption in United Kingdom indicating 196 odd million of lb. Why, 10 years ago, the clearances were just as heavy *per head*, if the population at that time is taken into account. There has been a vast increase in liquid measurement no doubt, but that is to be deplored, for the people are 'stewing' strong Indian and Ceylon teas, to their detriment of course. The teas are now cheap enough in all conscience and if 3 minutes' brew were the universal practice instead of the exception, as respects the majority, 250,000,000 lb. to 300,000,000 lb. would be consumed by the people in the United Kingdom who now take so vigorously to tea drinking owing, in a great measure no doubt, to coercion brought about by *bad trade* unfortunately!

"TIN CANS FOR TEA.—Send to 'The Self-opening Tin Box Company, Limited' for their list of sizes and prices and a sample tin to show you what the lever tin is like. It is perfection and should suit the American market, and most excellently so for the Chicago Exhibition and for the United Kingdom too. These tins can be opened and closed hermetically again in a moment, and they can be used over and over again. Flavour in them will be never lost. They are made all sizes and very cheap. [I have sent for prices and sample.—J.F.] Referring to your appendix to lecture and taking the United Kingdom consumption of

Tea ..	@	1/6 per lb.
Coffee ..	@	£5 per cwt.
Cocoa ..	@	£5 per cwt.

£17½ millions sterling represents the total value of the lot. The *duty* alone on tobacco last financial year come to over £10 millions sterling and what the value of alcohol sold each year is now I know not, but it increased itself by £20 millions in the last 10 years; so I read somewhere the other day. This is awful and the Board Schools must teach the rising generation something on these questions—how to prepare tea, coffee from the green berry and cocoa from the nib for instance, or with bad years in front of the nation its proud position of late years will be followed by years untold of *distress* and decay. Two hours per month or 24 hours per year could be well spent in inculcating such necessary knowledge and the young boy would take the news home to their elders. Send lecture also to Dr. Cameron, M.P. for Glasgow, who is taking up the food and drug act to amend coffee adulteration with chicory.

Mr. Wright's suggestion as to school-board teaching is not at all a bad one: how to make tea, coffee and cocoa properly for drinking purposes should be quite as practical and careful a lesson as one on sewing or playing the piano for little girls at Board Schools. I must report to you about the "self-opening" tins.—In another note Mr. Wright remarked that "the heavy importations of low China tea were no doubt causing an increasing demand for strong and *flavoury* high-priced teas from India and Ceylon for blending purposes;—but such importations, on an increased scale too, must result badly and may therefore be expected to come to a close soon. Meantime they are doing positive harm to Indian and Ceylon planters."

TEA ON THE NILGIRIS.

The history of tea cultivation on the Nilgiris dates from the year 1835, when some boxes of plants were sent from Calcutta to the Nilgiris, and at the same time to Coorg, Mysore and the Agri-Horticultural Society at Madras. The plants received on the Nilgiris were planted chiefly at the Experimental Farm in the Kaity Valley between Ootacamund and Coonoor, and they are cared for by Colonel Creive and M. Perrottet, the French botanist. They had been raised from seed brought direct from China by Mr. Gordon, the Secretary of a Committee, specially appointed by Lord W. Bentinck, then Governor-General, to consider means

or the introduction of the tea industry into India. The experiment appears on the whole to have been a failure, at least as regards the Madras Presidency, although a few plants are said to have survived in each locality to which they had been sent. General Cullen, Resident of Travancore, writing to Government in October, 1859, with reference to reports which he had received of the growth of tea at Coonoor, says: "The tree thrives well in the Travancore country, both at the level of the sea and altitudes of 1,800 and 3,200 feet. I first met with it in the coffee plantation of Mr. Huxham in the year 1841 on the route from Quilon to Courtallum at a farm called Cahdoorly about 40 miles inland and 600 or 700 feet above the sea. There are some ten or fifteen trees from 20 to 25 and 30 feet high; they were, I believe, introduced during the Government of Mr. Lushington, who, I believe, also introduced those formerly at Kaitiy on the Nilgiris."

Attempts were made at different times to manufacture tea from the bushes on the Nilgiris, but without success. It was not until some years later that Mr. Mann of Coonoor succeeded in producing fair drinkable tea from the Nilgiri plants. Thus encouraged, Mr. Mann brought with him from China in February, 1854, a good supply of seed of the best description collected by Mr. Fortune, author of "Wanderings in China"—this gentleman was sent by the Court of Directors to China to collect plants and seed with the view of introducing the culture into the North-West Provinces—from the finest plantations in the country, and applied at once to Government for land in the neighbourhood of Coonoor to form a nursery. After many delays, during which a large number of the seedlings died—the remainder were only saved by being sent to Wynaad—Mr. Mann succeeded in acquiring a piece of land near Coonoor which is now known as the Coonoor Tea Estate. The seedlings were planted in grass land to save time, the forest land not being ready. As early as 1856 the tea produced from these plants was favourably reported on by the London brokers. Mr. Mann, however, appears to have been disheartened by the difficulty of procuring forest land to extend his estate, as will be seen from the following extract of a letter to Dr. H. Cleghorn, then Conservator of Forests, when referring to a second importation he writes in April 1855:—"I got another small supply of seeds from China brought round in the same way," (i.e., in earth in which the seeds germinated during the voyage) "which I put down in my nursery at Coonoor immediately they arrived, and scarcely lost a single plant. About 2,000 of these I planted out, though still very small, in the forest land in November, of the same year, and the remainder, about 800, remained in the nursery till November, 1856. I was convinced from the way those plants came on that the tea plant would grow well there, and applied through the Collector to the Government for a suitable piece of forest land for a tea plantation, which, if they had granted me, I would at once have returned to China and brought over a large quantity of seed; but I could get nothing but poor grass land, on which nothing would grow without being heavily manured; and to my repeated solicitations they at last sanctioned two cawnies of forest land subject to all kinds of restrictions; so I gave the thing up, and went on with the coffee, though I still think, if given fair play, the tea plant would not only grow well on the Nilgiris but pay well too."

Dr. Cleghorn, in a visit made a few months later, was struck by the thriving condition of the plants in Mr. Mann's nursery, and called his attention to the quantity of seed falling from the trees. Almost simultaneously with the formation of Mr. Mann's garden at Coonoor, Mr. Rae of Ootacamund had obtained a grant of land seven miles from the station, which now constitutes the estate known as Dunsandle, which has lately been leased by Mr. Best, son of the Hon. Justice Best of the Madras High Court.

Mr. Rae experienced similar difficulties to those of Mr. Mann in securing suitable land. Shortly after this a garden was begun at Kotagiri, and in 1863 the estate known as Belmont

was formed on the Bishopsdown property in Ootacamund. When Sir William Denison was Governor of the Madras Presidency in the early sixties, some direct encouragement was afforded to the tea industry by introducing in 1863 skilled manipulators from the North-West Provinces, distributing in 1864 a supply of tea seed procured from the same source gratuitously, and by forming in the same year a small tea nursery for raising good and fresh seed at Dodabetta within the Government Cinchona Plantation. The manipulators remained eighteen months; their services did not appear to be much appreciated. The nursery at Dodabetta was of little use to Government or the public, and after a short time was leased to a private planter. The energy of the Nilgiri planters has sufficed for the success of the enterprise without the fostering aid of Government. The introduction of the Waste Land Rules in 1863 was, however, the measure which set this energy free. By the end of 1869 there were probably some two or three hundred acres of tea cultivation in the Nilgiri District. At the Agricultural Exhibition held at Ootacamund in 1869, no less than eighteen exhibitors appeared, and the exhibits in some cases proved of very good quality. The teas were, with two exceptions, black. Reporting on this product Mr. J. W. Breeks, late Commissioner of the Nilgiris, wrote: "I attach great importance to tea, viewed as an investment for English capital on these hills. Several private individuals have commenced its cultivation here. . . . As far as soil and climate go the practicability of growing tea on the Nilgiris has been established." At his request the Government sanctioned samples of tea being forwarded to England for brokers' opinions. Many of the exhibits were pronounced good, and some very good, the values ranging from 1s 4d to 1s 6d per pound. Soon after this the Government requested the Commissioner to report as to what steps should be taken to develop the enterprise. The planting community being consulted suggested the following measures:—

- (1) Free tenure of land for a certain period.
- (2) The introduction by Government of experts to teach the best method of manufacture.
- (3) The purchase of Indian instead of China tea by the Commissariat Department.
- (4) The importation and raising by Government of the best kinds of hybrid China and Assam seed.

The first concession was partially accorded by Government, the second refused, as also the third; the last was approved, but the approval was practically inoperative. The land taken up for tea cultivation on the Nilgiris now exceeds ten thousand acres.—*Asian*.

PLANTING NOTES FROM COORG.

Coorg, Sept. 24.—The efforts made to induce Tamils to settle temporarily or otherwise in the Santikoppa District have, in some cases, ended in sorry failures. They were an indolent, squalid and altogether unsatisfactory lot, and so insanitary in their habits as to render the neighbourhood of their lines and drinking wells filthy and noisome in the extreme. All coolies are more or less insanitary, but the other castes are generally careful to preserve their water supply from pollution. It was hopeless trying to enforce sanitary measures, as they would not desist from continuing to offend in the same way. The wonder is that the mortality amongst them was not greater than it was, given, as they were also, to eating indiscriminately all sorts of deleterious things. They consumed a surprising amount of medicine, but their general health continuing unsatisfactory, the few deaths amongst them served to scare away the better lot of them whom it would have been desirable to keep. The dregs that were left were, probably, the wretchedly poor and friendless ones for whom there was no attraction to return to their villages, even though the rains had been favourable there and the growing crops promised well. There was, of course, not much use to be got out of coolies of this description, and so it was deemed advisable, on some places, to get rid of them, and they were settled with and sent away. Reports of

the altered condition of affairs in their countries brought about by timely rain, which reached the coolies, had much to do with making some of the better class, who held land, in their villages abscond. In one case, I believe, two people were especially sent up from the plains with glowing accounts of the change for the better that had taken place there to induce people to return and cultivate their holdings. While we do not mind getting rid of useless coolies, it is very annoying to lose a fine body of men and women. This happened here very much to my surprise, as the people were keeping very well and appeared to be quite contented. Some one mischievously inclined instilled the stupid notion into their heads that the maistry would get all their pay, and they would derive no benefit by remaining and working here. All that they could be told to the contrary did not convince them and they went away in a body, 30 strong. The loss of the labour was not fortunately felt at all, because as these people ran away there were fresh arrivals from below the Ghauts who more than made up for the deficiency. We had the former at a time when other labour is difficult to be had and this helped us to a great extent.

The maistry, or contractor, is the chief sufferer. The cost of taking out warrants being R4-4 per head, would, in the case of so many absconders in his case be almost prohibitive. Of course he could recover the money from the coolies if he should succeed in catching them. Act XIII of 1859 would, as far as Coorg is concerned, work very satisfactorily if the Police in the districts could be depended on to apprehend defaulters. The small trouble they give themselves in this respect is apparent from the large number of warrants that are returned with the intimation that the persons wanted are not to be found. Matters are not much bettered by sending some one to point them out, unless, it is said, they are prepared with tips. "Bobbies" make their wishes in this respect known by going through a pantomime of taking snuff or something of that kind! Assertions of this kind are very difficult to prove. The only way to do it is to get the policemen fixed in a hole by pre-arrangement; but ordinary natives of the cooly class are wanting in the ingenuity of carrying through a scheme of the kind indicated to a successful issue. The following is an illustration of the hardships entailed on maistries, as labour contractors are called here, owing to the unsatisfactory working of the Act. Some time last year a maistry here took out a warrant against a defaulter and pointed him out to the Police, who arrested him. He was, however, liberated on another man, a Madiga, giving bail for his appearance on a specified date in Court at Mercara. He did not turn up and the maistry obtained a decree for R28 or thereabouts against his surety. There was nothing gained by it, however, as it was found that all the earthly possessions of the latter did not in value amount to anything near that sum! This shows the little interest the Police take in promoting respect for the Law. It was a palpable neglect of duty, as no enquiries whatever appear to have been made as to whether the man was a proper person to accept as bail; and they are not made to suffer for their misdeeds! When the way in which matters stood was brought to the notice of the Shubidar at Mercara, he issued another warrant against the defaulter. He was evidently powerless to do anything more. This time the Police appear to have been more careful, a fairly well-to-do gowda being selected as the man's surety, with the result that the former took good care to keep him company all the way up to Mercara as the safest means to avoid loss. No one is compelled to take advances. The maistry seeks them from the planter and the cooly from the maistry; and surely it is not too much to look to Government for protection against defaulters. It is, therefore, to be hoped that the powerfully supported Memorial to the Government of India on the subject will meet with success.

All coolies are, as I have said, more or less insanitary in their habits, and in order to enforce the strict observance of the rules for the better sanitation of cooly lines, drawn up by Drs. Banks and Marsden, it will be necessary, I am afraid, to insti-

tute a system of fines. The sunflower plant is said to effectually drain places and dispel malaria; it might therefore be advantageously planted about cooly lines. It would, perhaps, tend to keep the coolies in better health. The introduction of Tamil labour into South Coorg has been more of a success, I believe, there being large number of that class of coolies working contentedly in parts of the District. On some estates in North Coorg good numbers of Tamils have been settled for some years. The great thing is to get the right stamp of people. Efforts in this direction have, however, proved so discouraging that it would not be surprising if they were entirely discontinued for the future.

It is about time for Puthur coolies, who began to come in in July, to return to their villages to reap their paddy. These coolies, who are less skilled than the Canarese, have usually enjoyed an advantage over the latter in being allowed extra remuneration in the shape of rice supplied to them at lower rates than those ruling in the bazaars, or 2 annas per man per week. It is surprising the small extent of discontent this gave rise to amongst the Canarese and others, who seemed to be quite satisfied that there were good reasons for it, as the Puthur coolies lived entirely on rice and therefore could not live as cheaply as they, who are chiefly raggi consumers. The concession appears to have been made on European places with the twofold object of encouraging the people to become attached to them, and to prevent their being drawn away by native landholders who always allow rice. Nevertheless, it was an anomaly and, as such, has been rightly discontinued on most places this season, without, it is gratifying to notice any serious diminution in their ranks. They will begin to return here again about November, when they come in very usefully for manuring and the second digging. Some of the more intelligent ones can also be trained into very decent pruners. The work on local paddy fields being about entirely finished, the Kurumbers will be putting in appearance seeking work on places. They are especially handy at shade lopping. Unfortunately their numbers have been considerably diminished this side owing to the outbreak of cholera in the Nellore village near Suntikoppa, those who did not die having made tracks to put themselves out of the reach of danger. The wavy green expanse of paddy fields in the valleys between the jungle-clad hills forms a beautiful feature in the landscape. They are copiously supplied with water this season, as the rainfall has been well over the average. Shade planting and lopping forms, it may safely be said, an annual charge on most if not all places. The object of lopping young growing trees is to give them a good length of stem and enable them to form thick leafy heads well above the coffee. This ensures the free circulation of air. If the leafy hearts, which may be made to spread by cutting off the ends of the branches growing upwards, become too thick, rendering parts unwholesomely dark, the intervening branches are sometimes cut out to enable the sunlight to penetrate the mass of foliage. In lopping up trees care is taken to make them grow as straight stems as possible. It makes them look better, and straight timber is obtained. In new clearings, where much shade is not required during the early years, the trees are kept continually lopped up to help on their growth. Clearings are usually planted very closely with shade to get them soon under cover. After a time the trees that are in excess of requirements are gradually rung out. Some contend that trees do all the better if allowed to grow at their own sweet will and pleasure. But I believe it has been proved otherwise by experiment, parts being left unlopped and they compared very unfavourably with the parts that had been lopped.

During lopping the opportunity is taken to ring out objectionable bad *jak* trees and the older ones to make room for the growing good kinds. I have heard of trees being wholly cut down in Munzerabad, Mysore. This must cause very severe damage to the coffee. Here a ring is cut into the stem and the trees are left to dry standing. As they fall to pieces gradually and do not all come down at the same time the damage is reduced to a minimum.

Bad *jak* trees keep the coffee about them in check till they are killed. Clearings are sometimes planted under forest shade, but better kinds of shade are also added, the object being to gradually eliminate the forest trees. The coffee under some do so badly that these are killed first. *Nundi* is said to be a very bad tree for coffee, but I have seen a very good sheet of coffee under it. It appears to do no harm when grown up with the coffee. The fact seems to be that all old forest trees that have got a good hold of the ground are more or less detrimental to coffee. Thinning out shade excessively, especially in old places, results in increase of borer owing probably to the sudden raising of the temperature caused by letting in so much sunlight. The *buté* tree is *par excellence* the best forest shade for coffee, as is evidenced by the trees under it being always full of large, glossy, dark green leaves. The benefit results from its being of the leguminous order. As the *palwan*, which was made use of very largely as temporary shade, belongs to the same order it is now being planted out on some places under the more durable kinds. Different varieties of trees of the leguminous order, which are not surface feeders can be obtained at the Madras Agri-Horticultural Gardens. Fortunately the list of trees suitable for coffee is a long one. The *jak* was prime favourite at one time but it has lost that high place. It has not, I believe, been found to answer quite as well when it has grown old. The *noga* has come into general favour for some years, owing chiefly I fancy to its rapid growth. After a certain age it is subject to attacks from a parasite to which it eventually succumbs. It lasts long enough however, to make fine timber; and as one of the objects of shade planting now-a-days is to get up a variety of shade and have continual relays of young growing trees successively taking the places of the older ones as they are eliminated to prevent the land becoming sick, it lasts long enough to be very useful. The *attie*, or jungle fig, will probably never go out of favour. In some former notes I said that an unfailing way of growing large numbers of these plants from seed was to pass the fruit through cattle, dry and pulverise the dung and broadcast over prepared nursery beds. I was made to say that the seed should be passed through cattle dung. I meant that the cattle should be fed on the fruit. Another good way is to plant *attie* twigs along the road sides, where they would be constantly under the eyes of the Superintendent, and come to no harm during the monsoon. A good percentage of plants can be obtained in this way for planting out the following season.

I am very sensible of the great honour a planter of Mr. Graham Anderson's ability and experience does me in holding such a flattering opinion of my writings as to consider them of service to the planting community; and much regret having misrepresented his statement about burying in weeds. But I cannot help thinking the mistake was well worth making, since it was the means of eliciting the able letter from him which he sent you on "The Weeding of Coffee Estates." He appears to have hit on the right explanation as to why borer is severer in some soils than in others, and all planters would do well to take note of it. Temperature must have a great deal to do with it, and the teachings of agricultural science go to show that this is influenced by the manner in which the soil is worked and its colour. In the latter case the application of marl (being white) tends to keep places cool. Carbonate of lime would answer the purpose equally well besides being useful in neutralising the formation of injurious acids in the soil.

During August we had some very fine weather which was doing all the good in the world. Sunshine with intermissions of rain was the rule. Sick patches were beginning to make marked improvement under these genial conditions. Towards the early part of this month we thought that the monsoon had been played out; it appeared, however, to set in afresh on the 17th instant and wet weather continued till the 22nd. Yesterday was a deliciously fine day, and today

promises to be the same. Leaf disease has appeared badly in some patches, and is, I hear, very bad in the Bamboo. Excessive wet weather has been the cause of it. Digging is being pushed on and supplies are beginning to look up.—*M. Mail*, Sept. 27.

CEYLON TEA IN AUSTRALIA.

The Melbourne *Argus* of 14th Sept. has the following:—

Auction sales of Indian and Ceylon tea were held this afternoon. The Indian teas consisted of 2,503 chests and 601 half-chests ex "Clitus," out of which 1,924 chests and 402 half-chests were sold. Bidding throughout was rather slow, and prices realised were generally easier, the lower grades showing a decline of 0½d per lb. Fine teas, however, fetched full prices. * * * Pekoe fetched 6½d to 11d, orange pekoe 7½d to 1s 2d, flowery pekoe and flowery orange pekoe 1s 2d to 1s 5d; broken pekoe and pekoe fannings 5d to 7½d, pekoe souchong 5½d to 8½d, (and for a small line 5d), broken pekoe souchong 5d to 6½d, and souchong 5d to 5½d. The Ceylon teas consisted of 245 packages ex "Anstral" and "Parramatta," all of which were sold at 5½d to 6d for pekoe souchong, 6½d to 8½d for pekoe and orange pekoe, and 11d to 1s 1½d for broken pekoe. * * * Ceylon fancy teas (in 1oz. packets and boxes), grown on Nuwara Eliya, were sold as follows:—77 packets golden tip at 1s 8d per oz. d.p., 13 packets and 15 boxes silver tip at 1s 9d and 2s 4d per oz. d.p. respectively. Privately a considerable business has been done in medium Ceylon at, say, 7½d to 9d. Our compilation of tea statistics for the week ended Saturday last, 10th inst., is as follows:—

	Corresponding Week		
	Last Year.	—	
	Lb.	Lb.	
Entered for bond	769,965	362,426	
Duty paid	{ Ex ship	401	2,130
	{ Ex bond	103,638	192,089
Exportation	{ Ex bond	152,357	165,646
	{ Under draw-back	27,843	65,440

The Custom-house statement of receipts and deliveries of tea at the bonds for the last week, together with the stocks in bond at the close of the week, is as follows:—

	Deliveries.			Stock on Sept. 10
	Receipts into Bond.	For Home Consumption.	For Export.	
	Lb.	Lb.	Lb.	Lb.
China	14,230	89,754	124,145	2,797,083
India	258,152	7,089	445	* 410,482
Ceylon	20,296	5,562	14,496	† 164,163
Totals	292,678	102,405	139,086	3,371,728

* Not including shipments ex "Bhundara."
† Not including shipments ex "Austral."

The Melbourne *Age* of Sept. 17th says:—

Teas have large sales; 200 half-chests of Ceylon sold from 5½d.

The Sydney *Daily Telegraph* of Sept. 17th says:—

Some little business was done in tea, sales of 140 packages Ceylon ex "Austral" being mentioned at from 5½d to 12d, and 50 at 5½d. A cable from Colombo received yesterday advised an advance of ½d on common teas and of 1d on mediums.

THE AMSTERDAM MARKET.

Amsterdam, Sept. 9.

The cinchona bark auctions to be held in Amsterdam on September 29th will consist of 459 cases and 5,108 bales, about 445 tons, divided as follows:—From Government plantations, 63 cases and 602 bales about 47 tons; from private plantations, 396 cases and 4,606 bales, about 398 tons. This quantity contains of druggist's bark; *Succirubra* quills 174 cases; broken

quills and chips 176 bales, 109 cases; root, 82 bales Calisaya quills 112 cases; broken quills and chips 36 bales, 32 cases; root 24 bales. *Lancifolia* quills 17 cases; broken quills and chips 15 cases. Manufacturing bark: *Ledgeriana* broken quills and chips 3,428 bales; root 840 bales. Officialis broken quills and chips 45 bales. Hybrid, broken quills and chips 448 bales; root 29 bales. The manufacturing bark contains about 17½ tons sulphate of quinine, or 4.42 per cent. on the average. About 1 ton contains 1.2 per cent.; 62 tons contains 2.3 per cent, 121 tons, 3.4 per cent.; 109½ tons, 4.5 per cent.; 49 tons 5.6 per cent.; 31 tons, 6.7 per cent.; 14 tons, 7.8 per cent.; 10½ tons, 11.12 per cent sulphate of quinine.—*Chemist and Druggist.*

NOTES ON PRODUCE AND FINANCE.

THE DECAYING TEA TRADE OF CHINA.—The Chinese tea-grower receives plenty of advice as to the best means he should adopt to revive his departing tea trade. A report by the Belgian Legation at Peking published in a Brussels paper, has the following on the subject:—The tea trade in China is passing at the present time through a period of depression for which no other remedy can be suggested than the withdrawal of the export duty to which this article is subject. But this would be a very serious measure to adopt, the duty bringing in from £720,000 to £1,000,000 per annum, and the resources of the Chinese Government will hardly admit of their relinquishing this sum. The following statement shows the fluctuations of the export trade during the last four years:—1888, 2,167,562 piculs; 1889, 1,877,331 piculs; 1890, 1,665,396 piculs; 1891, 1,750,040 piculs. It is evident that if, in the future, the diminution is as constant and as regular—for the increase of 1891 over 1890 is only due to a delay in the export—it will be necessary to adopt serious measures if one of the chief articles of Chinese trade (silk only being superior to it) is to retain its importance. It is black tea, comprising the varieties known as "Congou, Oolong, Souchong, Ponchong, Flowery Pekoe, Orange Pekoe, and Scented Caper," the export of which has chiefly diminished, whilst the other qualities, and particularly green tea, appear to maintain their position. From 1887 to 1891 the export of black tea, fell off to the extent of 428,000 piculs, and it is chiefly in the export to England and her Colonies that this decrease has shown itself. Russian consumption continues to make great progress, but the development of this market cannot compensate the Chinese producer for the loss of the English market, which has become dependent upon the products of India and Ceylon. The producers of the latter country are making headway owing to the personal supervision which they exercise over their plantations, to the use of machinery, and finally to the almost complete absence of middlemen between the producer and the consumer. It should, on the other hand, be recognised that certain Chinese teas—Hankow, for example—have within late years deteriorated in quality, and are no longer what they were formerly. In order that the Chinese industry may resume its flourishing condition, it is necessary, apart from the reduction of the export duty by the Chinese Government, that the Chinese producer should take more care in his cultivation, that he should look well after his land, that he should not prepare his product so hastily, that he should extend the use of machinery, that the granaries where the crop is gathered should be weatherproof, and, lastly, that he should exhibit that spirit of enterprise which is absolutely indispensable at the present day.

THE WATER USED IN TEA BREWING.—We print elsewhere a letter signed "Pilgrim" in which the writer calls attention to the importance of the water question in tea brewing, and points out the difference in flavour of tea brewed in various parts of England and Scotland. It is well known in Mincing Lane that certain teas suit certain districts because of the nature of the water in those districts, and we have heard of cases where tea tasters used toasting teas, say, in Dublin, Glasgow, or Manchester, become so perplexed by the

difference of flavour due to the different quality of the water in London that they have imported water from their own district by way of experimenting with their palates. If tea varies so considerably in flavour according to the water used, does not this point to the advantage possessed by a local dealer who buys his tea to suit the water which his customers use, over the seller who supplies one class tea for all buyers? We agree with our correspondent that it is a matter worthy of more attention than it receives, although we can assure him the dealers in Mincing Lane are quite aware of the influence of different waters in the brewing of tea.

A GROCER'S LAMENT.—The following letter expresses the sorrows of a grocer who objects to the sale of tea by all sorts and conditions of men. Planters, on the contrary, are rather indifferent as to who sells the tea so long as it is sold, although, no doubt, it is an advantage even to the grower when his tea is handled by an expert. *Fair Play*, writing to a grocers' paper, says:—"During the last few years the trade in blended and packet tea, especially in the former, has assumed an importance which was not thought possible only a short time ago, and the business has been pushed in various ways with an amount of energy which could hardly be surpassed. Legitimate warfare in trade no one can fairly object to, but the case stands on an altogether different footing, when, as in the case in question, the retail dealers, principally through the medium of more or less sensationally worded advertisements, are invited to support with their orders, and thus to extend very materially the businesses of a class of traders who are their most active opponents. The grocers are, in fact, asked to buy of competing retailers, having shops scattered over London and the country, which may be numbered by the score or hundred, although, of course, the fact that such is the case is very carefully concealed from those to whom they appeal for wholesale business. Do the retail trade really grasp the situation? I think not, for otherwise none of them would adopt such a suicidal course as to support with their orders the very traders who, either through their shops or by direct appeals in the papers made to the public, are doing their utmost to destroy the grocers' trade. Until recently it has been regarded as a cardinal maxim in business that a trader must elect to do either a wholesale or a retail trade. But lately a new class has sprung into existence, who, by means of extravagantly worded advertisements (which in many cases pay a very poor compliment to the intelligence of the readers to whom they appeal), have, at any rate for a time, apparently found it possible to successfully combine the two. I cannot, however, think this will long continue the case, when the grocers fully recognise the effects likely to result to themselves from encouraging this dual way of trading. The retail dealers at the present time are no doubt subject to an amount of competition never before experienced, but that is obviously no reason why this should become greatly intensified through their own want of thought. The larger the wholesale trade done by the dozen or the hundred shop men, the cheaper they can sell retail. These remarks, although they apply more or less to other groceries have a special bearing in the case of tea, where the attempt is being most conspicuously made to supply those whom the sellers are at the same time endeavouring to supplant. Now, in tea, my own idea would be not only to absolutely decline to support the enemy, but for the grocers in the various districts to arrange among themselves to obtain a fractional profit on sugar and to drop the price of tea in proportion. As twenty pounds of sugar are consumed to one pound of tea, a very easy arithmetical calculation would show what could readily be done, with the result of completely ousting the new form of competition, which is so heavily burdened with the cost of advertisement, postage, and the like. Tea fresh out of a chest, and judiciously selected by a grocer who knows his business and the taste of the district, ought at least to leave no chance to the butcher, or baker, or butterman, who are now striving so hard to oust the

legitimate trader. Of course, if the grocer throws up the sponge, and buys his tea wholesale where he buys pork chops for his lunch, the question is ended. In the same way, to buy tea of people who deliver the same thing carriage-paid to all his connection is equally fatal. Some are even to be found who are blind enough to publicly act as agents for their bitterest competitors, but this extremity of meekness and self-implication is happily uncommon."

COFFEE IN GUATEMALA.—Some planters seem to make coffee cultivation pay. One of the largest of the coffee growers of Guatemala is General Manuel Barillas, the late President who owns large estates which are connected by cart road and rail with the Pacific port of Champerico, and are said to be among the most favourably situated plantations in the whole Republic. These estates are roughly valued at £100,000, but it is commonly believed that General Barillas' fortune may be put down at over £1,000,000. The finest quality of Guatemala coffees are consumed by England and Germany. France imports a little by way of Havre. The poor kinds are exported to the United States, where the finest qualities are not in demand.—*H. and C. Mail*, Sept. 22.

TEA AND THE WATER USED IN INFUSING IT.

To the Editor of the *Home and Colonial Mail*.

SIR,—Although it is generally admitted that the nature of the water used in making the domestic cup of tea plays some part in its action upon the leaf, I do not think sufficient importance is attached to it. I will give you my experience with some tea from a well-known Assam garden. With London water this tea was rough in flavour, but of great strength. In the Highlands of Scotland it had quite another flavour, was altogether softer, and more like a leaf blended with Ceylon tea. I was afterwards staying in the South of England, where the water was impregnated with iron and the tea was totally different in flavour from that produced from the same leaf elsewhere. Where the water is chalky the result of a brew of tea is again different, so that it seems that the water question is one of considerable importance in buying tea for certain districts. I should be glad if any of your readers with a knowledge of chemistry would give their views on this matter.—I am, sir, yours, &c.,
PILGRIM.
—*H. and C. Mail*, Sept. 22.

BANANAS FOR THE TABLE.

There are as many kinds of bananas as there are kinds of apples—medium sized ones, such as we see in the North; big ones a foot long; thick ones, almost like small muskmelons; and little ones only three or four inches in length. When you visit a fruit stand you are likely to select the biggest and handsomest bananas you see, and there is just where you make a mistake. The smallest bananas are in nearly all cases the sweetest and juiciest, the tiny "fig" banana being the best of all.

The rind should be thin, and there should be no ridges or corners to it. The larger the ridges the coarser the fruit. The plantain, which is the very coarsest kind of banana, has enormous ridges. This species is not fit to eat without being cooked, but when boiled or baked or fried is delicious. Any coarse banana—that is, one having a thick rind with large ridges—is good for cooking.

All bananas contain starch while green, which upon ripening is changed by nature's wonderful chemistry into sugar. Now if the banana is taken just after its rind has begun to grow golden, but is still streaked with green, it will contain a great deal of starch, which will make it palatable when cooked, while the small amount of sugar which has been formed will give it a sweetness like a sweet potato. Strip the rind off, and boil it until soft, and it will make one of the nicest vegetables you ever ate.

It is one of the commonest sights along the Amazon to see groups of half clad Indian men and women squatting around little camp fires roasting bananas, and having endless mirth trying to pick them out of the hot coals without burning their fingers. We are all used to fried bananas, but we are prone to forget that for this purpose they should not be fully ripe, as that makes them too soft and too sweet. Above all, a banana roasted or fried should be served hot, for as soon as it becomes cold it grows tough and unpalatable.—*Grocer and Trade Journal*.

VARIOUS NOTES.

DISCREPANCY IN CINCHONA ANALYSES.—In our issue of September 3rd we called attention to a parcel of 89 bales of Ledgeriana shavings from the Government plantations in Java, which was sold by auction in Amsterdam on August 25th at the parity of 11½d to 12½d per lb., and the published quinine sulphate test of which was 125 per cent. Our Amsterdam correspondent now points out that this percentage was declared by the official analyst in Java, where the Government barks are tested, but that when re-analysed in Amsterdam the bark was found to contain only 9·8 per cent of quinine sulphate. Hence the price paid at auction gave a unit of nearly 1½d per lb, instead of one of less 1d per lb. at which the official analysis declares the sale to have been effected. "There are sometimes," adds our correspondent, "big differences between the Java Government tests and those made independently in Amsterdam." The buyers evidently place most reliance upon the latter, which does not say much for the efficiency of the Java Government laboratory.—*Chemist and Druggist*.

WHITE-ANTS AND MANGO TREES.—If the bark of the trees is attacked by white ants, it must be first scraped off at all parts where the animals have made tunnels and painted with kerosine. Let the ground be dug between the trees as deeply as necessary, the soil turned over and watered with phenyl, if procurable; if not, with kerosine and water. In Ceylon a decoction of the leaves of Mauritius hemp is used for expelling white-ants, but I fear, a correspondent writes, you have got into too bad a state for that to be efficacious. It has the advantage of being of course quite harmless to any trees. In using the phenyl, put some in a pail and add water till it is of the colour and consistency of good milk. (Every plantation should keep phenyl. It is perfectly safe with foliage; carbolic acid and kerosine are not. It is exceedingly good for mealy bug.) Corrosive sublimate and Paris green will both destroy white ants; dissolve in water and pour into the holes. But be careful not to poison the trees by putting these poisons too close to the roots. Corrosive sublimate is very popular here being used dry. The planters have told me that one white-ant eats a grain, dies, and is eaten in turn by another, who dies and so on till the nest is exterminated. I cannot quite credit this, but the poison has a very strong effect on white-ants. Of course care should be taken in dealing with corrosive sublimate in bulk, as it is an exceedingly dangerous poison. After you have well poisoned the white-ants, remember to manure the trees well, so that they can have strength to recover. If it is possible to flood the plantation for a few days the ants would have to retire, but this is rarely possible here at least. I do not think it would hurt the trees, as I have seen splendid old trees growing in water. I should like to know the results of these suggestions should you find time to inform me, as I am collecting together all kinds of notes on destructive insects and methods of destruction.—*Indian Agriculturist*, Sept. 3.

THE PALAIS INDIEN TEA HOUSES,
LIMITED.

Directors: William Livingstone Watson, John Berry White, Richard Blamey Magor, John Robert Boyson, Robert Gordon Shaw, George Seton, Thomas Longb, M. P. Secretary: F. A. Roberts. Registered office: Rochester Buildings, 133, Leadenhall Street, London, E. C.

The following is from the report of the directors, to be made to the members at the first ordinary general meeting to be held at the office of the company, on Monday, the 26th inst.:-

The directors beg to submit their first annual report on the operations of the company, together with the accounts made up to June 30, 1892.

In accordance with the terms of the prospectus the business were taken over as from the commence, ment thereof respectively. The purchase money paid by the company (apart from shares allotted to the vendor, some of which were transferred to the original guarantors) was the actual cost of fitting up and establishing, and this sum has been placed to block-account.

It will be observed that only 5,055 of the 6 per cent. Preference shares were applied for out of 10,000 offered for subscription. These were taken up by a small proportion of the shareholders of the Associated Tea Planters, Limited, and considering the large body interested in developing the trade in Indian tea, the directors feel that it was a very meagre response to their appeal. They hoped, however, that this sum would have proved sufficient to have sustained the business already opened in Paris until they should become remunerative, when no doubt further capital would be provided.

Owing to the considerable outlay required on advertising and in maintaining a good service in Paris, and owing to the bad season due to the dynamite scare and other causes, the loss on the first year's working of the three restaurants has proved greater than was expected. Although this loss is diminishing steadily it is evident that a certain sum must be provided to meet it for one or two years. The directors felt bound to make some efforts to plant agencies for the sale of Indian tea in other large towns in France, and it will be seen that an outlay of over £70 has been incurred for this purpose, but any such outlay is quite inadequate to the necessities of this branch of the business.

Advertising also on a large scale is necessary specially now that the experiments both in Paris and the Departments have proved that only a little outlay of capital and patience is required to see Indian tea supplant to a large extent the very inferior China tea now used, and to secure a considerable development in the extent of the trade. Indeed the whole efforts have been so much in the nature of advertising that it would not be unreasonable to view the deficit as a just expenditure with that object. Rents and advertisements during the past fourteen months account for more than two-thirds of the total loss, so that the gross profits have been almost sufficient to meet all other working expenses and in the initial stage of a business of this description such a result may be considered encouraging.

It is with great regret that the directors now find themselves hampered for want of sufficient working capital, letting alone what is necessary in the business is to be judiciously extended. The shareholders, therefore, must take this matter into their serious consideration. To enable them to do so the several houses are treated separately in this report, and considerable information is furnished. Taken as a whole, the noticeable features are the steady increase in the sale of dry tea, the gradual reduction of the losses, and the large percentage of gross profit shown. There are ample facilities at each of the premises for doing a remunerative business. For its development time would be required, even if the articles sold were well-known; but when, as in this case, the restaurants are established to introduce an entirely new article to cultivated people

like the Parisians, it will be fully realised that no progress can be made without a reasonable amount of capital also.

It is hardly reasonable to expect those who are not shareholders, or interested in the development of the Indian tea trade, now to furnish further capital, the directors, therefore, earnestly appeal to those who have a stake in the company to provide what is needful.

The Paris houses have during the past year been visited by several of the directors and shareholders, as well as the secretary, all of whom give most favourable reports of the situation and suitability of the various premises, and speak in high terms of the manner in whom the business is conducted. Many most flattering notices have appeared in the Press, and the directors feel that it would be most unwise to sacrifice the outlay that has been undertaken so far, or permit the enterprise to languish for want of funds, when there is no doubt that it can be brought to a successful issue.

WHOLESALE DEPOT: 25, BOULEVARD BONNE NOUVELLE.

The wholesale depot was moved on Jan. 1, 1892, from 204, Rue de Rivoli, to 25, Boulevard Bonne Nouvelle. Since then the retail houses have been supplied with tea, &c., at cost price instead of at a profit of 25 per cent. as previously. Notwithstanding these changes the business has increased and the losses have also been slightly reduced, as may be seen from the following comparative statements of takings and losses:-

Periods.	Gross Takings.		Nett Loss.	
	Tls.	Avge.	Tls.	Avge.
	per month	per month	per month	per month
	£s.	£s.	£s.	£s.
8 mos. to Dec. 31, 1891	58,139	7,267	5,297	662
6 mos. to June 30, 1892	44,458	7,409	3,941	657

The following statement shows the monthly sales of dry tea for fourteen months, the weights being given in kilogrammes (1 kilo. being equal to 2 lb. 3 1/2 oz. avoird.) During the four months, March to June, 1892, a special account was opened with a Paris merchant in China tea only, particulars of which are given separately.

1891.		Kilos.
May	480
June	408
July	360
August	245
September	365
October	538
November	553
December	451
		Special account
		China Tea.
1892.		Kilos.
January	526
February	561
March	519
April	675
May	830
June	601

Total sales for fourteen months, 8,618 kilos.
Less special account China tea, 1,506 kilos.]

Total sales of blended tea, 7,112 kilos,
Equals 15,669 lb.,
of which 75 per cent Indian tea and 25 per cent China.
The report, which is very ample, also gives full particulars of the provincial agencies.—H. and C. Mail, Sept 23.

HOW LIME JUICE IS MADE.

In a recent report the United States Consul at Kingston gives the following description of the manufacture of lime-juice in Jamaica. The juice in its crude state is obtained either by running the limes through an ordinary cone mill, when the same is convenient and the fruit to be had in sufficient quantities, or by placing them in a squeezer especially adapted to the purpose, which

seems to be the simpler and more usual plan. To clarify the same requires straining and filtration, when some foreign substance is added to prevent decomposition of the vegetable matter, in which shape most of the juice is shipped from the island. In order to concentrate, it is strained from the seed and pulp and placed in a copper battery and boiled on the same principle as sugar, care being taken not to scorch or burn it, as that destroys the acid. The more densely the juice is concentrated, the more valuable it is; but it is not advisable to go too far, as it burns easily without forming a crust on the copper. No iron vessel must be used, as the iron turns the acid black. From the latest data the amount exported, which was doubtless about all that was made, was 53,884 gallons, of which 44,492 gallons went to the United Kingdom, 110 to Canada, and 9,282 to the United States. The average valuation in the export list is 20 cents per gallon, but the price for the raw juice ranges from 18 to 20 cents according to the supply and demand, while the concentrated juice sells according to the percentage of citric acid it contains. Substantially the same process is adopted in the manufacture of sour orange juice.—*Globe*, Sept. 23.

CEYLON TEA IN SYDNEY.

In the *Sydney Trade Review* of 16th Sept. Messrs. H. W. Carey & Co. say:—

Ceylon teas: Each week's arrival by the mail steamer has been generally quickly absorbed at steady prices, although the quality has been somewhat indifferent, there having been few fine teas among them. Sales have been made of common rough leaf Souchongs $4\frac{1}{2}$ to $5\frac{1}{2}$ per lb., Pekoe Souchongs 6d to $7\frac{1}{2}$ per lb., Pekoes 7d to $11\frac{1}{2}$ per lb., broken Pekoes 9d to $1s\ 2\frac{1}{2}$ per lb.

In the *Sydney Daily Telegraph* of 20th Sept. we read:—

Tea had some attention, 110 chests common Ceylons being placed at $5\frac{1}{2}$ d to $5\frac{3}{4}$ d and 70 chests Indian up to 11d.

In its issue of the 21st the same paper says:—
Tea is dull. At auction a few hundred packages China were sold at from 5 $\frac{1}{2}$ d to 6 $\frac{3}{4}$ d. Very little disposition to operate was shown. Privately 100 boxes scented orange Pekoe were placed and about 100 packages Ceylons ex "Massilia" at about 6 $\frac{3}{4}$ d.

NEW CROP TEA.

Retailers desirous of increasing their tea trade and enjoying a reputation for always keeping fine tea should take pains to secure from the early arrivals of new crop Japan tea, a supply sufficient to carry them to the beginning of next season. The finest tea is now available, and such as for appearance and flavor will be hard to match some months hence.

As regards fine Formosa there is no such precaution necessary, many regarding the September offering the better. The first picking is generally light as regards flavor and strength while just the reverse is true of Japan, the first picking being the finest. In buying Formosa avoid tea that is rank, or too highly burnt. The quality of Formosa tea depends greatly upon the time and character of the fermentation. The longer it is carried on, the nearer the tea approaches a Congou.

It is always in order for a retailer to acquaint consumers with these facts, and induce many to lay in enough new crop tea for a year and thus save the carrying of stock, by a plan which affords customers the highest satisfaction.

Green teas may be selected at any time, as the method of curing etc., does not make it necessary to avail of the early receipts in order to secure the finest grades. There are five green tea districts in China, designated as "Moyune," "Tienkü," "Fychow," "Taping," and "Pingsuey," grading in quality in the order named. The "Moyune" district produces two grades

"Nankin" and "Packlong"—the former, a full, rich strong, toasty tea; the leaf of a dull, pale green in color and quite free from coloring matter. Young Hyson is the finest leaves and is graded into first, seconds, thirds and fourths.—*American Grocer*, Sept. 7.

[The *American Grocer* does not condescend to mention Indian or Ceylon tea! We had personal experience of equal prejudice in Australia, and lo! the change between 1880 and 1892. A similar process will take place in America.—*Ed. T.A.*]

TEA GROWING IN AUSTRALIA.

Experiments are going to be tried with a view of testing the soil and climate of certain localities in Australia for the cultivation of tea. It was announced some time since that a tea-planter from Assam had arrived in the colony with the intention of ascertaining what could be done with the hybrid variety of tea obtained by crossing the China with the Assam tea plant. It seems that the visitor had an idea of experimenting with this hybrid at Mildura, to see whether the humidity from the irrigation water would counteract the dryness of the climate. It may be also tested in some of the moist valleys in Gippsland and elsewhere. One paper suggests that tea culture in Australia might be a recommendable venture under the bonus system; or a tea-growing company might be started. According to Müller, the tea plant has proved hardy in the lowlands at Melbourne, where, in exposed positions, it endures quite unharmed light night frosts, as well as the free access of scorching summer winds. But it is in humid valleys, with rich alluvial soils, and access to springs for irrigation, that the most productive tea fields can be formed. The greater the rainfall in any region otherwise adapted, the richer the yield of the tea plant. It comes into plentiful bearing of its product as early as the grape vine, and earlier than the olive. Its culture is not difficult, and it is singularly exempt from fungus diseases if planted in proper localities. Pruning is effected in the cool season, in order to obtain a large quantity of small tenders leaves from young branches.—*Auckland paper*.

[There are large areas of tropical and subtropical Australia where tea would flourish, but the dearthness of labour puts commercial success out of the question. India and Ceylon grow and can continue to grow all the tea the world wants.—*Ed. T.A.*]

VARIOUS NOTES.

QUININE MANUFACTURE IN ITALY.—The two Italian quinine factories (in Milan and Genoa) produce together from 1,000,000 to 1,250,000 oz. of quinine salts per annum, two-thirds of which are exported. So, at least, says a German official report on the trade of Italy.—*Chemist and Druggist*.

LIBERIAN COFFEE IN JAVA.—It is reported that the Government compulsory cultivation of coffee in Java will soon strike into another line. It has been decided to experiment officially with Liberia coffee in the Preanger districts. The *Locomotief* says that the cultivation of Liberian coffee has come more and more into favour in European planting enterprise there from its making better head against the diseases which beset Java coffee, and from its commanding equally high prices in the market.—*Straits Times*, Oct. 1.

A GOOD CROP OF GINGER in Jamaica may yield as high as 2,000 pounds, but the average yield of dried and cured ginger, ready for the market is from 1,000 to 1,500 pounds. It need not be peeled for two or three days after digging, if kept from the sun, but after peeling the roots are soaked in water over night, washed, cleaned and weighed, than put on mats and turned over carefully at midday for six or eight days, until cured. Three pounds of green ginger makes one pound of the dry root of commerce.—*British and Colonial Druggist*.

TEA IN ITS PRIME IN CHINA, AND THE FIRST BEGINNINGS OF THE TEA ENTERPRISE IN INDIA IN 1848-51.

These are the principal topics dealt with in a second charming book by Robert Fortune, author of "Wanderings in China." On the first occasion Fortune visited China as a plant collector or a great English firm of florists. On the second journey, while devoting special attention to his special mission of obtaining seeds and plants of "the best teas of China," for his employers, the then puissant "Hon. East India Company," he did not neglect the collection of other rare and beautiful plants in which China abounds; and few men have enriched his native country and the world outside China with so many botanical, horticultural and floral treasures as did this accomplished writer, enterprising traveller and conscientiously careful observer. His enthusiasm in connection with each find of rare and beautiful trees, plants and flowers is delightful to read about and contagious in its effect. As regards tea he was the first to dissipate the popular idea that green and black teas were made from distinct species of plants, *Thea viridis* and *Bohea*; and he came to India in 1851, with his four years' experience and observation in China, just in time to prevent the young enterprise ending in failure instead of the grand success which it has achieved from the absurd idea which prevailed amongst Indian authorities that tea required the same culture by irrigation which was applied to rice! On many of the experimental plantations on the slopes and in the valleys of the Himalayas he found the tea plants sickly, dying and dead from water-logging and being grown on flat, undrained land. The most successful plants were grown where means of irrigation were most deficient. He was sent to China to collect the very best tea plants; and he succeeded in finding them on the lower slopes of the higher mountain ranges of China, between 25° and 31° North, the best of all growing between 27° and 30°, where not only was the soil good, but the natural drainage was perfect. The very frontispiece to his book "Visit to the Tea Districts of India and China" is reassuring to tea planters in Ceylon whose estates are on the slopes of high and precipitous mountains. The grand difference between the Ceylon mountain plantations and those of China and we may add of India,—the Himalayas and the Nilgiris,—is, that, whereas in China and India the summits of the mountains are generally barren from the wash of soil downwards, a large proportion of our hill ranges are not only cultivable to the summits, but in some cases have the richest soil on the highest altitudes. Even the "lowcountry" tea estates of Ceylon are generally on steep although not lofty knolls, with undulations in all cases sufficient to secure perfect drainage into rivers and streams below. Besides good soil and drainage (a yellow-coloured somewhat stiffish clay if well mixed with humus, being appreciated), Mr. Fortune indicated conditions of climate—temperature and rainfall—which are well fulfilled in Ceylon, except that cold, down as low as 40°, 32° and even 28°, is utterly absent from our lowcountry plantations in Ceylon. Perhaps this absence of cold alternating with tropical heat accounts for some absence of the delicate flavour in the lowcountry teas which distinguishes those grown up to 5,000-6,000 and even 7,000 feet altitude, the compensatory advantages in the former case being luxuriant growth and strength of product. But Robert Fortune, writing in the first year of "the fifties," while recognizing the fact that the tea plant could be grown (although

not in a commercially profitable scale) in Britain, America and Australia, seems to have as little appreciated the idea of Ceylon growing tea as of India availing herself of her indigenous product, which was ultimately found to be superior, not only to the inferior China plants first imported, but to the very best, carried with such care and success to India from "the Bohea mountains" of China to India by himself. The now varying "jāts" of tea existing in India and Ceylon, from indigenous large-leaved Assam, to the most minute-leaved China variety, with all possible sizes and qualities between, must be attributed to the bringing back to India of its own degenerated tea from China and the resulting hybridization or mixture which ensued. But Robert Fortune well performed his duty; and we have more than once expressed our disagreement with Col. Money and other writers who regard the introduction of China tea to India in the time of Lord William Bentinck and his successors as an unqualified evil. We believe, on the contrary, that the results have been the production of hybrids better suited for culture, especially on estates of high altitude, than either the original Assam or its degenerate, or at any rate diminutive, offspring in China would have been. Although Mr. Fortune, very strangely, never referred to the indigenous tea of Assam as preferable or even equal to the China plant, and although, naturally enough, with his prepossessions as to altitude and latitude, he did not anticipate the growth of tea on a commercial scale in Ceylon, he indulged in anticipations regarding the use of tea as a beverage by the natives of India, and of benefits resulting to them from the practice such as the people of the tea districts of China enjoy, which, unhappily, have not been fulfilled and which are not likely to be fulfilled unless the small farmers of certain portions of India themselves take to growing and preparing tea for household use. It seems to us that it would be almost impossible to exaggerate the benefits which the wretched rayats of India would derive from the general use of a warm, cheering and, we insist, nutritious diet such as tea is. Tea is the real "staff of life" of millions of Chinese,—millions who are poorer even than the depressed because (largely) improvident and debt-encumbered labouring classes of India. We are glad, therefore, to believe that amongst the natives of Ceylon the use of tea as a beverage is increasing to a very encouraging degree. If only the 300 millions of India consumed even a few ounces *per caput, per annum*, the additional demand and additional market would be far more important than America, Russia and the nations of Continental Europe can be for many long years to come. The accounts which Fortune and all succeeding writers give of the almost incredible poverty of the masses in China, many of whom live on 2½d or even 2d per diem, awakens our sympathy for the classes of Chinese who are thrown out of employment as artisans (box-makers) and transport coolies by the lessened foreign demand for China teas. Mr. Fortune describes in a most graphic manner the long rows of coolies he encountered on some of the mountain passes and paths, carrying boxes of tea which had to perform 24 or 26 days' journey before reaching their destination! The inferior teas were carried, two boxes to a cooly, one box at each end of a bamboo "pingo." These boxes were thrown on the ground at every rest taken by the coolies, and were thus greatly injured, as was the quality of their contents. The finer teas were carried on an arrangement of bamboos, which prevented the boxes' ever touching the earth. In this case there was only one for each cooly, the

bamboos being fixed in the ground when the cooly rested on the road and with the box secured to the top, laid against the wall of the building in which the coolies slept. Mr. Fortune estimated the gains of the tea growers of China in his time at a very moderate proportion of what accrued to middlemen and merchants, and his information led him to believe that plots or plantations of tea wore out and were renewed every nine or twelve years. This article is written on a property running from 4,660 to 6,075 feet elevation, where we regard the tea plant as only attaining full bearing in the 8th-10th year after planting out; while, with proper culture and occasional treatment with manure, there is no idea of the bushes wearing out for half a century at least, if even then they are not, in this forcing but recuperative climate, in their prime. In contrast with Mr. Fortune's statement of the short life of a probably severely plucked tea plantation, is the notice by the traveller Cooper of some tea trees of gigantic size he found growing, if we recollect aright, near a Chinese inn, the authentic history of which gave them an existence of five centuries. Judging by the well-supported statements regarding yews, cypresses, oaks and other trees, which have seen even a thousand years of life, we find nothing improbable in Cooper's statement; and we certainly see no reason to doubt that Ceylon tea estates, especially those at high altitudes, if they receive justice in cultural treatment may survive and yield luxuriant returns of leaf for several successive generations. In Ceylon we have heard of the "incumbents" of Buddhist temples leasing temple lands to European tea planters and sacrilegiously appropriating the rents to their personal use and indulgence in luxury and vice. But we have not heard of any of the "monks" here imitating the Buddhist and Taoist "priests" of China in regularly growing, preparing and selling tea in quantities to middlemen or merchants. Many of the Buddhist priests of Ceylon might be and probably are worse employed, for we all know who the personage is who finds "mischief still for idle hands to do." Here we take leave for today of Mr. Fortune's fascinating and instructive narrative of his adventurous and abundantly successful journeys through the beautiful river-valleys and the grand mountain-ranges of China, and, we may add, of India. But there is much of interest regarding not only tea and tea soils and climates, but also the remarkable geological features and botanical productions of China generally,—with their striking analogy to similar conditions in the Himalayan provinces of India,—to which we must revert in another article.—Our notice of a book published in 1852, that is forty years ago, is due to the kind attention of a friend who picked up the volume at a bookstall, read it with great interest himself, and presented it to us for perusal and notice. We have to thank him for an intellectual treat; and we believe our readers will appreciate the interesting information we have thus been able to resuscitate.

Terraing hill slopes has always been a favourite system in tea culture in India; and we recollect the favourable impression created in our mind by this mode of cultivation as we saw it in Darjiling as applied to tea and in Java on some of the Government cinchona plantations. But, unless the soil is very deep, there is the risk of raw subsoil being brought up to the roots of the plants, the process is in all cases an expensive one, and there is danger of the terraces collecting water during rainstorms and being swept away. Mr. Fortune, with his commonsense views and

his experience of culture in China, described terracing as being equally unnecessary with irrigation, although he emphasized the necessity of good drainage. As regards the carriage of tea seeds, too, Mr. Fortune anticipated the principles which are now generally applied; and he specially recommended the use of warden cases for the transport of seeds as well as seedlings and good plants. On this subject we must quote:—

In the autumn of 1848 I sent large quantities of tea-seeds to India. Some were packed in loose canvas bags, others were mixed with dry earth and put into boxes, and others again were put up in very small packages, in order to be quickly forwarded by post; but none of these methods were attended with much success. Tea-seeds retain their vitality for a very short period if they are out of the ground. It is the same with oaks and chestnuts, and hence the great difficulty of introducing these valuable trees into distant countries by seeds.

In 1849, however, I succeeded in finding a sure and certain method of transporting tea-seeds to foreign countries in full life; and as this method will apply to all short-lived seeds as well as to those of the tea-plant, it is important that it should be generally known. It is simply to sow the seeds in Ward's cases soon after they are gathered.

My first experiment was tried in the following manner. Having procured some fine mulberry-plants from the district where the best Chinese silk is produced, I planted them in a Ward's case in the usual way, and watered them well. In two or three days, when the soil was sufficiently dry, a large quantity of tea-seeds were scattered over its surface, and covered with earth about half an inch deep. The whole was now sprinkled with water, and fastened down with a few crossbars to keep the earth in its place. The case was then screwed down in the usual way, and made as tight as possible.

When the case reached Calcutta the mulberry-plants were found to be in good condition, and the tea-seed had germinated during the voyage, and were now covering the surface of the soil. Dr. Falconer, writing to me upon the receipt of this case, says, "The young tea-plants were sprouting around the mulberries as thick as they could come up."

During this year (1849) large quantities of seeds were sown in other cases between the rows of young tea-plants. These also germinated on their way to India, and reached their destination in the Himalayas in good condition.

When the news of the success of these experiments reached me from India, I determined to adopt the same plan when I packed the cases which I was now taking round under my own care. Tea-seeds were therefore sown in all the cases between the rows of young plants.

Fourteen cases having been packed and prepared in this manner, I had still a large quantity of seeds—about a bushel—remaining on hand. These I determined to dispose of in the following manner. Two glazed cases had been prepared to take a collection of camellias from China to the Botanic Garden at Calcutta. The tea-seeds were emptied out in front of these cases and a small portion of earth thrown in amongst them. A layer of this mixture, which now consisted of about one part earth and two parts seeds, was laid in the bottom of each case, and the camellia-plants were lifted gently out of their pots and placed upon it. The spaces between the plants were then filled up to the proper height with this mixture of tea-seeds and earth, and a little soil was sprinkled upon the surface to cover the uppermost seeds. The whole was then well watered, bars were nailed across to keep the earth in its place, and the lids of the cases were fastened down in the usual manner.

My collections of plants and seeds, which now filled sixteen glazed cases, were in this state when I left Shanghai.

When the cases were opened in Calcutta the young tea-plants were found to be in good condition. The seeds which had been sown between the rows were also just beginning to germinate. These, of course,

were left undisturbed, as there was room enough for them to grow; but it was necessary to take other measures with those in the camellia cases. On opening the latter, the whole mass of seeds, from the bottom to the top, was swelling, and germination had just commenced. The camellias, which had now arrived at their destination, were lifted gently out and potted, and appeared as if they had never left their native country. Fourteen new cases were got ready, filled with earth, and these germinating seeds were sown thickly over the surface, and covered with soil in the usual way. In a few days the young plants came sprouting through the soil; every seed seemed to have grown; and by this simple plan about twelve thousand plants were added to the Himalayan plantations.

Many attempts are yearly made by persons in Europe to send out seeds of our oaks and chestnuts to distant parts of the world, and these attempts generally end in disappointment. Let them sow the seeds in Ward's cases as I have described, and they are almost sure of success. If they are to be sent to a great distance, they should be sown thinly, not in masses. The plants arrived in equally good condition at Saharanpore, where they were handed over to Dr. Jameson. In view of the fact, so well known to planters who have imported seed from India, of the short period during which tea seeds retain their vitality, it is curious to read Mr. Fortune's description of the mode in which the Chinese tea cultivators treat the seeds they collect:—

In the black-tea districts, as in the green, large quantities of young plants are yearly raised from seeds. These seeds are gathered in the month of October, and kept mixed up with sand and earth during the winter months. In this manner they are kept fresh until spring, when they are sown thickly in some corner of the farm, from which they are afterwards transplanted.* When about a year old they are from nine inches to a foot in height, and ready for transplanting. They are planted in rows about four feet apart. Five or six plants are put together in each hole and these little patches are generally about three or four feet from each other in the rows. Sometimes, however, when the soil is poor, as in many parts of Woo-e-shan, they are planted very close in the rows, and have a hedge-like appearance when they are full grown.

The young plantations are always made in spring, and are well watered by the rains which fall at the change of the monsoon in April and May. The damp moist weather at this season enables the young plants to establish themselves in their new quarters, where they require little labour afterwards, except in keeping the ground free from weeds.

A plantation of tea, when seen at a distance, looks like a little shrubbery of evergreens. As the traveller threads his way amongst the rocky scenery of Woo-e-shan, he is continually coming upon these plantations, which are dotted upon the sides of all the hills. The leaves are of a rich dark green, and afford a pleasing contrast to the strange and often barren scenery which is everywhere around.

The natives are perfectly aware that the practice of plucking the leaves is very prejudicial to the health of the tea-shrubs, and always take care to have the plants in a strong and vigorous condition before they commence gathering. The young plantations are generally allowed to grow unmolested for two or three years, or until they are well established and are producing strong and vigorous shoots: it would be considered very bad management to begin to pluck the leaves until this is the case. Even when the plantations were in full bearing I observed that the natives never took many leaves from the weaker plants, and sometimes passed them altogether, in order that their growth might not be checked.

But, under the best mode of treatment, and with the most congenial soil, the plants ultimately become stunted and unhealthy, and are never profitable when they are old: hence in the best-managed tea-districts the natives

* Sometimes the seeds are sown in the rows where they are destined to grow, and, of course, are in that case not transplanted.

yearly remove old plantations and supply their places with fresh ones. The length of time which a plantation will remain in full bearing depends of course on a variety of circumstances, but with the most careful treatment, consistent with profit, the plants will not do much good after they are ten or twelve years old; they are often dug up and the space replanted before that time.

In Ceylon tea seed is sown in nurseries as soon as possible after it ripens and is gathered: no planter would ever think of keeping the seeds for four or six months in sand or otherwise. It seems significant that no mention is made of pruning in the case of the China tea plantations or plots, which became unprofitable and had to be renewed in ten or twelve years. Prices must have been good, and labour of cultivators and carrying and manufacturing coolies rated on a very low scale indeed to render the enterprise at all profitable under such conditions and in the absence of rolling and other machinery. The above extract is from the chapter in which Mr. Fortune sums up the results of his observation and experience in the tea districts of China. The botany of the black tea country, in the absence of thermometrical observations, enabled Mr. Fortune to judge what the characteristics of the climate were, and the geology indicated the mineral constituents of the soil. As we have already mentioned, the botany and geology of the mountain tea districts of China were found reproduced on the Himalayan ranges in India. The cosmopolitan nature of the tea plant, however, is shown by the wonderful way in which it has flourished in Ceylon, in conditions geologically, botanically and climatologically so different to those of its habitat in China. Amongst the natural productions of the tea districts of China are the camphor laurel and the tallow tree, with such pines, as *Pinus sinensis* and *Cunninghamia lanceolata*; while tea on the slopes of the Himalayas has replaced pines and deodars; oaks, elms and birches, magnolias and other trees which are foreign to Ceylon, where all attempts to introduce the deodar have as yet been unsuccessful. We mentioned a yellowish, clayey soil such as is common in Ceylon, but it may be well to quote what is said about tea soil and situation:—

The soil of the tea-lands about Woo-e-shan seemed to vary considerably. The most common kind was a brownish-yellow adhesive clay. This clay, when minutely examined, is found to contain a considerable portion of vegetable matter mixed with particles of the rocks above enumerated. [Clay slate, quartz, dark micaceous granite, conglomerate, and fine calcareous sandstone and dolomite limestone.—Ed. T.A.]

In the gardens on the plains at the foot of the hills the soil is of a darker colour, and contains a greater portion of vegetable matter, but generally it is either brownish yellow or reddish yellow. As a general rule the Chinese always prefer land which is moderately rich, provided other circumstances are favourable. For example, some parts of Woo-e-shan are exceedingly sterile, and produce tea of a very inferior quality. On the other hand, a hill in the same group, called Pa-ta-shan, produces the finest teas about Tsong-gan-hien. The earth on this hillside is moderately rich, that is, it contains a considerable portion of vegetable matter mixed with the clay, sand, and particles of rock.

By far the greatest portion of the tea in this part of the country is cultivated on the sloping sides of the hills. I observed a considerable quantity also in gardens on the level land in a more luxuriant state even than that on the hill-sides; but these gardens were always a considerable height above the level of the river, and were consequently well drained. It will be observed, therefore, that the tea-plants on Woo-e-shan and the surrounding country are growing under the following circumstances:—

1. The soil was moderately rich, of a reddish colour, well mixed with particles of the rocks of the district.

2. It was kept moist by the peculiar formation of the rocks, and the water which was constantly oozing from their sides.

3. It was well drained, owing to the natural declivities of the hills, or, if on the plains, by being a considerable height above the watercourses.

These seem to be the essential requisites as regards soil, situation, and moisture.

In China and in India most of the tea cultivation is carried on so far north as between 25° and 30°, and in both places the temperature ranges from 100° to freezing point. In the Ceylon tea districts the mercury rarely or never exceeds 90° in the shade, and still more rarely does it descend below 40°. Snow, which is a near neighbour of tea in China and in the Himalayas, has never been seen and cannot occur in Ceylon; while the rainfall is generally sufficient and well distributed without being excessive. Planters with only Indian experience to guide them have been greatly surprised that tea should flourish as it has done in Ceylon, an island without a winter and 20° nearer the equator than the plantations of Assam and Darjiling. They fall back on the idea, that, having gone up like a rocket, our descent will be of like rapid character; but our climate is humid as well as hot, and therefore we cherish the belief that tea plantations here, especially in our mountain regions, will be as lasting as those of Darjiling on which snowy Kinchinjunga looks down or those in the valleys of Assam through which the frequently flooded Brahmaputra pursues its course to a junction with the Ganges and the ocean. The tea farms of China are of small extent and are cultivated in a style very different from the scientific system pursued in India and Ceylon; and, as far as we know, tea in China is never packed on the land or even in the district where it is grown. It is finally prepared, fired and packed at the ports of shipment, its previous treatment being generally not conducive to the retention of its good qualities. After going into the long transit and changes on tea in Great Britain, Mr. Fortune thus concludes his chapter on tea production in China:—

Let me confer a boon upon my countrywomen, who never look so charming as at the breakfast-table by a quotation or two from a Chinese author's advice to a nation of tea-drinkers how best to make tea. "Whenever the tea is to be infused for use," says Tung-po, "take water from a running stream, and boil it over a lively fire. It is an old custom to use running water boiled over a lively fire; that from springs in the hills is said to be the best, and river-water the next, while well-water is the worst. A lively fire is a clear and bright charcoal fire.

"When making an infusion, do not boil the water too hastily, as first it begins to sparkle like crabs' eyes, then somewhat like fish's eyes, and lastly it boils up like pearls innumerable, springing and waving about. This is the way to boil the water."

The same author gives the names of six different kinds of tea, all of which are in high repute. As their names are rather flowery, I quote them for the reader's amusement. They are these: the "first spring tea," the "white dew," the "coral dew," the "dewy shoots," the "money shoots," and the "rivulet garden tea."

"Tea," says he, "is of a cooling nature, and if drunk too freely, will produce exhaustion and lassitude; country people before drinking it add ginger and salt to counteract this cooling property. It is an exceedingly useful plant; cultivate it and the benefit will be widely spread; drink it, and the animal spirits will be lively and clear. The chief rulers, dukes, and nobility esteem it; the lower people, the poor and beggarly, will not be destitute of it; all use it daily, and like it." Another author upon tea says that "drinking it tends to clear away all impurities, drives off drowsiness, removes or prevents headache, and it is universally in high esteem."

There is no answering for tastes; and while we should scarcely think ginger and salt more agreeable additions to tea than the butter and meat which the Tartars mix with their brick tea, the Chinese cannot understand our sophistication of tea with milk and sugar, while the Russians, with better reason, contend for the superiority of their own elegant flavouring of lemon peel. With sugar and milk, or still better cream, however, tea is a substantial food as well a pleasant and cheering beverage. Mr. Fortune left no doubt of the fact that green and black teas were made from the same species and that *Thea viridis* and *Thea Bohea* were merely different names for the same species. He gave details of the preparation in both cases, and showed that the essential difference between green and black tea was that the latter was withered and oxygenated, while the former was not. After describing the manufacture of green tea Mr. Fortune writes:—

It will be observed, then, with reference to green tea—1st, that the leaves are roasted almost immediately after they are gathered; and 2nd, that they are dried off quickly after the rolling process.

Black tea.—When the leaves are brought in from the plantations they are spread out upon large bamboo mats or trays, and are allowed to lie in this state for a considerable time. If they are brought in at night they lie until next morning.

Then follow the details of the manufacture of black tea, after which Mr. Fortune writes:—

It will be remarked, therefore, with reference to the leaves which are to be converted into black tea—1st, that they are allowed to lie for some time spread out in the factory after being gathered and before they are roasted; 2nd, that they are tossed about until they become soft and flaccid, and then left in heaps, and that this also is done before they are roasted; 3rd, that after being roasted for a few minutes and rolled, they are exposed for some hours to the air in a soft and moist state; and 4th, that they are at last dried slowly over charcoal fires. The differences in the manufacture of black and green teas are therefore most marked, and I think fully account for the difference in colour, as well as for the effect produced on some constitutions by green tea, such as nervous irritability, sleeplessness, &c. This is shown in some observations made by Mr. Warrington, of Apothecaries' Hall, in his paper which I have already quoted.

"The question presents itself, then," says Mr. Warrington, alluding to the variation of physical and chemical properties in green and black teas, "from whence do these distinguishing peculiarities arise, and to what are they to be attributed? From observations made in other directions, in the course of the routine work of the establishment to which I am attached, I had formed in my own mind certain conclusions on this subject. I allude to the exsiccation of medicinal herbs; these are for the most part nitrogenous plants, as the *Atropa belladonna*, the *Hyoscyamus niger*, the *Conium maculatum*, and others. The plants are brought to us by the growers or collectors from the country, tied up in bundles, and when they arrive fresh and cool they dry of a good bright green colour; but on the contrary, it is found that if they are delayed in their transit, or remain in a confined state for too long a period, they become heated, from a species of spontaneous fermentation, and when loosened and spread open emit vapours, and are sensibly warm to the hand: when such plants are dried, the whole of the green colour is found to have been destroyed, and a red brown and sometimes a blackish brown result is obtained. I had also noticed that a clear infusion of such leaves evaporated carefully to dryness was not all undissolved by water, but left a quantity of brown oxidised extractive matter, to which the denomination *Apothem* has been applied by some chemists; a similar result is obtained by the evaporation of an infusion of black tea. The same action takes place by the exposure of the infusions of many vegetable substances to the oxidising influence of the atmosphere; they become

darkened on the surface, and this gradually spreads through the solution, and on evaporation the same oxidised extractive matter will remain insoluble in water. Again, I had found that the green teas, when wetted and re-dried, with exposure to the air, were nearly as dark in colour as the ordinary black teas. From these observations, therefore, I was induced to believe that the peculiar characters and chemical differences which distinguish black tea from green were to be attributed to a species of heating or fermentation, accompanied with oxidation by exposure to the air, and not to its being submitted to a higher temperature in the process of drying, as had been generally concluded. My opinion was partly confirmed by ascertaining from parties conversant with the Chinese manufacture, that the leaves for the black teas were always allowed to remain exposed to the air in mass for some time before they were roasted."

Here, then, we have the matter fully and clearly explained; and, in truth, what Mr. Warrington observed in the laboratory of Apothecaries' Hall may be seen by every one who has a tree or bush in his garden. Mark the leaves which are blown from trees in early autumn; they are brown, or perhaps of a dullish green, when they fall, and yet, if they are examined some time afterwards, when they have been exposed to air and moisture in their detached state, they will be found quite as black as our blackest teas. On variations in tea, very sensible remarks are made:—

I believe that the Woo-e-shan plant is closely allied to the *Thea viridis* and originally identical with that species, but slightly altered by climate. On the closest examination I was only able to detect very slight differences, not sufficient to constitute a distinct variety, far less a species, and in many of the plants these differences were not even visible. The differences alluded to were these—the Woo-e plant showed less inclination to throw out branches than the Hwuy-chow one, and its leaves were sometimes rather darker and more finely serrated.

But it is possible to go into a tea-plantation in any part of China, and to find more marked distinctions amongst its plants than these I have noticed. The reason of this is obvious. The tea-plant is multiplied by seed like our hawthorns, and it is perfectly impossible that the products can be identical in every respect with the parent. Instead therefore of having one or two varieties of tea plant in China, we have in fact many kinds, although the difference between them may be slight. Add to this, that the seeds of this plant are raised year after year in different climates, and we shall no longer wonder that in the course of time the plants in one district appear slightly different from those of another, although they may have been originally produced from the same stock.

For these reasons I am of opinion that the plants of Hwuy-chow and Woo-e are the same species, and that the slight differences observed are the results of reproduction and difference of climate.

On the principles thus propounded we have no doubt that marked varieties of tea have already been produced in the different districts of Ceylon, and that more will follow, let us hope, in the direction of improved "jât." Mr. Fortune, in concluding his notice of the tea plant, anticipated its possible cottage cultivation for use in Britain thus:—

Those persons in England who possess tea-plants and who cultivate them for pleasure, should always bear in mind that, even in the tea-districts of China, this shrub will not succeed when planted in low wet land: and this is doubtless one of the reasons why so few persons succeed in growing it in this country. It ought always to be planted on a warm sloping bank, in order to give it fair chance of success. If some of the warm spots of this kind in the south of England or Ireland were selected, who knows but our cottagers might be able to grow their own tea? at all events they might have the fragrant herb to look upon. But Britain can now be supplied with tea from her own dependencies, of such good qualities and at

such cheap rates, as to place beyond the region of the practical cultivation of the plant save as an ornament and a curiosity. We have no room for Mr. Fortune's graphic descriptions of the various scenes on the Himalayas in which he found tea-growing experiments conducted; but we cannot refrain from giving our readers what is said of a district near Almora, to show how greatly facilities of transit by railway were needed in India 40 years ago—a need now happily so largely supplied in India and also in Ceylon:—

The soil of this extensive district is most fertile, and is capable of producing large crops of rice on the low irrigable lands, and dry grains and tea on the sides of the hills. From some cause, however, either the thinness of population, or the want of a remunerative crop,* large tracts of this fertile district have been allowed to go out of cultivation. Everywhere I observed ruinous and jungle-covered terraces, which told of the more extended cultivation of former years. On "land and cultivation" Mr. Fortune thus summed up his views:—

From the observations already made upon the various tea-farms which I have visited in the Himalayas, it will be seen that I do not approve of low flat lands being selected for the cultivation of the tea-shrub. In China, which at present must be regarded as the model tea-country, the plantations are never made in such situations, or they are so rare as to have come under my notice. In that country they are usually formed on the lower slopes of the hills, that is, in such situations as those at Guddowli, Hawulbaugh, Almorah, Kutoor, &c., in the Himalayas. It is true that in the fine green-tea country of Hwuy-chow, in China, near the town of Tnn-che, many hundred acres of flatish land are under tea cultivation. But this land is close to the hills, which jut out into it in all directions, and it is intersected by a river whose banks are usually from 15 to 20 feet above the level of the stream itself, not unlike those of the Ganges below Benares. In fact, it has all the advantages of hilly land such as the tea-plant delights in. In extending the Himalaya plantations this important fact ought to be kept in view. The cultivation of tea in the valley of the Brahmaputra may appear to be opposed to such views; but all the Assam plantations are, of course, well above the normal level of the great river and its tributaries, though at times some of them are flooded. On the use of tea by the natives of China and its hoped for use by the natives of India, to which we alluded, we must quote what Mr. Fortune says:—

In these days, when tea has become almost a necessary of life in England and her wide-sprading colonies, its production upon a large and cheap scale is an object of no ordinary importance. But to the natives of India themselves the production of this article would be of the greatest value. The poor *paharie*, or hill peasant, at present has scarcely the common necessities of life, and certainly none of its luxuries. The common sorts of grain which his lands produce will scarcely pay the carriage to the nearest market-town, far less yield such a profit as will enable him to purchase even a few of the necessary and simple luxuries of life. A common blanket has to serve him for his covering by day and for his bed at night, while his dwelling-house is a mere mud-hut, capable of affording but little shelter from the inclemency of the weather. If part of these lands produced tea, he would then have a healthy beverage to drink, besides a commodity which would be of great value in the market. Being of small bulk compared with its value, the expense of carriage would be trifling, and he would have the means of making himself and his family more comfortable and more happy.

Were such results doubtful, we have only to look

* The crops of this district, such as rice, mundoo, and other grains, are so plentiful and cheap as scarcely to pay the carriage to the nearest market town, much less to the plains. In Almora a maund of rice or mundoo sells for something less than a rupee, of barley for eight annas, and of wheat for a rupee.

across the frontiers of India into China. Here we find tea one of the necessities of life in the strictest sense of the word. A Chinese never drinks cold water, which he abhors, and considers unhealthy. Tea is his favourite beverage from morning until night; not what we call tea, mixed with milk and sugar, but the essence of the herb itself drawn out in pure water. Those acquainted with the habits of this people can scarcely conceive the idea of the Chinese existing, were they deprived of the tea-plant; and I am sure that the extensive use of this beverage, adds much to the health and comfort of the great body of the people.

The people of India are not unlike the Chinese in many of their habits. The poor of both countries eat sparingly of animal food, and rice with other grains and vegetables form the staple articles on which they live; this being the case, it is not at all unlikely the Indian will soon acquire a habit which is so universal in China. But in order to enable him to drink tea, it must be produced at a cheap rate; he cannot afford to pay at the rate of four or six shillings a pound. It must be furnished to him at four pence or six pence instead, and this can easily be done, but only on his own hills. If this is accomplished, and I see no reason why it should not be, a boon will have been conferred upon the people of India of no common kind, and one which an enlightened and liberal Government may well be proud of conferring upon its subjects. Here we must close; but, at a future time, we may, perhaps with interest to our readers, quote some of the graphic descriptions, of scenery, natural productions, men and manners, with notices of Buddhism and the other religions and antiquities of China, which are to be found in this charming book.

PLANTAINS.

The following extract is taken from the last report of the Botanical Garden at Demerara.—

The generally accepted opinion of botanists is that the Banana and Plantain are but forms of one species. Yet, from an economic point of view, the two are widely separated, for in regard to utility as a food-product, the banana cannot be compared with the plantain. Without explaining all the differences, it may be briefly stated that while the banana is a pleasant, agreeable and much-appreciated fruit, it has judging by the preference of the people of torrid lands, little economic value as a food-product; the plantain, on the other hand, is regarded as intrinsically one of the best natural food-products in the world. Yet the opinion of the botanists is in a way supported by the non-scientific observer, for except in rare instances, only after long and well-trained field experience can one plant be distinguished from the other when not in flower or fruit. When in fruit, however, the case is different. There is then a character, observable at sight, which requires to be pointed out for the veriest novice in the subject to be able to tell which is which. In the banana, after the fruit has set, the succeeding clusters of flowers, often a hundred or more in number, and their large embracing bracts, drop away, leaving a clear, absolutely naked, long extended and still elongating stem or axis, hanging tail-like two to three feet beyond the fruit, with the firmly compacted mass of unopened bracts and flowers, bud-like, at the end; while in the Plantain the stem ceases to extend more than twelve or eighteen inches beyond the fruit, the succeeding clusters of flowers and bracts all opening to the very end, and remaining persistent, withered and dry—the trash as it is called in colonial phraseology—permanently attached to the stem. In the Banana the axis continues to grow as long as the fruit hangs, cluster after cluster of flowers, with their bracts, opening and dropping away, a mass, like an enlarged Nelumbium-bud, still unopened, remaining at the far extended end when the bunch is cut; while in the Plantain the growth of the axis is arrested soon after the fruit sets, the abortive flowers opening, and remaining attached, from end to end of the stem. A single exception to the rule obtains in the case of the Dwarf or Chinese Banana (*Musa*

Cavendishii), in which, as in Plantains, the abortive flowers and their bracts are constantly persistent. The texture of the plantain is such that at whatever stage it is used, whether green or ripe, it must be cooked to make it palatable. It is this quality in the plantain which makes the great economic difference between the two fruits. Plantains are chiefly used by the populace while still green—*i.e.* cut at some period before they are full grown. They are cooked either by boiling or roasting, chiefly the former. To successfully peel a green plantain without soiling it, the operation must be performed with wet hands or with the fruit immersed in water. The plantain contains a measure of tannic acid, and consequently in boiling in a metal pot has a tendency to turn very dark. This may, however, be prevented by boiling a little fat with the fruit—say a bit of fat pork. Green plantains are also used for making soup. For this purpose they are boiled and then pounded in a mortar, when they form a homogeneous mass, like dough, which is put into soup and eaten with it. In the mature, but still green stage, plantains are roasted and eaten with butter, pepper and salt, and in some cases cheese. In this state they are delicious. The plantain parts with its beat very rapidly, and in cooling it loses, to the palate, much of its best taste. It is spoiled by re-warming. For this reason roast plantains are usually served wrapped in a table-napkin, for, to be enjoyed at all, they must be eaten before they cool. When ripe—that is, when the skin has turned yellow—a fruity character is assumed, and then they are used either baked whole in an oven, or cut in slices and fried. Baked ripe plantain has much the taste of baked apple, but with a distinctive flavor, and a much more tenacious nature. Lastly, gathered green, dried and ground or pounded, an excellent meal or flour is produced, which makes delicious custards, puddings, gruel, etc., and is highly palatable and nutritious.

Plantains being the staple food of the Creole population, Plantain cultivation is a firmly established industry. Three or four varieties are grown, one or two of which, however only on a very small scale. Two color-varieties, presenting hardly any distinction in the character of the fruit, but with the stems and stalks of the leaves blackish in one and green in the other, are most generally grown, and form the bulk of the cultivation. They pass under the names of the Black and White, Common or Cow, and sometimes Maiden Plantain. The others are the Giant, or Horse, and the Barooma, both very large-fruited kinds, the latter of which is not much grown. Plantains give a heavier yield than Bananas from the same land. They delight in the stiff, newly empoldered clay lands of this colony, not objecting to the slightly saline element found where the sea or river has invaded the place periodically at spring-tides while it was lying fallow under the natural bush-growth. Such lands yield heavily, but the crop is liable to suffer, if the seasons for the first two years after planting prove very wet, from the Plantain-disease of the colony. On dry land it does not do much damage. Introduced to such land it soon disappears again. The disease which effects Coconut-trees, from which many are from time to time lost in ill-drained situations, appears to be identically the same. In both cases it takes the form of internal decay, the substance turning to a sodden, offensively scented, putrid mass. The plantains produced by diseased trees are black inside, but not soft like the interior of the stems and root-stocks of the plants. They are, of course, quite unfit for food. Its nature has not yet been determined, though it has been observed closely in the fields, and samples of the affected parts have been examined by distinguished mycologists to ascertain whether or not it be of fungoid origin. The aboriginal Indian inhabitants of the interior do not, as a rule, cultivate this fruit, though they grow here and there in their cassava fields pineapples and a few bananas.—*Garden and Forest.*

[Is the distinction above made between plantains and bananas understood in Ceylon? Our idea has been that the fruits we call plantains are really bananas.—*Ed. T.A.*]

TROPICAL PRODUCTS: THEIR CULTIVATION IN DIFFERENT COUNTRIES.

CEYLON AS A FIELD FOR PLANTERS.

Before a general meeting of the members of the London Chamber of Commerce, held on the 25th June, Sir ARTHUR N. BIRCH (late Lieut.-Governor of Ceylon) in the chair, Mr. J. FERGUSON (Hon. Corresponding Secretary of the Royal Colonial Institute and of the Imperial Institute) delivered an address on the "Production and Consumption of Certain Tropical Products with reference to their cultivation in Ceylon, namely, Tea, Coffee, Cacao or Cocoa, Coco Palm Nuts, Fibre and Oils, Cinchona Bark, Cinnamon, Cardamoms, Rubber, Pepper, &c."

He said, Sir Arthur Birch and Gentlemen,—I fear that you will have been anticipating, from the rather discursive title of my paper, that it is to cover a very large area, and to lead you into the consideration of a mass of varied statistics. But I will spare you the latter as much as possible this afternoon, and will endeavour, in the treatment of my subject, to be concise enough to suit even a city audience in business hours.

My object is to refer (1) to Ceylon as a field and school for the tropical agriculturists; (2) to some of the staple products cultivated in that island, and exported thence; and (3) to the present position and prospects of such staples with reference to the world's production and consumption thereof.

Ceylon is well-known as one of the most beautiful and attractive of British dependencies. It is a paradise to the botanist, but of scarcely less importance to the naturalist generally; and it is historically, socially, and scientifically interesting. But it is from the planting and commercial point of view that we are now to regard it, and I would begin by saying that the island is one-sixth less than Ireland in area, and has, to-day, a population of about 3,050,000. For situation, while poetically described as a pearl-drop on the brow of India, it may be said to occupy a central position in Southern Asia, its capital, Colombo, being now the greatest calling and coaling port for the mail and commercial steamers in the Eastern seas. At this time, when the London press is full of the records of disasters from hurricanes, volcanic eruptions, and big fires, the position and circumstances of Ceylon are of special import to the British capitalist, the merchant, and planter; for we can speak of an almost complete immunity from cyclones, such as occasionally ravage the shores of the Bay of Bengal to our north; from the earthquakes and eruptions which distinguish Java and the Archipelago to our East; and from the hurricanes bred in the Gulf of Mozambique, which periodically devastate the sugar island of Mauritius, and the Zanzibar coast in the west. The wind and rainstorms which usher in the monsoons occasionally inflict some damage on our crops, but there is no comparison in this respect between the risks attaching to cultivation in our island, and those experienced in Mauritius and the Eastern Archipelago.

With such advantages, and with ready and comparatively cheap means of transport to the European markets, with a good system of roads and railways in the island, and with a favourable climate, it might be supposed that Ceylon should be the paradise of the cultivator and exporter. But here, as elsewhere, it has been demonstrated very clearly, in spite of occasional exceptions, that only in the sweat of his brow is the planter or business man to earn his livelihood, or, at any rate, his competency. Although covered with vegetation, which is always green and luxuriant, Ceylon, has, on the whole, but indifferent soil—only here and there are there rich alluvial sections, or valleys, or plateaux, with fertile deposits. The great compensation is in a forcing climate—the constant alternation of sunshine and rain over at least the populous south-western division of the island; so that, as the exaggerated illustration runs, if you stick an iron crowbar in a macadamized road in Colombo, it must needs begin to sprout. Certainly no such thing as a dry fence can exist with us, since every post and stick touch-

ing the earth is soon ready to send forth shoots. Our tropical rains, too, are peculiarly rich in ammonia—a very important matter where leaf production is concerned, and one to which I shall have to refer by-and-bye, and there is scarcely any month of the year without some rain, though the temperature is high enough to minimize its effects, save in respect of vegetation.

The next great advantage for the planter in Ceylon is a good supply of free, cheap labour. The immigrant Tamil coolies from Southern India, under proper management, are among the most docile and useful of field or factory workers. Many years ago, in the height of coffee prosperity, when scarcity of labour was often the cry, it used to be said that the planting enterprise in Ceylon depended entirely on the Tamil coolie, and that a number of abundant grain harvests in Southern India, superseding the necessity for his leaving home, would bring ruin to the Ceylon planter, who might as well shut his store door and return home. Since then there has sprung up a considerable supply of indigenous, or resident Tamil labour in the island, while this is, in certain districts, supplemented by Sinhalese men, women, and children, who have taken kindly to the light work of tea-leaf plucking. Still our plantations continue to be very largely depended on immigrant coolies, and, with the competition offered to us in Southern India, by the Straits Settlements and Burmah, it is quite necessary that everything possible should be done to encourage and maintain an ample flow of such immigrants to Ceylon.

We are accustomed to say that Ceylon is the best field and school in the world for the training of the tropical planter. This saying is based, not simply on the interested opinion of our very good selves, but on the observation of scientific gentlemen connected with Kew, or other botanical, agricultural, and chemical institutions, who have visited us; of travellers who have been able to compare plantation work in different colonies; and on the evidences of intelligence, skill and experience in the development of our local enterprise. A young man properly graduating as a planter in Ceylon is bound to acquire much practical knowledge respecting the best treatment of the plant and soil on which he is engaged; in regard to the proper management of coloured labour—(and nowhere are labourers treated more kindly)—including the learning to speak the coolies' language colloquially; he is expected to understand not only the mysteries of seed nurseries, of planting, draining, and road making; but to be able to design and superintend buildings, whether in wattle and daub for cooly lines, or in brick and stone for his own bungalow and factory, and the more he is, or becomes, of a practical engineer, land surveyor, and even physician for his coolies, the better. To know something of chemistry and geology, of soil constituents and manurial applications is no drawback, but the reverse to such colonists. Many of our planters, after they have learned the nature of their work, are anxious to experiment—backed by the expert in Mincing Lane, the machinist, or the analytical chemist, or by all three, in the hope of turning out a better, or better prepared product, of securing a more abundant crop, without injury to the plants, or waste of soil; or of economizing in their field or factory work, in freight or other expenses, by some mechanical contrivance or improvement. For such improvements there is still plenty of scope in connection with nearly every department of tropical agriculture. Supported by the local press—(and Ceylon produces an organ, the monthly *Tropical Agriculturist*, unique among English periodicals, and which finds its way to the Agricultural Department in Washington, whilst it is highly valued all over India; in Australia, East and South Africa, Central and South America, in fact, all round the tropics)—there is a constant interchange of ideas, experiments, and criticism in our island. Therefore it is no wonder that, to have earned the reputation of being a reliable, experienced planter in Ceylon, should pretty well be a passport to respect, if not profitable employment, in any part of the tropical world. In this region the Ceylon

trained planter, like the Scotchman, who is never so much at home as when he is abroad, promises to become ubiquitous. The first great exodus took place after the collapse of our coffee, when some 300 planters gradually left Ceylon, and began cultivation in the jungles of Perak and Johore, of the Straits Settlements, in North Borneo or "New Ceylon," in the tobacco fields of Deli, Sumatra; in the sugar-growing regions of Northern Queensland; while I found some of them in 1884 in the vineyards and fruit orchards of California, and orange-growing in Florida. Others went to try coffee on the Blue Mountains of Jamaica, to revive cacao planting in Grenada, to open coffee and cinchona plantations for the President of Guatemala, and to supervise coffee investments in Brazil. Farther, two ex-Ceylon planters of experience have lately returned from a Trans-Andean Expedition in Peru, where they explored and selected arge areas of fine land for tropical products, these areas lying along the tributaries of the Amazon, and being taken up for the Peruvian Corporation of London, while another gentleman, Mr. J. L. Shand, closely connected with Ceylon, has just been reporting on cultivation in Johore and North Borneo.

New Guinea and Madagascar have been explored by Ceylon planters, and among the pioneers in the hill-country of East, or rather Central Africa, at this moment are men trained in our island.

An illustration of what is thought of such training in other lands came under my notice the other day. One of our planters was travelling through a West Indian island. The director of the local Botanic Gardens, greatly interested in his cacao field, and seeking the opinion of his Ceylon visitor on the different kinds he had growing together, was reminded by the latter of one result in the probability of his different plants *hybridizing*. "Ah!" said the director, "that word alone teaches me a lesson as to your training, such a suggestion I have never heard from any West Indian Planter."

But it must not be supposed that there are no black sheep, nor ill-trained men, nor those who decline hard work, among Ceylon planters. Indeed, the joke is that a few under the last category, who have come to the country with capital, having, by sheer good luck, so invested that they have been able in a short time to return to the old country with scarcely a day's hard work to their credit, but with the prospect of a fair income,—have gone about saying that "the old fogies" who toil and slave out there for long years "have no brains, Sir." In other cases, no doubt, it has been a question of "capital" *versus* "experience," and sometimes these commodities are somehow, after a time, rightly or wrongly, exchanged! Then there is what we call the "tropical swing"—the tide and ebb of prosperity—the alternation of prosperity and depression, not unknown, I take it, in the city of London, as in the plantation colonies of Britain.

In Ceylon we have freely demonstrated the great law of the "survival of the fittest," for there are some products which though experimented with, have never proved a success. Among these is *Cane Sugar* for which, even if we had the needful expanses of rich alluvial soil, our persistently moist climate in South-west Ceylon—the populous occupied side—is not suited; although fifty years ago a great deal of money was spent before this was conclusively demonstrated. Again, more recent experiments and investments have shown that Ceylon can never be much of a *tobacco*-growing country, and yet in certain districts the natives do grow a great deal of tobacco for themselves, and some, at least, sent home by Europeans fetched good prices. In growing *cotton*, too, we have not had much success. But on the other hand, we profess to know from the best of practical experience and success, as much about *spice*-yielding trees and shrubs and their bark and seeds; about palms, their nuts, fibres and oils; about *cinchona*, coffee, cacao and tea, as all the rest of the world put together: and we aim at turning out the very best of products under these heads.

Let me run over the staple products thus indicated, with reference more especially to the purpose

of this paper; and first I will take the spice CINNAMON, which has longest been identified with Ceylon and, indeed, is the only one of our principal products of which we can speak as indigenous. For, we have not only the cinnamon shrub growing in Colombo and in the cultivated plantations of the Negombo and Morotuwa districts; but we have the same cinnamon as one of our most striking forest trees in the interior. There it blazes out at certain seasons in every shade of pink, crimson and scarlet. Nowhere else does the cultivated cinnamon grow so well or produce bark of so fine a quality as on the Coast of Ceylon. The island has been famed for this spice since the dawn of historical records. Merchants in Rome traded in cinnamon in the time of Augustus, contenting themselves with nothing less than 100 per cent. profit, and this, the price then prevailing for the rare precious bark, of *8l.* sterling per lb. amply covered, even with all the risks attending the annual trading expedition in its transit across Egypt and down the Red Sea to the Far East. The command of its cinnamon was the main attraction in Ceylon to the Portuguese and Dutch, and indeed also to the British in the early days. Because of its spice, Ceylon was considered, in the 16th and 17th centuries, the most valuable gem in the crown of Portugal; and yet at that time, and up to 1767, there was no systematic cultivation of cinnamon, while until fifty years ago the trade was a Government monopoly.

With the abolition of the monopoly and heavy export duties, the cultivation and export rapidly increased; but alas, as with so many other products, the prices fell in correspondence from *8s.* to *5s.* to *2s. 6d.*, and now to a rate (*1s. 2d.* to *1s. 6d.*) which is said barely to cover the cost of cultivation and careful preparation. This is partly owing to the fault of Ceylon growers themselves, in starting and persisting in a trade in "*chips*," which affects the demand and price for the properly *bated* spice; but it is due still more to the competition of inferior cinnamon from Java and other parts of the Eastern Archipelago, and to large quantities of cassia from China. We have to consider, too, that cinnamon is scarcely a necessary food product. Indeed its consumption largely depends on the demand for incense in Southern Europe and other Roman Catholic countries, although a certain quantity is worked up in chocolate—notably in Spain. So far as I can learn, the world's production of the true cultivated cinnamon does not exceed three million pounds, Java and the Malabar Coast supplementing the Ceylon supply; but of cassia, double or even treble this quantity is collected and shipped from China, Siam, Sumatra and other parts of the Far East.

Ceylon can produce finer cinnamon than any other land, and if only the price afforded a fair profit to the planter, our permanent supply could easily be increased 50 or even 100 per cent., but of late years a good deal of cinnamon cultivation has had to be abandoned, the land being used for coconut and other palms and fruit trees.

I will next talk of PEPPER, a spice closely allied with cinnamon in the early days in the records of the Ceylon trade. "3000 lb. weight of Cinnamon and Pepper" was the gift sent by the King of Kandy to the King of Holland, when invoking his aid against the Portuguese in 1602. The Dutch paid special attention to the pepper trade, and Ceylon pepper was by them very highly prized, their Ceylon Governor in 1740 considering it a more important article than coffee, because he did not fear an over-supply. In this respect I believed until lately he was a true prophet; for I had considered that pepper was one of the few tropical products for which the demand was in advance of the supply, but I learn that of late supplies have come in from the Eastern Archipelago in much larger quantities, that pepper is likely to fall to *2d.* a lb. From Ceylon, the Dutch exported nearly half a million pounds of pepper 150 years ago, but strange to say, ever since the export has fallen off, until when the British arrived, at the beginning of this century, it did not exceed 100,000 lb., and now, in spite of attempts to revive the cultivation on the part of European planters, and of encouragement to the natives through the Botanical Gardens

the export from Ceylon, apart from local consumption, does not exceed a few hundred pounds. From India, the export in a single year has been as much as 12,000,000 lb., Java and Sumatra sending three times that quantity to Europe; while the Malayan Peninsula, Siam, Borneo and other parts of the Eastern Archipelago contribute to make up the rest of the world's production, which is estimated at seventy million pounds.

CARDAMOMS, or "grains of paradise," on the other hand, are a spice which, freely cultivated and exported from Ceylon in the time of the Portuguese (between three and four hundred years ago), and also in that of the Dutch, afterwards, like pepper, fell off to a few hundreds or thousands of pounds; indeed, the Ceylonese had, some thirty years ago, begun to import some from India for local consumption. This, however, was one of the products which the coffee planter (when his staple failed) began to cultivate with profit, and thus the export from Ceylon has risen from 9,000 lb. in 1873-4 to 400,000 lb.; and Indian planters have been complaining that the rush in Ceylon is likely to spoil the market, if it has not already done so. Altogether there are about 5000 acres cultivated with this spice on Ceylon plantations, apart from small plots in native gardens, the produce of which is chiefly consumed locally; and although I do not think there is much room, even if there were encouragement, for extension, yet I see no reason why Ceylon should not keep up a steady export of from 400,000 to 500,000 lb. of cardamoms. Travancore, Coorg, and Mysore supply the greater part of the Indian production of cardamoms, a market for which is found in the Presidency towns as well as in Europe. India, of late years, has not exported more than 400,000 lb. of cardamoms; latterly, indeed, only half that figure has been reached, although the Customs accounts show for all spices (chiefly ginger and pepper, with cardamoms) a total export of nearly 25,000,000 lb.

The price of cardamoms in the London market has certainly fallen steadily in correspondence with increased exports from Ceylon, so that while the highest quotation was 9s. 1d. in 1880-1 when we shipped 16,069 lb., it fell to 5s. 2d. five years afterwards, when our export was 154,405 lb., and now that we send you more than 400,000 lb., it is only a little over 2s. So that here is another product, like "Cinnamon," the cultivation of which, if suggested in new lands, to you gentlemen—capitalists of the city of London—should be met with *Punch's* well-known negative, "Don't;" or, at any rate, with only very cautious encouragement.

Still more has that lesson been impressed by the logic of facts in reference to our next product, CINCHONA, the history of which in Eastern lands, and the metamorphosis resulting in the Cinchona bark and quinine trade, is probably without parallel in the whole history of agriculture and trade. The result has brought little or no permanent benefit to the planter, with the ruin of the bark trade as formerly conducted; but the consequent cheapening of quinine has proved an immense gain to humanity, especially in malarious countries, and the full extent of this has, as yet, by no means been realized. Systematic cinchona culture was first begun in Java; but Mr. Olements Markham was not far behind with his earliest batch of plants for the Nilgiris from South America, and, from the depot formed at the Royal Botanic Gardens at Kew, seed soon after reached the Ceylon Gardens. For a long time, though, our director could hardly get a planter to look at what they knew as "a medicine plant." The first private experiment was begun in 1863-4 by a Kandy firm, one former partner in which (Mr. Leake) I am glad to see in the room, and who still maintains a close connection with Ceylon. By-and-bye plants were taken and put out to grow as ornamental trees, or as groves or shelter belts. After some years it was found, on stripping or coppicing such trees, that the return per tree or per acre was not simply handsome, but enormous, and gradually it dawned upon a good many that here was not only a suitable quick-growing plant, but a commercial product of high value. The

steady failure in coffee which about that time set in, gave an impetus to the rush after cinchona, until there was scarcely a coffee district—nay, a plantation—which had not cinchona planted right over it. The few early planters, of course, profited heavily, some to the tune of 100% or more per acre cultivated; but there were only a few acres in most cases.

One old planter is fond of narrating how his partners threw away 35,000*l.* to 40,000*l.* because they would not allow him to put 150,000 cinchona plants on the boundaries and among the coffee in opening their plantation in the early sixties, an arrangement which (after striking off half for deaths) would certainly have given 40,000*l.* worth of bark seven to ten years later. In 1880 high-water mark for Ceylon bark may be said to have been reached, when a quantity from trees eight years old realized 10s. per lb.; while as high a price as 15s. 8*d.* was got for renewed bark from the Nilgiris. Is it any wonder, then, that the Ceylon planters, with their coffee crops growing smaller by degrees and beautifully less, should have all gone in for cinchona, until, in 1883, it was estimated there were 60,000,000 of plants or young trees growing in our hill-country? and men counting on one-half, one-fourth, or even one-tenth, of the return per tree that had been actually got by their neighbours, could not fail to reckon that fortune was within their grasp. For instance, seeing that seven to eight-year-old trees had actually given 15s. net per tree of bark, what could be safer than to count at least on an average of 2s. per tree, in which case it was plain that by 1888 to 1890 there would fall some five to six millions sterling to be distributed among the lucky Ceylon cinchona growers! How that dream vanished is, perhaps, to most of you a familiar tale. In the first place, hard necessity, or the failure of his coffee, forced the Ceylon planter ("my poverty and not my will consents") to harvest bark from young, immature trees, and exports ran up from 500,000 lb. in 1879 to nearly 12,000,000 lb. in 1884, and to close on 16,000,000 lb. (as a maximum) in 1887. Even though such bark did not realize heavily, yet, seeing that the total supply from all countries, a few years before, did not equal 2,000,000 lb., the natural result was a great fall in price. "Who could have supposed," said an experienced ex-cinchona merchant to me the other day, "that when we gave out 75,000*l.* in advances to South America on contracts based on 48 to 50 cents of a dollar per lb. for 2 per cent. bark, Ceylon was going to bring the price down to 1*d.* the unit!" But such was the case. Howard's quinine, which was 12s. 2*d.* in 1878-9, fell to 2s. 4*d.* by 1886-7, and is now not much over 1s. per ounce. Very speedily the systematic cultivation of cinchona in Ceylon was discontinued, save on a few estates in the Uva province, where unusually rich bark can be grown and the risks of failure of plants are very few. But everywhere else tea took the place of cinchona, and over a wide expanse young plants of the latter were pulled out as weeds, until, from 60,000,000 trees in 1883, a liberal calculation now cannot make more than 7,000,000 to 8,000,000 of cinchona trees over two years old as growing in Ceylon, and the export of bark in the last four years has diminished to one-third of its highest figures. In proportion as the Ceylon export has fallen off, however, so has that of Java—where the planters, less pressed for funds, were able to allow their trees to mature—gone on increasing, and the bark is a much richer one. Java, in fact, along with Ceylon and India, now controls the market, leaving but little room for South American bark.

My estimate of the World's PRODUCTION, or rather SUPPLY OF BARK AND CONSUMPTION OF QUININE, *quantum valeat*, is as follows:—

CINCHONA BARK.							
Quinine required, total in ozs.	Exports, Java, lbs.		Exports, Ceylon, lbs.		Exports, India, lbs.		Total of quinine, ozs. out of bark from Java, Ceylon, India, mil.
	mil.	p.c.	mil.	p.c.	mil.	p.c.	
1892	9	8	4	5	2	2	7½
1893	9½	8½	4½	4	2½	2	8½
1894	10	9	4½	3½	2½	2½	8½

There is in this reckoning a margin left for a fair proportion of South American bark; but if prices should improve, it is quite certain that Eastern lands could increase their exports, although if prices keep low for some years to come, and less and less attention be given to the trees, it is possible we may see a much smaller supply and a reaction in prices. Meantime, no one can be encouraged to plant *cinchona* in new lands, any more than *cinnamon* or *cardamoms*, at any rate until the demand and prices improve very considerably.

Rather different is the case of the next product I will venture to mention, namely **INDIARUBBER**, for which I understand there is a large and growing demand at remunerative prices, while there is the prospect of the supply from South America, Africa, and the East—nearly all from forest trees—gradually falling off, or at any rate below the requirements of manufacturers. If it be true, as I learn, that the one province of Para in Brazil has developed an export equal to 17,000 tons per annum in a favourable year, and worth 300*l.* a ton or five millions sterling, all the rubber being got from systematic tapping of forest trees, there ought certainly to be room for extensive planting experiments, with a view to the supply of the future. In Ceylon, considerable attention was given to the cultivation of *Caoutchouc* or *Indiarubber* yielding trees over a dozen years ago, when we were hard pressed for products to take the place of coffee, and for some years great hopes were expressed that the industry would become a profitable and permanent one. Sample parcels of Ceylon Ceara-rubber harvested from trees eight to ten years old sold as high as 4*s.* per lb. It was stated that ten years' old trees yielded $\frac{3}{4}$ lb. of rubber daily: this would pay fairly well if there were a sufficient area and number of trees to work over. But the rush into tea and the greater ease with which returns could be got from this product, together with the long time required by rubber trees to mature, and the greater expense in tapping and harvesting, discouraged further planting, and I cannot speak of more than 450 acres in all Ceylon as now being cultivated with rubber plants. However, of late years Dr. Trimen has been able to report very favourably of experiments under his direction in the Botanical Gardens, and attempts are now being made by the Ceylon Forest Department to grow the tree in jungle clearings. The Gardens have also sent plants and seed to North Borneo and East Africa. In Colombo we have endeavoured to bring together all the information about rubber into an "Indiarubber Planters' Manual," and there can be little doubt if the Ceylon garden and forest experiments go on well during the next few years, that planters will once more take up the industry, and there should be a large extent of land fit for such cultivation, although unsuited perhaps for more popular but delicate products. Meantime, there is in the European and American demand, and market prices, great encouragement to cultivate generally in the tropics, the plants which yield the rubber and guttapercha of commerce.

I might here refer to several minor products such as **GAMBER**, **KOLA-NUT** and **ERYTHROXYLON COCA**, in which interesting experiments are being made in Ceylon under the auspices of Dr. Trimen and the Botanical Gardens (backed up by Kew, whence aid is always readily procurable), and of a few of our planters; but these have not yet advanced to the importance of planting industries, and I must pass on to consider the **COCONUT*** **PALM** industry and the different commercial products derived therefrom. There are said to be over a thousand known species of palms, but not more than 25 are found in Ceylon, though these include the best known and most useful, more particularly the coconut, palmyra, areca, kitul, or jaggery, and talipot palms. These are of vast importance for food and other domestic and general purposes to many millions of the people of India and Ceylon as of other tropical

lands; but commercially, so far as the markets of Europe and America are concerned, we need notice only the **COCONUT PALM**, with the kernel of the nut used in many forms, the oil prepared from it and the fibre from the husk. This palm constitutes a very important garden and plantation industry in Ceylon, chiefly in the hands of natives—Sinhalese and Tamils—who extended the cultivation of palms very greatly with the money which the coffee industry and the trade created by it put in their way. Altogether we reckon there are over 500,000 acres in Ceylon covered with from 40 to 45 millions of coconut palms, yielding annual crops worth perhaps about two millions sterling; the greater part of which is consumed in the island; but of which, in a favourable season, perhaps nearly one million sterling worth is sent away, chiefly in **COCONUT OIL**, **COIR FIBRE** and **YARN**, **NUTS**, **COPRA** (the dried kernel), **DESSICATED COCONUT** (a new preparation for confectionery), **ARRACK** and other minor products. Some of the largest oil-expressing mills in the world are to be found in Colombo, and over 400,000 cwt. of coconut oil was last year exported, apart from 100,000 cwt. of coir fibre, yarn and rope; some millions of nuts and large quantities, perhaps 300,000 cwt. more of **COPRA**, **POONAC** and **DESSICATED COCONUT**. In all, in a favourable year we make up about 80,000 "shipping" tons of freight with the exported produce of our coconut palms; but the trade, especially in oil, is far from leaving the margin of profit that it once did. African palm oil and other competitors have gradually brought down the price of Ceylon coconut oil from 50*l.* per ton, which I remember it to have been thirty years ago, to not much more than half, or well under 30*l.* at present. Save where there is a good local market for the nut and its contents, or proximity to the American market, as in the West Indies, there is not much encouragement therefore to Europeans to plant with coconuts. But still, in suitable parts of Ceylon, where the tree comes into bearing in less than the average period (which is about fifteen years), a coconut plantation is not without its attractions to the capitalist, for it is assuredly the most stable and long-lived of cultivated tropical products. Altogether, I estimate there are over three millions of acres under the coconut palm alone in the world. It may be of interest to give the distribution of the exports of coconut palm products from Ceylon for last year and the total exports for five years; and these will be found in an Appendix.

I now turn to **COCOA**, the product of the **CACAO** or **CHOCOLATE** tree. (There is great danger of this product being confounded in name with the palm, and indeed many English consumers believe that their cocoa drink has to do with the coconut palm. Since Mincing Lane has stereotyped "Cocoa" in place of "Cacao," the distinction we have tried to make in Ceylon is to leave out the "a" in the name of the palm and its products, this spelling being also more in harmony with the botanical name of the latter.) Cacao is supposed to have first been introduced into Ceylon in the time of the Dutch, and it was certainly grown in the Botanical Gardens 75 years ago, but not until 1872 was its systematic planting commenced by the late Mr. R. B. Tytler, and now we have about 13,000 acres cultivated with this product, the total export for last year being over 20,000 cwt.

This, although to a certain extent satisfactory, indicates but slow work in the development of a tropical industry, at least in Ceylon—which in less than a dozen years saw such wonderful development in respect of coffee, cinchona, tea, &c.—slow especially when the encouragement of a good demand and remunerative prices is considered. But our experience of cacao in Ceylon fully accords with that of the Dutch authority on the culture in British Guiana, when he wrote eight years ago that "there is no agricultural production that requires more care, trouble, patience, perseverance, and outlay, than cacao;" but against this adverse experience, which he said generally lasts over the first ten years of the plant, there followed, perhaps, a century of success, during which time the cacao tree, if properly

* To distinguish this palm and its products from "Cocoa" the product of Cacao (the chocolate tree) we in Ceylon spell the palm's name now as "coconut."

cared for, yields steadier crops and handsomer profits than almost any other product. At any rate, in Surinam there exist, according to Mr. Berthelink cacao plantations which have descended from generation to generation, representing great wealth in their annual crops, and which after a long course of years have lost no jot of their productiveness, but have rather increased in value. In Java there is, however, on the whole, no doubt a better soil for cacao than in Ceylon; with us the area can never be very greatly extended, because of the plant requiring both good soil and an exceptionally sheltered situation; for it has been found that strong wind is a great and almost fatal enemy to it in its early years. Those who do own well-established cacao plantations in Ceylon, in the West Indies, Java, or Guiana, may therefore be congratulated on having a product for which the demand is well in advance of the supply, and the price of which is less subject to fluctuations than that of most tropical products. I am hopeful still that we may see an appreciable addition to the cultivation in some parts of the low country—by the native villagers in their gardens, as well as by planters; also in the rich province of Uva, when Sir Arthur Gordon's Railway Extension is in full working order, and the resources of the district can be adequately utilized. So far, what the Ceylon cacao planter especially prides himself upon, is the improved preparation of his product for the London market. The industry is scarcely more than a dozen years old in Ceylon (only 120 cwt. were exported in 1880), and yet in that period more improvements have taken place in the preparation of the pod than has been in the case in Guiana and the West Indies during the century*. I see in the room one of the Ceylon pioneers in this planting industry who recently visited some of the finest West Indian plantations, and he was simply astounded at the rough, primitive way in which the factory work was done, while another gentleman, writing to me the other day, says that after seeing the Trinidad system of claying over the pods, he did not think their "cocoa" was food for men, far less for gods, alluding to the high-sounding name *Theobroma*. This is, of course, going a little too far; for all the cocoa that comes to the London market is no doubt equal to yielding a most nutritious beverage; and I am aware that West Indian proprietors aver that their system of preparation is less expensive. Nevertheless, I think there can be no question of the superiority of the Ceylon system and product, as indeed is proved by the price obtained. There is little doubt that if Ceylon produced 50,000, or even 100,000 cwt. of cocoa in place of 20,000, a ready and profitable market would be found for it. This, then, is a product, the cultivation of which on suitable fertile soil in sheltered situations, whether in Ceylon or elsewhere in the tropics, provided cheap labour is available, can be strongly recommended to capitalists or pioneer planters.† In

* Many inquiries have been addressed to me by persons interested in the West Indies as to the causes of the much higher prices reached by the Ceylon product. So far as I am able to judge I believe it to be almost wholly due to the greater care and skill employed in the processes of manufacture, and especially to the copious washing and thorough drying of the beans. I do not think it possible to attribute it to any general superiority in the cacao here grown, both as to the "Old Red" and "Forastero" varieties, though no doubt it is the former sort alone which exhibits the peculiar light colour of the interior so appreciated by the chocolate maker.—*Dr. Trimen in his Report on the Royal Botanic Gardens of Ceylon for 1891.*

† Mr. John Hughes, of 79, Mark Lane, Consulting Analytical Chemist to the Ceylon Planters' Association, sends me figures to show that the crop from the cacao plant is not so exhausting to the soil as that from the tea-bush:—

"One thousand pounds weight of Trinidad cocoa-seed, as removed from the pods, contains as follows:—

Appendices, will be found the figures for export and distribution of Ceylon cocoa, and also an approximate estimate of the world's production and consumption.

I have now to refer to COFFEE, once the great staple product of the planting industry in Ceylon. Beginning with an export of 30,000 cwt. in 1837, our crops increased until in 1870 we shipped more than a million cwt., and we continued this, more or less, on to 1875 and 1877, the greatest area planted being 275,000 acres.

Most of you, gentlemen, are aware of the woful change effected through the operation of a minute fungus on the coffee leaf, first noticed in 1869, and which, though fought against for twelve years, with all that practical skill and science and experimental treatment could devise, gradually wore out the coffee fields in all the older districts, and so affected what has been retained in cultivation, that last year only 90,000 cwt. were exported from about 40,000 acres, thus carrying us back in Ceylon to the position occupied in respect of coffee well nigh fifty years ago. The spread of the disease can only be compared to that of the *oidium* and *phylocoera* in the vine; for the coffee industry in Southern India, in Java, and the East generally, all suffered in the same way; and although the younger plantations in the richer portion of Mysore and Coorg, and in some parts of Java, as well as in the Uva and parts of the Dimbula and Dikoya districts in Ceylon, have resisted its ravages so as still to yield remunerative crops at the high prices recently available; yet there does not seem sufficient encouragement to justify fresh cultivation within the area troubled by the fungus, at least of the same species of coffee. The time has not yet come when young clearings of Arabian coffee in Ceylon could be expected to escape a full dose of the fungus. The case is rather different in new regions, and planters from Ceylon have been experimenting in the Malayan Peninsula, in North Borneo, Northern Queensland, on the Blue Mountains of Jamaica, as well as in Brazil and Guatemala, and, last of all, on the hill ranges of Nyassaland in East Africa, whence very good accounts have recently been received of coffee planting prospects. Attempts made in virgin soil, in the midst of primeval forests in Perak, in the Malayan Peninsula, are said to promise very well. Certainly the relation between supply and demand in respect of coffee—the high prices prevailing, and the limited supply of a really fine product, notwithstanding the wide extension of cultivation in Brazil, and much progress in Central American States—would seem to encourage capitalists and planters to do their best to open up new coffee-growing fields. In this connection I may refer to the recent mission of two reliable and experienced Ceylon planters on behalf of the Peruvian Corporation to the upper valley of the Amazon in East-

Nitrogen	23½ lbs.
Potash	10½ "
Phosphoric acid	8½ "
Lime	2¼ "
"Whereas 1000 lb. of made tea leaf contain:—					
Nitrogen	45 lbs.
Potash	22 "
Phosphoric acid	8 "
Lime	2½ "

Mr. Hughes adds:—"From the above results it will be seen that cocoa as a crop cannot be considered as exhausting as tea. The principal mineral constituent in both cacao and tea is *potash*, hence the importance of the soils selected being as rich as possible in this particular mineral constituent is very obvious. I should imagine that cacao soils should be generally a rich loam capable, under favourable climatic conditions, of producing crops of good quality for a great number of years with but little manure. I believe it will be found that tea will require manuring if estates are to keep up their yield of made tea of good quality; but that cacao, if planted on a naturally good and suitable soil, will continue in a flourishing condition and yield well for many years without any manure whatever."

ern Peru, where they found a wide expanse of rich, well-watered forest land, admirably suited for the cultivation of coffee and cacao, and already steps have been taken to send out small colonies of cultivating settlers—Italians chiefly—under the charge and direction of Scotchmen, planters and gardeners, to make a beginning in the Perene valley. Of course the lack of a good and cheap labour supply is the difficulty in opening up new land for tropical products in most countries.

The preparation of coffee, through steadily improved processes and much ingenious machinery, was brought nearly to perfection in Ceylon during the palmy days of the enterprise; and by degrees the improved machinery found its way—in many cases from Colombo—to the Indian districts, to Java, Guatemala, and Brazil. Now, of course, we in Ceylon can only stand aside and watch the progress of our neighbours, there being no prospect of our exceeding, even if we reach, an export of 100,000 cwt. of coffee, for many years to come.

My remarks, so far, however, chiefly apply to the best-known coffee, the Arabian, or rather Abyssinian shrub. Among the efforts made by Ceylon planters to fight the fungus were several for the introduction of new coffee seed from regions unaffected by disease. In this way selected seed from isolated plantations in Mysore, from Mocha and more especially seed of a new species of coffee from Liberia, West Africa, were procured. But none showed immunity from the fungus; on the contrary, in some cases the disease seemed to revel more abundantly in the new clearings. But in the case of Liberian coffee, though fungus-stricken, the bush or tree was a much bigger and more vigorous one than that of the Arabian species, requiring, however, a longer time for the tree to bear crops and for the berries to mature. These facts, coupled with the abundant appearance of the disease, discouraged the promotion of the enterprise—began very freely in different districts—with Liberian coffee, and tea proving a success just at that time, the new coffee was discarded, abandoned, and in some cases the plants were pulled out to make way for tea. It is now generally felt in Ceylon that those concerned were too hasty in giving up their trial of Liberian coffee. This is shown not only by the experience gained over the area (1,500 acres of all ages) still left to us, from which nearly 3,000 cwt. were exported in 1890; but still more by what has been done in Johore, North Borneo, and especially Java. Dr. Trimen, our very observant, shrewd Botanical director, as the result of a visit to Java last year, has written in his Official Report to the Ceylon Government, a few months ago:—"I am more than ever of opinion that the cultivation of Liberian coffee in Ceylon was too hastily abandoned, and would be still a profitable one." It is in this direction, then, that we may hope for some further coffee-growing in Ceylon. Native villagers are already being encouraged to grow the Liberian plant, which, like, cacao, is admirably adapted to many of their gardens, while the crops are easily gathered and are readily sold in a good market. In the valleys of Uva again we may soon find the robust Liberian coffee freely planted along with cacao even under European auspices. Still it can only be the day of small things with Coffee, though we may have a revival of cultivation, for a long time in Ceylon; and therefore, apart from Brazil, Central American States and Java, so far as British enterprise is concerned, the hope of fresh supplies must be directed chiefly for the present to the Straits Settlements, North Borneo, and the ranges of Zambesia and Nyassaland in East Africa, together with what may be added from plantations in Jamaica or adjacent territory where, however, labour is by no means certain or cheap enough to enable much to be done. In Appendices, will be found the statistics of export and distribution, and also an estimate of the world's production and consumption of coffee.

Finally, I have to direct your attention—and that very briefly—to what is undoubtedly the most important division of Ceylon planting enterprise at the present time, namely, **TEA**—our staple product

now *par excellence*. There is little need for me here to recapitulate facts within the cognizance of most of you, and which have recently formed the subject of correspondence in the public press; but I may say that although there is a tradition that the Dutch tried tea cultivation in Ceylon and failed, it is more likely that the first tea plants introduced into Ceylon were from Assam, in the time of Governor Stewart-Mackenzie, in 1839-40. Soon after, tea plants were brought from China by the Messrs. Worms, uncles of the present Under-Secretary of State for the Colonies, and planted by them on "Rothschild" and neighbouring properties. The plants grew fairly well, and the owners imported a Chinaman to show how tea should be made; but he proved a rogue, each lb. of tea costing about 5*l.* sterling to produce! This experience and the success of coffee deterred any farther tea experiments till 1866, when a gentleman, now in this room (Mr. Leake) made a first importation of Assam-hybrid tea seed, but notwithstanding the cultivation that followed, and some successful attempts at tea-making, the planting industry cannot be said to have been fairly commenced before 1875, by which year about 1,000 acres were planted, and indeed only 10,000 acres were cultivated with tea by 1880; but by 1885 the extent had risen to 100,000 acres, while 1890 saw this area more than doubled, and now we count about 255,000 acres planted with tea, or very nearly the maximum extent ever reached by coffee. In the same way our exports, beginning with 3,000 lb. fifteen years ago, got to be over 3 millions by 1885; 47 million lb. five years later, in 1890; 68½ million lb. in 1891; and this year they are to be nearer 80 than 70 million lb., I suppose. Ceylon has therefore in less than seven years, sprung up from quite an insignificant position, to rank alongside of India and China—the two greatest tea-producing countries of the world. The wonder now is, of course, that the admirable fitness of the south-west moist zone of Ceylon to grow tea was not seen thirty or twenty years ago. No country in the world is more capable of producing leaf crops: we have a constantly high temperature, with rains (rich in ammonia) every month of the year, and we find in tea a plant so hardy and adaptable that it flourishes from the sea-border to the tops of our highest plateaux or mountains. Tea is indeed so hardy that it can be grown with some care in temperate regions, as may be seen at Earl's Court Gardens at present, and I saw it flourishing in the open air at Washington in 1884; but not, of course, so as to produce proper and plentiful flushes. But still it is not alone soil nor climate so much as an abundance of suitable cheap labour that is necessary to the success of a tea-growing country, and here Ceylon, like India and China, has the advantage.

The cleanly and better mode of preparation adopted for Ceylon, as for Indian tea, give it a great advantage over that of China, and should cause tea grown in British Dependencies to be preferred throughout Europe and America.

Much has also been done by improved machinery and factory arrangements to ensure the better and more economical preparation of tea in Ceylon. But I consider that there is still plenty of room for the application of the skill of the agriculturist in the field, of the planter and his assistant in the factory, as well as of the chemist, the machinist and the tea expert, in order to secure even greater improvements in cultivation and preparation.

As regards the future of tea in Ceylon, there is no reason why we should not see the planted area still farther extended, and the export thereby increased, provided remunerative prices are maintained. Although the greater portion of the land best fitted for tea is no doubt already planted, still out of 300,000 acres reserve in the hands of owners of plantations, there must be a good deal that could be put into tea if only the "will it pay" condition is satisfactorily answered. It is possible too that the Sinhalese may take to growing tea freely in their village gardens, and so add largely to production, selling the leaf perhaps to

the nearest factory. But, to balance this we expect a large local consumption of our commoner teas to spring up among the natives both of India and Ceylon. Universal tea drinking could not fail to benefit the mass of the people; for most true is the old adage in the East, that there is nothing more dangerous to drink than brandy *except* water!

If there is to be a struggle for existence, in the face of the tea supply increasing out of proportion to demand, we in Ceylon believe that with our advantages of climate, labour supply and ready means of transport, we can hold our own against India, China or Java. What we want now is to get the people of America and Australasia, as well as many on the Continent of Europe, to use Ceylon and Indian teas as freely as do the people of the United Kingdom, and then we should have an assured market. Of the prospect of progress in this direction, we hope to hear this afternoon from the Ceylon Commissioner to the Chicago Exhibition, and very satisfactory are the latest statistics showing the great increase in Ceylon tea exports from London. In the Appendix will be found the latest statistics of production and consumption, &c. Meantime, as regards production generally, I cannot help being reminded of the commentary which these modern times must suggest on the well-worn saying, that he was the greatest benefactor of mankind who caused two stalks of corn to grow where only one grew before. In the present depressed state of British agriculture, our farmers at best will scarcely agree in this dictum of the famous Dean of St. Patrick's; and much the same experience has been realized through the over-production of some of our tropical products.

I think it will be seen by any one who studies the statistics which I offer with this paper, that there is very little encouragement to attempt the cultivation of *Tea* in other countries, than those in which it is at present established—at any rate with reference to the markets and requirements of Europe and America. This I have also shown to be the case in regard to *Cinchona Bark*, *Cinnamon* and *Cardamoms*, and to some extent in respect of the produce of the *Coconut Palm* and *Pepper*. In the case of the firstnamed (Bark) the commanding position once held by Ceylon has been acquired by Java; but in all the rest, as to a great degree in Tea, our island holds the pre-eminence. The case is different in regard to *Coffee*, probably *Cacao* ("Cocoa"), and certainly *Rubber*. For the cultivation of each and all of these valuable products in new lands there is much encouragement, and, whether it be in Peru, and the valley of the Amazon, in East Africa, Borneo, the Malayan Peninsula or in Ceylon itself, there is room for the pioneer, the planter and the capitalist to do what they can to add to the supply.

I have ventured to take up a very wide subject in dealing with the position of the several important products referred to, and my treatment has been, I am conscious, very inadequate; but, whatever else may be the result, I trust enough has been said to excite increased interest in the island whose industries have afforded me a text:—the first and most enterprising of Crown Colonies and the best school for tropical planters in the world. That there is still ample room for experiment and extension in Ceylon may be judged from the fact that of sixteen million acres, the area of the Island—or say twelve millions, excluding lakes, tanks, lagoons and rivers, little more than one-fourth, or three and a quarter million acres, are so far, under cultivation.

I might have alluded to several other products, to the supply of which British capital and skill might be directed. In *Fibres* for instance there is much scope, Ceylon being quite a paradise for the growth of fibrous plants. There are also some valuable medicinal plants in demand, as well as other food products. There are valuable timber supplies to be rendered available, as well as farther cultivation to be facilitated, by Railway extension to North Ceylon, while plantations of ornamental and useful timber trees are likely to prove remunerative. In passing, I may farther say that there is room for the proper development of our Plumbago Mines, yielding

even now over 20,000 tons a year; and of hidden wealth in Precious Gems every year as are dug out to the value of 20,000, every year on their own account by the Sinhalese. In all such directions, and in enterprises appertaining to a British Dependency, I feel sure your capital would, at least, be more wisely and safely invested, from time to time, than it has been, when given to projects in Foreign States such as the badly governed, unreliable Republics of South America.

APPENDIX.

ESTIMATES OF THE WORLD'S PRODUCTION AND CONSUMPTION OF COCOA, COFFEE, AND TEA.

[Compiled by Mr. J. Ferguson for "Ferguson's Ceylon Handbook and Directory."]

I.

COCOA: PRODUCE OF "THEOBROMA CACAO."

APPROXIMATE ESTIMATE OF THE WORLD'S PRODUCTION AND CONSUMPTION.

<i>Production.</i>	
COUNTRIES.	Cwt.
Brazil	60,000
Celebes and adjacent Islands	8,000
Ceylon	20,000
Central America	85,000
Trinidad	140,000
Dominica 2,000; Grenada 30,000; Jamaica 5,000; San Domingo 10,000; St. Lucia 3,000; St. Vincent 3,000; Total	53,000
Ecuador and Peru	200,000
Venezuela	206,000
Guadeloupe	2,000
Guiana (French) 2,000; (Dutch) 30,000; (British) 6,000; Total	38,000
Hayti	38,000
Martinique	7,000
Mexico	20,000
Philippines	5,000
Réunion	1,000
Total cwt.	877,000

Consumption.

COUNTRIES.	Cwt.
America, North and Central	90,000
America, South	65,000
France and Dependencies	195,000
Italy, South Europe and Mediterranean	80,000
Germany and North Europe	55,000
Spain and Dependencies	170,000
Switzerland and Central Europe	60,000
United Kingdom	100,000
United Kingdom non-cocoa-producing Dependencies	25,000
West Indies	35,000
Total cwt.	875,000

Another estimate gives the total production and consumption of cocoa at 80,000,000 lb. The consumption of cocoa is constantly increasing; especially in Latin Europe, and in the United States, where its use has increased sixfold since 1860, while that of tea and coffee has not more than doubled. There is no reason to fear over-production for many years to come. Trinidad has 43,360 acres under "cacao and coffee" according to assessment, but this must be chiefly under cacao alone, for the export has been as high as 150,000 to 160,000 cwt. in one years.

II.
THE WORLD'S PRODUCTION OF COFFEE.

Countries.	Estimated Area under cultivation.	Present Max. Export of Coffee.	Estimated Local Consumption.	Total Max. Production.
Brazil (including exports from Rio, Santos, Bahia, Pernambuco, and Ceará) ..	2,500,000	465,000	35,000	500,000
Java, Sumatra, and Dependencies ..	500,000	50,000	7,000	57,000
Ceylon ..	45,000*	4,000	300	4,300
India ..	250,000	18,000	2,000	20,000
Central America and Mexico (all countries between United States and New Granada) ..	600,000	70,000	15,000	85,000
Venezuela, Colombia or New Granada, Peru, Bolivia, and Guianas ..	400,000	40,000	10,000	50,000
Hayti and San Domingo ..	320,000	35,000	8,000	43,000
Cuba and Porto Rico	260,000	25,000	10,000	35,000
The remainder of West Indies (Jamaica, &c.)	45,000	5,000	2,500	7,500
Arabia, Madagascar, Mauritius, Réunion, Abyssinia, Mozambique, and North-East Coast of Africa	320,000	12,500	22,500	35,000
Natal ..	600	20	80	100
Liberia, West Coast from Congo to Cape de Verde Islands, including Lagos, Sierra Leone, Gambia, Gold Coast, Elmina, St. Thomas, St. Helena, &c., &c. ..	150,000	8,000	12,000	20,000
Philippines (Manila), Celebes, and rest of Eastern Archipelago	55,000	7,500	3,500	11,000
Sandwich Islands and rest of Pacific Isles, including Fiji and New Caledonia ..	8,500	500	700	1,200
Total ..	5,454,100	740,520	128,580	869,100

The value of the world's production of coffee (about 17 million cwt) would be about 70 millions pounds sterling in the wholesale markets.

ESTIMATE OF THE WORLD'S CONSUMPTION OF COFFEE.

	Tons.
Continent of Europe ..	435,000
United States and Canada ..	280,000†
Mexico, Central American States and the West Indian Islands ..	30,500
Brazil and the rest of South American States ..	36,500
Asia including India, Java and the Eastern Archipelago ..	37,000
Africa ..	25,000
United Kingdom ..	14,000‡
Australasia and Pacific Isles ..	5,000
Total tons ..	863,000

* Including native gardens and Liberian coffee.

† What tea is in the United Kingdom coffee is to the United States, and more specially the Southern States.

‡ The consumption of coffee in the United Kingdom rose to 16,730 tons so far back as 1847; since then consumption has declined.

This is about the total result in a year of abundant production. In 1820 the world's consumption of coffee was not more than 200,000 tons.

[For further information as to these Estimates and Explanatory Notes, reference can be made to "The Ceylon Handbook and Directory."]

III.

APPROXIMATE ESTIMATE OF THE TEA PRODUCTION OF THE WORLD.

	Area cultivated	Production.	Exports
	Acres.	lb.	lb.
China ...	10,000,000	a1,040,000,000	b240,000,000
Japan ...	750,000	c100,000,000	c45,000,000
India ...	380,000	130,000,000	125,000,000
Burma and Andamans ...	20,000*	2,000,000	...
Ceylon ...	255,000d	80,000,000	d79,000,000
Java ...	70,000e	12,000,000	e10,000,000
Natal ...	300f	70,000	...
Fiji, Jamaica	500f	30,000	...
America (Brazil, California, and other small producing countries)	10,000	800,000	100,000
" " (Besides Mate tea, indigenous or wild)	20,000,000	5,000,000
Straits Settlements and other small producing countries	600g	20,000	5,000

Total acres 11,486,400 1,384,920,000 504,105,000

a Of the 300 millions of population of China and its dependencies everyone who can possibly afford it, it said to drink tea morning, noon, and night, a wise habit in a country where the water is specially dangerous from bad sanitation, &c. The area of unoccupied land suitable for tea planting is practically unlimited, and as of the tea planted much remains unpicked every year; it may be presumed that the cost of the beverage is not much hindrance to tea drinking among almost all the adult population. The cost of the raw leaf is said to be 2d. a lb.; picking, firing, land-carriage, and duties, export duty and freight and charges, make up the cost of the better teas to 8d. a lb. Inferior tea is often sold at a loss at the China ports as well as in London.

b Including about 45 millions brick and other tea sent to Thibet, Central Asia, &c.; 65 million lb. to United Kingdom; 35 million lb. to America (besides Japan); 70 million lb. to Russia, including the export to Siberia as well as Russia overland; 20 million lb. to Australia and other places.

c In 1886-7 Japan sent 12½ million lb. to Canada and 34¼ million lb. to United States, altogether 47½ million lb.; but latterly the export has fallen off. In Japan, as in China, the people drink an immense quantity of tea.

d A good deal of young tea; exports in season 1891 were over 68 million lb., and in 1892 they will be probably close on 79 million lb.

e The Assam hybrid plant is now beginning to be chiefly cultivated in Java. English machinery is being introduced for preparing tea, and "Java" tea is now an acknowledged competitor of Indian; cultivation and preparation being carefully attended to.

f Acreage chiefly of young tea.

g Russia is trying to grow tea in Central Asia, having a plantation at Soukhum Kaleh, to be worked by Chinese coolies; also, tea is being tried in the Caucasus.

* Part indigenous tea in Upper Burma.

IV.
ESTIMATE OF TEA CONSUMPTION OF THE WORLD.

	lb.
Australasia <i>a</i>	32,000,000
British North America <i>b</i>	21,000,000
British West Indies, Guiana, and Honduras	300,000
British West and South Africa and adjacent Isles <i>c</i>	3,000,000
West-Central Asia, apart from Russia <i>d</i>	3,000,000
Tibet, Persia, and East Asia outside China	40,000,000
Ceylon <i>e</i>	600,000
China <i>f</i>	800,000,000
Europe, Continent of (apart from Russia) <i>g</i>	18,000,000
India <i>e</i>	3,000,000
Japan	55,000,000
Java	2,000,000
North Africa (Morocco, Egypt, &c.)	1,000,000
Russia (in Europe and Asia) <i>h</i>	78,000,000
South American States <i>i</i>	15,250,000
Straits Settlements and Eastern Archipelago	1,000,000
United Kingdom <i>j</i>	210,000,000
Channel Islands	750,000
United States, with Pacific Coast <i>k</i>	76,000,000
Total lb.	1,359,900,000

a Australasia now gets 9 to 10 million lb. Indian and Ceylon tea, the rest from China and Japan.

b Canada gets 8 million lb. tea from the United Kingdom, and 13 from China and Japan.
c Two million lb. are reported as imports into Cape Colony and Natal.
d Afghanistan, and territory beyond, get 1 million lb. Indian tea and 1½ China through India.
e Tea is taking the place of coffee among the natives of Ceylon and India as a drink.
f See note to China under Production.
g Germany 4¼ million lb.; Holland 5½; Denmark 1; Norway and Sweden ½; France 1½; Austria 1½; Spain and Portugal 1; rest 3.
h Half this quantity is conveyed overland from China *via* Siberia, and the other half by sea through the Black and Baltic Seas (Odessa and Kronstadt) or through Germany. Tea cost Russia about 6 million pounds sterling per annum some time ago.
i Including the consumption of Mate tea.

j In 1717 the tea sold in England was 700,000 lb.: in 1787 it had risen to 19 million lb. received in 27 ships. In 1886-7 the deliveries were over 221 million lb.; but in 1887-8, through the use of more of the stronger India tea, the total fell to 218,200,000 lb. (86 million Indian, 117 China, 12½ Ceylon, 3 Java). In 1887 the United Kingdom home consumption was 183,630,000 lb.; export 34,741,000 lb.; transhipped 9,014,000 lb.; total 227,391,000 lb. In 1891 the total imports were 239,345,774 lb., deliveries for home consumption 200,065,005 lb., for re-export 32,983,334 lb. Of the home consumption 97,854,612 lb. were Indian, 51,393,481 lb. Ceylon, 48,950,554 lb. China, 1,866,358 lb. other countries.

THE PALMIRAH PALM AND THE FIBRE INDUSTRY.

* * *

The history of the industry is briefly told. It was started in the beginning of 1891. Mr. Appleby, an Agent of the firm of Messrs. Vavasour & Co. of Colombo, came to Jaffna and instructed the people how to make fibre from the stalks of the palmyra tree. The industry was altogether a new one; but considering the short time that has elapsed since it was started, it has attained very large proportions. It has no doubt brought large sums of money into the Province and benefited numerous classes of the indigent population. The quantity of palmyrah fibre shipped from the different ports of Jaffna during 1891 was 450 tons and its value over R122,000. But the continuance of the industry cannot any longer be countenanced. The process of tearing away the stalks has already proved detrimental to a very large number of the trees. We have from time to time pointed out the danger of extirpation with which the palm is threatened. Not long ago, we quoted the remarks which Dr. Trimen made, in his report on the Botanical Gardens, on the trade on palmyrah fibre, which had sprung up in Jaffna. In the Report on Forest Conservancy, Mr. A. M. Walker makes a few observations which are very pertinent. He says that what is sought for is the petiole of the leaf and only the ends of old leaves which have already dropped should be stripped; but the people in their greed for money pull off stalks which have not died off completely and thus the naked stems of the palms are exposed prematurely and many trees die off. Mr. Walker hopes that in Crown lands at least a check would be given to the New trade and that only trees which would any how be felled for their timber, will be stripped of their leaves. Mr. Twynam in his report on the Northern Province refers to the ruthless destruction of palmyrah trees consequent on the new industry. He says that as many as one thousand trees has been destroyed in the island of Elnavottee alone by the stalks being torn off. Mr. Twynam has we think but done his duty in calling the serious attention of the Government to the recklessness with which the palm is attacked.

Well has Mr. Twynam said that it would be a bad day for the Northern Province when the palmyrah palm is killed out. We cannot but echo his sentiments. For ages past the palmyrah has been an important food and timber yielder to the people of this Province. To as many as three-fourths of the local population it is the mainstay. The produce of the palm and the uses to which it is put are so many and varied that the Tamil proverb says that the palmyrah benefits its grower a thousand years during its lifetime and a thousand years after its death. The products of the palmyrah are numerous and they are so well known to our readers that we think it needless for us to enumerate them. Of these products there has been an extensive trade in Jaggery and timber with Southern India. During the last two years however there has been a decrease in the export of these articles. The obvious reason is that the fibre industry by damaging the trees for immediate profits has seriously affected the export trade with India. In 1890 the timber exported was 262,315 pieces valued at R60,000, whereas in 1891 it has gone down to 177,047 pieces valued at R44,146. In Jaggery the fall was one half. The case is so serious as to demand the urgent and earnest attention of Government. We feel it our duty to urge on the authorities the necessity of immediate interference with a view to putting an effectual stop to an industry

which, whatever benefit it may at present confer on the people, threatens to deprive them in no long time of the chief sources for their food supply. —Jaffna "Patriot," Oct. 7th.

NOTES ON PRODUCE AND FINANCE.

THE IMPORTS OF TEA IN INDIA.—The Indian authorities are puzzled by the fact that the imports of tea have nearly doubled in five years, the quantity imported last year having amounted to 6,353,000 lb. Much of this tea, it is said, is re-exported, some by sea and some across the frontier. But a substantial proportion remains in the country, though a great part of this is inferior China tea consumed by people who cannot afford the better Indian tea. It is not a sign that Indian tea is unpopular in India because a European firm in Bombay advertises that it regularly supplies Ceylon teas to various clubs, military messes, and private individuals in Western India. Coals are occasionally conveyed to Newcastle, and Scotch Whisky is still sold in Ireland.

THE TRADE IN CHINA TEA.—Sir Charles Dilke, in a recent speech, made some reference to the China tea trade. Messrs. Lloyd, Matheson, and Carritt, in a letter to the *Standard* say:—"Sir Charles Dilke made several statements upon China tea which display extreme ignorance on the subject, and we should like to draw attention to the actual facts. So far from the consumption of China tea being 'almost extinct, and Ceylon sending three times as much tea as China, and India three times as much as Ceylon,' as Sir Charles Dilke stated, it will be seen from the warehouse returns below for the first eight months of this year, that the consumption of Ceylon tea was only four million pounds in excess of China, while even India is not twice as much, and further, the import of Ceylon tea to the end of this year will probably only slightly exceed that of last, while the export from India for the same period is expected to show no increase at all; in fact this season's crop from India is expected to be less than last year, but it is not sufficiently late in the season for this to be apparent.—Delivery of Indian tea from Jan. 1 to Aug. 31, 1892, 72,000,000 lb. ditto Ceylon, 43,750,000 lb.; ditto China, 39,750,000 lb. We feel obliged to reply to this incorrect assertion of Sir Charles Dilke in the interests of the trade, and also in consequence of the misleading statements one reads in the press from time to time with regard to China tea."

A "NEW LONDON TEA MARKET."—We see by the prospectus of the New London Tea Market, Limited, that the "advisory Board" of the concern informs grocers and tea dealers "that a new tea market has been opened to enable a grocer to purchase his teas at London market rates, and thus dispense with the wholesale dealer's profit of 1d. to 4d. per lb. The formalities of and conditions imposed by the present London Tea Market make it almost impossible for a grocer to purchase his teas there, and the tendency is to increase the stringency in favour of the leading wholesale houses. The lots are made as large as possible, often upwards of 100 chests in one lot, a prohibitory quantity to an ordinary retailer. The object of this company is to remove all obstacles which at present prevent an ordinary grocer, able to pay cash, from buying at London market rates, and this is carried out as follows:—The company purchases its teas at public sale (or direct from plantations) in large lots, and offers the same to its members in lots of from one chest upwards at the actual public sale price, charging only a small brokerage (2½ per cent.) for the trouble and expense involved. A catalogue of all offers, with public sale price and full description of each tea, is sent every week to each member three days before sale day, in order to give him time to sample any lot and send his orders, which will be invoiced as before mentioned at the actual public sale price. To suit the convenience of buyers of blended teas, any lots purchased from

catalogue can be specially blended for members at a cost of about 1d. per lb., and forwarded as required in one or more lots. All contracts for teas purchased by the company are open to the inspection of any member, which proves beyond doubt the *bona fides* of the company's dealings. A fee of 5s. per annum is payable in advance by each member as subscription to catalogue and samples, but in order to test the company's system the first 300 members elected will be admitted free of fee until March, 1893, when any such members can elect to continue or resign. We now invite those who wish to improve their tea trade, and are able to pay cash, to make application for membership, in doing which there is no responsibility attached."—*H. and C. Mail*, Sept. 30.

AN ATTACK ON INDIAN AND CEYLON TEA.

After brooding all this time over the matter, and observing with long faces the rapid decay of the tea trade of China, the champions of Chinese tea have dropped into pamphleteering. No doubt, in its way, the pamphlet entitled "Theine versus Tannin, or China tea versus Indian and Ceylon tea," published by Stuart Cranston, Glasgow, and Whittingham & Co., Limited, 91, Gracechurch Street, is a well-arranged and skillfully directed attack on Indian and Ceylon tea. Briefly, the argument is this:—The late Chancellor of the Exchequer asserted, "on the authority of impartial judges, that the tea now supplied to the people goes further than it used to do when the tea came from China alone." Mr. Stuart Cranston, of the firm of Stuart Cranston & Co., has, in the interests of the public health, been kind enough to make an enquiry into the relative values of Chinese teas and those of India and Ceylon. He gives the result, adding also the report of an independent analyst—Professor Dittmar, LL.D.—and in the form of a report to the Chancellor of the Exchequer, argues that Indian and Ceylon teas yield a little more theine than Chinese, but very much more tannin. Theine is an alkaloid identical with caffeine, and that element of tea which imparts its sustaining and refreshing qualities. Tannin is an acid very injurious to digestion. The Chinese, by their system of preparation (according to Mr. Cranston), extract the tannin at the expense of a little of the theine, and the Indian and Ceylon growers do the reverse. After submitting some credentials, including one from Sir Robert Hart, which "entitle me to be heard on the subject," Mr. Cranston goes on as follows:—

THE TANNIN BOGEY.

"Tannin forms the basis of colour, and its presence in all tea-leaf, when chemically acted upon by oxygen of the air in 'rolling,' and subjected to great heat in 'firing,' causes the public palate to mistake bitterness for quality, and the eye to assume that blackness of liquor indicates strength, whereas it is the result of over-fermenting and over-firing. Those experts were also victims to this fallacy when they caused you to argue that 'Indian and Ceylon teas are more economical than China tea.' They ought to have said Indian and Ceylon yield a little more theine and a great deal more tannin, and so deceive both the palate and the eye!

"Why do we drink tea? It is in the hope of being exhilarated and refreshed. What active principle creates this sensation? It is theine, and in this principle China, Indian, and Ceylon are much nearer—than is commonly supposed—in the amount they yield out in minutes' infusion. This period of maceration is considerably less than is allowed by nine-tenths of tea-drinkers, but is a fair and reasonable time for the purpose of comparison. A longer period would be in favour of China, as the succeeding paragraphs and analyses will demonstrate, and when we consider the time allowed for the tea to draw—the time it stands upon the table between the first cup and the second—it will be found that the time of infusion is more often fifteen minutes than ten.

"But when we come to the question of tannin—that most objectionable and pernicious property in tea—we

find that both Indian and Ceylon yield more than double and in many cases nearly treble, the amount of tannin as compared with China. The practice of housewives of pouring a second supply of hot water upon the already opened-out leaves extracts the tannin to the very dregs, and under this almost universal practice we believe that Indian and Ceylon yield from four to five times more tannin than China similarly treated.

"What would be thought of a distiller who collected the 'foresbot' and mixed it with the whisky in order to add to its 'hite' on the palate?

"Something akin to this is perpetrated by the Indian and Ceylon planters, because they collect and retain all the tannin, while the Chinese discard tannin as a waste product. This is the one radical difference in the two systems, and explains why the Indian and Ceylon yield 6, 9, and 11 per cent of tannin, while China tea yields only 3 and 4 per cent. The most remarkable fact is that all three yield nearly the same amount of theine. In China—immediately after 'withering,' and before 'rolling' 'fermenting' and 'firing'—the raw leaf is placed in boxes perforated with holes and subjected to great pressure, which causes a large quantity of thick viscid greenish juice to exude, carrying with it the bulk of the tannin—doubtless, at the same time, some of the natural colouring matter, some of the gum, and other extractive matter, which are all soluble in water, tending to rob the infusion of some of its colour and juiciness, and also some of that active principle which by chemists is called theine. The Chinese thus act upon the hygienic principle of sacrificing a little of the 'good' in order to get quit of much that is 'evil.' Contrast this process with Colonel Money's reiterated instructions in his prize essay, page 124—"The roll is ready to make up into a ball when it is in a soft *marshy* state, and when in the act of rolling it gives out juice freely. None of this juice must be lost; must be mopped up into the roll again and again in its passage up the table, and finally into the ball when made up."

A FEW CRUMBS OF COMFORT.

After doing his best to prove that Indian and Ceylon teas are very injurious, Mr. Cranston introduces the following in praise of the Indian and Ceylon planter:—

"We do not wish to place you (Mr. Goschen) or ourselves in the unpatriotic position of speaking against the produce of our own Colonies, nor in favour of that of the Empire whose Government was apparently so tardy in repressing those dreadful riots and massacres of 1891; and who, on other occasions, have done so much to alienate our sympathies, and whose tea hongs turned out some dreadfully sophisticated tea in years gone by—now happily a thing of the past.

"We do not believe that one chest of adulterated tea has been imported into London from any country since the Foods and Drugs Act came into operation.

"As far back as 1881 we urged Indian planters to alter their system by sending us teas with less tannin and more of the softness and refreshing property of China tea; nor do we consider it unpatriotic to repeat our advice now, for it is quite within the power of both Indian and Ceylon planters to eliminate the tannin during manufacture, and so to render us quite independent of China for 'soft,' healthful, and harmless teas.

"Such a change would give an immense impetus to the consumption of both Indian and Ceylon at the expense of China tea.

"Considering that the quality of the raw leaf brought India and Ceylon is so much finer (than that of China), and as their planters have the command of every modern appliance (while the Chinese have few or none) they ought to be able to send us teas of the finest flavour, and free from excess of tannin to the great advantage of the public health.

"If this remarkable displacement of China tea continues by reason of their 'softness,' the Chinese will soon learn, in self-defence, to retain the tannin and send us 'hard' teas to compete with Indian and Ceylon teas upon this special characteristic—

it will be a keen race between the three; and then the condition of the public health will be in a perilous state.

"What will the medical profession say if 'this—by no means remote—contingency should come to pass?'"

AN OLD STORY RETOLD.

Then follows a long chemical treatise on tea in support of the argument, tempered with a kind of dietetic philosophy, of which the following is a specimen:—"The late Mr. Isaac Cawdson—a very worthy man, well versed in tea—was the first to stimulate us in our study of this important question; and his opinion is worthy of being here quoted, in support of our own personal contention and physical experience when drinking tea, namely that 'the small extra amount of theine given up by Indian and Ceylon teas, as compared with China tea, is overpowered and neutralised by their much greater amount of tannin,' and therefore proves the truth of Mr. Cawdson's personal sensations to which he gave expression long before Ceylon tea was known:—'Indian tea satisfies, but does not refresh; China tea refreshes without a feeling of over-satisfaction, and is not followed by a sense of depression and heaviness such as is caused by Indian tea.' Many of the best all round judges of tea—who are engaged in the trade—have entirely discarded Indian and Ceylon teas in favour of China for their own drinking because of the effect they feel after drinking the different varieties."

THEY REGRET THE DECADENCE OF THE CHINA TRADE.

The opinion of this "worthy man well versed in tea," seems to have stimulated Mr. Cranston to some purpose. It seems to us, however, that the gist of the whole thing is to be found in the following:—"We, the undersigned, importers, brokers and wholesale tea dealers, regretting the decadence of the China tea trade, in which we have no pecuniary interests, other than that of selling and buying on the market—like our neighbours—and have studied early proof copies of Mr. Stuart Cranston's memorial to the Right Hon. G. J. Goschen, Chancellor of the Exchequer upon the question of 'Theine versus Tannin,' we cordially endorse his arguments; and from our position as dealers in all kinds of teas and our experience as tea tasters, we are able to roughly substantiate the accuracy of analysis by Professor Dittmar, LL.D., F.R.S., so far as it relates to tannin; the amounts of tannin stated against the individual teas described by Mr. Stuart Cranston conform to our sensations of palate at the tasting board day by day; and believing that the gravity of that question in its bearing on the public health merits the utmost publicity, we humbly crave of the right hon. gentleman that he will receive the memorial and deal with it according as he in his enlightened judgment and ability may determine:—Harvey Twining, Rehd. Twining and Co.; J. Mason Harrison, Harrison and Crossfield; E. H. Absolom, Meares, Absolom and Yong; Thomas Hilhouse, Rehd. Hilhouse and Sons; Williamson, Clondsley and Webb; Browne, Rosenheim and Co.; Thomas F. Easterbrook, for Wm. Ford and Sons; George Clark and Co., Hankow, China; H. S. Hancock, of Hancock, Bros. and Co., Brokers; Rothwell Marshall and Co., Brokers, 59, Eastcheap; Alexander Campbell, Kewkiang, China; Moffat and Heath, Brokers, 38, Mincing Lane; H. Johnson, Broker, 9, Mincing Lane; H. F. Cornish, late Broker, 9, Mincing Lane; Herbert Townsend and Co., Brokers, 39, Eastcheap; W. W. King and Son, Hankow and Shanghai, China; Wilson, Collins and Wilson, 25, Eastcheap; R. Beazley and Co., Idol Lane; Cassar, Hyde and Co., exporters, 27, Mincing Lane; Moss and Blum, exporters, 32, Fenchurch Street; Edwin Gamman & Co., importers, 65, Fenchurch Street; Theodor and Rawlins, brokers, 71, Eastcheap; Hamilton Brothers and Co., 157, Fenchurch Street; Henry Carus Wilson, manager for the Asiatic Tea Agency; James Sanderson and Co., St. George's House, Eastcheap; Fergusson and O'Jell, brokers, 5, Great Tower Street."

Mr. Cranston's pamphlet must be met by a counterblast, or it may work some mischief. There are points in it to be refuted, and doubtless the Indian and Ceylon Tea Associations will deal with the chemistry of it. As a sensational attack on the Indian and Ceylon tea trade, issued to the Press in the dull season, it is, no doubt, a clever move; and it is clear that, if Mr. Stuart Cranston has taken all this trouble out of consideration for the health of his fellow-creatures, Glasgow possesses a real philanthropist.—*H. and C. Mail*, Sept. 30.

GUTTA PERCHA MANUFACTURE.

The Gutta Percha Manufacturing Co., Ltd., publishes its prospectus in the Bangkok papers. The capital is \$600,000, and the object of the company is to get gutta-percha from the leaves and twigs, instead of cutting down the trees, according to M. Rigole's patent. The great merit claimed for this invention is that it allows the trees from which the gutta is extracted to be utilised continuously during their natural life. It is proposed to purchase the Pulo Obia Estate (\$40,000) and establish a factory and plantation there, in addition to the arrangements for procuring a regular supply of leaves and twigs from Borneo and Johore. The working capital is to be \$275,000; \$80,000 for the factory, \$20,000 (half purchase money) for Pulau Obia, M. Rigole \$30,000, planting 66,000 trees \$10,000, contingencies \$20,000, funds in hand \$110,000. The annual expenditure in manufacturing 6,000 pikuls of gutta-percha calculated at \$1,123,500 giving a total net profit of \$971,500 per annum or 150 per cent. per annum on the whole capital. The *Bangkok Times* says:—

The history of how M. Rigole came to hit upon the process which the new Company will purchase hereafter is curiously interesting. Some four years ago MM. Seligmann-Lui and Serullas—the latter a botanist, and the son of a distinguished savant—came out to the East under the auspices of the French Government, to inquire into the methods of gutta-percha gathering, with a view to introducing scientific processes. They visited Tonquin, the Malay Peninsula, Java, Sumatra, and other likely places, everywhere finding the natives pursuing the wasteful policy of felling the gutta-bearing trees, with infinite labour, and with a minimum of results. The *modus operandi* might be compared to that of a butcher slaughtering a cow for the sake of her milk, instead of judiciously titillating her under periodically. The experiments which M. Serullas made were valuable in so far as they indicated the particular variety to the *Isonandra* or gutta-bearing trees, which gave the best results, and the possibility of tapping them without injury. By inspissating the sap thus obtained he produced a sort of gutta-percha, samples of which he submitted to a Singapore syndicate. Tests, however, showed that his process oxidised the gum, and as that rendered it useless for insulating purposes it was valueless to electricians, the largest consumers. The process, too, proved excessively expensive.

Contemporaneously with these researches a French doctor named M. Dieudonné Rigole was pursuing similar investigations. After spending some years in Tonquin in the service of the Government his attention was drawn to the importance of the question, and at his own expense he visited the forests of Sumatra about three years ago. There he made the important discovery that the greatest percentage of sap was to be found in the twigs and leaves of the trees, and not—as the Malays imagined—in the trunk. The next difficulty was the production of chemically pure gutta-percha at a remunerative rate. This difficulty he satisfactorily overcame nearly a year ago, the samples exhibited at private tests, both in Paris and Singapore admittedly possessing far higher insulating properties than any hitherto put on the market, and commanding correspondingly high prices, while the cost of manufacture was greatly diminished. The value of the discovery was at once apparent to M. Rigole's supporters, and

they now propose to buy the rights, which have been patented in most of the European countries and in the United States, and form a Company on the lines set out in the prospectus. The prospects of the enterprise are apparently far from exaggerated by the promoters. Already large cable companies in Europe have turned their attention to it, and are desirous of purchasing the product. They have offered as much as 1,200 francs per picul for the new gutta-percha in large quantities—a price leaving a profit of not less than 150 per cent and possibly of as much as 200 or 300, if the process is further improved.—*Singapore Free Press*.

CHINA V. INDIA AND CEYLON TEA.

The correspondence which has taken place in our columns upon the trade in China tea has reference to one of the most remarkable features of modern commercial history. Less than fifty years ago Indian tea was practically unknown to the consumer. It is true that in 1838 a small parcel was exported to England, and that thenceforward a trade in it gradually arose; but only within the last twenty years has there grown up a general knowledge of the capacity of the Indian Empire to oust China from the tea market. Most of us remember the time when tea was nearly everywhere understood to be exclusively the product of China, and when no proprietor of packet tea would have thought of submitting the article without a pictorial representation of showy Mandarins and equally gaudy labourers obviously belonging to the Celestial Empire. In many cases the tea was altogether, or in part, the produce of India, for even then considerable quantities of the unrecognised leaf were being placed upon the market, and the pictures were devised merely for the purpose of satisfying the popular demand. Within the last few years, however, the trade has been founded on a proper basis, and the public now hear so much about Indian and Ceylon tea that there is a danger of their forgetting China in that connection. Indian names are given to proprietary blends, and the Mandarin is falling into complete obscurity, and making way for pictures of dusky maidens. This change is completely justified by the extraordinary transformation which the trade itself has undergone. Fifty years ago, as we have said, our tea supply was derived entirely from China; but in the first eight months of the present year the inhabitants of the United Kingdom consumed seventy one and a half million pounds of Indian tea, and only about twenty-two and a half million pounds of the article were imported from China. Two years since we imported from China considerably more than half as much tea as came from India, but this year the proportion, so far, is much below a third. The rapid growth of the Indian trade, however, has been less remarkable than that of the Ceylon trade. Tea was not cultivated on the island, which has gained a somewhat unmerited reputation for "spicy breezes," until irretrievable disaster overtook the coffee plantations. In 1873 the first parcel of tea, weighing only twenty-three pounds, was exported; yet in the United Kingdom alone the consumption of Ceylon leaf in the first eight months of this year was, in round figures, forty-one and a quarter million pounds or nearly twice as great as the consumption of China tea. About two years back the proportion was exactly the other way. Perhaps it is useless to inquire into the causes which have brought about such a revolution of trade; but we believe these causes are not to be found solely in the relative merits of China and other teas. The public taste has been educated to the more pungent Indian and Ceylon growths, and is willing to sacrifice something of the delicacy which is undoubtedly possessed in a high degree by the finest teas of China. The Indian and Ceylon planters, however, owe their success primarily to their own enterprise. They have always been ready to adopt improvements in the methods of growth and preparation, while their rivals have obstinately persisted in following the practices which had been pursued in their country from time im-

memorial. As a result, the trade of our Empire and Colony has advanced by leaps and bounds, and that of China has, so far as the United Kingdom is concerned, receded almost as rapidly. Four or five years ago the authorities in China awoke to the disastrous results which were attending the indifference, and worse than indifference, of the growers, and efforts have since been made to introduce improvements and to provide greater security as to quality. Whatever may be done in this direction, it is probably too late for the people of the Celestial Empire to regain a preponderance in the tea trade of this country. They have simply been supplanted by rivals whom, only a few years ago, they regarded with contempt.—*Standard*, Oct. 1.

PLANTING IN FIJI.

Aug. 1892.

COCONUTS.—We escaped a blow this last season, and the consequence is that the export of copra will, I should say, be greater than it has been since 1886, when we had an awful hurricane. All the coconut planters are in better spirits than they have been for years past; and the trees are looking and bearing like they used to do in former years.

TOBACCO.—The Fiji Tobacco Company, of which Mr. Lanyon, a former Ceylon planter, is the manager, has fairly started, and hopes are entertained that the Company will be fairly successful in spite of the fact that the kind of tobacco they are growing (for wrappers) is at a low price at the present time. An experienced tobacco planter has started on his own account, and is making cigars for the local market out of leaf grown by himself. He cannot supply the demand for his cigars which are highly spoken of. The only fault I can find with them is that they want ripening. He makes them well and packs them in very neat well got up boxes.

TEA holds its own, and nearly all that is grown meets a ready local sale. Alpha has not extended its operations, but another estate called Masusu has planted up another 100 acres or so; and it is to be hoped that others will enter into tea planting.

SUGAR.—On the Rewa the large Company are offering higher rates per ton of cane to induce the small planters to enter into the cultivation again. The former contracts have expired, and from what I hear the higher rates offered will have the desired effect. The smaller plantations and mills will this year, if all goes well, do much better than last season. The Colonial Sugar Company are opening up their new place at Labasa very fast. A lot of new coolies have gone there this year, and in 1893 I expect everything will be in full swing.

LABOUR.—Three vessels with full complements of coolies came in this year. Most of them were ordered by the C. S. R. Company. Only one schooner recruited Polynesians, and she was fairly successful. The men cost £15 a head and were engaged for three years. The same vessel will be leaving again shortly. The price has been raised to £20 a head, and the Government Agent is to get instructions to try and get the men to serve for five years. No Line Islanders (Tokolano) have come in this year. They are a bad-tempered lot of men as a rule, and are not liked, and are only really suitable for coconut plantations and in districts where there is only a small rainfall.

GUBERNATORIAL.—Our present Governor's time will soon expire, and we are wondering who will be his successor. During his term of office, Sir J. B. Thurston has put the financial position of the colony on a satisfactory footing. He has worked very hard; has been Governor, Colonial Secretary and Native Administrator all combined, and thus saved the colony a lot of money which would have been expended in salaries. He has served the planters in that he has not needlessly interfered with our labourers. Ordinances have been passed by which we can work our men better than formerly, and are able to get men who systematically shirk their work properly punished. For all these points great credit is due to him, but nevertheless Fiji has not taken those strides ahead which I expected.

LAND IN FIJI.—I should say that there are fewer small planters, the backbone of every new colony, than formerly. Fiji, I think, requires to be properly advertised before it has a chance of getting the men I refer to. Experienced tropical planters in all parts of the world ought to be informed that, if they like to try Fiji, they can get land readily, and in any part of the group they may fix on to try the cultivation they wish to go in for. This land ought, at first, till something proves successful, be given them for nothing or a mere nothing. By this I mean if anyone is willing to come out here and try any kind of cultivation, he should be able to get up to 300 or 400 acres free, provided he only paid survey fees and agreed to have a small portion of the land granted to him cleared and planted up in three years' time. No delay ought to take place; when once a man has chosen a piece of land that he thinks suitable, of course by land I mean land that is not in the occupation of or likely to be used by Fijians, of which there are hundreds of thousands of acres available. Likely settlers ought also to be fully informed of the cost of and how labour is recruited and the kind of ordinances the men can be worked under. Until something of this kind is done I really do not see what inducements there are for small planters to come out here to try their luck and spend their money. Wishing Ceylon a prosperous season,—Yours faithfully.

A. J. S.

THE AMSTERDAM CINCHONA AUCTIONS.

AMSTERDAM, Thursday evening.

At today's bark auctions only 3,130 packages Java bark out of a total of 5,567 were sold, over 40 per cent of the supply being held at limits over the market value. The average sale-unit was 6½c, or 1½d per lb. (the same as at the last sales), and the principal buyers were the Auerbach factory, Mr. Gustav Briegleb (of Amsterdam), the Frankfort factory, and the Brunswick factory. The following prices were paid:—Manufacturing barks in quills, broken quills and chips, 9c. to 69c. (=1½d to 12½d per lb.); ditto root, 11c. to 49c. (=2d to 8½d per lb.); druggists' barks, in quill, broken quills and chips, 9c. to 17c. (=1½d to 12½d per lb.); ditto root, 10c. to 16c. (=1½d to 3d per lb.).—*Chemist and Druggist*, Sept. 29.

NOTES ON PRODUCE AND FINANCE.

A CORRESPONDENCE DEBATE ABOUT TEA.—A casual remark made by Sir Charles Dilke at a meeting of the Chelsea Board of Guardians to the effect that the consumption of China tea was on the way to extinction in this country, not only drew from Messrs. Lloyd, Matheson and Carritt the letter which we published last week, but it has led to further correspondence in the *Standard* upon what one writer calls "this universally interesting topic," tea. * * *

A TEA-TASTER'S OPINION.—A tea-taster, writing on the same subject, says:—"It has become too much the rule of late for householders to vie with each other in buying tea at the lowest price, rather than to take a pride in having the best. Retail dealers have taken advantage of this craze for cheapness, and some profess to sell the finest tea at one shilling and sevenpence per pound. This is manifestly impossible, as large quantities are sold weekly, at the Commercial Sale Rooms, at and above two shillings per pound, to which has to be added the duty and all expenses. Many of the public believe these and similar statements, the result being that in many houses where nothing but fine wine is drunk really fine tea is unknown. There is no reason whatever that as great pride and pleasure should not be taken in having the finest tea carefully prepared as in putting a bottle of old port on the table. A cup of fine Ceylon or Darjeeling tea can be quite as well appreciated by a trained palate."

A SNEER AT INDIAN AND CEYLON TEAS.—This reminds another correspondent that there is a good opening here for a sneer at Indian and Ceylon

and an opportunity to deliver himself in praise of China teas. Cha Sze accordingly writes: "Your correspondent, 'Tea Taster,' is quite right as to the inferior quality of tea consumed in most houses where it is the usual thing to offer you a cup of tea which, to a cultivated taste, is simply undrinkable, and this when the preceding glass of wine has been carefully selected, and is of the choicest kind. If it comes to quality—real quality—we must go to China for the true tea flavoured kinds, with the delicious pekoe flavour only to be found in China teas, such as are used and appreciated in Russia. The Indian and Ceylon teas have nothing more than strength and pungency to commend them, and, from the different manner in which they are prepared, must necessarily contain a much larger quantity of tannin than the China leaf. To those who prefer this pungency and more or less rankness, the Indian and Ceylon teas will undoubtedly be most appreciated; but for choice richness of tea, flavour, and bouquet, let them procure Russian China tea, and they will at once recognise the difference. Such tea cannot be bought under half-a-crown per pound, and the difficulty is to get it in these days, when the popular and—may I add—degraded taste runs on nothing but strength and pungency. Nevertheless, it is to be had, and I would recommend those who appreciate a really choice cup of tea, free from injurious properties, to try this Russian tea, and if they get the right thing, the difference in flavour and smell compared with Indian and Ceylon teas will be a revelation to them."

HE DOES NOT HAVE IT ALL HIS OWN WAY.—The importer of tea from China is evidently tired of the waiting game, and is determined to make things "hum" on his own account, if possible. He is not having it all his own way in the correspondence debate, for "Inquirer" asks, with a touch of irony, "Cha Sze" would confer a great benefit on myself, as doubtless on very many of your readers, if he would kindly state where the Russian China tea which he so strongly recommends, and the difficulty of procuring which he admits, can be obtained." And "Cingalese" says:—"It is rather staggering to read the assertion of your correspondent, 'Cha Sze,' that for 'real quality' in tea we must go to China. It is true that the first steamer or two from Hankow bring every season a few parcels of more or less 'fine' tea, which fetch, say, from 1s 8d to 2s 4d per lb. for the Russian market, but the quantity of fine tea we get from China is a bagatelle to the amount of rubbish the Celestial Empire sends us. For pure rich flavour and bouquet high-grown Ceylon, Darjeeling, and Kangra Valley teas are not to be beaten, and if people would only take the trouble to pour off their East Indian teas, after infusing for three to five minutes, into another teapot, they would not have to complain of too much pungency or tannin. But after all, 'the proof of the tea is in the drinking.' In 1851 the home consumption of China tea was 112,000,000 lb., in 1891 it was 59,000,000 lb.; in 1881 the home consumption of Indian and Ceylon together was only 49,000,000 lb., in 1891 it was nearly 150,000,000 lb., and up to date this year the home consumption of Ceylon tea has almost doubled that of China, and, what is more, fastidious Russia is even buying Ceylon tea now."

TEA AND THE COMPLEXION.—Now we now exactly why tea has gained so much in popular estimation of late. It is used for the complexion. "It is well known," says the *Daily Telegraph*, "that physicians have often to urge upon ladies equipped with weak nerves restraint from over-indulgence in strong decoctions of the precious products imported from China, Assam, and Ceylon. But still quite recently the medical ban has not been evoked by consumption of the tea leaf in a dry state. Nevertheless, it appears, on undoubted authority, that cause for prohibition in this respect has arisen. It seems that there is a spreading idea among young women, and especially among domestic servants, that a pinch of unwatered tea-leaves is an infallible aid to the acquisition of a good complexion. In many instances

the believers in this infernal cosmetic have taken so many pinches that they have become seriously ill. Nevertheless they have still elected to suffer to become beautiful, and strong locks have had to be placed on tea-caddies by stern mistresses and house-keepers. Indeed, the desire for the leaf seems gradually to assume the form of a craze. It resembles opium-smoking or dram-drinking, and is thoroughly pernicious. Is it impossible that the appetite may have originally been created by the "facing" of Chinese teas with arsenic—a long-reputed skin-improver?"—*H. and C. Mail*, Oct. 7.

THE ATTACK ON INDIA AND CEYLON TEA.

To the Editor of the *Home & Colonial Mail*.

Sir,—We have read Mr. Stuart Cranston's, of the firm of Stuart, Cranston & Co., remarks on China tea *v.* Indian. We are surprised that a man in his position could be so ignorant of what he has been writing about. Mr. Cranston can no more persuade the British public to give up drinking Indian tea and go back to China tea than he can persuade people to believe that black is white.

Facts are stubborn things, and, write as he likes he must acknowledge that the United Kingdom consumes about double the quantity of Indian tea it does of China, although a few years ago the reverse was the case.

Mr. Cranston tries to make the consumer believe that Indian tea is more injurious to health than China tea, and talks about tannin and theine as if he were an analyst. He tells us that Indian tea contains two or three times as much tannin as China tea; such is not the case. Indian tea certainly does contain a little more tannin than China, but the proportion, instead of being two or three times as much, as Mr. Cranston states, is only about a fourth more than China, and, considering that Indian tea contains more theine and extract we think that a comparison between Indian and China tea, even from an analyst's standpoint, would not be unfavourable towards the former.

Mr. Cranston seems to think that the tannin could be extracted from Indian teas by the planters before shipping to this country, and talks about the Chinese extracting this tannin from their teas. Such an idea is absurd, and it is well seen that he has never been a practical grower of tea himself or he would never write such nonsense. His advice to Indian growers is really amusing, and if any of them would follow it (which I don't think they will), he tells them they will be rewarded by their Indian becoming like China tea, *soft and harmless*.

If the Indian planters will not follow his advice, he tries to frighten them by stating that the Chinese will soon learn, in self-defence, to retain the tannin, and send to this country hard teas to compete with Indians. We have read all kinds of nonsense written about teas and tea-growing, but Mr. Cranston's remarks are about the worst we have read for some time. We should strongly advise him to go with the times, and let the Chinese look after their own interests. If he remains much longer in the tea trade he must sooner or later grasp the fact that the consumers of tea in this country will not drink China tea when they can get good Indian tea at reasonable prices; and why should they, as there is no comparison in the relative value between Indian tea and China.

With reference to another matter to which one of your correspondents recently called attention viz., "Tea and the Water used in Infusing it," we have experienced similar results to those of your correspondent from many samples not only from Assam, but from all the districts of India. There is, however, one fact which we would like to draw attention to—namely, really fine, pure, indigenous Indian tea will come out well in any water; and it is only the hybrid teas, or teas of some peculiar flavour, which come out so differently in different waters.—Hoping you will excuse us taking up so much space in your valuable paper, we are, Sir, yours, &c.,

Belfast, Oct. 5.

VALENTINE AND CO.

To the Editor of the *Home and Colonial Mail*.

Sir,—As you point out, the importers of China tea have dropped into pamphleteering because they have no other resource. Mr. Cranston's pamphlet will have no effect. Indian and Ceylon teas have too firm a hold on the market to be disturbed by such a tirade. What is the value of the analysis he produces? It is a well-known fact that different analysts, even with the best intentions, produce marvellously different results. The pamphlet appears to me to be a dead failure, and it is particularly appropriate to the close of the silly season.—Yours,
—*H. and C. Mail*, Oct. 7. MINCING LANE.

TEA COMPANIES' REPORTS.

To the Editor of the *Home and Colonial Mail*.

Sir,—In perusing the various Calcutta financial papers, such as *Capital* and others, I notice that at this period of the year almost all the Calcutta tea companies publish for the benefit of their share holders, and no doubt also for the instruction of their managers or directors, pretty ample *interim* reports, in which the general situation as regards crop, outturn, price realised for the produce up to date, and frequently also the expenditure compared with the estimates, are referred to. A special advantage of this system is that it keeps up the interest of shareholders in the progress of their affairs and final results at the end of the season, whether good or evil come upon them, with somewhat less of a shock than would otherwise be the case.

The system is a very good one, and in view of the fact that most of the London tea companies defer the publication of their final reports and accounts until very far on in the spring, it might, I think, be very well imitated by them.

Would you kindly give publicity in your columns to this suggestion, and if possible ascertain whether the idea commends itself to any or many of your correspondents who have interest in the London tea companies?

It is only right to mention, perhaps, that a limited number of the more go-ahead and well-known companies *do* publish such interim reports, although as a rule they are a little late in issuing them, and I would suggest that the date of such issue should be, as near as possible, just six months from the approximate date of the issue of the annual report or of the annual general meeting.

Such reports need not necessarily give agents or secretaries very much trouble to compile, as only brief and general figures, such as are no doubt readily available in the companies' books, are all that would be wanted.—I am, Sir, yours, &c., A SHAREHOLDER.
—*H. and C. Mail*, Oct. 7.

CHINA TEA.

Sir Charles Dilke once spent twenty-four hours in Shanghai, and thereby qualified himself, as we all know, to speak authoritatively on Chinese questions. But though aware of that fact we had not, perhaps, realised that it involved, as a necessary consequence, exceptional knowledge about Tea. It was at the Chelsea Board of Guardians, last week, that he was able to silence all disputants by the extent of his acquirements on that point. "The consumption of China tea was (he said) almost extinct in this country. Ceylon sending three times as much as China, and India three times as much as Ceylon!" Whereupon a Guardian who had been presuming to criticise the quality of the tea supplied withdrew from the discussion in deference to the Chairman's "exceptional knowledge on the subject."—"The incident is, perhaps, not of much importance, except as illustrating the truly "exceptional" knowledge which is commonly displayed by speakers who venture to deliver themselves on Chinese topics. For let us see how Sir Charles' figures work out. The delivery of China tea during the first eight months of this year was, in round numbers, 40,000,000 lb. Three times that quantity would give Ceylon 120,000,000 lb., and three times that quantity

again would give India 360,000,000 lb.: a gross total of 520,000,000 lb.! whereas the actual figures were—for China, 39 750,000 lb.; Ceylon, 43,750,000 lb.; and India, 72,000,000 lb. Or, lest the deliveries of eight months only should be condemned as misleading, let us take the estimated import on the current twelve-month. China is expected to send, altogether, about 55,000,000 lb., which would give, by Sir Charles Dilke's table, 165,000,000 lb. for Ceylon, and 495,000,000 lb. for India! instead of 70,000,000 lb. and 108,000,000 lb., which are the actual estimates. There seems to be a fascination about "China's millions." Except that Sir Charles is belittling instead of magnifying facts, we might almost be reminded of a missionary enthusiast lamenting over the 400,000,000 of benighted heathen for whose chastening this rivalry has, perhaps, arisen.

The real figures, however, are discouraging enough and must surely end by starting even the Chinese Government out of its lethargy. Tea may be only one item in the commerce of the Empire; the quantity exported may be trifling compared to the great internal consumption; English demand may be only a single feature of the export trade. Still, a demand which once amounted to nearly 200,000,000 lb. is a consequential item; and China may rest assured that the Russian demand which seemed at one time to be growing as fast as the English shrank, will prove, in the long run, a delusive reed. It seems probable indeed that both the Russian and English markets have reached, temporarily, their approximate limits, both of expansion and contraction. It is unlikely that China tea will disappear completely from the latter, but the size of Russia is not an exact criterion by which to measure her capabilities of purchase. The bulk of her population will have to abate their taste for alcohol before they will have money to spare for buying tea; and nothing is more likely than that India and Ceylon will succeed, by-and-by, in conciliating the Russian as they have captivated the English taste. Already Ceylon teas have obtained an entry into the Russian market, and considerable shipments have been made this year to Odessa. With Japan gradually supplanting her in the United States China might therefore see reason to bestir herself vigorously indeed, if Orientals could ever be induced to look beyond the requirements of the hour.

Unwillingness to adopt the machinery which is employed to such economical purpose by its rivals may have something to do with the decline of China before their competition; though the excellence of her best teas goes to show that it is chiefly in an economic sense that that form of competition tells. Negligent cultivation is probably more important. The unpruned trees growing in comparatively uncultivated grounds, which have been so often depicted, cannot be expected to yield an average crop comparable with the bulk of the carefully-tended India and Ceylon leaf. But does this not bring us back after all to the question of inland taxation which seems to thwart every prospect of commercial development in China? How, it may be asked again, can tea which is subject to an average tax of 30 per cent. compete with tea which is put on board ship free? Would not that 30 per cent. just enable the grower to expend on his plants the time and attention they require? Chinese Tea merchants appreciate the situation; and certain inquiries made, lately, from Peking would seem to indicate that the Government itself is at last awaking to the truth of the fable of the golden egg. But even if the Board of Revenue could be brought to decree the immediate abolition of *lekin* and the reduction of a Customs valuation which is so monstrously in excess of the reality—there would remain very much to be done if China is to hold her own in the world's market. All who are interested in the China trade must be content to put their hands in their pockets and exhibit something of the enterprise which has helped forward India and Ceylon. It has been truly said that the English housewife who would buy a pound of China tea can actually not procure it. She can buy pure Assam, or pure Ceylon, as much as she wants;

but China is only procurable as a mixture with other kinds. There may be shops in existence which form an exception to that rule, but they are practically non-existent to the everyday buyer. Nor is the slightest attempt ever made to challenge the standing advertisements that Ceylon teas beat the world in cheapness and fragrance and flavour and every other virtue. We may be certain that Japan as well as India and Ceylon, will take care to be adequately represented and to advertise, each, the excellence of its produce, at the forthcoming Chicago Exhibition. The desirability of China Tea being similarly pushed to the front has, we know, been mooted. Have arrangements been perfected for carrying out the proposal? All this requires money and effort, and it may be argued that it is the Chinese, as the people most interested, who should take the necessary action. But Chinese require help and guidance. The Chinese Government need that Sir Robert Hart should impress upon them the danger to their revenue, instead of contending, as he once did, that there is no evidence that the trade is in need of fiscal relief. Chinese merchants need to be put in the way of opening shops and of having them advertised in London and other great cities, and of having provision made for the supply of China tea, as well as models of Chinese junks, at the forthcoming American Exhibition. We believe, as we have already said, that they appreciate the situation, and would be willing to contribute to those ends; nor do we believe that the majority of foreigners interested in the trade would refrain from giving their meed of help if those projects were taken energetically in hand and given purpose and shape. If all concerned, from the Government down to the grower, would put their shoulder to the wheel, we are far from believing that the consumption of China tea is "almost," or likely to become, "extinct." But there never was a time in the world's history when it was more necessary for men to help themselves: and Chinese tea men are certainly no exception to the rule.—*L. and C. Express*. Oct. 7

A NEW TEA DRIER—Mr. Humphry Aram Hole, tea planter of Atgram, Sylhet, has applied for registration of an invention for "An improved tea drying machine which can also be used for withering fresh tea leaf."—*M. Times*.

IS AMERICA AS A RICE-GROWER TO COMPETE WITH INDIA?—The *Pioneer* states:—

The latest American papers received contain some news of considerable interest to the rice exporters of Rangoon and Calcutta. The new rice crop in the Southern States is said to be the most extraordinary ever raised in America, and if the statements of the New Orleans press can be credited, one can well believe it. The bulk of the rice hitherto grown in the United States was raised in South Carolina and Georgia on their low-lying lands: but some pushing men from the Western States migrated southwards some half dozen years ago, and their energy and enterprise have resulted in an enormous extension of the area of cultivation. Louisiana alone will raise more rice this year by a hundred million pounds than the entire United States ever raised before. Two years ago there were some 12,000 acres cultivated in rice; this year the area had risen to 179,000 acres; and we are told that next year the acreage will be doubled. Within the last few years the export of rice from India to South America has been rising rapidly; last year it amounted to 1½ million cwt.; and there is even a small trade with the United States. With the enormous development of rice cultivation in the Southern States, however, it is plain that the competition for these markets will become much more acute. Unless the present season in the Southern States is to be accepted as altogether abnormal, the chances are that Indian grown rice will be gradually excluded—a somewhat disconcerting prospect if we remember that, omitting the last two years, when the conditions were abnormal owing to a failure of the harvest in Japan and an extraordinary demand in Europe, the exports of India have been practically stationary.

MR. WILLIAM JACKSON AND HIS TEA MACHINERY.

What Mr. John Walker was in regard to coffee machinery, that and much more Mr. William Jackson is with reference to the appliances required for the manufacture of tea. We say "much more," because coffee machinery went little beyond a good pulper, while tea requires withering, rolling, fermenting, drying, sifting and sorting and cutting appliances, all of which Mr. Jackson has invented or improved and provided for the use of tea planters. What the extent of the benefit thus conferred on his brother planters by Mr. Jackson (he began life as a planter) must be, we can judge from one fact mentioned in an article which appeared in the *Calcutta Englishman* last year. The writer stated that the 3,000 of Jackson's rollers sold had each saved the labour of 120 coolies: that is, 360,000 coolies in the aggregate. This, apart from putting an end to weary night work and the hard, slow and objectionable process of hand rolling. Scarcely less are the merits of Mr. Jackson's driers, culminating in the grand "Britannia" capable of turning out 300 to 400 pounds of well and equally dried tea. Compare this with the process of tea roasting, as so many of us remember it in pre-machinery days and as thus graphically described in the article to which we have referred:—

After rolling the leaf it had to be dried, and in the whole of the British colonies not a tea-drying machine of any kind existed in 1870. The leaf was dried on the old Chinese method over charcoal fires, one pound of charcoal being required to produce one pound of dry tea ready for the market, and allowing for wastage, it required eight pounds of wood to make a single pound of charcoal: consequently eight pounds of firewood went to the production of one pound of dry tea.

Here, again, by this primitive method of drying the quality of the tea often suffered, as a bright clear charcoal fire would give off a much greater heat than the dull one newly replenished with fresh charcoal. No even temperature could be relied on for drying the leaf by means of these fires, and no even flavour could be produced in the tea.

With hundreds of these fires spread over the floors of large drying-houses, the effect of the fumes on the health of all who were engaged in the work may be imagined. Nor was this all. The charcoal had to be made in the forests, and as this was one of the operations which planters could not control, it was a part of the system of tea-making to which they most strongly objected.

The "Britannia" requires only three-fourths of a pound of wood fuel to dry a pound of tea, in a machine which, acting automatically, needs only the attendance of a few coolies to feed it and remove the perfectly and equally dried tea,—unhealthy charcoal fumes and weary and depressing night work being obviated. Mr. Jackson's fame as an inventor and gradual perfecter of tea machinery is largely founded on his Excelsior roller, the crank principle of which is said to be—has been, indeed, held by the Supreme Court of this island—to be unique. But Mr. Jackson is evidently determined to gratify his honourable ambition of being a "universal provider" of tea machinery for all branches of manufacture; and "not standing on the order of his going" he has just succeeded, by improving on patents for which he honestly paid, in providing a withering machine, which promises to be as great a boon to planters as those by which the processes of rolling, drying, sifting and cutting have been so wonderfully facilitated, that the language used by the *Calcutta* journalist is really not exaggerated, when the results of Mr. Jackson's useful inventions are summed up thus:—

It is undoubtedly due to William Jackson's determined efforts in inventing and adapting his inventions to the manipulation of tea leaf that the British possessions of Assam and Ceylon have been able to compete so successfully and profitably with China in the economical production of tea, and are now making a good profit on 9d per lb. It is also in a great measure due to William Jackson's efforts that the British public have now the boon of being able to get a far cleaner and better tea at 1s 2d per lb. than could be obtained for 3s per lb. 20 years ago. Most of our readers are acquainted with Mr. Jackson's rollers, driers, sifters and cutters; but of his most recent achievement they may be glad to have details. We therefore quote from a pamphlet issued by Messrs. Walker Sons & Co., Limited, Colombo, by whom the witherers are to be manufactured, Mr. Jackson's description of his patented adaptation and improvement of Turton's Cyclone, which has yielded good results in India:—

The machine will be made in one size, the chamber of which will be 6 feet 6 inches square, two sets of rails inside and one on either outer side.

The framework of the chamber will be made of teakwood, and the lining of corrugated iron, and a neat English section of rail used.

Sixteen wrought iron trolleys will be supplied, with 320 wire mesh trays with teakwood frames, each 3 ft. 6 in. by 3 ft. square, and capable of taking 800 lb. of green leaf at a charge.

A 5 ft. dia. Blackman fan for a speed of 400 rev. per min. will be supplied with each machine, and the whole got up in a very neat substantial form.

No air-heating stove will be supplied unless specially ordered, and this will be charged for extra.

I made a test of the machine on the Great Western Estate under the following conditions:—

Very wet day, with atmospheric temperature standing at 65°. Leaf came in from the garden as wet as it could be at 11 a.m., at 11-30 the machine was charged with 800 lb. temperature raised to 85 degs., and the machine fan started, and at 5-30 p.m. the leaf was ready for rolling. No test could possibly have been made under more adverse circumstances, and if the leaf is kept over night before being treated, the machine will do a large amount of work, equal to the best system of natural withering.

The apparatus will save an enormous amount of withering space and buildings, and being controllable, the Planter can manipulate his leaf just as suits him best. Price in Colombo R4,000.

Moro even than in India, we believe, have Mr. Jackson's excellent and substantial machines been purchased; and he has determined to show his gratitude for the past and his determination to slack no effort to secure favour in the future by resolving to employ Mr. A. F. Corrie, a well-known Ceylon tea planter, to itinerate through the tea districts at his (Mr. Jackson's) expense,

For the special purpose of chatting over the successful and unsuccessful methods of operating our machines, and helping Planters by suggestions and otherwise to get into the best system of manipulating the leaf by our appliances, and I much trust his services may be useful in our mutual interests.

Mr. Corrie will be fully qualified to suggest and advise, for Mr. Jackson states:—

To show that I retain the keenest interest in my patent machinery after it has reached the tea houses, I have engaged the services of Mr. A. F. Corrie, a successful Planter and user of our machinery, have sent him to Messrs. Marshall, Sons & Co., in England, to gain all the latest information at headquarters. From the "note by Mr. William Jackson," in which the above is stated, we quote further:—

I have also to state that I have purchased from the Patentees in Ceylon their patent for the exclusive right to make and use Brass Battens on rolling surfaces, and although these Brass-mounted Rollers are a little more expensive than the wooden ones, this extra cost insignificant, when compared with the great improvement effected in the

working and durability of these machines, and I would strongly advise planters requiring more rolling power to carefully look into this before making their selection.

I have also purchased from the Patentee in India and Ceylon his patents for a withering machine, many of which are doing excellent work in India, and have done for some years. One of these has been erected on the Great Western Estate, and through the courtesy of Mr. Thomas Mackie I am allowed to state that proprietors and managers may inspect this machine by making appointments with Mr. Mackie.

Believing as I do that it is of the first and greatest importance to wither the leaf well, I have given the most careful attention to this machine, which promises to be a great success, and as users of it in India state that it withers leaf quite equal to the best natural system. I think it would be well for those interested to have a look at it. Finally Mr. Jackson states that his personal efforts will be continued in the field which he has made so much his own:—

I now leave for England to continue my efforts in improving and keeping tea machinery up to the mark, and I thank all who have contributed to make my visit to your world-famed Island such a pleasant one. The pamphlet which we are noticing, and from which we have quoted, contains the memoir of Mr. Jackson which, with the reproduction of an excellent photograph, appeared in the *Indian Planters' Gazette* and was copied into the *Observer*. From this it appears that Mr. Jackson must be in the prime of his physical life and intellectual energies; for he was born so late as 1849, on Lord Kintore's estate, Keith Hall, Aberdeenshire. From earliest childhood the instinct of the future engineer and machinist was so strongly developed that "Geordie Widd" (Wood) had to threaten to put baby Jackson in the furnace, if he "speered ovy mair questions about the thrashing machine." But neither by fire nor by watery mud was his useful life destined to be terminated; for in his advent to Assam, where his genius was developed in the direction of machinery, he had a somewhat narrow escape, thus described:—

When he reached Kookleamook, the steamboat station on the river, it was about 4 p.m., and a letter awaited him from Mr. John giving instructions to put himself in the bearer's hands who would bring him safely to Mazengah. This was done, and the first two hours was spent in a dugout boat which took him into a *bheel* or shallow piece of water, the edges of which terminated in mud in which the buffaloes wallow. Here an elephant was waiting him, which was brought alongside the boat, and caused to kneel down in the mud for Mr. J. to mount.

On attempting to do this, however, the monster beast trumpeted so loudly, that Mr. Jackson made a bounding leap, and landed himself headlong in the mud and water as far from the beast and boat as he could, out of which mess he was lifted by the coolies and put on the *hattie*, and in this state reached Mazengah about 10 p.m. little or none the worse of the fright he had got. Then after much experience of wearying work through the night hours, necessitated by the absence of such appliances as now, thanks mainly to him, are at the disposal of every manufacturer of tea,

He made his first resolution in the lonely midnight hour that he would produce a machine that would do the work so as to give him time for sleep at any rate, and before 3 a.m. next morning he had made a model disclosing exactly the motion imparted by coolies in rolling leaf on tables by hand.

His career since then, with the interruption of the litigation with Mr. Kinmond, who bears witness to his honorable conduct, has been successful in every sense. He has succeeded in providing appliances of the most superior and effective quality for the use of tea planters; and none of these at least will grudge him, or his agents

Messrs. Marshall of Gainsborough and Messrs. Walker of Colombo, the due rewards of hard work, of brain and of body, well and honestly done. Mr. and Mrs. Jackson reside on the banks of the Dee, not far from Aberdeen, whence the magistracy and leading inhabitants went not long ago to see how their villa and Mr. Jackson's model-rooms and workshop looked when illuminated by the electric light.—Many will join us in good wishes for Mr. Jackson's extended life in good health and accompanied by well-deserved prosperity.

THE TEA ROLLER PATENT CASE.

THE PETITION OF APPEAL.

The following is the petition of appeal in the case William Jackson of Aberdeen v. Alfred Brown of Colombo, the Colombo Commercial Company, Limited.

The petition of the above-named defendants humbly sheweth:—

(1.) On the 13th of September, 1892, your Hon. Court set aside the judgment of the District Court of Colombo in your petitioners' favour, and entered judgment in favour of the plaintiff with costs.

(2.) Your petitioners, being desirous of appealing against your Lordship's judgment of the 13th day of September, 1892, to Her Majesty in Council, hereby apply to your Hon. Court to have the said judgment brought before your Hon. Court collectively by way of review.

The following are the grounds of your petitioners' proposed appeal and reasons for submitting that the case is a fit one for appeal to Her Majesty in Council. (a.) That the claim in this action was to restrain the appellants from an alleged infringement by them of a patent granted to the respondent, and for damages and in value exceeding Rs.5,000 and costs of suit. (b.) That the claim involved questions of public importance and interest in that it was sought to restrain the appellants from using or selling at invention of great practical utility in the tea enterprise of Ceylon.

And for further reasons for appealing from the said judgment the appellants would submit as follows:—

I.—The Hon. the Supreme Court has failed to appreciate what is at issue between the parties, and has misunderstood the facts upon which this action must be decided.

II.—The learned Chief Justice has found that the plaintiff had a perfect legal right, and did appropriate to himself and secure by patent all the novel and useful mechanical contrivances contained in the Standard and developed in the Excelsior and that, therefore, he is in possession of a patent for a machine illustrating a principle in the conversion of motion which had never before been practically applied, which is described by the learned Chief Justice as follows:—

"By peculiar mechanical means and contrivances developed in the machine a manner of rolling tea is secured to be substituted for, and made to resemble, tea rolled by the human hands."

And the learned Chief Justice has read the word "it" in the fourth issue settled in the District Court to refer to the said invention. The appellants submit that this view of the plaintiff's invention is incorrect.

(1.) The Standard roller was never patented in Ceylon, and public right to the Standard roller had been acquired, one of these machines having been imported into Ceylon in 1879, and used to roll tea leaf on Loolecondura estate in the district of Hewaheta, Ceylon, from that year—as admitted by the respondent in his evidence in the District Court.

(2.) The plaintiff obtained on the 4th day of July, 1881, in conformity with the provisions of Ordinance No. 5 of 1859, a grant under the public seal of the Island of Ceylon for the sale and exclusive privilege of making, selling, and using a certain new and useful invention entitled—"An invention for improvements in machinery or apparatus for rolling tea leaf," and in the specification of this invention filed by him he declares what, he considers to be novel and original and therefore claims as the invention. *First.* The

arrangement for transmitting motion to the top rolling surface through the case or jacket surrounding it whereby such rolling surface is left free as regards vertical movement from the mechanism producing it. *Second.* The arrangement for turning over the jacket B to give ready access to the upper and under rolling surfaces. *Third.* The combination in machinery or apparatus for rolling tea leaf of a crank shaft having three crank movements so arranged or constructed as to cause the rolling surfaces to move simultaneously across each other all substantially as hereinbefore described—and the plaintiff having claimed the above three points of novelty in his invention has disclaimed all else (Harrison vs. the Anderson Foundry Company, L. R. 1 App. Ca. 574)(G221) and his invention cannot be infringed except in respect to these three points of novelty.

(3) The word "it" used in the fourth issue settled in the District Court, refers to the first claim of novelty of the plaintiff's invention set forth in the first of the issues settled in the District Court, and not to plaintiff's machine as a whole.

III. The appellants deny that they contend, or ever have contended, (1) that because the connecting plate or link "performs the part in machines which is assigned to a connecting rod, therefore everything connected with it can only be a connecting rod" (2) Or "that it is not possible to speak of 'case or jacket' as including the four sided box from lid and bottom and through which the upper rolling surface passes." (3) Or "that the thin cylinder of metal which is inserted as a lining to the cylinder of the defendants' machine and which confines the upper rolling surface and which is moveable at will corresponds to the 'case or jacket' of the plaintiff's machine," i.e., the case or jacket as described by the plaintiff himself in his evidence in the District Court.

IV. The defendants contend, and have always contended, that the 'case or jacket' of the plaintiff's machine is the four sided box from top to bottom through which the upper rolling surface passes and from which it receives its motion, and that the 'case or jacket' which is made of wood in the model of the plaintiff's machine, which is moveable at will, and which contains the leaf being rolled corresponds to and is the exact equivalent of the thin cylinder which is made of brass in the model of the first defendant's machine, which is also moveable at will, and which also contains the leaf.

V. The appellants submit that their machine cannot be "the result of an adoption of the mechanical principles and contrivances which found practical adoption and arrangement in the plaintiff's machine varied no more than in unessential form, but with certain improvements made by the defendants, and which are practically useful only in connection with it," because, if this were so, then it would be possible to take one of the plaintiff's machines and adapt to it the improvements in tea-rolling machinery possessed by the first defendant's machine, whereas the appellants submit that it is impossible to use the improvements in tea rolling machinery possessed by their machine in conjunction with the means used by the plaintiff for imparting motion to the top rolling surface.

VI. The appellants submit that on the facts found by the learned Senior Puisne Justice, judgment should have been given for the defendants in this action.

The learned Senior Puisne Justice finds "that the best evidence in this case proves that the 'case or jacket' is the sides which surround the upper roller which forms a space or box into which the tea leaf is poured, and which keeps the leaf together while it is being rolled between the surfaces of the two rollers. The projections which connect this case or jacket with other parts of the machine have been called by some of the witnesses a connecting rod, and in a sense that part of the projection which joins the case to the gearing is a connecting rod, but the latter part of the evidence, and I think a reasonable use of the words, leads me to the conclusion that a part of the "jacket is

the thickened band which passes round the case or jacket," and which at once serves to connect it with the gearing, and to give it strength."

The appellants beg to submit that the definition of the "case or jacket" properly laid down by the learned Senior Puisne Justice is in their opinion absolutely correct; but they do not agree that the thickened band which passes round the "case or jacket" can be held to be a part of the case or jacket. And the appellants submit that the learned Senior Puisne Justice has misunderstood the evidence of the scientific witnesses with reference to this part of the machine.

The appellants contend, and they submit that their contention is fully borne out by the evidence of the scientific witnesses both for the plaintiff and for the defendants, that the thickened band is a connecting rod formed into the shape in which it is used to carry and lend support to the case or jacket. The learned Senior Puisne Justice appears to consider the connecting piece alluded to as that which connects the box with the gearing. The appellants beg to submit that that is not what the scientific witnesses stated. The connecting rod is that which connects and completes the driving mechanism. The undoubted mechanical authority, D. J. M. Rankine thus defines a connecting rod (Rankine's Applied Mechanics p. 458):—"The pieces which are connected by link work if they rotate or oscillate are usually called crank beams or levers. The link by which they are connected is a rigid bar which may be straight or of any other figure. The straight being the most favourable to strength is used when there is no special reason to the contrary. The link is known by various names under various circumstances, such as coupling rod, connecting rod, crank rod, eccentric rod, &c. It is attached to the pieces which it connects by two pins about which it is free to move."

VII. The learned Senior Puisne Justice finds that "the motion is not transmitted precisely at the same place or in the same way in the defendants' machine as in the 'plaintiffs,' and he goes on to say 'but the exact way in which the motion is transmitted is not the question.'"

The appellants would beg to submit that on the contrary this is the whole question. It is the way or arrangement of transmitting motion to the upper rolling surface which the plaintiff states has been pirated by the defendants, and, if the Senior Puisne Justice finds that the defendants do not transmit motion to the upper rolling surface in the same manner as the plaintiff does, then the defendants have not pirated the plaintiff's invention.

Wood, V. O., in Curtis vs. Platt (S. T. R. N. S. 246) has laid down that "if you find a specific mechanical improvement claimed then you must hold the person strictly to that particular mechanical device which he has claimed for effecting the object he had in view, and if he says it is to be done in one precise and particular way, he must be held to that one precise and particular way, and those who have, *bona fide*, employed a different system and a different way must not be held to have infringed."

VIII. The appellants submit that to form a correct opinion on the merits of this action it is necessary that the following points be kept distinctly in view:—

(1) That the plaintiff stands or falls by what he has specified and claimed in his *Excelsior* patent, and that the defendants stands or fall by what they have manufactured, sold, and used. (2) That the *Standard* roller, a machine which carries into effect the principle of rolling tea leaf confined in a box between two superposed rolling surfaces was in use and publicly known in Ceylon for some years previous to the date on which the plaintiff filed his specification of the *Excelsior* roller: (3) That the *Standard* roller was never patented in Ceylon. (4) That the plaintiff's *Excelsior* patent is for an invention of a new combination of well-known parts, and not for a new invention.

In the *Standard*, *Excelsior*, and *Triple Action* tea rollers the idea or principle is to confine a certain quantity of tea leaf in a box having neither top nor bottom, and to operate on the leaf so confined by two

rolling surfaces, the one placed at the bottom and the other at the top of the box; so that, virtually, these rolling surfaces form the top and bottom of the box, and it will be seen that, as the tea leaf becomes rolled and compressed together, it is necessary to approach the two rolling surfaces, and, to permit of this being done, the upper rolling surfaces in the Standard, Excelsior and Triple Action tea rollers has been made of less area than the inside area of the box. In the Standard roller the driving mechanism is directly attached to the upper rolling surface in such a manner that vertical movement of the upper rolling surface is impossible, and, therefore, to approach the two rolling surfaces of the Standard roller the cumbersome method of raising up the heavy lower rolling surface had to be adopted.

The plaintiff, in his Excelsior roller, to avoid this cumbersome method of approaching the two rolling surfaces, gave up positive driving of the upper rolling surface, and attached his mechanism directly to the box, leaving the upper rolling surface to be pushed about by the sides of the box, and perfectly free, as regards vertical movement, from the mechanism operating it, and this free vertical movement is the very pith and marrow of the plaintiff's first claim. It is the result sought by the arrangement of transmitting motion adopted and patented by him.

The appellants beg however to submit that though the plaintiff's Excelsior roller possesses advantages not found in the Standard, still that both the Excelsior roller and the Standard roller have serious defects which cannot be avoided with the arrangement of transmitting motion to the upper rolling surface adopted in these two machines, viz., giving positive motion to only one of the parts, leaving one to be pushed about by the other. The upper rolling surface in both these machines has no rolling effect, its sole office being to keep the charge of leaf pressed hard down on to the lower rolling surface which does all the work. The upper rolling surface in both these machines has to be made a working fit to the box, or the box would very soon be broken to pieces by the impact of the lid on it, and the leaf is therefore contained in practically an air tight box, and it will be readily understood that great heat is generated in the leaf while it is being rolled, whereas it is very advantageous to keep the leaf cool while undergoing this process of manufacture.

In the Triple Action tea roller sold by the appellants, positive motion is imparted to all three parts, viz., the box and the two rolling surfaces independently of each other, no one of these three parts driving the other, and not only is the appellants' roller outside the spirit of the plaintiff's claim, but it is submitted that it is equally clearly outside the letter of it. The top rolling surface is not driven "through" the box: both are driven by one and the same reciprocating part, but neither transmits motion to the other. It is submitted that it cannot be said that these two things are identical. In the ordinary construction of steam engines the slide valves are driven from the same shaft that drives the fly-wheel, but it cannot be argued that therefore the slide valves drive the fly-wheel.

This arrangement of independently driving the three rolling parts, viz.:—the box and the two rolling surfaces, it is submitted, has enabled the first defendant to avoid the two serious defects contained in both the Standard and Excelsior rollers previously alluded to. As the upper rolling surface of the Triple Action roller is not driven by the sides of the box which surrounded it, the first defendant is enabled to provide ventilation by leaving a free margin of space between the upper rolling surface and the surrounding case or jacket, and again as the upper rolling surface of the Triple Action roller is not driven by the case or jacket surrounding it, the first defendant was able to give the upper rolling surface of the Triple Action roller an independent rolling motion; so that the leaf is being operated on at both ends of the case or jacket, whereas in the Standard and Excelsior rollers the leaf is being rolled by the lower rolling surface alone.

The appellants submit that the substance of the matter is that the plaintiff has claimed a definite mode of driving the upper rolling surface, viz., that it gets

its motion not from any part of the mechanism, but from the sides of the box surrounding it, and that is a totally different thing, it is submitted, from the sides of the box being driven by the same thing that drives the upper rolling surface.

To be within the claim of the plaintiff, it is submitted that it must be the sides of the box that do the driving.

The appellants deny that the bearing in the bow bracket of the defendant's machine can be regarded as the equivalent of "the case or jacket" of the plaintiff's machine as held by the learned Chief Justice, but for the sake of argument allow them to be mechanically equivalent, and still the defendant's machine would not infringe the plaintiff's patent, for by the substitution of this mechanical equivalent, distinct improvement in tea rolling machinery are obtained for a distinct purpose, which cannot be obtained by the arrangement used by the plaintiff, and the appellants submit that it is quite open to any person to substitute a mechanical equivalent for another without infringing that which it is substituted for provided that a distinct public benefit be obtained by the new method over the old. Lord Westbury, L.C., remarks in *Curtis vs. Platt*, with reference to a patent taken out by Mr. Platt for improvements applicable to mules, &c., might in this matter be paraphrased thus:—*Mr. Brown*, although he to a certain extent avails himself of the same elements, yet put them in a different continuation he makes their effect on the upper rolling surface different, he makes the results different. It has been urged that *Mr. Jackson's* invention is capable of or might be made to produce a result co-extensive and co-equal with *Brown's* invention. If it is so, all I can say is that *Mr. Jackson* has not given to the world the benefit of a description of the mode by which they may be effected. I think it is a very material thing * * * that in comparing the two things together the result on the work done by *Brown's* patent are *treble*, and if *treble*, *treble* more beneficial than the work done by *Jackson's* patent.

The appellants submit that the above exactly deals with the point at issue in this action, and they further submit that the superior usefulness of the Triple Action roller cannot be attributed to the improvement added to the invention secured by the plaintiff's patent, because the mechanism used by the first defendant to produce this desirable result cannot be used in conjunction with the arrangement patented by the plaintiff for the transmission of motion to the top rolling surface, and the appellants again rely on the doctrine laid down by Lord Westbury in *Curtis vs. Platt*, with reference to the doctrine of mechanical equivalents when directed to secure a certain end that was previously well-known.

The rolling motion given to the rolling parts of the Triple Action roller, viz., the case or jacket and two superposed rolling surfaces, is obtained by an arrangement of mechanism consisting of two opposing vertical crank shafts, each having two crank pins connected by connecting rods, plates, or pieces, and it is the motion produced by these two connecting rods, plates, or pieces to which the rolling parts are attached that rolls the tea leaf, in continuation with an additional rolling motion given to the upper rolling surface taken from a continuation of one of the opposing crank shafts.

Because one of the motions given to the top rolling surface is isochronal with the motion given to the case or jacket, it does not follow that, therefore, either drives the other. In all rolling machines on the principle of the Standard, Excelsior, and Triple Action, the motion given to the top rolling surface must be more or less isochronal with that of the case or jacket, to prevent the one coming into collision with the other and, indeed, if this latitude of interpretation be allowed, it might be argued with equal force that the arrangement used in the Standard roller, viz., that of driving the case or jacket by the upper rolling surface, is the same as that used in the Excelsior roller, viz., driving the upper rolling surface by the case or jacket, and the Plaintiff's Patent is void.

With reference to the specification of the Triple Action roller filed in the Ceylon Patent Office, and considered as part of the evidence, despite the objection of Appellants' Counsel, the Appellants would submit as before that the issue is not what they have said or written, but what they have done to the effect of infringing the Plaintiff's patent, and that the specification, at best admissible in evidence only for purposes of prejudice, is so admissible only when it is an absolutely true description of the machine that is said to infringe, and that with reference to this specification the Appellants have pointed out the clerical error which has rendered it an erroneous description of their machine. The proof that the word "by" is a misprint for "of" will be found in the preamble of the 1st Defendant's specification, where it is stated that the leaf is rolled or twisted by the combined action of the table, the hollow cylinder, and the lid, all of which have motion directly imparted to them.

Lastly, with reference to the finding of the District Judge, viz:—"As the Excelsior was an improvement on the Standard, so the Triple Action roller is an improvement on the Excelsior, and is decidedly a far more efficient and satisfactory machine," the appellants would beg to suggest that the D. J. intended to convey not that the first defendant had added improvements to the peculiar means of transmitting motion to the upper rolling surfaces which the plaintiff had patented, but that (both the plaintiff and the first defendant working on what was admittedly public property, viz. the rolling of leaf contained in a box between two superposed plates) the improvements possessed by the Triple Action roller were greater, more useful, and more advanced than the improvements possessed by the plaintiff's Excelsior roller over the Standard machine.

Your petitioners therefore pray

1. For a certificate in terms of section 781 of the Civil Procedure Code, to the effect that the present case in value and nature fulfils the requirements of section 42 of the Courts Ordinance 1859, or that it is otherwise a fit one for appeal to Her Majesty in Council.

2. That upon grant of such certificate and upon security being duly given for the costs of the respondents the judgment of the Supreme Court, dated the 13th day of Sept. 1892, be brought before your Hon. Court collectively by way of review, and that the judgment of the District Court of Colombo, dated the 2nd of May, 1892, be restored and confirmed.

3. For his costs in this behalf incurred, and for such other reliefs as to your Honorable Court shall seem meet.

Settled by Messrs. D. F. Browne and F. Dornhorst, Advocates.

(Signed) HECTOR VAN CUYLENBURG,
Proctor for Defendants-Appellants.

BARK AND DRUG REPORT.

(From the *Chemist and Druggist.*)

LONDON, Oct. 6.

CINCHONA.—The auctions held here on Tuesday were very small in extent, and consisted principally of Ceylon bark. The catalogues comprised:—

	Pkgs.	987 of which	804 were sold
Ceylon cinchona	...	74	do
East Indian cinchona	...	30	do
Java cinchona	...	277	do
West African cinchona	...	466	do
	1,824	1,385	

The assortment was very poor; no yellow, and few grey barks of Eastern growth, being offered, but there were some very fine parcels of red chips and shavings, both original and renewed, from Ceylon. At first the prices appeared to show a lower tendency, but the competition gradually improved, and at the close of the sales the unit was practically equal to that of the previous auctions, and slightly above the average at last week's Amsterdam sales. It may therefore be placed at 1½d all round.

The approximate quantities purchased by the principal buyers were:—

	Lbs.
Agents for the Mannheim and Amsterdam works	164,185
Agents for the Auerbach works	50,990
Agents for the Frankfurt o/M. and Stuttgart works	47,148
Messrs. Howards & Sons	18,214
Agents for the American and Italian works	12,655
Agents for the Brunswick works	8,940
Sundry druggists, &c.	24,760
Total quantity sold	326,272
Bought in or withdrawn	20,660

Total amount of bark offered 346,932
 ESSENTIAL OIL.—Lemon-grass oil is quiet at 1½d per oz on the spot; for arrival there are buyers at 1½d "c.i.f." terms.

NOTES FROM SOUTH-EAST WYNAAD.

There is now so much life and hope among the planters in S.-E. Wynaad, that a few words as to what I saw and heard, during a run through the district will, I think, be interesting.

First, as to the old staple, coffee. Leaf disease is much less virulent than of old; there was a great improvement in this respect last year, and it is even much less this season. There are great discussions as to the cause of this. It is asserted by some that the improved cultivation is quite sufficient to account for the improvement in the healthiness of the trees. A leading planter declared his opinion that leaf disease is caused by the earth-bound diseased condition of the coffee roots, and is not climatic in any way.* He believes that if the soil had always been dug up among the trees thoroughly, there would never have been much damage from disease. However, there is very much less damage from leaf this year, and last year, even where digging of the soil has not yet been attempted; and the general opinion is that the disease is wearing itself out, and the improved cultivation is the outcome of greater confidence, from the improved appearance of the trees.

Stirring up of the soil is now generally carried out, though in many different forms. Deep renovation pits cut close to the stem of the tree, three feet by two feet, and two feet deep, cutting off all the principal lateral radical roots, turning sub-soil to surface, the pit being filled up, with prunings, weeds and surface soil to supply food to the young spongiolate feeding roots that start from all the old cut roots. I saw one amazing change in an old estate that two years or so ago seemed hopeless from leaf disease; the trees were there, and the soil splendid, one of these big pits to every tree has made a new place of it again. They are now granted trees full of wood and crop. Elsewhere continuous trenches two feet deep were dug across the hill side between every alternate row of trees, but as these trenches could not be filled up soon enough, and remained open during last season's hot weather, subject to a drought of 151 days, the improvement has not yet been marked, the trees only now beginning to feel the benefit and make root, though on another Tea estate, where with prunings and manure the trenches were at once filled up, the improvement is most striking. Another planter is digging deep trenches three feet wide by two feet deep between all the rows of trees, not across the hill side, filling up at once with weeds and soil; others are digging up the whole soil eighteen inches deep to within a foot or less of the tree stems, others again are only digging nine to twelve inches, while some are loosening the soil with forks into big clods. Others again are making eighteen inch pits in the centre of four trees, and some are making deep pits three feet cube, and spreading the dug up soil over the a joining surface,

* This opinion was prevalent in Ceylon above time, but experience falsified it. The better the soil and the stronger the bushes the greater, no doubt, the power of resistance, and those which have survived in Southern India cannot but benefit by the cultural operations described; some of which would be equally beneficial in the case of tea.—Ed. T.A.

leaving the pits to be filled in time with weeds and wash, while there are planters still continuing the old system of scraping and burying weeds. It is evident that any system of tillage is of benefit to the trees, and the more thoroughly it is done, the better; the cost varies from R10 to R25 per acre.

There is also great diversity in the systems of pruning in vogue. On one large property Laboret's old Jamaica system of pruning is carried out. The only wood left for bearing must be direct from the primary branches. All secondary wood after crop is ruthlessly removed, and almost all the enormous growth of young shoots, caused by such severe pruning is handled off during the rains, leaving only the few shoots on the primary branches for next crop. Other men are encouraging all the wood they can get on their trees, removing nothing but heart wood and suckers, to let light into the centre, occasionally cutting off dead wood and excessive growth. Every variety of pruning is to be seen between these extremes; but the general idea is that leaf and cover to protect the blossom during the hot weather saves crop, and experiments are being made to find the effect of pruning at different periods of the year, instead of immediately after crop, in the hottest weather.

The subject of manure is also one that gives rise to great variety of opinion. One leading planter considers the application of all organic manure a waste. He is a firm adherent to Ville's principles, and urges that the mineral deficiencies of the soil should alone be supplied. On these grounds he has been applying bone alone or rocks, as containing lime and decayed Feldspathic potash. His neighbour confines his attention to cattle dung only, and carts in dry bratties at a cost of five rupees per load from great distances all round. One planter was applying bones and poonac to help some heavily bearing trees. Another denies the possibility of benefit from poonac, and I saw large quantities of cattle dung in the neighbourhood of coffee, which had apparently been wasting away for years, as not worth applying.

I heard of the application of saltpetre, but could learn of no special effect as yet, and I saw that ashes had been applied to young plants as a preventive of leaf disease. Borer have been very destructive this last year, encouraged by the long drought, and large numbers of trees are being removed and their places re-supplied. A great authority from Coorg expressed his opinion that the success of Coorg, compared with Wynaad, was partly attributable to the greater occurrence of Borer in that district, and the consequent regular re-planting of damaged trees, so that there was hardly any old coffee trees in the Coorg Bamboo District. But there is very great difficulty in bringing on supplies in Wynaad. Many men, in the past difficulties with leaf disease, discontinued planting out supplies, and I only saw one good field of young coffee more than two years old. Plants put out last year and this season are generally coming on well. Great care is taken in planting, plants being carefully removed from the nurseries with extractors in ball, or planted out in baskets, or in split bamboos, this last being now preferred. Several extensive plantations have been opened out in the past three years in Nellacotta District and in some of them too much regard has been shown to the rapid establishment of a large extent of coffee without that careful consideration as to exposure and aspect, which experience in the past history of Wynaad coffee should inculcate. With other products now available, hardy plants that will flourish anywhere, it seems a pity to plant coffee in other than the most favoured hill-sides. But it seems to be considered that shade is a panacea for all the difficulties hitherto experienced with coffee. Shade for coffee is now a most important branch of study for the planter. Some successful estates have been opened under the original forest trees, but the damage done to old coffee by the frequent fall of some great tree, and the difficulty of rearing new shade, is altogether against this system, while it is only a few of the forest trees that are really friendly to coffee, and it is much better to have only such trees under which coffee

is known to thrive. Blackwood, tara, the different cedars and figs, are always preserved, but these must be supplemented with young shade plants, put out with the coffee. Grevillea is planted out largely for this purpose, but I noticed that there was more atee shade grown than anything else, though effort is made to vary the trees planted out as much as possible, jack, grevillea and cedar interspersed among the atees.

Cinchona, which has been the ruin of many a fine field of coffee in Wynaad, is now being rapidly eliminated. There are still fine fields of cinchona, originally planted by themselves, or in fields where the coffee has been killed out. It is quite certain that the two will not thrive together, and I saw coffee that had been relieved of the cinchona coming round wonderfully. Cinchona of good quality is still an adjunct to a planter's resources, and should pay for some cultivation, but it seems to be left entirely to itself.

I saw some ledger being planted out on only one estate, and that too among coffee, and on a most promising your property, and by a planter who has always made coffee pay. This more than anything impressed me, as to the diversity of opinions current among planters. There was only one subject on which they were all united, and in this matter they could allow no heretic views, this was that the depreciated Rupee had itself solved the Currency Question so far as they were concerned.

My pen has so run away with me that I must leave my notes on Tea, Gold and minor products to another day.—*Madras Times*, Oct. 12.

VARIOUS NOTES.

BANANA CULTURE.—With us the banana is regarded as a luxury, though in some countries it is a staple article of food and in others is destined to become so. For several years experiments have been made with a view to extend its culture. Great Britain seeks to increase its growth in her tropical colonies, and Germany sees in the banana a most nutritious sausage for feeding its soldiers, that will be cheaper than the maize it has recently used in army rations. The banana is a curious as well as important article. It may be called a "fruit" as above, but it might with equal propriety be termed a "vegetable," and its original was a flower, being the lily. Its producing power is stated to be forty-four times that of the potato, and, according to Humboldt, a hundred and thirty-three men can be fed with bananas grown on an area that would only produce enough wheat for one. Supposing that this applies to an average yield of a little less than thirty bushels of wheat to the acre, the culture of bananas would maintain a population of not far from half a million people to the square mile. The bananas can be ground into a meal, which will keep as long as flour, and which is claimed to be more nutritious than meat, and can also be used economically in the manufacture of beer. Then the skin contains a fibre from which can be manufactured a durable and fine cloth, while the juice of the skin forms an indelible ink and can be fermented into a good vinegar. It is not impossible that spreading a knowledge of these facts will result in a large extension of banana culture in the Colonies. The business is a paying one, and should offer an inviting field for an industry which promises so well for those who engage in it, while it would enable many to obtain an abundance of cheaper food than is now available to them. It would seem that this prospect is opening out, as wide areas are reported to have been bought with a view to banana culture, for the production of meal and cloth.—*Horticultural Times*, Sept. 12.

STATISTICAL FALSEHOODS: A DISINGEN-
 UOUS ATTEMPT TO BOLSTER
 UP CHINA TEA.

It is an old saying that figures can be so dealt with as to represent anything, that by a transposition in fact, or the quotation on one side only of the question it is desired to represent, the truth can be made to appear to rest in precisely the opposite direction to that in which fair representation would apportion it. There has never, perhaps, been a fuller and more decisive exposition of this statement than was exhibited when Sir Arthur Gordon desired to make it appear that the financial condition of our harbour was so unfavourable as to prevent any further expenditure being incurred upon it. According to Sir Arthur Gordon's figures the revenue derived from our harbour was considerably below the annual outlay incurred upon its maintenance and working; but when his figures came to be analysed it was proved that in the expenditure stated by them had been included the payments made for the sinking fund, or in other words the gradual paying off of the capital outlay. When this was eliminated from the account, it was demonstrable that, so far from our harbour revenue being insufficient to meet the annual expenses connected with it, there remained a very material excess of revenue over expenditure. Of a similar character of misstatement has been the assertion made during the course of correspondence in the *London Standard* to the effect that the tea of China still maintains a high position in the home consumption of that article. This assertion was put forward by a firm of brokers of high standing, which occupies perhaps a leading position among these brokers whose business had for very many years been almost exclusively confined to dealing with the tea imported with Great Britain from the Celestial Empire. According to what that firm wrote, and by its quotation of figures, it would have seemed that China tea still occupies a very important position in the item of home consumption; and, had it remained uncontradicted, the conclusion might naturally have been come to by the general public at home that all that it had read as to the rapid supersession of the China variety by those of India and Ceylon growth was a palpable falsity. Fortunately for the exposition of the truth there have not been wanting those capable of demonstrating the incorrectness of the interpretation put upon the figures quoted. These had been taken from official sources; and to those not fully acquainted with the specialities of the tea trade would have seemed to be authoritative as to the correctness of the deductions made from them. But it is a significant fact that, by stopping short of full analysis of the returns made use of, black was made to appear white and white to assume the tint of black. We do not pause to dilate upon the manifest injustice—nay, downright dishonesty—of such a course. As to this our readers may well be left to judge for themselves. The imports of China tea and those of India and Ceylon were no doubt correctly given, but the fact was absolutely ignored that a very large proportion of the imports from China were destined for re-export and never entered at all into the consumption by British tea drinkers. When these re-exports were allowed for, it was proved, that, of all the tea drunk throughout England, Scotland, Ireland and Wales, only about 17 per cent was of Chinese growth, and that the balance of 83 per cent was exclusively of that of India and Ceylon. Sir Charles Dilke was therefore most certainly correct in the statements he

made upon this matter of the home consumption of tea. But he was, perhaps, not sufficiently well acquainted with the technicalities of the published returns to be able to state his case with that succinctness which was necessary to carry full conviction. It needed the after-dealing with the subject by another firm of brokers to bring to light and expose the fallacies whereby the champions of the China tea trade had endeavoured to bolster up the assertions made by them. All causes must suffer by such a disingenuous statement of their case, and Ceylon has especial reason to complain that, in conjunction with its great neighbour, India, it has been exposed to a *suppressio veri* for which it must be difficult, nay quite impossible, to find any palliation or excuse whatever. The bulk of the China tea for which home use was claimed never penetrated into the country further than the bonding warehouses to which its was temporally consigned. Foreign markets, foreign purchasers and foreign users absorbed this bulk; and this fact was, we fear, studiously kept back in order to make it appear that the superiority claimed for the consumption of India and Ceylon varieties had been wrongfully asserted.

THE PRESENT PRICE OF TEA AND
 LOCAL PRODUCTION.

We constantly hear it said that wisdom and prudence should dictate caution as to the opening out of fresh areas of land for tea planting in Ceylon. It is argued that until new markets can be found for some of that we already produce further increase in production is likely to be injurious to the stability of our present greatest industry. Opposed to this view have been the statement of such men as Mr. Roberts of Messrs. I. Rucker & Co., whose view has all along been that the British market can absorb all that Ceylon can send to it up to the high figure of 100 millions of pounds annually. That Mr. Roberts and those who shared his opinion were not altogether wrong has been shown by the extraordinary manner in which China tea has made way for that of Ceylon and India in Mincing Lane. But we as tea planters have to take a somewhat different standpoint to that upon which Mr. Roberts founded his assertion. Great Britain would almost certainly absorb all we can send her up to the figure mentioned; but then the question arises whether her people are ready to pay the price for which alone it would be worth the while of our planters to supply her. Very recently we have been favoured with a marked increase in the rates obtained for our teas in London, and the consensus of home expert opinion seem to justify the hope that this increase may prove lasting, may continue at all events for some considerable time. But when that opinion is asked to account for this improvement it is distinctly stated as being due to a restriction of export from this island during the last few months. Were our export again to increase, or to promise to greatly further expand in the near future, the question might well be asked if the improvement in price now noticeable would be likely to be maintained. Now, if we are to go on adding field to field as there has been so marked a tendency to do during the last few years, it is certain our figures of export must again rise, and then, to judge from all experience, there will follow a recession of the prices to old standard at which tea cultivation cannot be made remunerative, at all events

to those who have incurred the cost of opening up and planting new land. Therefore, we hold that the recent advance in price founded upon a restriction of export affords conclusive evidence of the wisdom of those who hold that we should wait the development of new markets before we go rashly to work extending our present area of cultivation. The ungenial weather, of course, mainly accounts for the recent diminution in the quantity of our export. With tea, however, this is not so significant as it would have been with coffee or other products, because the method of plucking and the quality of the tea produced largely affects the weight of the general output. It may well be that the counsel of late so freely tendered as to the results to be dreaded to a continuance of the practice of overplucking has had something to do with the diminished weight of our exports, and if so the latter fact is perhaps not altogether to be regretted. Compensation for this is to be found in the higher price obtainable for a lower return in quantity. However this may be, we now see that a restricted export is an important element in maintaining better prices. To unduly swell that export by hasty extensions, before new markets are opened, would, we feel sure, lose us much of that advantage.

COCHIN FOWLS.

To keep Cochins in health when confined they must—more than any other variety—he *plentifully* supplied with green food; if not, their digestive system soon suffers, and the plumage becomes ragged and scurfy. Particular care must also be exercised to prevent overfeeding, as this breed has a special tendency to accumulate internal fat, causing sterility, disease and even death. Indian corn is, therefore, not good for them. In severe cases of this prejudicial fattening the hinder part of the body almost touches the ground, penguin-fashion, and rupture is a frequent result. The most beneficial course in such an event is to allow the bird to *sit* for as long as five or six weeks, feeding her very sparingly till the system is reduced, by which means a cure may often be effected. Cochius have great merits, the chief of which are their hardiness, their winter-laying qualities, their large size, and the *extremely* small space in which they may be kept. In illustration of the last point we may refer to Mr Tomlinson's account of his own yard. If they are sparingly fed on everything except green food, *this* being given liberally, they are scarcely ever ill; but these two conditions are essential. Perhaps the greatest drawback to these good qualities is the unearthy howl, rather than crow, of the cocks, which makes it in towns impossible to keep them, where but for this they would be the very best fowls for the circumstances. Their rather coarse quality of meat and deficiency of breast are also faults, though for home use they are profitable, as the legs, which are very large, are, in our opinion, and that of many others (and the same remark may be made of the Brahma) far superior to those of other breeds. We speak, of course, of young birds; the leg of an old Cochin is certainly an unmanageable morsel—From "*Wright's Illustrated Book of Poultry*" for October.

SOME VEGETABLE.

RECENT PUBLICATIONS.

Le Potager d'un Curieux. By Messieurs Paillieux and D. Bois (second edition. Paris, 1892).

Variety is the great characteristic of man's diet, as it is of man's raiment. Still, to confine our remarks to such articles of food as are derived from the vegetable kingdom only, it is curious to note that the number of fruits and vegetables usually found in the best-stocked market is a mere trifle in com-

parison with the total produce which might be used as food. Some nations have a much more extensive diet than we have, and a highly competent authority asserts that "one would sooner make a list of vegetable produce left uneaten by Chinamen than enumerate all the articles which they actually eat."

Among the most promising of the plants introduced in the *Potager d'un Curieux* three are especially worthy of notice, namely, *Arctium Lappa*, var. *Japonicum*, *Soja hispida* and *Stachys affinis*.

Arctium Lappa, var. *Japouicum*, described also as *Lappa major*, is simply a variety of the cosmopolitan "Burrs." The fleshy root of the plant grows and swells rapidly in deeply trenched soil; so much so that it can be obtained one inch thick in the space of three months, and yields a vegetable resembling salsify or scorzonera, but of quicker growth, very white and tender, and easily made very palatable by proper cooking.

Soja hispida is a Chinese plant of the order Leguminosæ, which is remarkable for the large proportion of fat and of nitrogenous matter contained in its seeds. It is from the *Soja* that the Chinese and Japanese manufacture the "vegetable cheese," a highly nutritious paste which can hardly be recognised from cheese made of milk and the "Shoyou," a condiment of everyday use, which appears to enter largely in the composition of many of the patent "sauces" made in England.

Soja is not very delicate as a fresh vegetable, as the seed, which is the eatable part of the plant, has a very thick and hard skin. But it might be removed before dishing up. The plant is so prolific, so perfectly hardy and disease-resisting, that it would be worth while to devote some time and care to its improvement. Most varieties of the *Soja* ripen their seeds too late to be of much use in northern Europe, but several of them might be grown easily in North America.

Stachys affinis, otherwise *S. tubrifera*, first introduced to notice by Monsieur Paillieux, can be said to have attained in Europe the position of a standing vegetable. In France it is fast becoming popular as *Stachys*, or "Crones du Japon," and it is recognised in England as the "Chinese Artichoke." It is a perfectly hardy vegetable, consisting of the fleshy, pearl-white, underground stems of *S. affinis*. The tubers, although very watery to all appearance and easily crushed between the thumb and fingers, contain a rather high proportion of albuminous and gummy substances, and therefore constitute a not altogether despicable food. The tubers intended for propagation should be kept in sand over winter, planted out in rows or on mounds early in spring and left to themselves, with the exception of occasional weeding all through the season. The tubers are not wholly formed till the vines die off. They will stand any amount of frost if left in the ground, and they are all the more delicate for being pulled up just before cooking.

A good deal of attention is paid by the authors to such plants, or parts of plants, as are well adapted for being pickled in vinegar, so as to introduce some variety in the "pickles," too commonly made exclusively of gherkins, small onions and bits of cauliflower. The West India Gherkin (*Cucumis Anguria*), the tuberous *Nasturtium* (*Tropæolum tuberosum*), the *Martynia*, the Chinese Artichoke, and last, not least, the *Mioga*, the unexpanded flower of a sort of Ginger (*Amomum Mioga*), are specially recommended for pickling.—*Garden and Forest*.

THE SHORT TEA CROP in the Assam valley is said to be turning out the most disastrous on record. At present the decrease in the output as compared with that of last year is upwards of three million pounds. Rain is very much wanted both for the tea and rice crops, and, unless a heavy shower falls, the season will close even earlier than last year. The actual exports from May to September, inclusive, were 50.75 million lb., against 53.47 million lb., during the same period last year.

Correspondence.

To the Editor.

INFORMATION WANTED AS TO THE
APPLICATION OF ELECTRICITY IN
AGRICULTURE.

Elk Hill Farm, Coonoor, Nilgiris, Sept. 26.

SIR,—In the August number of your interesting paper the *Tropical Agriculturist* appears a short extract headed "The Electric Light in Agriculture" (page 118). This affirms that by simply placing a number of conductors (lightning-rods, I assume) round a field, active currents can be produced by which the crop is increased 50 per cent.

I should be greatly indebted to you if you or any of your numerous subscribers could give me some plain directions as to the manner of carrying out a similar experiment, keeping in mind, however, that I am intensely ignorant of practical electricity.

CREIGHTON.

TEA NOT OVER-PRUNED IN CEYLON.

Sept. 30.

DEAR SIR,—When Mr. Hughes expressed his opinion as to the evil effects of your London Correspondent's suppositionary excessive pruning of tea in Ceylon, he was evidently not fully cognizant of what actually takes place after we prune our bushes.

The prunings are either buried or they are not.

In the first case the soil is more or less generally broken up during the process and therefore made more capable of absorbing rainwater, and there is consequently less waste during this time than when the bushes are fully covered with leaves. When the prunings are not buried they completely cover the ground and so shade it from the scorching effects of the sun until the bushes have renewed their foliage and they form a better preventative of wash and waste of soil on steep land than any system of digging or holing for the purpose of their burial could do.

At the higher elevations, where moss forms a perfect carpet of green on the surface of the soil, a thorough good scorching every second year when the bushes are pruned must be more beneficial than the reverse.

Look at the appearance of our fields 15 or more years old and study their returns, and you will not be alarmed as to the longevity of our bushes. I know such fields which are looking as well and doing as well as ever they did. A word or two in reference to Jackson's puff of our neighbours over the water. Borjulli, with its 15 maunds or 1,200 lb. per acre, at a cost of 3½d per lb., must be a very rare exception indeed.

In your issue of the 15th inst. you give a list of 28 Indian Tea Companies owning 70,000 acres of tea in cultivation, the returns from which ranged from 265lb. to 672 lb. per acre, at a cost of from 6½d to 1s 0½d per lb.

The dividends paid by these companies ranged from less than nothing to 17 per cent.

I see nothing much to be afraid of there, and must therefore sign myself yours truly,

SCEPTIC.

WEEDS AS MANURE.

Marakona Estate, 19th Oct.

DEAR SIR,—With reference to your footnote to my letter of 15th September, I have the pleasure of stating that I have tested my system of using weeds for the saving of wash and also as a manure in the cultivation of coffee, cinchona, cacao and tea to my entire satisfaction, and am now carrying out the same system on this estate with marked success in the cultivation of cacao.

I now send you by this morning's train three samples of the most suitable grasses to plant on steep land (where great loss of soil is occasioned by wash) for the purpose of checking the wash, saving and making soil and retaining the rain. And eventually the weeds are worked into the soil with any other patent manure as may be found necessary.

The following is a list of the samples sent with particulars of native names, etc., on which I would like you to give me the technical names.

No. 1. Native name: Tamil, Moorogu-pillu; Sinhalese, Unnura-wall. (*sic.*)

No. 2. Native name: Tamil, Pallara-coddii. Sinhalese, Gotukola.

No. 3. Native name: Tamil, Sivan coddie; Sinhalese Undupiyali.

No. 1.—This grass is specially suited for the purpose of retaining moisture, as it grows to the height of about four inches with a very small depth of root. It is useful as a clover for feeding cattle, and also serves the purpose of a manure, if hacked down and allowed to rot. This operation can be repeated as soon as it grows up again, which means a continual collecting of decayed vegetable matter. In addition to this you will find that this grass is a surface feeder, and the roots do not penetrate to any depth in the soil. I do not consider it as good as some other grasses of deeper root, for the purpose of manuring, for in my opinion it is the roots which constitute the manuring qualities; for instance look at the native paddy fields, how they first turn the turf over and allow it to rot! It was only the other day that a planter remarked, when asked if he believed in this system of allowing weeds to grow as a manure, etc.: "What about exhausting in the soil?" Talk of exhausting the soil when at that very moment the "cream" of his soil was rolling down the ravines in the shape of liquid mud.

No. 2.—This creeper grows to an even height of about two inches, but of thick growth, which helps it to retain moisture save wash, etc. Growing to a small height it was the trouble of hacking. The roots go down to a somewhat deeper depth than the former. It will serve as a good manure if cut and applied with patent manures in holes.

No. 3.—This grass is in my opinion the best, as it requires no cutting whatever and makes a thick covering on the top of the soil, and has a thick network of roots under the surface, which go down to a deeper depth than the two preceding ones. It is the best of the three in manuring qualities.

As to their respective qualities of retaining the nitrogen, either in the leaves or roots, kindly refer to analysis,—Yours faithfully, J. HOLLOWAY.

FOOD FOR POULTRY.

DEAR SIR,—In reply to E. H. B.'s letter in your issue of the 22nd inst. I would suggest her trying "Indian corn." It contains both egg and bone making material, whereas paddy is chiefly composed of starch,

I am not aware that the price of Indian corn is at present, but when I used it I found that a measure of Indian corn goes much further than a measure of paddy, besides being in every way much better and more nourishing food for poultry, so that even if the price of Indian corn is the same as paddy it is still nevertheless more economical than paddy, or, in other words, a handful of Indian corn is more filling than one of paddy. For chickens it should be ground.

Lewis Wright, a great authority on poultry, says:—"Cheap as it is, we would warn everyone that it never pays to use rice as the food of laying birds."

He goes on to say: "Rice contains less than half the flesh, or egg-making material of several other grains and is useless, except when mixed with milk for fattening fowls."

Attached is a table, showing the various foods in the order of their richness in the nitrogenous or flesh forming substances. L. T.

There is in every 100 Parts.	Warmth & Fattening.		Starch.	Bone makers Materials.	Husk or Fibre.	Water.
	Flesh Forming.	Fat or Oil.

NOTES FROM SOUTH-EAST WYNAAD.

Considerable progress has been made in tea cultivation this year. Forty maunds of seed have been purchased for different plantations in Wynaad from the owners of the old Surrey Estate Tea Seed Bearers, and with the nurseries planted by themselves there will be quite a million tea plants ready for the field next year, which is a fair beginning, and the amount of seed that will be available next year will be largely increased. The advantage of pure Assam seed is not universally admitted. A considerable admixture of China hybrid is still stated to improve flavour, but although this strong Assam has an astringent taste that may not be liked by itself, as far as the grower is concerned, the blending should be done by the buyer, and the long price obtainable for strength secured. The question of quantity is also a consideration. The large leaf and much more vigorous growth of the Assam variety must tell favourably in this respect notwithstanding the very large crops that have been gathered in Wynaad, which were lately quoted by "St. Louis," the older fields on one estate in Wynaad having given over 1,700 lb. to the acre, and this from by no means good hybrids. The plucking is rather coarse, principally because finshings are not got in quick enough, and the price this tea has hitherto fetched has not been encouraging. The experiment was made, by running some leaf through, a distance of 56 miles, to a well known Factory on the Nilgiris, to try what the best machinery, and latest knowledge of manufacture might have on the quality. The result has been most satisfactory for the character of Wynaad Tea, for in spite of poor *jat*, very coarse leaf and long transport, the tea has turned out better by 2½d. than the previous average, showing how much good manufacture has to do with price. Tea making has now commenced on a small scale on the Pandalur field of tea of Assam *jat*, which is now three years old. These trees were left to grow as they would until July of this year, when they were cut down to the three feet, and notwithstanding

this waste of growth, they have now a very respectable spread. Many of them measured over four feet across. The first flush was taken in towards the end of September, and there is a great show of the delicate light new leaves over the field now, which is already nearly covering the ground, and is a most refreshing sight, as a promise of what Wynaad may be a few years hence. I have lately turned up a list of the Coffee Estates in the Devalah and Pandalur Districts of S. E. Wynaad in 1875. There were at that time 20 Coffee Estates in Devalah, with an area of 2,174 acres under coffee cultivation, in the Pandalur District 10 Estates with an area of 1,080 acres under coffee, these two districts now entirely belong to the different gold mining companies, and there is not 200 acres in all under tea and coffee and cinchona that is cultivated.

Two of the Devalah Gold Mining Companies are still doing thoroughly good mining work. The Indian Gold mines are still keeping its mill at work, obtaining something under 100 ounces of gold per month, from all the upper stopes, while a deep exploration tunnel is being carried below. This tunnel cuts the reef from an adit near the Mill House, at a perpendicular depth from the outcrop of the reef on the Hill above of over 400 feet, and giving a depth of backing on the reef itself of over 1,700 feet for stoping. The tunnel has now been carried on the reef itself for a distance of over 700 feet, proving the existence of a continuous lode running up to 25 feet in thickness. The facilities for mining and crushing are almost unparalleled. The mine is selfdrained, the stone being taken to the mill in tramcars by gravitation, the only labour is bringing back the empty cars. The mill is worked by Turbines with constant water-supply, but unfortunately the ore is very poor and though 2 dwt. to the ton covers all cost of mining and milling; even this poor value cannot yet be depended on. One day a decent face is exposed and then comes almost barren quartz, the stone is so patchy,

On the Devalah Moyer, exploratory work alone is being carried out, the mill is not being worked. The mine is most interesting. From the outcrop on the top of the Hill, where extensive natives' works were found, the reef was followed by a winze, about 300 feet down the hill, and a tunnel was driven to cut the reef along which it has been followed for several hundred feet, while at the same time the winze is being continued in depth on the reef, so that the size and continuance of the lode may be thoroughly proved, both the tunnels heading and the winze are being driven by compressed air with Rook drills of which there are now three at work. The winze is now some three hundred feet below the tunnel level. The descent is by ladders, the winze following the reef, and was more than I could face. The engine for compressing the air, and the workshops where all the work required in the mines is carried out, were in admirable order. But the most interesting of all the mines at the present time is one that has just been taken up by two Planters who have leased the mine and plant, from a Company that has spent its capital; and with their own money, the experience and knowledge acquired from watching the work done in the district during the past fifteen years, and with British grit to back them up, they have put the deserted mill into good order, added the saving apparatus, that they think has been the most successful, and have opened up a new mine to the reef, and if successful will re-ascitate the industry. Their doings are being watched with the greatest interest. A little work is also still being carried on by the Perseverance Company, and I saw a nice little lump of gold, the result of their last trial crushing. But Devalah and Pandalur bazaars and villages are but remnants of the past. There are still fine public buildings—Post Office, Telegraph, Public Bungalow and the road is worthy of Ceylon. I saw sweepers scraping up the leaves and dirt among the shanties, but behind the houses is a sea of cattle dung, which was formerly so valued. There is now no cultivation in the neighbourhood where it can be utilised.—*M. Times*, Oct. 21,

PRINCIPLES OF FRUIT CULTURE.

Fruit culture is afflicted with many evils, and for those evils numerous cures are prescribed, usually with little or no effect, and so the two-fold evil of harm to the fruit and the infliction of nostrums goes on to the detriment and no small discouragement of fruit-growing. And the evil will continue, if not increase, till a more rational course is pursued, namely, carrying out the principles that apply, suiting the treatment to the condition as circumstances may require; in other words, giving through, intelligent culture. This is not a panacea, but it strikes at the root of most of the evils, and puts fruit culture on a successful basis. A knowledge of the principles that apply is necessary to distinguish and direct as circumstances may require, suiting the culture to the varied demands of climate, sorts of fruit and soil, and other circumstances of our widely diversified country, never losing sight of general principles that necessarily apply to all, which must be repeated, or harm will as certainly result. Experience has demonstrated that, under all circumstances, a dry, deep soil is the best, stagnant water not then being able to harm the roots, or the extreme heat and cold reach them. This is the first thing to be considered yet few avail themselves of it. There is considerable trouble and expense, for most soils must first be drained and otherwise treated to be fit for an orchard. This is imperative; no high success can be obtained without it. Equally important is fertility, but with great qualification. It is well known that fruit trees, like other crops, are usually in need of manure; but, what is less considered, it is equally important to avoid excess. There must be enough enrichment for a full growth, both of wood and fruit—no more, no less—and this be kept up, change being always more or less hurtful. More growth will result in immature wood, too tender to withstand the cold of winter, or if barely escaping, not coming cut in that sound condition required for best growing fruit. As to the amount of fertility, it is not all dependent upon the quality of the manure applied. There is the thinning out of the fruit and wood remaining, supplying thus far the place of manure. Cultivating and mulching the soil will also aid. The true orchardist will avail himself of those means, and of the manure, if any, which is required to secure the desired vigour, which favours the soundest and healthiest growth, both of wood and fruit, keeping the balance established between them to their mutual benefit, particularly as to the wood, as good wood is necessary to produce good fruit. Such a growth will be abundantly able, with hardy sorts, to withstand our severest winters and our hottest and driest summers, the size, roundness and quality of the fruit increased, with more perfect maturity, and what our observation has impressed us with as more important still, is less blighting of the blossoms and the premature dropping of the fruit.—*Horticultural Times*, Sept. 26.

THE CEYLON TEA FUND.

MEETING AT KANDY.

Minutes of proceedings of a meeting of the Standing Committee of the Ceylon Tea Fund held at Kandy on Friday, the 14th day of October 1892, at eight o'clock in the morning.

Present:—Messrs. Giles F. Walker, Chairman, Planters' Association of Ceylon; A. L. Cross, Kandy; J. Anderson, Kandy and Matale West; A. W. Lloyd, Chairman, Haputale Association; W. D. Gibbon, Kandy; A. E. Wright, Maskeliya; A. Melville White, Kandy and Kelebobka; Hon. J. J. Grinlinton, Kandy; and A. Philip, Secretary of the Planters' Association of Ceylon, Kandy.

The notice calling the meeting was read.

The minutes of proceedings of a meeting of the Standing Committee held at Kandy on Friday, the 2nd day of September 1892, were taken as read, and were confirmed.

CEYLON TEA AT THE WORLD'S COLUMBIAN EXPOSITION AT CHICAGO IN 1893.

Read (I.) letter from the Colonial Secretary stating that the Governor in Executive Council was prepared to give effect to the proposals of the Association in terms of the resolution passed at the general meeting specially convened for the purpose of considering how funds could best be raised to ensure an adequate representation of Ceylon at the World's Fair, and Columbian Exposition at Chicago in 1893. (II.) Letter from the Colonial Secretary acknowledging the vote of thanks to His Excellency the Governor passed by the Planters' Association in general meeting in connection with his action as regards the representation of Ceylon at the Chicago Exhibition. (III.) Letter from the Ceylon Chamber of Commerce transmitting copy of resolution approving of the proposals made by the Planters' Association for raising funds for the adequate representation of Ceylon Tea at the Chicago Exhibition. (IV.) Letter from Mr. H. K. Rutherford making suggestions for raising the necessary funds. (V.) Letter from the Special Commissioner World's Columbian Exposition notifying that the Government had granted free Railway freights on exhibits for the Exhibition.

Read letter from Messrs. John Fraser, Joseph Fraser, and Wm. H. Morrison suggesting that, considering the impossibility of many estates contributing such a quantity, the contribution for Fancy Teas be reduced to three pounds of each grade, the difference being made up in commercial teas.

Resolved (I):—"That in the case of exhibits of fancy teas 3 lb. of each grade of such teas will be accepted, the balance of 5 lb. in each instance to be made up by substituting commercial teas for general exhibition purposes."

(II). "That a copy of this resolution be transmitted to the Special Commissioner, and that the Special Commissioner be asked to favour the Planters' Association with 700 copies of the rules re contribution of estates and other products for the World's Columbian Exposition with the amending resolution about fancy teas to be circulated by the various District Associations to every member."

Read letter from the Colonial Secretary transmitting a copy of a report from the Assistant Commissioner World's Columbian Exposition showing the progress made to date in the work of constructing the main and miniature courts for the Exposition.

THE FUNDS ALREADY VOTED FOR THE EXPOSITION AND THE DESIRABILITY, OR OTHERWISE, NOW THAT AN EXPORT DUTY IS SANCTIONED, OF SETTING ASIDE PART OF THEM FOR OTHER PURPOSES.

Resolved:—"That in view of the planting community having subjected themselves to a special tax for the World's Fair at Chicago, the Standing Committee of the Tea Fund resolves that the balance of the funds voted for the World's Fair by the Standing Committee and not yet appropriated for that purpose shall be devoted to the furthering of Ceylon tea interests elsewhere."

BASIS OF SUBSCRIPTION TO THE TEA FUND, AND THE DESIRABILITY OF REDUCING IT.

Resolved:—"In view of the funds for the World's Fair having been otherwise provided for, but that a great necessity still exists for pushing Ceylon teas in other parts of the world as well as in America, the basis of subscription to the Ceylon Tea Fund be reduced from 25 cents to 10 cents per 1,000 lb. of green tea leaf made during each six-monthly period, and that the reduction do take place as from 1st July 1892."

CEYLON PLANTERS' TEA COMPANY OF NEW YORK.

Considered the following resolution passed by the Committee of the Planters' Association of Ceylon at a meeting held on the 2nd September 1892:—"That Messrs. Watson & Farr's letter be referred to the Standing Committee of the Ceylon Tea Fund with a recommendation from the Committee of the Planters' Association for its favourable consideration,

and that a copy of this resolution be forwarded to Messrs. Wattson & Farr through the Secretary, Ceylon Association in London." Resolved:—"That a grant of 9,000 lb. of Ceylon Tea in three instalments of 3,000 lb. each at intervals of two months be made through Messrs. Wattson & Farr to the Ceylon Planters' Tea Company of New York, and that Messrs. Darley, Butler & Co. be requested to purchase and forward teas similar to those they are in the habit of sending to that Company."

CEYLON TEA IN RUSSIA.

Considered correspondence. Resolved:—"That the Standing Committee of the Ceylon Tea Fund will be prepared to vote a grant or grants of Ceylon tea to Mr. Rogivue for the furtherance of his enterprise in Russia on the receipt from him of samples of the kind of teas required for the Russian market, such teas to be shipped from Colombo, and to be delivered at any Russian port that may be decided upon by Mr. Rogivue, who would be required to pay the import duty on such tea."

CEYLON TEA IN SIERRA COUNTY, CALIFORNIA.

Read letter from Messrs. Whittall & Co., advising that the tea for California had been delivered to Messrs. George Stewart & Co. on behalf of Mr. J. C. Dunbar and enclosing debit note for cost of same.

CEYLON TEA IN BRITISH COLUMBIA.

Read letters and copy telegram from Mr. C. E. H. Smons.

CEYLON TEA IN MEXICO.

Read letter from Mr. W. E. Master.
The Standing Committee of the "Ceylon Tea Fund" then adjourned.

A. PHILIP,

Secretary to the Planters' Association of Ceylon.

TEA ROOT CARVING.

For more than a hundred generations there has been a guild of artists in the populous Chinese province of Fo-kien whose life work is the conversion of the gnarled and interlaced roots of the tea tree into things of beauty, that is to say, beauty from a celestial point of view. The herb, the leaves of which gladden western palates in the form of Oolong, Hyson and Souchong, is a hardy plant and takes a firm hold on mother earth. Its roots seem to have no regular law of growth. Sometimes they develop very much as a beard sprouts from the chin; at others they separate and move along parallel lines as if they were a lignose centipede. In general, it may be said that they make one large, clumsy mass, from which shoot out anywhere from three to thirty rootlets. Their surface is never smooth but always irregularly corrugated. The value of a root depends upon its size, its outline, its freedom from decay, and its suggestiveness of some everyday object.

The roots are dug from the soil and allowed to thoroughly dry in the open air under a shed or else in a moderately warm room. The loose earth is carefully removed, as is the loose bark and all pieces decayed, cracked or worm-eaten. The artist then determines what is to be done. The favourite types are dragons, buffaloes, cows, carnivores, bears, mandarins, priests, howling dervishers, dancers or mystic heroes. If the root cannot be worked into one of these shapes it is converted into a pedestal or platform for a figure piece. The primary operation consists in sawing it into rough shape. This is done with a fine cross-cut, and the clean edges removed by rubbing them on tiles or bricks. Sometimes a root is bent by softening it with steam or boiling water, and then twisting it in any desired direction.

Now comes the hardest task of all. The most valued piece is that which shows no art and seems perfectly natural. The carver goes over the block, removing here a fibre and there a set of roots, here thinning out one on the under side and forcing it down, and there burning another and expanding it at the burned point. I have one in my drawing-room which is a capital

figure of a dragon, rearing and opening his jaws as if to spring upon his prey. Careful examination shows that nothing has been added to the mass, but that hundreds of fibres, knots and corrugations have been skillfully removed.

In nearly every instance a human figure, made in the same manner, or carved from a wood of the same colour, or else made partly from tea roots and partly from carved wood is added to the first piece. The designs are endless in this field. Learned men lecturing birds, mandarins standing on dragons, boys riding cows and other ridiculous quadrupeds, dancing beggars, men fighting each other, are the commonest groups, but of the more uncommon there are thousands. One famous artist in Foochow claims to have produced, with the aid of his apprentices, over fifty thousand different designs, and, judging from his stock on hand, his claim seems reasonable enough.

The tea-root carvings are seldom very costly, running from 2s. to £2. Nine-tenths bring less than 8s. each. A handsome set of a dozen can be purchased for 80s., which will decorate a drawing-room or hall better than a bric-à-brac many times more expensive. The figures are strong, durable, and in no danger of fracture by Bridget or Ah Sin. Outside of their æsthetic value they are of interest in showing the wonderful ingenuity and economy of our Chinese cousins.—*Forticultural Times*.

NOTES ON PRODUCE AND FINANCE.

THE TEA DISCUSSION.—As wind-up to the correspondence in the *Standard* a correspondent signing himself "Ahom" goes what the Americans call "bald-headed" for "Cha-sze," who sneered at Indian and Ceylon tea. He says:—"Your correspondent 'Cha-sze' must either be joking or ignorant of the qualities of tea when he advises the use of the rank, unfermented class of teas sent from China to the Russian markets. Does he know those teas to be more or less poisonous and analogous to the *digitalis* (foxglove) in their effects, from the unchanged character of the essential oils contained? Does he know that one thousand years before China ever grew the degenerated shrub as known in China, the tea tree grew in rank luxuriance in the Assam jungles, from which it was introduced into China? Does he know that the Chinese admit the use of no less than two hundred substitutes or adulterants for tea, the least injurious being sloe, beech, chloranthus, and willow leaves? Does he know that the Chinese paint their teas with Prussian blue, black-lead, copperas, gum, and soapstone powder, &c.? Does he know that Indian, Assam, or Ceylon teas are pure, uncoloured, and unadulterated, solely for the reason that Indian planters could not afford it? Does he know that large cargoes of China 'tea' have been seized and destroyed in the United States in recent years as unfit for consumption, and as he ever heard of one chest of Indian or Ceylon teas so destroyed? Is he aware that about three years ago the Shanghai Chamber of Commerce decided to send 'intelligent Chinamen' to Ceylon to learn tea manufacture? 'The tail now wags the dog,' and China tea is snowed under, *i. e.*, nowhere."

THE TEA BROKERS' ASSOCIATION ON THE SUPPLY OF TEA.—The Tea Brokers' Association has decided to try and limit the supplies of Indian tea at public auction to 35,000 packages per week up to the end of the year. The amount brought forward last week was exceptionally large, namely 52,355 packages, or equal to 4,500,000 lb., the estimated value of which was £25,000. The future course of the Indian market will be regulated to a great extent by the quantity available for shipment to this country, the estimates ranging from 105,000,000 lb. to 110,000,000 lb. The statistics for this season, that is from June 1st, show that the deliveries of Indian and Ceylon teas of both growths exceeds the imports. The total quantity of Indian landed during the past four months amounted to 80,340,632 lb, and Ceylon 28,535,546 lb., while the deliveries reached 32,309,700 lb. and 24,819,274 lb. respectively. The stock on Indian tea on September 30 was,

however, 27,343,362 lb., compared with 25,959,810 lb., at the corresponding date last year; but the present supplies of Ceylon are 104,876 lb. less, namely, 16,477,414 lb. With respect to values, the low-priced Indian and Ceylon teas are still $\frac{1}{2}$ d. per lb. below the prices ruling twelve months ago, but the finer qualities are higher. Assam, for instance has been sold on garden account by auction at an average of 1s 0 $\frac{1}{2}$ d per lb., whereas last year the average was 10 $\frac{1}{2}$ d. Darjeeling is also higher, 1s 1 $\frac{1}{2}$ d, against 10 $\frac{1}{2}$ d per lb. The small visible supplies of Ceylon and the deliveries exceeding imports have kept prices of these sorts strong, and the average price for last week was 10 $\frac{1}{2}$ d. against 10 d per lb. for the same week last year.

VALUING TEAS BY ANALYSIS.—No doubt it will be a long time before the tea taster will complain—even if he ever does so—that his occupation is gone; but we notice, says the *Grocer*, that analytical chemists are trying to compete with him in his business. Already in France some firms, it is stated, prefer to buy large parcels of tea on the results of an analysis by a competent chemist; and now we hear that the Germans, who generally lead the van in these matters, are following suit. The chief constituents which confer quality upon tea are known to be the theine and the “extract,” and upon an estimation of these a buyer may feel safe in making purchases. The other day two German chemists, A. Domergue and O. Nicolas, examined a number of samples for a leading firm of tea merchants with the following results:—

Commercial varieties.	Extract.	Theine.
Assam	53.85	4.39
Flower of Pekoe (1) ...	48.18	4.25
do do (2) ...	43.60	3.78

TEA, COFFEE, AND COCOA, IN BOND—According to the “B” Bill of Entry, showing the quantities of bonded goods remaining in the Customs and Excise; warehouses of the United Kingdom on Sept. 30, the stock of tea was 84,237,216 lb., against 87,846,350 lb. on the same date of last year, and 81,290,147 lb. on the corresponding date of 1890; the quantity of coffee was 148,057 cwt., against 162,310 cwt. and 220,602 cwt. cocoa, 12,511,854 lb., against 13,637,696 lb. and 12,602,399 lb.

A SELANGOR COFFEE COMPANY.—Under the title of the Selangor Coffee Company, Limited, a company has just been registered with a capital of £15,000 in £1 shares. The object is to acquire land in the Straits Settlements and to carry on thereat or elsewhere the business of tea and coffee planters in all their respective branches.—*H. and C. Mail*, Oct. 14.

NOTES FROM PEERMAAD.

A friend who is rather good at the banjo, and is horribly fond of that dear old Irish song “The Wearin’ of the Green,” when called upon for “only one more,” sang as an encore a verse somewhat to the following effect:—

So I sent a 1 lb. Packet to Her Gracious Majesty, And the Queen’s commands came out last Mail, “I like your Peermaad Tea.”

I have so far received but a poor response to my request for particulars of yield, per acre, of tea, but the following are at your disposal, the rest will follow shortly:—

	Elevation feet.	
Mount ...	3,350	400 lb. per acre from 70 acres
Mai Mul’ay ...	4,000	340 ” ” 70 ”
Stag Brook ...	3,350	380 ” ” 50 ”
Granly ...	3,550	218 ” ” 40 ”

Our monsoon has been very peculiar.

Rainfall in June, inches 12.63, the lowest on record. July, inches 58.05.

Heaviest days
...	19th & 20th	11.21	In.
...	22nd	2.23	”
...	23rd	10.91	”
...	24th	3.50	”
...	25th	2.83	”

Total in a week; inches 30.71, and the only accident that occurred in the district was the loss of the larlylar with two cart loads of rice, at the Peryar crossing and of one bandyman.

It is satisfactory to see prices (for tea) improving again and while it is with no undue (I hope) amount of pride and satisfaction that I am able to chronicle the success of the Tea Enterprise in a country where I have spent nigh 30 of the best (?) years of my life, yet I would offer a word of timely warning to any who may imagine that Immense Fortunes (capitals, if you please) are to be made in tea even at Peermaad. On some future occasion I may perhaps be tempted with the Editor’s permission, to publish a series of articles which are in course of preparation on the Coffee and Tea Enterprises in Tavancore, for the past 30 years, i.e., practically from the commencement, though no one knows better than myself that the subject is deserving of an abler pen than mine.

I have lately seen some young coffee clearings, both Arabian and Liberian, in which I am not altogether uninterested, that bid fair to be a success, and I shall watch their growth and development with no little amount of interest. That the back of Leaf Disease is broken up, here at any rate, I have no hesitation in affirming; and given suitable land, careful opening, shelter and partial shade, plants from selected seed and careful and judicious management, with high cultivation, I see no reason why old King Coffee, as a writer in the *Trop. Ag.* used to call him, whether of Arabia or Liberia matters but little, but of the latter for choice, should not be the Grand Old Monarch of the future generations of planters. If *Le Roi est mort* then *Vive le Roi!*

THE PALAIS INDIEN TEA HOUSES, LIMITED. (PARIS BUSINESS.)

At a recent meeting of this company, the Chairman made the following remarks on the working of the company up to the present time:—I have but few observations to make, as the report is very clear and comprehensive, and shows the monthly working of each of our department. Had this company been started as an ordinary trading concern, the loss shown would need some explanation; but I would remind you that, when the company was started, the projectors did not hold out any hope that it could, at first, pay expenses, and no capital was sought from anyone except those interested as tea-growers, and who were prepared to wait for the indirect benefit which would accrue to the industry from extending the taste for pure Indian teas in France and on the continent generally.

I think we may fairly claim that we have effected this object, as a very material increase in the consumption of Indian tea in France and on the continent has taken place since the commencement of our operations, as shown by the Board of Trade returns.

The progress made from a mere profit and loss point of view is, to anyone acquainted with this class of business, most encouraging, and there is every reason to hope that if we continue at the pace at which we have started, we shall before any considerable time elapses, not only cover expenditure, but be able to show a fair margin of profit. Having had some experience myself in the working of a similar undertaking, I am perfectly satisfied with the figures shown in the report.

During the depressed state of the industry in 1880-81, I, and a few friends, started a small company in this country to educate the taste of the public up to an appreciation of Indian tea, without any admixture of tea from other countries. The first and second years of this venture were most disheartening, and we were about to abandon it with the loss of the small capital invested therein, when at the commencement of the third year, a turn came, and we then began to more than cover expenses. From that time forward the improvement went on with rapid strides and we have since earned an average dividend of 20 per cent. on the small capital of £5,000 invested.

I am quite sure that similar results may be looked for from the Palais Indien, but we *must* have more capital to continue the enterprise, and we appeal in our report to our existing shareholders to subscribe further—and to those connected with the Indian tea industry generally, who are not shareholders—to subscribe something in proportion to their stake in the industry.

I do not wish to make invidious comparisons, but it is a remarkable fact that in this, as in all other efforts that have been made during the last few years to extend the use and improve the position of Indian tea, the onus has fallen almost exclusively on the tea growers of Assam and Darjeeling, the very districts which have least to gain by such exertions, seeing that the character of their product is more assured, and requires less support than that of the newer districts of Ochar and Sylhet and the Doars. The enterprise and energy of our friends in Ceylon have brought their tea most favourably before the public, and have caused their industry to attain the well-deserved success which we find it enjoys.

I can only conclude by recommending the subject of my discourse to the attention of all who are interested in the extension of the consumption of Indian tea in new quarters of the globe.—*H and C. Mail*, Oct. 14.

TO GIVE FLOWERS AN ARTIFICIAL COLOR.

Subsequent upon the notes which we printed from our Paris correspondent regarding the artificial coloration of flowers, we have had some inquiry as to how the trick is done. We have given one method of doing it which is successful, but perhaps the simplest method, says the *Chemist and Druggist*, is that suggested by Mr. Wm. Brockbank, in the *Gardner's Chronicle*. It is to place the cut flower in solutions of aniline and similar dyes. Aniline scarlet dissolved in water to about the transparency of claret has a very rapid action on flowers, coloring them pink and scarlet. Indigo carmine produces beautiful blue tints. The two combined dye various shades of purple, with curious mottled effects, some parts of the flower becoming pink and other parts blue and purple. Greens are produced by using the blue dye with the yellow. Indigo and cochineal are not very satisfactory. Amongst some of the effects produced are the following. Lily of the valley flowers become beautifully tinged with pink or blue in six hours, narcissi are changed from pure white to deep scarlet in twelve hours, and delicate shades of pink are imparted to them in a very short time. Yellow daffodils are beautifully striped with dark scarlet in twelve hours; the edges of the corona also become deeply tinged, and the veining of the perianth becomes very strongly marked. It is well to note that it is by the passage of the colored solutions through the vascular tissue of the flowers that the effect is produced, and the result is beautifully seen in white tulips, which in a few hours become prettily marked with pink, blue, or whatever the colour of the solution may be. So also with snowdrops, leucojums, white lilac, and many other familiar flowers.

Very singular results are obtained in the variegated leaves of the aucuba and ivy. Single leaves with their stalks placed in aniline dye-water, began to color in about three hours, and in twelve hours had their margins deeply coloured. Forced leaves of the Swedish turnip grown in the dark are very susceptible to color.—*Pharmaceutical Era*.

VARIOUS NOTES.

TEA ROOT CARVING.—The article on this subject on page 364, from the *Horticultural Times*, is interesting and may prove suggestive. Root stems of coffee bushes in Ceylon are converted into legs for tables and the more slender stems into walking-sticks. But we are not aware that our local cabinet-makers have turned their attention to the wood, stem or root of the tea tree. Nicely polished and carved specimens will, doubtless, figure in the collections sent from Ceylon to the Chicago World's Fair.

JAPAN TEA.—The *Japan Gazette* says:—Taka Shoten is a Japanese tea firm in Kobe which for years past has been exporting black tea prepared in Japanese style and also brick tea to Vladivostock. The brick tea has been received with greater favour than anticipated, but the black tea is unpopular and is considered much inferior to that from China. This, according to the *Nichi Nichi*, is due not only to the want of skill of the Japanese in preparing the tea, but also to the unfavourableness of the soil and climate of Japan. The export of black tea in competition with that from China is impracticable, and the Takeda has therefore decided to ship no more immediately after preparation, but to store it in godowns for a year or two and then mix it with China tea for export. This plan, it is thought, will make the export industry to Russia a success, though of course the experiment remains to be tried. The brick tea, we are told, is prepared from the black tea powder and one would naturally expect that it would be received with equal disfavour as the black tea. The reverse, however, has been the case, and our contemporary explains that this is because the brick tea manufactured here is pure tea, while in China other than tea leaves are usually mixed with the tea.

Considerable attention has lately been drawn to the eucalyptus or the blue gum of Australasia, and the Forest Department would be well advised did they pay more attention to its propagation in Northern and Eastern India. More has been done in the Nilghiris, but chiefly by private enterprise, and where large spaces are available extensive planting might be laid down. The bark, leaves, and fruit of the tree, all possess valuable qualities, and though its use as a rain attractor has seemingly escaped notice, its great height and quick growth place it in the first rank in this respect. But perhaps the most important recommendation of the tree lies in the decoction made from the leaves which is used for preventing scaling in boilers. The oil, which we presume is expressed from the ripe fruit,* may or may not possess all the therapeutic qualities ascribed to it, and either as an illuminant or lubricant cannot be expected to hold its own against kerosine or vaseline; but it may be found useful in the manufacture of soap and cosmetic. The scent derivable from maceration of the flower would hardly recommend itself to general public favour, being almost overpowering in pungency; but doubtless when blended with a perfume less pronounced, it would be agreeable enough. The timber from its liability to split and crack is unfortunately not suited to all purposes, though posts and rails made from it last a long time, and if painted with a mixture of sulphate of copper and gurjan, or, perhaps, eucalyptus oil, resist effectually the attacks of the white-ant, borer, and other destructive insects. As the eucalyptus grows quite as luxuriantly in most of our hill tracts as in Tasmania, it might be as well to ascertain what other plants attain perfection on land affected by it in that colony, with a view of their introduction here, and the Government of India in the Agricultural Department might reproduce the Tasmanian reports in the different *Gazettes* for the benefit of the public.—*Indian Agriculturist*.

* We never heard of oil from the fruit; it is distilled from the strong-smelling leaves.—*Ed. T.A.*

NEW PATENT TEA APPLIANCE BY MR. JACKSON.—In a list of patented inventions in the *Indian Engineer* we find the following:—No. 325 of 1891. William Jackson, of Nuwara Eliya, in the Island of Ceylon, Engineer, for "Improvements in application of air blast or exhaust apparatus for keeping tea leaf cool whilst being operated on in Tea Rolling Machines." (Filed 16 h September 1892)

THE USES OF THE PLANTAIN. A correspondent writing to the *Sugar Journal* on the uses of the banana says:—"I don't think that the health-giving properties of the banana are appreciated by the people of our large towns, where the fruit is so cheap. They merely look upon it as a cheap edible when other fruits are scarce or out of season; but in slices the banana makes an excellent salad served with any kind of dressing: cured it is far more palatable than meat; boiled as a vegetable while green in the skin for one hour and peeled before sending it to the table it will be found excellent, and would make Paddy smile and think he was in old Ireland again. It also makes an extremely delicious pudding for children, served with sweet milk and some sugar, and baked for one hour in a moderately quick oven. Many people in different parts of the world can, with truth, say in regard to the banana, 'This is what I live on.' A very good breakfast dish is to be made by frying slices of banana in the hot bacon fat with plenty of pepper, and serving together as one does a dish of bacon and eggs."

SOY BEAN AS CATTLE FEED.—Professor Georgeson of the Kansas Agricultural College, writes to the *Industrialist* that he is filling a small silo with a portion of the Soy Bean crop in order to test its feeding value when so preserved. He has four varieties, two of which are so far advanced toward maturity that the leaves have begun to fall, while in the others the seeds are only half-grown. The plants were grown in rows thirty-two inches apart in loam of only fair quality, which has not been manured, and the yield of green plants is about five and one third tons to the acre. The growth has been made in exactly three months. Its feeding value compare favorably with that of Clover and Alfalfa in nutritive qualities, and the ripe beans are only excelled by oilmeal. Cattle and hogs eat all parts of the plant greedily, and even the dry bean-straw thrown into the yard after the beans were threshed out was all eaten by the cattle. But, perhaps, the quality which will be most highly appreciated in Kansas is its power to withstand drought, so that not even the severe drought of last year affected it disastrously. When all these qualities become known, Professor Georgeson thinks it must take a leading place among our fodder plants.—*Garden and Forest*.

THE PRODUCE OF INDIAN FORESTS.—Mr. Ribbentrop, Inspector-General of Indian Forests, has issued an announcement that the Government of India will publish unofficially, as appendices to the "Indian Forester," a series of notes on the produce of Indian forests. These publications will, it is hoped, by degrees increase the public knowledge of Indian forest produce, especially with regard to its utilization for manufactures or trade, and will at the same time serve as the most convenient record of facts available for the compilation of the Imperial Institute handbooks. Mr. Ribbentrop has no doubt that Indian forests contain still many undeveloped, and in some instances even undiscovered, treasures in the shape of tanning materials, oils, resins, dyes, fibres, paper material, &c., and even as regards timber, a fact which has been brought prominently to his notice by the recent development of the trade in Padouk.—*London Times*.

WEEDS INDICATING SOIL.—Weeds are not often either respecters of persons or of soils, but usually grow apace with the crops unless diligently resisted by the aggressive farmer, though the fact that some kinds of weeds only grow on rich soil, and their presence indicates fertility, is well understood by farmers. The common thistle cannot be grown successfully on thin, cold soil. Possibly its seed might germinate on such land, but it could not amount to much. The common mallows, growing in gardens, and often a great nuisance there, will not grow in fields of ordinary fertility. On the other hand, mullein and ragweed grow better on poor soil than on any other, probably because other plants run them out if the land is rich. A story is told of a blind man who was very wealthy, and who has made much of his money buying and selling land. Driving one day with his servant to a piece that had been commended highly, he asked "Can you find a thistle here to hitch the horse to while I walk about the land?" "No," was the response, "but here is a mullein that will do as well." "Drive on," said the blind man, "a soil that grows mulleins rather than thistles never does for my buying."—*Horticultural Times*, Sept. 12.

THE

TROPICAL AGRICULTURIST

MONTHLY.

Vol. XII.]

COLOMBO, DECEMBER 1ST, 1892.

[No. 6.

MR. E. J. YOUNG ON OOTACAMUND AND THE
MADRAS GOVERNMENT CINCHONA
PLANTATIONS.

N a second brochure on "My Mission to Southern India," dedicated to his brother planters, Mr. Young records the impressions he received during a week's visit to Ootacamund, and the cinchona plantations on Dodabetta and at Nedevuttam. Mr. Young was enchanted with the scenery, which for grandeur and beauty are almost unsurpassed. The climate, too, from its dryness (not 45 inches of rain per annum as Mr. Young states, but a little over 50 inches) is exceedingly pleasant and salubrious, and with the rich soil is all that could be wished for cinchona culture although not for a remunerative yield of tea leaf. The elevation of Ootacamund is not, as Mr. Young states, 8,000 feet, but only 7,000, exactly the height of the lofty table land of Ceylon, "Horton Plains" which resemble the South of India sanitarium in soil and general surroundings, although the Ceylon station gets at least twice the rainfall which falls on the Plain of Ootacamund. On the cinchona plantation up the side of Dodabetta, however, and especially at Naduvatam, there is abundance of rain 100 to 150 inches per annum occasionally at the latter station. Mr. Young does not take a sanguine view of the success of the mountain railway, which is in course of construction from the foot of "the ghats" to Coonoor, 6,000 feet above sealevel, to be ultimately carried 1,000 feet higher into Ootacamund. Mr. Young dwells on the paucity of goods traffic downwards, but this traffic will increase as well as that in passengers, Ootacamund being, deservedly, a favourite health resort, not only by Europeans in the Presidency, but others beyond it. The success of this mountain railway will be watched with interest in other parts of India and Ceylon. Much of it will be on the Rigi principle, lines on which principle we expect will ultimately enable visitors to our island, tourists and residents to ascend with ease to the summits of Pidurutalagala, Adam's

Peak, and others of our Ceylon mountains. Mr. Young recommends for adoption in the case of Nuwara Eliya and its neighbourhood, the system which the Madras Forest Department has carried out in Ootacamund of planting large plots of eucalypts, especially blue gums, and Australian acacias, and which are now valuable for purposes of shelter as well as for timber and fuel. The leaves and small twigs of the blue gum are also valuable as yielding an essential oil largely used in medicine and on the virtues of which, especially as a cure for rheumatism, Mr. Young is quite enthusiastic. Mr. Jameson who, under Mr. Lawson, is in charge of the exquisitely beautiful Botanical and Public Gardens at Ootacamund, indoctrinated Mr. Young into the method of distilling this oil. From a recent visitor to Ceylon from the Nilgiris, Mr. Brown, who is employed on one of Mr. Stanes's properties, we received a bottle of this oil, "Oleum E. Globulus," prepared by himself at the Felixstowe Laboratory, Coonoor, and we have just had presented to us, as an infallible cure for rheumatism and other ailments, including diphtheria, (which has been cured by the inhalation of steam from a decoction of blue gum leaves,) a phial of Tasmanian Eucalyptus oil. If all that is said of this substance is true and if the demand increases, Ceylon now possesses so many blue gums that it could well be a source of manufacture and supply. As we saw and greatly admired the well-grown trees of *C. officinalis* on Dodabetta and the *succirubras* at Naduvatam in 1877, we are not surprised that Mr. Young should be struck with the gigantic survivors of poor McIvor's first plantings. We are rather surprised, however, that Mr. Young should have told Mr. Lawson he never heard of cinchonas being manured. Why, the thousands upon thousands grown amongst coffee in Ceylon received the full benefit and profited by it, of the manure applied to the main culture. In noticing the Nilgiri Plantations reports, too, for a quarter of a century or more, we have constantly quoted statements as to the wonderful effects of ammoniacal manures in increasing the cinchona alkaloids, especially quinine. The cinchonas are simply no exception to other cultivated plants which respond to the application of fertilizing matter, and Messrs. Lawson and Hooper are wisely following out the policy which poor Broughton recommended in his time. If ever the cultivation of coffee and cinchona revives in Ceylon, manure must be liberally applied to obtain the best results. Here as on the Nilgiris, of course, only the best species, and best varieties of hybrids will be employed: Ledgerianas, *Officinalis*, with *Magnifolia* and other good

hybrids as tested by results of alkaloids in the barks. At present, certainly we in Ceylon must give first and second place to Java and India in regard to cinchona culture. As to tea we can hold our own, but we suspect the statement of our good friend Mr. Young that Wynaed is no more likely to succeed with tea than the higher slopes of the Nilgiris, will be sharply challenged,—judging from sanguine letters in the Madras papers.

Having thus given a general idea of the contents of Mr. Young's pamphlet, we now proceed to take over a few interesting extracts:—

The usual mode of travelling in Southern India is by a curious vehicle called a Tonga, which is usually drawn by two horses or good sized ponies. It has two seats back to back, suspended on two wheels, and is covered by an awning, and being very light is admirable adapted for hill travelling and I cannot understand why it has never been introduced into Ceylon in place of our Cumbrons Coaches.

At the top of the Coonoor pass the road skirts two or three estates under European management; and near the road itself I saw some fairly cultivated coffee; the trees looked healthy and vigorous and were kept in good order and reminded me of the days of yore when the bushes flourished in our midst; but further back, the coffee fields had a weedy and semi-abandoned appearance, and I was told by planters this was the customary cultivation in that part of India.

The public gardens are a most agreeable resort; they are well cared for, and laid out prettily and with taste, and contain many rare and interesting plants from all quarters of the globe. They appear to be singularly adapted by nature for charming scenes and this has been cleverly taken advantage of and augmented by art, and the delightful results are probably heightened by the beautiful views afforded all around over mountain, hill, and dale; with bungalows peeping out here and there from amidst the forest of Acacias and Bluegums.

I made several pleasant visits to these gardens, and carried away a deep impression of their beauty; they are, I believe, about 50 acres in extent, and have an extensive conservatory, a Herbarium, and a good Library which contains many rare and valuable works; and the whole reflects the greatest credit on those in charge. I have seen nothing in the East to compare with them.

Surrounding the Sanatorium are large plantations of Bluegums the property of Government. These woods are of all sizes and ages, and add greatly to the beauty of the place, and give it a homelike and cosy appearance, recalling Scotland to one's memory; indeed Ooty, with its environments, reminded me greatly of the neighborhood of Dunkell.

The Eucalyptus globulus not only adds to the beauty of the scenery, but forms a shelter to the whole town during the prevalent winds; and is a most profitable cultivation for fuel, affording also a useful essential oil which has found a sound footing of recent years in the pharmacopœia.

Eucalyptus oil, distilled from leaves of Eucalyptus globulus, is now used in hospitals, as the best cure for Influenza, Rheumatism, and Lumbago; and is an antiseptic; and has moreover replaced in Surgery Carbolic acid.

I tried this oil for an attack of Lumbago, and found its effect marvellous; the best way to apply is to put about a table spoonful into a hot bath, and then lie in the bath for some time; the result is speedy, and efficacious, and I can recommend it in the same manner for Colds and Chills; and also to remove aches and stiffness after long rides and great exposure to heat or Cold. It has a most soothing and restorative effect, and produces sleep. No bungalow should be without a bottle of this invaluable medicine.

It is now distilled in considerable quantities at the Ooty Botanical gardens; and the Curator, Mr. Jameson, very kindly initiated me into the secrets of extracting the oil.

The distillation is carried out in the usual way; and a still such as is used for Arrack or Whisky would answer the purpose perfectly, care being exercised

that the oils should be distilled at as low a temperature as possible.

Adult leaves and small twigs are the best, and are richest in oils during the dry months. It takes 70 to 80 lb. green leaf to yield 1 lb. of essential oil, valued at present from 4s to 10s. per lb. in the London market; while to extract the oil the cost is, from first to last nearly £1 per lb., although it can undoubtedly be done for much less when carried out on an extensive scale.

The gardeos find a ready local sale for the oil at R5 per quart bottle. The natives buy eagerly, and are great believers in its curative properties.

To facilitate extraction, and also to increase the yield, the leaves and young twigs are put through a Chaff cutter; this operation breaks up the oil cells, and I consider it would be a still further improvement, (and suggested the idea to the Curator,) to pass all the leaves and twigs between rollers made somewhat after the fashion of Tea machinery.

The present system is to root up the tree, fell the wood for fuel, and extract oil from the leaves; this struck me as a very wasteful method, and I suggested that by topping the lateral branches, one tree would continue to yield leaves for many years, and thereby prove a still greater success commercially.

There is no reason why Ceylon Planters should not go in for this cultivation; particularly towards Dumbula and Nuwara Eliya, where the blue gum grows to such perfection, as it would prove a remunerative adjunct to tea.

I am strongly of opinion that the Ceylon Government should be guided by the Madras Authorities and plant up extensively all sorts of trees in the neighborhood of Nuwara Eliya, under the direction of the Forest Department. It would add greatly to the beauty of the place, and would, I am certain, in the long run prove remunerative.

Dodabatta is about three miles from the Ooty Club; and is on the steep side of a hill overlooking the town. A friend took me up there one afternoon, and we rode all over the place. It is planted with officialis, or Crown Bark; with a few Hybrids interspersed, and is a fairish cover, the trees being thinned out in many parts; they are well grown, strong and healthy, and I could not discover a sickly or cankered tree.

This garden was originally opened 25 to 30 years ago, and the trees have all the appearance of their age, and are well grown and set.

The soil and climate seemed to me perfect for this cultivation; the former is a dark rich friable loam of any depth, without the slightest sign of clay, or a stone anywhere about; and with all the appearance of what we call in Ceylon "Patnasoil." The average annual rainfall is about 50 inches.

Mr. Lawson informed me that very recently at Dodabatta 12 acres of the crown bark, 25 years of age, were uprooted and yielded 4,400 lb. dry bark per acre; the trees in question had been harked some 6 or 7 times, and the plot was the worst on the Estate.

After a most enjoyable drive without incident or adventure, we arrived safely at Mr. Lawson's hospitable bungalow in good time for breakfast, and received a hearty welcome from our kind host.

The bungalow is at the very top of Naduvattam, at an elevation of 6,000 feet above sea level, or say at the altitude of Nuwara Eliya; and the view from the front of the house surpasses anything I have ever seen. I can call to mind no other place with such grand glimpses of nature; nothing equal to it. Many beautiful scenes are to be met with in our own little Island but they dwarf into insignificance in comparison with the magnificent view, spread out like a panorama in front of Mr. Lawson's house.

At our feet stretches the Wynaed, estates being seen dotted here and there, with the cart road leading to the seaport at Calicut, winding down the face of the hills; till at last, all is lost in the haze of the low country.

Gold is found in the hills immediately below; and companies have been started with a view to working it but the results so far have been small, yet, I believe sufficient, to give encouragement to continue working. Towards the north is a parklike country, inter-

sected with ranges of hills beautifully tinted in varied colours, and interspersed with what appears in the distance to be lakes, and rivers, and this comprises the Mysore country. Mysore itself can I believe be seen on a clear day from Naduvatom.

At our back and towering over us, mountain upon mountain, are the Ootacamund hills; with the Sanatorium in the centre. The whole makes a wild and charming picture which language is quite inadequate to describe.

The Cinchona at Naduvatom is planted in two deep and well sheltered valleys running down parallel on each side of the bungalow.

The lay of land is very steep in parts, and indeed the trees seem to thrive and grow best on ground of that nature, owing no doubt, to the drainage being better, and no moisture lodging at the roots.

Both the climatic conditions and soil at Naduvatom are similar to those already described at Dodabetta; and are equally favourable to the growth of Cinchona.

The principal cultivated variety is *Succirubra*; but *Pubescens* mixed with a good many different species of Hybrids is also in evidence. In fact I recognised most of the Cinchonas grown in our Island. There are some younger fields, but the principal part of the cultivated area consists of trees from 25 to 30 years old, which are beautifully grown with magnificent stems, and form quite a forest, this being by far the finest show of Cinchonas I have ever seen. There is nothing in Ceylon to equal the size or evenness of the trees, but of course it must be borne in mind that we possess none of the same age.

What pleased me most was the extremely healthy appearance of the trees which appeared to have taken a firm hold as if in their natural habitat; not a single cankered tree could I discover anywhere, though I searched for one in every direction.

The whole cultivated area is well roaded, and in excellent order. I was there during the dry season, and the weeds had mostly been carefully trenched, or dug under, and the land had a highly cultivated appearance.

Mr. Lawson told me that fourteen acres of 25 years old *Succirubras* on the Naduvatom Estate, which had been barked 7 or 8 times, yielded on being coppiced 3,250 lb. of dry bark per acre. The trees were on poor ground, and many of them were dying.

I had long and most interesting conversations with Mr. Lawson on cinchona cultivation, and got an immense amount of valuable information from him on the subject; but there were many points on which we did not agree.

I explained that we had suffered most in Ceylon from canker, brought on by the excessive moisture of the climate; clayey, or damp soil, and consequent "Wet feet."* But this Mr. Lawson would not on any account agree to, and attributed canker in cinchona to poor soil and bad cultivation. Canker, he says can be surmounted, and almost invariably eradicated, provided the disease has not proceeded too far, by the following mode of cultivation:—

Cut parallel trenches 10 feet apart running across the face of the hill, and make them 2 feet deep by 1 foot broad, and into this put your manure, if procurable; and then scrape in and mix well together all leaves which are lying about, with weeds and top soil, till the trench is well filled up.

Mr. Lawson considers that excessive moisture at the roots, amounting to "Wet feet" has nothing to do with Canker, and that it arises simply from poverty or exhaustion of the soil, and can, if taken in time, be destroyed by a thorough system of cultivation as described above; moreover, he is of opinion, that weeds do little or no harm to Cinchona, and that it will be quite sufficient if they are cut down once during the twelve months.

I told Mr. Lawson that I had never before heard of manuring Cinchona; but he said it requires sustenance equally with any other plant, and that he preferred his system of manuring as already described to ours of pitting or forking-in, for the following reasons; the advantages of the system according to Mr. Lawson's idea being 3 fold, viz:—

1. It cuts all the whiplike roots on one side of th

tree within 2 feet of the stem; these roots producing very few feeding fibres; whereas from the cut ends of the roots large bunches of fresh feeding fibres are sent out into the trenches amongst the fresh soil and cool damp earth; and well out of the reach of the drying influence of the trying sun during the hot weather.

2. It is much cheaper than pitting, in the same proportion as digging a ditch to digging wells, the cost on the Government Estates being from R13 to R30 per acre.

3. By treating the land in this manner you bring up subsoil which eventually is made into rich surface loam, and thus the whole estate in the course of time, is renovated at a small outlay.

The great point is to cut the roots and let them get into fresh and *free soil*.

Most Ceylon planters, equally with myself, will be surprised at the foregoing views regarding cinchona cultivation, as we generally hold to the belief that cutting, or meddling with the roots, or manuring in any form whatsoever, brings on canker, which speedily kills the tree. That Mr. Lawson's treatment answers on the Nilgiris his magnificent fields of cinchona clearly testify; they speak for themselves; at the same time, I must beg to differ from my learned friend, as I consider his great success is not altogether owing to the mode of cultivation, but is due, in a great measure, to the perfect climate and soil of the Nilgiris which are so admirably adapted to this plant.

I came away deeply imbued with the impression that the [quinine] manufactory in a commercial sense is not a success; and that it would never answer, or pay, to start a similar establishment at Nuwara Eliya, as was at one time contemplated.

Another point which exercised my mind not a little, was the idea that the febrifuge is not all, or nearly all of it, extracted from the bark. Whether this is owing to climate influences, the water, or both; or whether it arises from insufficiency, or weakness of the chemicals and appliances used, I am unable to say; still I strongly hold to the opinion from all I saw and heard on the subject, that nothing like the full amount is extracted from the raw material.

I was told that on an average the factory extracts 3 to 4 per cent. of Quinine; considering therefore that the trees from which the bark has been harvested are 25 to 30 years old, perfectly healthy, and that the bark is mostly renewed, and very often is Crown bark, the average does seem absurdly low.

I went into figures with Mr. Lawson as to the acreage under Cinchona cultivation in Government hands, and into the approximate estimate of yield, were the whole to be coppiced, with the following result:—

Dodabetta cultivated	...	320 acres
Naduvatom	...	350 "
Pykara	...	250 "
		920 acres
Deduct acreage recently coppiced and young	...	120 "
		800 acres.

There are therefore 800 acres old, and well grown Cinchona, in Government hands, which I put down at an average of 3000 lb. per acre, or say in round numbers 2½ million lb. dry bark; however, I look upon this as a very safe estimate, and consider that 3 or even 3½ million lb. would be nearer the mark.

There are several Cinchona Estates in this neighbourhood in private hands, but I had no spare time to pay any of them a visit, however much I should have liked to do so. Nevertheless I cannot help remarking on one property which took my fancy immensely. It faces Naduvatom, and the cart road to Ooty skirts the estate. It is called "Liddesdale" and belongs to the "Nilgiri Tea and Cinchona Co., Ltd.," and is one unbroken sheet of 700 acres old Cinchona: mostly Hybrids, and high class varieties, which it would be difficult to beat. The lay of land, soil, and climate, of this valuable property are very similar to our Agras.

I came across three or four small tea gardens in the neighbourhood of Ooty and Naduvatom, but the plant does not look happy, nor does it answer on the

* We take leave to dissent.—ED. T.A.

Nilgiris. The fact is that both the soil and climate which are so favourable to cinchona militate strongly against tea: the rainfall is insufficient, and the soil much too dry and friable. For six months the bushes are nipped down by frost and the bitterly cold nights, and for a like period are unable to flush owing to strong wind and cold rain; hence the yield is insignificant, and the only way it can possibly be made to pay is when worked as an adjunct to Coffee or Cinchona; and also by getting a local sale for the produce through the Madras Presidency.

From all I could learn tea is also likely to be more or less a failure in the Wynad, where it has to contend against drought as well as the unhealthy season, which extends from March till June the best flushing months—when not even a cool can stand the climate.

Mr. Lawson took me for a charming walk of about three miles over the hill at the back of his house, where we had a splendid view of the far famed "Oucherlony Valley," which lay at our feet bathed in sunshine. Both in contour and size it reminded me greatly of Kelebobkka; being a long narrow basin backed by high hills on either side, with a cart road down the middle. The two valleys are also very similar in altitude, and lay of land, and each contains about a dozen different properties. "Oucherlony Valley" was originally a magnificent sheet of coffee, and I believe gave wonderful yields in the palmy times, but a good portion of it is now planted up with cinchona which thrives well, not only here but all over this country.

I was not able to get down to the coffee fields, but in the distance they looked thin and poor, and have no doubt here as elsewhere suffered from the scourge of leaf disease. I was told the yield is not nearly so great as it was in the time previous to leaf disease, and the cultivation is now giving way, in a great measure, to that of tea and cinchona.

One of the great drawbacks to the Sanatorium is the scarcity and costliness of public conveyances. The common Tonga and pair is the only vehicle to be had on hire; and indeed I was informed that on occasions of public gatherings and social festivities, it was often impossible to get a carriage for love or money.

I expressed surprise to several of the residents that the machine called a jinrickshaw had never been introduced into Ooty.

THE INDIAN TEA CROP OF 1892.

The clearances of this season's tea crop to 30th September total up 584,523 packages weighing 50,936,063 lb., and of the declared value of Rs. 2,66,32,158, giving an average of about annas 8 4/4 per lb., which must be satisfactory to the proprietors as compared with last season. Had, however, the Currency Bill been in operation and the rate of exchange fixed at 1s. 6d. there would have been a difference on the wrong side to those parties interested in tea gardens of about 37 lakhs of rupees, and which by the end of the season would possibly be doubled. It looks as if one-half of the tea crop had been exported up to 30th September, as the total crop is not likely to turn out as large as the latest revised estimate of the Tea Association, the weather in the Tea Districts having continued unfavourable.

It appears strange that out of the 584,523 packages which have already been exported, only 232,944 packages have been sold at the public sales, and that 351,579 packages have been on account of the proprietors. What is the cause of this? There are six large firms of tea brokers in Calcutta, all of whom look well after their business, and who, during the season, are tasting tea samples from early morn until late in the evening. At the commencement of the season, before the tea sales begin, all the brokers are inundated with garden samples for report and valuation, and after all their labour—and it must not be overlooked that tea tasting is more injurious to the health than B. and S.—they only get 40 per cent of the teas for their sales. Proprietors or their Agents may assert that the prices obtained

in the local market are not to be compared with the rates realised in the London market, but against this assertion it is very difficult to find many regular shippers who purchase their teas in the local market that have realised any large profits on their shipments. Generally it is all the other way, and it is only when an unexpected spurt takes place in the London market that shippers who have teas near arrival, make a good profit, but, subsequent shipments made after the news of the rise in London has reached here generally leave very unsatisfactory results.

Perhaps it may be that there are not buyers in the market (notwithstanding the operations of the largest tea dealer in England, who has lately commenced to make his purchases in this market) to take off a larger quantity of the crop, but it is not at all improbable that Agents' commissions have a good deal to answer for. Ceylon teas appear to have caused a falling off in the demand for our teas in both the Australian markets and in Bombay and Persian ports.—*Capital.*

THE WOODS OF ENGLAND; TENDENCY TOWARDS RE-AFFORESTATION.

Will the England of half a century hence look much more like the England of Elizabeth's time than does that of these days, and is the appearance of the country going back in any way to that which it presented in primitive ages? These questions will be sure to be asked by those who study the purport of a recent return procured by the Board of Agriculture respecting the extension of woodlands in England and Scotland. Many shrewd observers have long maintained that the plough has been going where it had no business to be, and that ambitious agricultural improvements upon which thousands have been spent to little purpose would have proved remunerative had they taken the form of planting young forest trees at a trifling original cost. It would seem that this opinion is gaining ground. The increase in the acreage under wood, though not rapid, is unmistakable. It has been steadily going on; at all events, since 1872, when the first trustworthy returns on the subject were published. Between 1888 and 1891 it had increased from 2,561,000 to 2,695,000 acres; and there are signs that it may go on at still greater speed. In a recent contribution to the small native literature of forestry, Mr. Nairne has pointed out that some discouragements to afforesting are coming to an end. In the northern parts of Scotland, where is so much waste land growing barely herbage enough for sheep, landowners did not care to plant much while the crofters' agitation was at full flood, though it must be mentioned that two-fifths of the entire surface planted in the last decade is in that country. It was not to be expected that, with very bad times and falling rents, they would care to make profuse outlays, the return for which would not begin to come in until after 40 or 50 years, and we are told of nurserymen who grew tired of cultivating year after year young forest trees, which they hunt to make room for a younger stock, and who sold what little they did sell at insignificant prices. In the districts to which Mr. Nairne refers it has generally been deemed preferable to turn tracts available for planting into sheep-farms or deer forests, and the preference is likely to survive. Those who are offered handsome rents for high moorlands or mountain wastes, where fir or larch would have a hard strife for life, are not likely to hesitate; they will take what comes in their way, and bid posterity look after itself. Between 1888 and 1891 there has been an addition of 31,000 acres to the wood and area of Scotland, which is not indicative of any great changes going on in the rural economy of the country, but which does speak of a removal of some of the former obstacles to afforesting. In England an increase of about 96,000 acres in the above-named period is recorded. But it is curious to note the conservative ways of the country. The counties which were

best wooded in Elizabeth's time are still so. Sussex, for example, still answers to the description given of it by Camden as being "pleasantly shaded by woods"—it is the second in extent of woodland of all the English counties, and there is a survival of primitive conditions in the fact that the Hants, Surrey, Kent, and Sussex have between them nearly one-fourth of the whole English Woodland.

Old ways will not quickly change; and it is not to be anticipated that young trees will generally take the place of wheat, cattle, and sheep. What is permissible to say is that the outlook for afforesting is better than it ever was. There are limits to the resources of the Norwegian and other forests, upon which even distant Australia make a drain. In a quarter of a century the Baltic ports may no longer send to the vast supplies upon which we have long counted. Canada and the United States have growing home demands to meet; and there is no new country to which we can look to give us, in abundance, the cheap timber needed in mining and the construction of railways. Will the rural economy of England and Scotland mere and mere conform to the altered conditions of supply? Political economists have always admitted that in the case of afforesting there might be a conflict between the interests of the community and those of a private owner. He, as a rule, cares to sow only where he will reap; and the harvest is very far off to him who plants the oak or beech, or even the larch or pine. If rich and public-spirited, he may, out of his superfluity, give wherewith to provide for his successors full-grown and valuable timber. But the temptation to most men to prefer returns coming in at the end of four or five years, or less time to those postponed, it may be three-quarters of a century is strong. He may have an estimate for planting fir and larch at, say, 40s to 50s an acre—that given by Mr. Nairne—even at less; the work will, at any price, appear too costly—the public benefit private imprudence. So much have some economists and writers upon forestry been impressed by the possibility of this contradiction that they have argued that the State should insist upon continuity of production. Such a policy is needless; something might be said for it if it were necessary that a sudden change should be made, and that large tracts should be without loss of time turned into woodland. Nothing of the sort is advisable; the history of English agriculture is full of warning against a policy of spasmodic "improvements" or changes carried out in a spirit of panic. What is required on the part of those who have the means to plant is that they study oftener than they do the capabilities of their estates to grow marketable timber. Some of those who plead poverty when counselled to plant trees whose generations of farmers have fought in vain against the stubborn poverty of nature have money enough to invest in dubious foreign investments, and provide for their families in ways which will be worthless by the time that goodly timber, a veritable mine of wealth to its owner, would have grown up.

It is interesting to know that the counties best wooded in Elizabeth's time are still so; it would be more satisfactory to hear of greater variety and fresh experiments being tried in districts where wood is rare. The returns which we have cited show a considerable area—about 311,351 acres—under woods or plantations in Ireland. But as to that country, it cannot be doubted that vast tracts of which no industry can make much as arable land are well adapted for the growth of timber. In Wales the additional acreage brought under wood between 1888 and 1891 was only 7,000. Will it be said that this is all that under a wise rural system should be added? From the growth of a taste for forestry and the spread of knowledge respecting it more is to be hoped than from crude, ambitious schemes fostered by legislation and carried out by a Woods and Forest Department of the country councils. For twenty experts in ordinary agriculture among landowners not

one is acquainted with the rudiments of woodcraft. Evelyn deplored in his time the "disproportionate spreading of tillage, caused through that prodigious havoc" wrought by those who would raze the "many goodly woods and forests which our prudent ancestors had left for the ornament and service of their country." A diffusion of the tastes which the author of "Sylvia" entreated would be a blessing all round. There would be the certainty that there would be no "disproportionate spreading of tillage," that forest trees of all sorts would have their fair share in our rural economy, and that there would be no wasteful use of timber without taking care to replenish the stock.—*London Times*, Oct. 21.

COOLIE LABOUR.

Sir,—There is a letter in your issue of August 27 on the coolie labor question which, though moderate in tone, yet does not deal with the matter from the broad political point of view from which politicians require to look. Humanitarians and social reformers are not always the best political guides, as in the instance of the C.D. (woman's) act in England and India. But I do not desire to argue the rights or wrongs of that Act, or the repeal of the same. My present object is to controvert some of the arguments used by Mr. Kirby. I have spent 19 years in Ceylon and India, and during that long period I have been engaged in various planting enterprises, and all the time I have employed colored labor; hence I may be considered competent to give your readers the other side of the subject. Mr. Kirby deals with the danger of a half-caste progeny arising in our midst, which is the sure result of the mingling of the dark races with those of the white, and the terrible demoralisation and degeneration which will ensue. He says the result of bringing a number of coolie women to Australia will be the flooding of Australia with the lowest sort of half-caste, and the Australian blood will become abased. This cannot but help raise a smile at the extremely narrow horizon which confines the views of Mr. Kirby. Let us widen out the matter, and see fairly how the introduction of coolie labor will be a blessing instead of a curse. Missionaries and others have an idea that the heathen are governed by low morals. Mr. Kirby may be surprised when I tell him that the ordinary coolie class suffers more injury from contact with the white man than the white man could possibly suffer from contact with it. They are guided by the stern rules of caste which act as a hereditary moral principle, and in their villages these rules are strictly enforced. It is only when the coolie tries to imitate the European vices that the power of caste ceases to restrain him. If Australia included only countries of temperate climate Mr. Kirby's arguments would have more weight, but large tracts of tropical lands lie waiting for tropical agriculture, and Mr. Kirby only proclaims his ignorance of tropical matters when he soars into utopian dreams of mythical labor-saving machines which will enable the white man to cultivate tropical lands. The Tamils are an intelligent, docile race, and it is a base libel to say that their women are so immoral that they would contaminate the people here. The coolie prefers to have his hut and domestic happiness to himself; but, as in all communities in all countries, even in Australia, there are women (and men, too) "of the baser sort;" the presence of these, however, does not corrupt the others. Careful selection of labourers and good fair treatment will result in a most useful class of labour being introduced into the tropical regions of Australia, and thereby releasing the latent locked-up wealth which awaits the enterprising planter. Then Australia would be dependent on no outsider for her supplies. Coconuts, cocoa, rice, coffee, tea, arecanuts, spices—all these products and many more would be produced in the country. Employment as managers and overseers would be found for your educated youth, new and remunerative channels would open out for your money, and fair sensible laws would control the coloured immigrant, and prevent any clashing or inharmonious contract

with the white labourer. In conclusion, I would beg Mr. Kirby not to malign a class of labourers, thus showing his utter ignorance of the subject in hand. Wise laws and a strong Government could easily control and arrange the introduction of Tamil coolies so as to prevent any conflict or antagonism between white and black labourers.—I am, &c.,

Buckalow, Broken Hill. W. A. TYTLER.

—*Adelaide Advertiser*, Oct. 11.

[We do not see how the tropical portions of South Australia are to be utilized unless by means of Indian labour, but for the sake of Ceylon we are glad to believe that the views which will prevail with the white settlers are those expressed by Mr. Kirby and not the optimist opinions of our good friend, Mr. W. A. Tytler.—*Ed. T.A.*]

FORMS OF ADULTERATION.

The most universally coloured article is butter (says *Food, Drugs, and Drink*), and it may with great confidence be asserted that there is hardly a pound of butter sold at the present time in this country which has not been doctored, mostly by the aid of a harmless vegetable colouring matter—annatto—in order to impart to such butter a rich golden colour. Butter naturally varies much in colour, according to the season, the breed of the cow, and mainly its food; and it is but rarely the natural butter possesses the colour to which the public is now accustomed. The desire of those who introduced this admixture was obviously to make their product appear richer and more enticing to the eye than nature had intended. One after the other the rest of the butter merchants had to follow suit.

Milk is also generally coloured by the milkman. Here the object is plain. Watered milk assumes, as is well known, the tell-tale sky-blue colour which at once betrays that the milk has been tampered with. To hide this the blue milk is again artificially provided by means of a yellow solution of colour with a rich creamy appearance. To hide the original fraud the second deception is practised.

Mustard, especially that which has been adulterated with flour, which in consequence also would look sickly pale, is brought up to the original colour of genuine mustard by the addition of turmeric, and a similar practice is beginning to be adopted in the pepper trade.

Sausages, both meat and skin, are dyed with aniline colours, for the purpose of hiding the colour of unhealthy or stale meat which may have been used. Jams, especially plum jam, are generally dyed with aniline colours, and sugar confectionery is hardly ever without such artificial dye. Ale is darkened with burnt sugar, as also are brandies and whiskies.

It must be admitted that in by far the majority of these cases the colour used is entirely harmless, and has no influence upon the health of the consumer. Yet there are a number of aniline colours which are positively poisonous, even when pure. Such colours are picric acid and its salts, Martius yellow, safranine, mettylen blue, dinitro-cressol, and aurantia. Others, unobjectionable in themselves, become poisonous owing to their mode of manufacture, which leaves in the products poisonous impurities, such as arsenic (rarely), salts of copper, tin, or zinc. The manufacturer of sausages or jams has not the least idea whether the colours he uses may not belong to one or other of the above, to which doubtless many others could be added, and even if the quantity of colour consumed by one individual may be exceedingly small it is palpably evident that no such manufacturer should have the right to use such colours. Almost every civilized country has passed legislative measures regulating the use of colours such as those referred to, but England, the mother of all Adulteration Acts, has done nothing, and has in this, as in many other points concerning the sale of food and drink, remained far behind most other nations, even including the equalling South American Republics.—*Pall Mall Budget*

PEPPER, PEPPERCORNS AND OTHER THINGS.

A grocer, speaking of pepper the other day, confessed that he was unaware that white and black pepper were both derived from the same plant. We supposed this was so well known that no one in the trade could be ignorant of the fact. The berries of the *Piper nigrum* are gathered as they begin to turn red, and when dry they form the ordinary black pepper, while white pepper are the same berries deprived of their pulp, or sometimes by blanching the outer layer of the berry. What is known as long pepper is the berry of the *Piper longum*; it is less powerful than the former, though a considerable article of commerce. Pepper was greatly prized by the ancients and sometimes even made a medium of exchange. The plant itself is a stout shrub, trailing or rooting at the ends, or rooting at the joints or climbing on trees. The stems grow to a length of 20 feet, bearing large ovate leaves and flowers and berries in spikes. It is a native of forests in India, and is everywhere cultivated in hot, damp, tropical countries. Sumatra produces the commonest and cheapest qualities, the heavier kinds of which are called "shot" pepper.

The term "peppercorn" is frequently heard in England, but the average grocer of the United States would hardly know that plain pepper was meant, should one of his customers ask for peppercorns.

In olden times grocers were called pepperers, and they formed an important part in the community when much of the food was salted meat, and pepper was in great request as a seasoning.

There is a dish called pepper-pot made of tripe shredded and stewed to the liquor of which small balls of dough are added, together with a high seasoning of pepper.—*American Grocer*.

NAILS IN FRUIT TREES.

Driving rusty nails in pear trees, as a preventive or cure for blight, has long been practiced in some sections of the country. The Fruit Trade Journal, of New York, refers to the use of nails in peach and other fruit trees, as follows:

A singular fact, and one worthy to be recorded, was written us by a gentleman who stated that while on a visit to a large peach orchard, in which every tree was totally spoiled by the ravages of the worm, with the exception of three, and these were the most thrifty and flourishing peach trees he ever saw. The only cause of this superiority known to the host, was an experiment made in consequence of observing that those parts of worm-eaten timber into which nails had been driven were generally sound.

A chemical writer on the subject says: "The oxidation or rusting of iron by the sap, evolves ammonia which as the sap rises, will of course impregnate every part of foliage and prove too severe a dose for a delicate plant of intruding insects."

This writer recommends driving half a dozen nails into the trunk.

Several experiments of the kind have resulted successfully.—*Florida Agriculturist*.

PLANTING NOTES FROM COORG.

Coorg, Oct. 29.—The condition of the roads has invariably been a standing grievance with the planting communities in perhaps all Districts. * * * Owing to the steep gradients of parts of the roads their bad state becomes a greater hardship and the wear and tear entailed on all draught animals must be very severe. There are some roads in the country which are never metalled. The important Mercara-Somwarpett road is one of them. During the wet weather there are regular puddles in parts and the slough-like hollows are usually filled in with boughs of trees, great blocks of stone or "D. P. W. mixtures" of sorts to render them passable. Sometimes the remedy is worse than the disease. I was told by an ex-Ceylon planter that it was a standing order of the Government of Ceylon that no part of its roads

should be made a steeper gradient than I in 14, and that nowhere had he seen roads kept in such excellent order as in Ceylon. A very different policy appears to commend itself to the authorities here, a policy which would deprive an industrial class engaged in the development of the resources of the country and adding materially to its wealth and importance, of the advantages of good roads. I shall not enlarge upon the subject further beyond expressing the hope that the ventilation it has received in the Press will be fruitful in bringing about some permanent good.

The important works of digging and, to a smaller extent, renovation pitting have now been in hand for some time. The latter is a luxury that cannot be largely indulged in unless labour happens to be exceptionally abundant. The benefit which results from it is fully recognised everywhere; but, owing to the slow progress of this work, it has to be limited to fields which are deemed to require it most, and is generally carried out in rotation. With regard to trench-ploughing, it is said that "the incorporation of subsoil with soil is a procedure to be adopted only with great caution," as, being more of the nature of the underlying rock, it tends to weaken the surface soil. Renovation pitting does not, however, operate in the same way, as it is only done some time after the coffee has been planted. The pits also form reservoirs for much valuable matter which would otherwise be dispersed and lost; and thus, in process of time, an increased depth of good soil is obtained. Some planters are of opinion that renovation pits answer very well in lieu of drains; indeed, they would appear to lower the level at which water stagnates, but they can only do so temporarily. The only objection, apparently, that can be urged against renovation pitting is that it prevents the soil being kept in a fine state of tilth. The intervals between the pits become by compression quite dense and hard, which, for reasons explained in Mr. Graham Anderson's letter on "The Weeding of Coffee Estates," would give rise to increased temperature. That an increase of borer would follow is very probable. The totals of the losses from borer this season were, in many cases, so appalling that Mr. Anderson's remarks in this connection are well deserving of the attention of all planters. From what can be gathered on the subject from agricultural works, there can be no doubt that keeping the soil in a fine state of tilth, by frequent stirring, would tend to keep places cool, as its capillarity is increased; and, for reasons which Mr. Anderson gives, the probabilities are that this would operate to some extent in checkmating borer. It was noticeable here that borer was severer in parts that had been renovated last year than in those that had been dug; but it was just the reverse as regards leaf disease. This defect in renovating pitting would perhaps be remedied by digging the parts renovated late in the year and filling in the pits; but unless they have been opened early in the year, it is generally considered undesirable to fill them in the same season. I have mentioned the practice on some estates of manuring in renovation pits. This is done in November and December, sometimes late, in pits opened between June and August. It has been attended by the best possible results. Two successive good crops have been obtained off fields treated in this way. Forking and loosening the hard intervals between the pits, without filling them in, has been found to act beneficially, as indicated by the improved appearance of the trees. There are fields of coffee all over the country which practically enjoy a complete immunity from leaf disease. It is evident that the conditions which obtain in these fields are unfavourable to the spread of the fungus. I must not omit to mention that a field here which had a bad attack of leaf disease 3 years ago has kept remarkably free of it ever since. The additional care and attention paid to it probably accounts for this. On the other hand, fields free of it in some seasons take it in other seasons, and it is invariably found that, where this is the case, the soil has become sour.

The excessive wet weather this year has considerably retarded the recovery of sick trees. The N.-E. Monsoon set in here on the 3rd instant, and since then there has been almost continuous gloomy weather with light rain and occasional heavy showers. The entire absence of thunder makes the resemblance to the S. W. Monsoon almost complete. Plenty of sunshine with occasional thunderstorms is normal October weather. This afternoon the clouds and rain were travelling up from the South-West. It is supposed that the excessive wet will prove hurtful to young supplies. Preparations for crop are being begun. It ripens earlier in the Bamboo than up here. On one place here, however, a few children have been put on gathering and are, I believe, bringing in a quarter of a bushel each.—*M. Mail*, Nov. 4.

GOVERNMENT CINCHONA PLANTATIONS.

We have received a copy of Mr. M. A. Lawson's Administration Report of the Government Cinchona Plantations and Quinine Factory for the year ending 31st March, 1892. The information concerning the work on the plantations is meagre, but we gather that no new acreage was opened during the year under review but that only young plants were put out in the fields where the old trees had been uprooted or had died out. From a statement showing the approximate number of plants in the permanent plantations, we learn that on the 31st March last there were 1,779,894, of which 34,200 were planted out during the previous twelve months. Whether this latter number represents the actual plants put down without any allowance for vacancies or only for vacancies up to the end of the monsoon, we have no means of finding out, nor are we aware when the last census of the old trees was taken. In the statement referred to there are only columns for "plants last year," "coppiced or uprooted," "planted in this year"; but considering the mortality which exists in every cinchona plantation to a greater or less degree, it would be more satisfactory if another column were added showing the number of plants that had died out during the twelve months under review. As it is, we are doubtful whether the grand total of, say, 18 lakhs gives even an approximate idea of the correct number of trees in these plantations. In January and February last ten acres of old *Succirubras* were uprooted at Naduvatam. These trees were very old and bad, and only yielded 40,150 lb. of dry bark, and this, too, of a very inferior quality, from a manufacturing point of view. The ground uprooted was replanted in March and April. This is much earlier than customary; but, adds Mr. Lawson, "it is in accordance with horticultural principles, and the result, so far, has proved satisfactory." Besides the up-keep of roads, bridges, buildings, &c., trenching and manuring was the chief work done in the field. The principal fertiliser applied consisted of a mixture of cattle dung, 20 parts, lime 1 part and wood ashes $\frac{1}{2}$ part, a quarter of a bushel being given to each plant. Experiments were made in planting out seedlings in the field earlier than the monsoon, but apparently such work requires extra care and expense, and with such a poor paying product as cinchona is, this change of the planting season is never likely to be adopted by the practical planter. Particular attention was given to the harvesting of cinchona seed and the raising of plants in the nurseries. Writing of this, Mr. Lawson remarks:—

"It has been often stated that the seed of cinchona is deteriorating, and this may be true in certain cases; but experience would tend to show that when the seed is collected from healthy trees, and taken only when quite ripe, it is perfectly sound; that it germinates freely, and produces vigorous plants. The cause of the great mortality which used to take place in the Government nurseries in former years was due to the seed being grown in too damp a soil, and to the plants being over-shaded and over-watered. Also the plants were put out in the beds far too close to each other; formerly the seedlings were pricked out at distances of 2 inches \times 1 $\frac{1}{2}$, but they are now pricked out 4 inches \times 4,

This allows all plants to become well developed before they are transplanted in the field."

The interest of planters in the Government cinchona plantations centres in the quinine factory. Here Mr. Lawson is doing splendid work. Though Government, so far, has reaped all the advantage, we believe that the day is not far distant when these quinine-manufacturing operations will prove of real benefit to the cinchona industry of Southern India. On the 31st March, 1891, the amount of bark in stock was 510,695 lb., and 53,833 lb. were harvested during the year, bringing the total to 564,528 lb., of which 147,670 lb. were disposed of, the *bulk* 144,500 lb. being used in the factory, thus leaving a balance in stock on the 31st March, 1892, of 416,858 lb., of which more than 60 per cent was *Succirubra*, or red bark, showing a very poor analysis. There were at the commencement of the year (*i.e.*, on 31st March 1891) 1,572 lb. of sulphate of quinine and 1,200 lb. of febrifuge in stock. During the year 4,425 lb. 14 oz. of quinine and 3,174 lb. of febrifuge were manufactured, making a total of 5,997 lb. 14 oz. of quinine and 4,374 lb. of febrifuge. Of these amounts 3,345 lb. 4 oz. and 3,019 lb. respectively, were disposed of during the year, leaving at its close a balance of 2,652 lb. 10 oz. of quinine and 1,355 lb. of febrifuge. From the foregoing figures it will be noticed that 144,500 lb. of bark gave an outturn of 4,425 lb. 14 oz. of quinine and 3,174 lb. of febrifuge. Turning to the cost of production, we find the expenditure for the year aggregates R75,805, of which R51,899 were for the maintenance of the general establishment and the upkeep of the estates, while the Quinologist Department cost R23,906. The receipts amounted to R77,066, of which no less than R75,262 were realised by the sales of quinine and febrifuge, which should apparently give a very handsome profit on the working of the factory during the year.

When the quinine factory was started at Nadavatham it was hoped that in a very short time the result of the manufacture of sulphate and febrifuge locally would lead to a largely increased consumption of these drugs in this country owing to their being placed within the reach of the very poorest classes. Mr. Lawson has spared no pains to bring this about, but so far his efforts have not met with the success that they deserved. For instance, we find in the present report this short paragraph:—"The sale of quinine in paper packets has increased during the year in most of the districts, but to no considerable extent. From one district the whole of the packets were returned with the remark that 'Next to no use is made of this medicine in this district;' also in another report it is gravely stated that the quinine causes itch." As it has been pointed out by the Surgeon-General, the sale of the powders depends quite as much, or perhaps even more, upon the interest which officials of the lower grades take in distributing the medicine than in the reduction of the price at which it is to be sold. The cost of the powders, as now sold, is, we understand, a trifle under cost of production. It is evident, therefore, that in this direction nothing further can well be done to popularise the medicine, but that now it rests with the subordinate District officials to make known to the people at large what a wonderful safeguard can be purchased for a few pias against the fevers which are prevalent at one time or other of the year in well-nigh every village in Southern India. Mr. Lawson quotes an extract from the *Chemist and Druggist* which takes exception to the sale of Government quinine to private individuals, as "such a course is undesirable for many reasons." It adds:—"In Madras we believe planters and private individuals are at liberty to purchase quinine in certain quantities from the Nadavatham factory. The English quinine makers, however, are about, it is rumoured, to protest against a continuance of this practice." Up to the present time Government quinine has been sold only to planters and other persons, when it has been ascertained that it was the intention of the purchaser to administer the whole of it to the coolies on his estates, and none has

been sold to the public direct. Such sales can only help to increase consumption, a consumption for which no one should more devoutly wish than the English quinine makers themselves. The whole future of the cinchona industry, in so far as European capital is concerned, depends on a largely increased consumption of quinine, and it is as much to the advantage of the manufacturer as of the planter that nothing should be left undone which would tend to this result. Since Mr. Lawson's Report was written, we understand work has been going on steadily at the quinine factory, and in his next Report we expect to be told that his stock of bark has been still further diminished. We hope also to find that the sales of quinine powders will have been very considerably larger; but this does not depend on the Director of the Government Cinchona Plantations but on the District Officers and their subordinates.—*Madras Mail* Oct. 29.

MACE AND NUTMEGS IN BANDA.—The spice growers on the island of Banda (Dutch Indies) had a very prosperous year in 1891 owing to the rise in the market value of nutmegs and mace. There are thirty-four nutmeg-plantations in the island, and the recent sale of two of these showed that this kind of property has increased very largely. The total output of nutmegs and mace in the islands of the Banda group in 1891 was about 14,580 piculs. The cultivation of nutmegs is extending to many of the neighbouring islands, but the trees there are not yet in bearing.—*Chemist and Druggist*, Oct. 22.

AN AMERICAN FRUIT DRYER.—Messrs. Ph. Mayfarth & Co., of Frankfurt-on-the-Main and of Mincing-lane, have already shown their evaporators, Ryder's Patent, to the Fellows of the Royal Horticultural Society, and yesterday and the day before they gave another demonstration, at the Society's gardens, Chiswick. The machine is an ingenious combination in which many of the mistakes of former inventors have been avoided, and will even in this country be of some use to producers in enabling them to postpone the sale of their products at times when the markets are glutted, and to make a saleable article out of their windfalls. Many evaporators are made, and the speciality of that exhibited is in the slope lines given to the flue or hot chamber—an arrangement which materially assists the passage of the drying agents, currents of hot air ascending from a nicely-adjusted furnace. The stove burns coke, coal, or wood; and the air which it has raised in temperature passes under the rows of wire trays in wooden frames containing the fruit to be dried. The chamber in which these trays are placed rests on the stone at an angle slightly inclined. The fruits being desiccated at present are apples, which remain from two to three hours in the chamber. The only preparation apples require before being dried is peeling, coring, and slicing, which is done simultaneously by a parer, corer, and slicer. There is no waste as the cores and peel are converted into apple jelly. Different fruits require varying periods of exposure to the evaporator—thus pears are dried in four to five hours, whilst plums take eight to ten. Not only fruits, but vegetables, can be preserved in the same manner, Messrs. Mayfarth show samples of spinach, turnips, red, white, and green cabbage, broad and French beans, pears, parsley, and prepared julienne vegetables that have undergone this process of desiccation. In preparing dried vegetables for food it is not necessary to soak them, but merely to boil them gently, whereas fruits require steeping in water for about ten hours before they can be cooked satisfactorily. During the evaporation the starch and sugar are converted into glucose, which retards the process of decomposition, so that the fruits can be kept for years.—*London Times*, Oct. 7.

NOTES FROM OUR LONDON LETTER.

LONDON, Oct. 21st.

GOOD PRICES FOR CEYLON TEA.

The week has seen the continuation of the recently established good prices for Ceylon tea, and there has even been an improvement upon those of late quoted. It is rather difficult to assign this improvement altogether to the restricted shipments from Ceylon, because there has lately arisen, side by side with the higher rates for your own teas, a very active demand for those of China, and the position of importers of those growths is described in the *Times* market report as a strong one, the prices for China "ruling very firm." Possibly this is because buyers of Ceylon have not been able to get all their wants supplied; and I should think this to be the case, because the same report states that while Indian teas advanced 2 to 3 points those of China only advanced by a single point. There seems to be every prospect that, certainly until after Christmas, the existing strong demand for all sorts of teas will be maintained.

THE CEYLON TEA PLANTATIONS COMPANY.

The Directors of the Ceylon Tea Plantations Company have declared an interim dividend of 7 per cent on the ordinary shares payable on the 27th instant.

A but little-known paper, called *Siftings*, has taken up the cudgels this week on behalf of

CHINA TEA.

The article appearing in it says the recent letters appearing in the *Standard* claiming superiority over China for Indian and Ceylon teas are a "lot of nonsense," and it asserts that the advance of the two latter sorts over that first-mentioned has only been due to their superior strength, which *Siftings* declare to be due only to the larger amount of tannin that they contain. We don't suppose a paper of the kind will have much influence, or that its partisanship will go any great way towards disturbing the public taste now so fully in favour of British-grown teas.

SIR CHARLES DILKE AS "AN AUTHORITY ON TEA."

The *West Middlesex Advertiser* declares Sir Charles Dilke to be "an authority on tea," but seems to regard his advocacy of certain blends for workhouses as to be somewhat mistaken. Referring to some recent supplies obtained, this paper writes:—"According to the Chairman, the tea now supplied to the house is the acme of perfection. If this is so, it cannot surely be the same as that given to the guardian in the afternoon of the Board meeting. That tea is extraordinary. It must be a blend fortunately little known and less used. It resembles tea in one thing and that only, viz., the colour; but here it sometimes misses it, and has a beautifully pinky hue. It would be satisfactory if the Chairman would explain if he "enthusias" on the tea supplied to the guardian or to the inmates."

THE DUTCH MARKET.

AMSTERDAM, Oct. 13.—The cinchona auctions to be held in Amsterdam on November 3rd will consist of 177 cases and 4,809 bales, about 414 tons, divided as follows:—From Government plantations, 61 cases and 366 bales, about 37 tons; from private plantations, 116 cases and 4,443 bales, about 377 tons. This quantity contains, of Druggists' bark: *Succiruba*—quills, 95 cases; broken quills and chips, 32 bales, 40 cases; root 14 bales; *Officialis* quills, 42 cases; and of Manufacturing bark: *Ledgeriana*—broken quills and chips,

3,714 bales; root, 775 bales; *Officialis*—broken quills and chips, 36 bales; root, 13 bales; Hybrid—broken quills and chips, 213 bales; root, 12 bales. The manufacturing bark contains about 18 tons sulphate of quinine, or 4.52 per cent. on the average. About 4 tons contain 1-2 per cent., 36 tons 2-3 per cent., 128 tons 3-4 per cent., 116 tons 4-5 per cent., 53 tons 5-6 per cent., 34 tons 6-7 per cent., 16 tons 7-8 per cent., 7 tons 8-9 per cent., 6 tons 10-11 per cent. sulphate of quinine.—*Chemist and Druggist*.

WHITE PEPPER VS. BLACK PEPPER.

Under the title "Grind your own Pepper," *Gorgantuas Gastronomies* discusses learnedly of the benefits to be derived from using the little "Moulin à Poivre" or table pepper-mill, which is used extensively in France, and which enables an epicure to have his pepper freshly ground, either fine or coarse, as he prefers, for different dishes. The writer of the article noted above makes a great mistake in saying, "above all, use white pepper for a table condiment."

White pepper is nothing more nor less than black pepper bleached with acids which destroy the finer aromatic properties, and no real connoisseur will ever use white pepper.

The pepper grains form on stems not unlike currants. The berries are red when ripe. The reddish pulp which surrounds the kernel is deliciously aromatic and when dried turns black.

In the preparation of the berries for market, if white pepper is to be made, this pulp is soaked off and the kernels bleached to make them sightly to the eye without any regard whatever for the pulp.

It is one of the most striking vagaries of fashion. Owing to the expense of the manipulation, white pepper costs about twice as much as black pepper, and yet is not as good or as intrinsically valuable.—*American Grocer*.

NOTES ON PRODUCE AND FINANCE.

PLAIN VIEWS ON THE CURRENCY PROBLEM.—The views expressed by the Darjeeling and Terai Planters' Association on the silver question find an echo among the planters on this side. The Darjeeling planters declare, in a memorial to the Viceroy, that the closing of the Indian mints to the free coinage of silver would result in the collapse of the Indian tea industry. The Association claims to represent not only European but Indian capital which during the past thirty years has been invested in the tea plantations of the hill districts of Dajeeling and Kurseong and in the district of the Terai. To that capital and to the resident community of skilled Europeans engaged in the industry, it is urged, the undeniable prosperity of the region in question is due; and the memorialists pray that "until such time as an international agreement is entered into by all countries having a silver standard, the Government of India, even if empowered by Her Majesty's Government in the way prayed for in the petition of the Indian Currency Association, will stay its hand and not interfere with the present condition of the currency system." They frankly confess that they are not convinced that a fall in exchange brings no advantage to the Indian exporter, and they declare that their own experience has taught them that the fall in the gold prices of tea has been the consequence of the "overproduction" of that commodity, and not of the decline in exchange. The adoption of the gold standard in India, with the issue of silver rupees limited, would, it is stated, "inevitably cause the price of the Indian rupee either to be stationary or to rise gradually or suddenly, while at the same time the price of the Chinese tael would be falling." The Chinese tea-growers would thus be enabled to undersell the Indian growers, and the memorialists are apprehensive that China would "re-gain the ascendancy that has been wrested from her." This is plain, and may be taken as a set-off to the

argument used in Lancashire to the effect that, under existing conditions, every fall in the gold price of silver gives the Bombay millowners an advantage over their Lancashire competitors. *The Times* correspondent cables that the Government, in acknowledging the Darjeeling planters' memorial expressing views contrary to those of the Currency Association, delivers itself of a long economic essay and concludes by stating that the adoption of the same standard of value by England and India—always assuming that standard to be good—would facilitate international trade, stimulate production in both countries, and place China at a disadvantage as compared with India in the production of tea and other commodities. The correspondent also adds that the mercantile community are dissatisfied with the attitude of the Government.

THE CHANGES IN THE TEA TRADE.—Among the manifold changes brought about during recent years by the increased competition manifest in all trades and professions, there is no department of the grocer's business which has undergone a greater change or has been more fiercely assailed than the tea trade, says the *Grocer*. Compared with the grocer, the tea merchant has doubtless been the greater sufferer of the two. "The good old times" of twenty years ago, aye, and less,—when merchants in selling, and our readers in buying tea, reaped profits on their sales and purchases in proportion to their knowledge, sagacity, and experience, are gone, never to return. At that time the leading City firms scorned to do business with any grocer who could not buy ten chests at once. Today, it may with truth be said, the same firms will gladly book an order for two chests from any safe man. This is mainly owing to the rapid extension of suburban districts, and the proportionate—disproportionate, perhaps, we should say—increase of grocers' shops. Blended and packet teas have obviously proved a desideratum to a large number of grocers throughout the country, as evidenced by the increasing sales of that class of tea by those firms who have laid themselves out for that trade and are vigorously pushing their "famous blends." That blended and packet teas of reliable quality, now obtainable from merchants of good repute, have been a boon to many of our readers, no one will attempt to deny. Much anxiety and expenditure of time have always been entailed by retailers in tasting tea, especially by those anxious to cultivate that branch of their business. They are now freed from this trouble, and are in a position to compete with their more formidable opponents. They are less liable to buy badly as the saying is, and can generally depend upon the mixtures being regular in quality and character. There are certainly advantages to the modern grocer, whose stock-in-trade is multiplying year by year, and whose tea business forms only a very small portion of his weekly turnover.

THE ART OF TEA BLENDING.—There is, however, another aspect of the revolution, says the authority we have quoted. Grocers of the old school, whose careers in that capacity date back into the sixties and early seventies contemplate the change with less satisfaction. At the time referred to, and before the prices of Indian teas were within the reach of the two-shilling canister, a trader who had spent some years in studying and tasting teas could almost always offer better value to his customers than could his more inexperienced rivals. It was only in the fitness of things, therefore, that he should reap the advantages of his knowledge and experience. Many of his opponents frequently knew little or nothing about tea, and had never thought it worth their while to take the matter up as a study. This state of things continued down to 1880 or thereabouts, when one or two enterprising tea agents conceived the idea that by a free course of instruction in the art of blending to the more ignorant grocers who were doing a fairly good tea trade they would ultimately monopolise the bulk of the business in the respective districts which they represented. How egregiously deceived they have been time has since proved. They little suspected that they were making rods

for their own backs. They captured fresh customers it is true, but overlooked the fact that ingratitude is the reward frequently received by those who seek to become benefactors of mankind. The new customers did not refuse to be taught the arts and mysteries of blending teas, but after picking the brains of their instructors they gradually returned to the firms with whom they had previously dealt, and who, it is needless to say, had been obliged to make up and offer blends.

GONE ARE THE GOOD OLD TIMES.—Now, what has been the result? The "kings" and "princes" of Mincing Lane have had to "climb down" to small orders and smaller profits. The experienced grocer, to whom we have just referred, finds himself on a level with younger and comparatively ignorant members of the trade, who can scarcely distinguish China from Indian teas. The time he has devoted, the knowledge he has acquired, and the capital he has accumulated, are now of little or no avail; while the would-be monopolist agents have discovered, to their chagrin, that they have become the first victims of their own folly. All things must have an end, and the change is doubtless in keeping with the spirit of the times in which we live. The enormous supplies from India and Ceylon have put an end to the scenes of animation formerly witnessed in and about the salerooms of Mincing Lane, when Mooings and Kaisows held the sway. Speculative purchases, then so rife, are now remembered as belonging to a past age. The then great event of the year—the first arrival of new season's tea—excites little attention now-days. Agents from the provinces do not now rush off to London to meet the ship before she docks. It is no longer a coveted distinction to be the first purchaser of new tea. There are now only reminiscences of what some few choose to term the "good old times." But, in our opinion, the tranquillity which characterises the produce markets of the present day is more calculated to promote a healthy tone than the conditions which prevailed in the speculative times to which we have referred.—*H. and C. Mail*, Oct. 21.

SOME INDIAN COMMERCIAL PRODUCTS.

The first five of the Handbooks which the Government of India has arranged to provide to the Imperial Institute for the illustration of the economic products of India treat respectively of Padak wood; Ipeacacanha; Sida fibre, jute and *Podophyllum emodi*. The object of the first of these tomes is to bring to prominent notice a timber which is abundant in the forests of Burma and the Andaman Islands, and has recently been introduced into the English market under the direction of Mr. Ribbentrop, C.I.E., the Inspector-General of the Indian Forest Department. The wood is reported to be about as hard as teak, is capable of taking a high polish, and is considered to be admirably adapted for furniture, panel work, parquetrie, windows, doors, etc., in fact, as a substitute for teak. It is also well suited for gun carriages, and it has been annually exported from Burma to Madras for this purpose since 1873. The Andaman red-wood or padak tree (*Pterocarpus indicus*) is described by Dr. Mason as "a majestic evergreen, whose yellow papilionaceous flowers scent the air, like the magnolias, for several hundred yards around. It is propagated by simply planting large branches in the ground at the commencement of the rains. There are two species, the red and the white, as distinguished by the Burmese, the red producing the finest timber, but the white padak is by far the finest ornamental tree." When the wood is thoroughly seasoned, it is said to be almost unaffected by alternate dryness and moisture of the atmosphere, and it is not attacked by white ants. The all round price of the wood in London last year was about £7-10 per ton, and £67 per ton for squares and £76 for planks was realised in Calcutta. The introduction of this wood—which has been favourably reported on by cabinet makers and carriage builders in England—into the London market dates from the Indo-Colonial Exhibition; but

though the timber is not being so generally used as one might have expected, yet its excellent qualities have been recognised, and every attempt is being made to extend its sale in England. Arrangements are being made to have a portion of the panelling and some of the furniture in the Imperial Institute made of padauk wood from the Andamans. With more careful selection the timber, it is thought, will probably secure increased sales, and the price rise above £10, the rate at which the most recent consignment was sold in London.

The medicinal ipecacuanha plant is a native of Brazil, and attempts are being made, but with only qualified success, to introduce it into India and Burma. The late Dr. Anderson, Superintendent of the Royal Botanic Gardens near Calcutta was the first person who conceived the possibility of the cultivation in India of this valuable shrub, and he took the first specimen to Calcutta in 1866; but, after many trials, it was reported that it could not be made to thrive. In the plantation near Darjeeling, however, the plants thrived better, and in 1874 there were some 64,000 plants growing there, in glass covered frames, at an elevation of about 3,000 feet. The rapid success of propagation was entirely due to the discovery that this plant, unlike most others, can be freely propagated by root cuttings. This is so far satisfactory, but we are not in a position to say whether ipecacuanha can be grown profitably as a crop. The success obtained in the cultivation of this product on the Nilgiris seems to justify the belief that it will pay to grow it there. A sample of the root of a plant two years old, grown in the Wynaad, was analysed by the Madras Government Quinologist, who found it to contain as much emetine as is found in the commercial drug. Dr. King says that ipecacuanha "is a humble creeping under-shrub of peculiarly slow growth; that it apparently requires a thoroughly tropical climate—by which I mean a pretty equal day and night temperature—the absence of a decided cold season, and an atmosphere pretty steadily and thoroughly saturated with moisture. We have proved that it cannot stand a hot sun, and that it is apparently impatient of stagnant moisture at its roots." The imports of ipecacuanha into England, chiefly from Brazil, amount annually to about 65,000lb of the value of some £15,000, so that there is only a comparatively small demand. But if the cost of cultivation on the Nilgiris permitted of the sale of the roots at a lower figure than those from Brazil, the demand might greatly increase in England and on the Continent. In the Straits Settlements, when a proper situation is found, the plant grows with all the luxuriance of its native country, so it might also be planted profitably there.

Sida fibre is a strong, fine, round fibre of excellent spinning properties, fit for higher textile purposes than jute, and has been recommended to the consideration of flax manufacturers. The suggestion has been made that sida might be successfully grown over a wide area where jute cultivation is impossible, and that Southern India or Bombay would prove better suited for the development of a sida industry than the damper regions of Bengal. There appear to be five descriptions of this fibre, but the *Sida rhomboides* is the variety that has been hitherto chiefly experimented with. Major Hannay, of Assam, was the first person to commercially draw attention to it, in about 1853; and it seems rather extraordinary that, notwithstanding the highly favourable reports which have been made about sida, no attempt, so far as we are aware, yet been made to cultivate it on a large scale. Its cultivation is attended with no difficulty, and its commercial value would appear to be favourable to an extended trial. One cause that operated against its cultivation was that the attention of the Calcutta fibre merchants, shortly after Major Hannay's discovery, was forcibly directed to the establishment in India of jute mills in opposition to those in Dundee, and for forty years sida was forgotten. It was not until 1880 that attention was again drawn to it, by the Bengal Government, which forwarded to the Agri-Horticultural Society of India samples of the fibre which it had received from Rajah Krishendro Roy, of Balihar,

in the District of Rajshahye. Mr. Cogswell, an eminent practical authority, twice reported on this article, and favourably on both occasions. The fibre, he wrote, has a glossy colour, "bright in the extreme and of a very high order. It is strong fine round, and of excellent spinning properties." A distinguished firm of chemists also reported highly upon it and said that as compared with jute, it possessed a relatively high percentage of cellulose, wherein lies the most important factor of its superiority over jute. In the Handbook on jute, Dr. Watt, while not omitting to mention the unfavourable report of the Agri-Horticultural Society of India, maintains that the intrinsic superiority of sida over jute fibre would seem to justify its experimental and systematic cultivation until a stock is produced that can be grown as readily and admit of as rapid decortication as is the case with jute. Nothing further, however, appears to have been done in the matter, and Dr. Watt may well say that, considering the infinitely superior quality of sida, "it is sorely worthy of the time and expenditure necessary to ascertain whether or not all these advantages are financially counterbalanced by a less acreage yield." The plant grows wild in the Nellore District, where it springs up after the North-East Monsoon, and could probably be easily cultivated at little cost. One drawback, however, to the success of this fibre is the difficulty experienced in extracting it, for it does not separate easily from the outer bark or inner wood. In Nellore it is extracted by beating the stems of the plant with a woden mallet and washing them during the intervals of beating.

Jute, the staple industry of Bengal, was known to the people of India from comparatively remote periods, and until the increased demand for cloth resulted in the importation of cheap European piece-goods, the industry was a thriving one. For a time the indigenous industry declined, but with the rapid progress in every other branch of enterprise a remunerative foreign trade was opened up, which has gone on increasing in a marvellous manner. In course of time machinery in England naturally superseded manual labour in India in the manufacture of gunny bags, etc. and the Bengal ryots, bowing to the inevitable, forthwith proceeded to discontinue the manufacture of bags and devoted their attention to the preparation of an extra quantity of fibre; and to such purpose that the supply soon outstripped the demand for home manufacture, and a large export trade was established in raw jute to feed the Dundee Mills. There the manufacture of jute into bags proceeded most successfully until 1854, in which year the Ishera Yarn Mills Company, (now the Wellington Mills) was established near Calcutta by Mr. George Ackland, a large owner of coffee plantations in Ceylon.* Other factories were built in quick succession; the trade in gunnies developed very rapidly; and in 1869-70 no less than 6½ million bags made in Bengal were brought into competition with the Dundee bags; in 1879-80 some 56 million bags were exported from India, and in 1889 no less than 109 million bags were exported, while the Indian consumption was 76½ million bags! The exports of raw jute are, however, far greater than those of manufactured jute, the former being valued in 1891-92 at about 7 crores of rupees and the latter at about 2 crores. In the opening of the jute season of 1890-91 the price of jute was about R4 per maund; as the supply greatly exceeded the demand the price fell in December, 1890, to R2-4-0. Owing to these low prices the cultivators suffered severely, and last year they curtailed the cultivation of this article and sowed rice and other crops. The season was also unfavourable. But all this, curiously enough, does not appear to have been known to the trade, with the result that, whereas at the beginning of the 1891-92 season the price was R3-8-0 per maund, it had risen—demand having soon greatly exceeded the supply—to R9-8 per maund in May of this year! A

* Mr. Ackland had been owner of coffee estates, as the head of the firm of Ackland, Boyd & Co., after the failure of which he went to Calcutta.—ED. T. I.

reaction in favour of jute planting has, as was mentioned in the recently issued Report, naturally taken place, and the area planted during the present official year must, says Mr. Thurston, be as great as if not greater than, that of 1890-91. For the information of the uninitiated it may be mentioned that jute is manufactured into cloth of different qualities ranging from substitutes for silk to shirtings, curtains, carpets, and guinies; into paper, chiefly prepared from rejections and cuttings, and into the coarser and stronger qualities of cordage. Where *sida* fibre excels jute is in its durability, and the perishable nature of the latter is thought to be fatal to its obtaining a position much higher than it has already attained. It has, however, it seems, a new sphere of usefulness viz., in the form of "juteite," the name of an explosive invented by a German chemist, which is composed of jute and glycerine, and which is reported to have many points of superiority over the numerous explosives now in the market.

As regards *Podophyllum emodi* and morinda, we may merely mention that the Indian roots of the former are reported as yielding 12 per cent of resin, whereas the American roots only yield 4 per cent. Owing to the peculiar property of the dye stuff obtained from morinda, cloth dyed with it is not attacked by white ants, and cloth so prepared is used in India to wrap round the account books of bankers and shopkeepers, and it might with advantage be more generally used for bookbinding and other purposes for which protection from insects is a desideratum. The plant, or small tree, seems to grow all over India. It is known in Madras as *Togari*. This is the *Morinda citrifolia*, or Indian mulberry, and large quantities of the roots are exported from Malabar to Guzerat and Northern India.—*Madras Mail*, Oct. 31.

THE BAMBOO—ITS MANIFOLD USES.

Editor *Farmer and Fruit Grower*.

1. It is impervious to mold and other fungoid growths, and probably this is the reason why European physicians in the Orient advise their patients in convalescence from climatic fevers to leave their houses built in European fashion and live in the bamboo bungalows of the natives. Experience must have taught them, for they did so in Java long before the germ theory was started.*

2. The bamboo partakes of the peculiarities of many palm trees, which in sea water are not attacked by the teredo or boring millusk, so destructive to all other wood submerged in water.

3. There are some varieties, highly prized by the Chinese, which grow in joints or sections four or five feet long; these are used for cheap aqueducts by fitting the end of one cane into another. They grow forty to fifty feet high, and canes fifteen or twenty feet long may be obtained. Why might not these be used for irrigating purposes in orange groves and truck farms? They will withstand a high pressure, if not weakened and rotted by being kept constantly wet. It takes thirty years to bring them to complete maturity, indicated by blossoming and seeding; but plantations propagated from suckers may be cut in four or five years. They are usually cut in the winter, as their wood is then hardest.

4. Probably the most important use to which they could be put in Florida would be in making slight temporary sheds or roofing for pineapples and summer gardens of various plants and vegetables, which do not quite relish the strong heat of the mid-summer sun. They could be much more easily manufactured into mats by softening in water and splitting, than the clumsy pine rails now used for this purpose can be made.

The almost innumerable uses to which the bamboo is put by the Oriental nations, of course, would find little acceptance with Americans, as that would imply the abandonment of nails for lashing and the house for the bungalow. It would

* The use of bamboo houses in Java is referrible to the prevalence of volcanic disturbance.—*Ed. T.A.*

make a serviceable windbreak for our orange groves if grown on the north and west sides.

There are several varieties that are considered hardy enough to grow in the orange belt at least. Among these are mentioned the *corypha*, the *aurindinaria falcata*, the *bambusa vulgaris*, the *endocalamus strictus*, the *endocalamus Hamiltoni*. L.P.

THE ECONOMIC USES OF LEAVES.

Of the three divisions of Nature's products, man is most chiefly indebted to the vegetable kingdom, whether for his food, medicine, or domestic comforts. Every part of plants and trees is more or less utilised by savage and civilised men, and a common category might be furnished by the various uses of the separate parts—the roots, stems, sap, bark, fruit and seeds and leaves. If we take the last-named, the foliage, apparently the most insignificant part of the plant, how dependent are we on these for food, clothing, medicine, dyes, stains, and various comforts.

The miscellaneous application of leaves for different purposes as domestic appliances, and for manufacturing uses, of themselves, would furnish a long list: some few of these we may pass under notice, because their adaptability and usefulness are mainly confined to tropical countries. It is true that some leaves have been utilised by the paper-maker, as in those of the dwarf Palm, Maize leaves, and others, but this is only on a small scale.

The leaves of many Palms are largely employed for making hats. Those best known are Panama hats, so named from being shipped from that port. These are made from the finely-plated fibre of the leaves of a South American Screw-pine (*Carludovica palmata*). These hats are much prized for wear in the tropics, being light and flexible, and can be washed and bleached repeatedly. The tree has no stems, the leaves have long slender petioles, springing from the ground they are some 2 feet long fan-shaped and four-parted, each segment being again ten-cleft, so that when folded in venation, each segment on its own rib, there are eighty layers in a young leaf. The tree occurs only on the slopes of Andes. About 200,000 dozens of these hats are made in Ecuador and different States of South America. These hats are distinguished from all others by consisting only of a single piece, and by their lightness and flexibility they may be rolled up and put in the pocket without injury. In the rainy season they are apt to get black, but by washing with soap and water, besmearing them with lime-juice or any other acid, and exposing to the sun, their whiteness is easily restored. The plaiting of the hats is very tedious and troublesome; the coarse ones may be finished in two or three days, but the fine ones take as many months to plait. It commences at the crown, and finishes at the brim. The hats are made on a block, which is placed upon the knees, and requires to be constantly pressed with the breast. The hats vary in price, according to fineness and quality, from 20s. to as many pounds.

The unexpanded fronds of *Livistonia australis*, prepared by being immersed in boiling water, are dried, and the fibre thus obtained is much valued for the manufacture of hats in Anstralia, which much resembles the celebrated Panama hats.

The rough leaves of the *Chumico* (*Curetella americana*) and of *Davilla lucida* are used for cleaning iron, and polishing and scouring wood. *Curatella alata* is used in the West Indies for polishing bows, sabres, &c.; and *C. sambaiba* in Brazil—indeed, they serve all the purposes of sand-paper to the Indians for polishing their blow-pipes and war clubs. The leaves of *Celtis orientalis* are used for polishing horns in the East Indies.

The foliage of *Guaiacum officinale* is very detersive, and is frequently used in the West Indies to scour and whiten floods, which it is said to do better than soap.

Leaves sown together are much used in India as substitute for the plates and dishes of more civilised life. It is not always poverty that leads natives to use them in preference to metal or porcelain articles

as caste or custom has often some influence in the matter. The leaves principally used are those of the Egyptian Lotus (*Nelumbium*), speciosum *Bauhinia* species, *Semecarpus anacardium*, *Butea frondosa*: those of the Banyan (*Ficus bengalensis*), by Brahmins, and the Plantain-leaf (*Musa paradisiaca*).

The leaves of *Bauhinia Vahlia* are used in the construction of the curious rude leaf bellows in Sikkim with which the natives of the hills smelt iron. These leaves, when sown together are used as plates, cups, rough table cloths, rain hats and caps. The leaves are shaped, and above a foot in breadth, and the same in length. Sewn together with twigs, they also serve for baskets for holding pepper, turmeric, and ginger, and are likewise used for thatching.

Under the name of "Chattahs," a kind of umbrella, hat or sunshade, is made in the East of the leaves of the *Lacuala peltata* and the Talipot Palm or a Plantain leaf. These Chattah hats are much worn by the ploughmen cow-keepers, and coolies of Bengal and Assam.

The large fan-shaped leaves of the Talipot Palm (*Corypha flabelliformis*) are like those of the Palmyra Palm, carried over the heads of people of rank as an umbrella and are also used for making books, and for various domestic purposes. The leaves are also put up into neat bracelets, worn by Santal girls in India. Those of *Vanda*, *Roxburghii*, split, are also worn by them as anklets. Those of another species *Barossus æthiopicus* occur as much as 12 feet across; they serve also for the manufacture of baskets, mats, ropes, and sieves. The leaves of *Nipa fruticans* attain a height of 15 to 20 feet, presenting a very handsome appearance resembling the fronds of huge Ferns. This graceful Eastern Palm is utilised in various ways, the principal being in the manufacture thatching for house roofs in the East called Ataps; this manufacture is quite an industry of itself and affords employment to many natives, chiefly women, the men simply bringing cargoes of the fronds to the women to be stitched with split rattans and made up. Atap roofs are the best adapted for these climates, for while the winds are never strong enough to blow them away, they afford the coolest protection against the sun or any kind of roofing known.

The leaves of the Palmyra Palm *Borassus flabelliformis* were formerly used like paper to write books on, and to this day they are applied to this purpose in Orissa, Southern India, and Ceylon, where an iron style is employed to write upon them; in certain parts of Bengal young children use them to write the alphabet lessons on. They are largely employed for making pans, bags, winnows, hats, umbrellas, and for thatching, &c. The leaf takes a dye well, and is worked up in Madras into pretty-coloured patterns in baskets and mats.

The slips of Talipot and other Palm leaves are coming into European commerce for the manufacture of ornamental braids, and in the construction of straw or Leghorn hats. The fibre obtained from the base of the leaves of the Chusan Palm (*Ohamærops Fortunei*) is used by the Chinese for making hats and coarse clothing. The sale of Palm leaves for decorative purposes in the town of Elche and Alicante in Spain produces a considerable income to the towns.

Kadjan mats, manufactured out of *Nipa* leaves, are indispensable for travelling purposes packed up in smallest compass when not required, each mat is capable of affording sufficient cover at night for two or three persons either in boat or forest journeys. They also form almost exclusively the material for side-walls and divisions within houses. The young leaf unfolded and dried, under the name of *Roko*, forms the favourite covering for cigarettes in the Malayan Peninsula in preference to paper.

The large leaves of the Teak tree (*Tectona grandis*) are used for plates, for packing, and for thatching. The leaves of *Cordia myxa* are employed as plants in Pegu, and to cover Burmese cheroots. In Bangalore the leaves of *Canna indica* are used by the natives in lieu of plates, to serve their Ragi or Millet puddings and other dishes on.

The leaves of the Papaw tree (*Carica papaya*) are employed by the negroes in washing linen, as a

substitute for soap. They have also the property of rendering meat wrapped in them tender, owing to the alkaloid papain which they contain, and which acts as solvent.

For cordage and other textile purposes, numberless leaves are used and they serve very generally for peeling and wrapping up small parcels in India.

In Guiana, Tibisiri fibre is obtained from the inner surface of the spiral leaves of the Ita Palm (*Mauritia flexuosa*); it is used by the Indians for making hammocks, &c. The leaves are cut before they are open, and the midrib separated by drawing each division of the leaf through the finger and thumb. After drying, the fibre is ready for use without further preparation. About a quarter of a pound may be procured from each leaf, and if the central leaf is left uninjured, no evil effect is produced on the tree. Bags or matting could be cheaply and easily made from this fibre, as well as hats similar to those known as Pamana.

The foregoing is only a brief enumeration of some of the many uses to which leaves are industriously applied.—P. L. SIMMONDS.—*Gardeners' Chronicle*.

NEWS FROM NORTH BORNEO.

Kandy, Nov. 3.

The following extracts from the *British North Borneo Gazette* may be of sufficient interest to your readers to warrant your publishing them. The Governor on his travels remarks on tobacco planting as follows:—

As regards the tobacco industry notwithstanding the unusually heavy rains and the terrible floods on the Kinabatangan some of the East Coast estates expect fairly good crops and Mr. Little writing on 12th instant informs me that "good results are anticipated in Marudu Bay. Tandik and Rarau are far ahead and Pitas is magnificent." Another Kudat correspondent who is well posted in planting matters writes "the estates are looking very favourable in Marudu Bay." So on the whole the outlook may be considered promising. Efforts are already being made by Deli planters, which I think will be successful, to re-establish some of the estates that have been closed: for there are many who (judging from the actual results of past operations) are convinced that with good land and capable management the industry must succeed.

Many unfortunate and often very expensive mistakes have undoubtedly been made in selecting and cultivating the crop which whether avoidable or not when very little was known of the soil and climate are not likely to occur again. Labour too is much cheaper and less difficult to procure than formerly, while the improved climatic and sanitary conditions on estates enable better work to be obtained and a larger proportion of the coolies to be effectually employed. Desertion also once so common as to threaten some of the strongest companies with ruin and to strain to the utmost the resources of Government and the energies of the police and magistrates is now of such rare occurrence that during my recent visit to the East Coast estates I did not hear of a single recent case.

On the whole therefore although pioneers may have to suffer here as they did in Deli I consider that the ultimate prospects of the tobacco industry are healthier and more promising now than they have ever been in the past, and I feel pretty confident that if land is carefully selected and cultivated and the crop properly sorted and fermented by trained Deli hands tobacco planting will become a profitable industry.

The Lang crop was one of the few which realised the expectations of the owners at last season's sales. Although this crop (consisting of over 350 bales) contained about 40 per cent of broken leaf it secured the high average of 1 guilder and sixty two cents a pound. Some large crops from other estates went for much less than their estimated value, but the fact that many of these were resold by the purchasers at

large profits is a sure indication of the real value of the local staple which there is little doubt will realise much better prices when the different companies establish a better reputation for even marks and sorting.

PROGRESS IN PROVINCE DENT.
MONTHLY REPORT FOR AUGUST.

PROVINCE DENT.

1. TRADE.—The following figures shew a marked increase as compared with the returns for last year.

	Imports.	Exports.
	\$	\$
August 1892	18,506 11	21,162 38
„ 1891	7,503 67	6,823 44
Increase	11,002 44	Increase 14,333 94

The returns up to 31st August as compared with last year are:—

	Imports.	Exports.
	\$	\$
Up to 31st August 1892 ...	91,841 35	124,133 45
„ 1891	37,218 89	50,990 95
Increase	54,622 46	Increase 73,142 50

The increase is due to the great activity in the sago trade. As compared with last year's output the figures for this year are very encouraging.

	Raw Sago Exported.	Sago Flour Exported.
Up to 31st August 1892	\$17,719 28	\$60,089 18
„ „ „ „ 1891	6,059 00	10,575 40
Increase	\$11,660 28	Increase \$49,513 78

LIBERIAN COFFEE IN BORNEO.

In commenting upon the article *Liberica v. Arabica* in our July issue, the *Madras Times* questions the statement as to Liberian bearing as soon as Arabian. We can assure our contemporary that in the third year a first though somewhat small crop is obtained while in the fourth year it bears continuously, after a year or two of this it settles down into giving its main crop about November, December and January although picking to some small extent is possible all the year round. This is at sea level no doubt the higher the elevation the longer the plant takes to bear and the worse the crop; the plantation our contemporary bases his statement upon was we notice situated at an elevation of from 500 to 800 feet, which probably accounts for the time the trees took to bear; Liberian Coffee should be planted as near sea level as possible as long as the land is dry.

LORD BRASSEY JOINS THE BOARD OF DIRECTORS.

The Right Honorable Lord Brassey K.C.B. has rejoined the board of Directors of the British North Borneo Company to fill up the vacancy caused by the retirement from the board of Sir Julian Goldsmid Bart. The vacancies caused by the deaths of Admiral Mayne C.B. and Mr. Myburgh Q.C., are not yet filled up.

Retirement of Mr. Callaghan late of Ceylon from the service of the Government.

Mr. F. G. Callaghan Resident Labuan and Province Dent resigned the Civil Service of North Borneo and left for England in the s.s. "Ranee" at the end of September. Mr. Callaghan joined in 1882 and has been some ten years in the service of the Company. Mr. Callaghan has served as Resident of the Darvel Bay District, and the West coast; and latterly as Resident of Labuan and Mempakol. We hear that all Labuan turned out to give the popular departing Resident a good "send off." We heartily wish Mr. Callaghan a pleasant voyage home and every success in the future.

COFFEE.—The Manager of Taritipan Estate, Mr. Johnstone, is energetic and has considerably improved the aspect of the place. All his young cocoa, shade trees and seedlings are doing remarkably well at a low elevation. A toukang (Small Junk) keeps up communication with Kudat at regular intervals. Victoria Estate in Kudat is looking up again. The trees are full of young cherries and Mr. Christian

Vos now secured a pulper from J. M. Lyon & Co. of Singapore. The other day the first free Hakka children labor was obtained to pick up the monkey coffee. I discovered a new species of cherry (?) which might be described as Kidney coffee. The tree was amongst others but distinguished by long pointed cherries. I visited Pitas Estate last month and Taritipan Estate once and was several times at Victoria Estate. An attempt to enter Bongon River was frustrated by the beacons being wrecked by the late storms.

EXPORTS OF TIMBER FROM BORNEO.

The s.s. "Teresa" Captain Slaker left Sandakan for Hongkong on September 5th fully laden with timber for the China markets shipped by Messrs Koh Heen and Company. The "Teresa" will probably return here for another cargo. She is a steamer of 751 tons register and 1,500 tons burden, and has accommodation for eight saloon, twelve second, and over two hundred steerage passengers.

The s.s. "Memnon" left for Hongkong on September 17th having on board as passengers Mr. and Mrs. Sturdee. The "Memnon" had on board a full loading of timber consigned to China by various Sandakan firms.

CLOVE CULTURE IN ZANZIBAR.

REPORT OF CONSUL PRATT.

Zanzibar is noted for being the principal source of the world's supply of cloves, and a report on the cultivation of this article of domestic economy may prove of interest.

When speaking of Zanzibar, we include the islands of Zanzibar and Pemba, three-fourths of the entire crop of cloves being produced in Pemba. Those grown on the island of Zanzibar are reckoned of superior quality and command the better price, but this is probably due to the fact that the owners reside here, and can thus give their affairs the benefit of direct supervision.

Certainly the conditions for their successful cultivation are most favourable at Pemba, where the rainfall exceeds that of Zanzibar, but the management being left to careless overseers, the result is the cloves are imperfectly cured and (but little care being observed in handling) are frequently marketed in an inferior condition.

The clove-tree was first introduced into this country by the then Sultan, Seyed Said bin Sultan, about the year 1830, since which time its cultivation has gradually extended, until it is now the chief industry of the islands.

The industry received a check in 1872, the date of the great hurricane. At least nine-tenths of the trees were destroyed at that time, so the larger part of those now standing are of new growth.

A peculiarity of the clove-tree is that every part is aromatic, but the greatest strength is found in the bud, which is the "clove" of commerce. The finest quality of cloves are dark brown in color, with full, perfect heads, free from moisture.

In the cultivation of the clove, the first thing to be done is the starting of the shoot. The seeds are planted in long trenches and are kept well watered until after sprouting. In the course of forty days the shoots appear above ground. They are carefully watered and looked after for the space of two years, when they should be about 3 feet in height. They are then transplanted, being set about 30 feet apart, and are kept watered till they become well rooted. From this time on the young trees require only ordinary care, though the best results are obtained when the ground about the trees is well worked over and kept free from weeds.

The growth of the tree is very slow, and five or six years are required for it to come into bearing, at which time it is about the size of an ordinary pear-tree and is usually very shapely. It is a pretty sight to see a young plantation just coming into bearing. The leaves, of various shades of green tinged with red, serve to set off the clusters of dull red clove buds.

As soon as the buds are fully formed and assume this reddish colour the harvesting commences and is prosecuted for fully six months at intervals, since the buds do not form simultaneously, but at odd times throughout the said period. The limbs of the tree being very brittle, a peculiar four-sided ladder is brought into requisition, and the harvesting proceeds apace.

As fast as collected, the buds are spread out in the sun, until they assume a brownish color, when they are put in the storehouse and are ready for market.

A ten-year-old plantation should produce an average of 20 pounds of cloves to a tree. Trees of twenty years frequently produce upwards of 100 pounds each.

The present season, commencing with July, 1889, is very favourable, and the crop will exceed that of any previous season. It will, in all probability, amount to 13,000,000 pounds, averaging a local value of 10 cents per pound.

The Sultan derives no inconsiderable portion of his revenue from this source, since the duty is levied at 30 per cent. ad valorem, thus placing to the Sultan's credit for the present year nearly if not quite \$400,000.

Besides the clove buds, the stems are also gathered, and form an article of commerce, commanding about one-fifth of the price of cloves and having about the same percentage of strength. To this circumstance is due the fact that ground clove can frequently be purchased in the market at a lower price than whole cloves.

For the past fifteen years the cultivation of cloves has been the chief occupation of the Arab planters, and had always netted good returns. It seems probable that it will continue to be a profitable crop, since the consumption of the article appears to keep pace with the inevitable increase of production.

Up to the present time the plantations have been worked with slave labor at comparatively small expense; but with stoppage of slave supplies from the mainland, great difficulty will be experienced by the planters during harvest time. One result will be an increase in expenses; but what the planters have most to fear is that the curtailment of the labor supply will entail a direct loss by rendering it impossible to harvest the crop until after it has blossomed, when it would be unfit for the uses of commerce.—*Oil, Paint and Drug Reporter.*

EDIBLE BIRDS' NEST COLLECTING.

By M. V. PORTMAN.

From the collection is generally made by convicts whom I have trained, as I don't often have the chance to go out myself, but when I do go, I find it the most enjoyable trip of the year.

The work is as follows:—

The edible birds' nest-building Swift *Collocalia nidifica* (or "Juciphaga") arrives in the Andamans about the end of November in each year, and as soon as the rain ceases, i.e., about the 1st of January, commences to build its nests in the caves which abound here.

The best qualities of nests are found in the caves in limestone and volcanic rock, but the bird also builds on serpentine, and soft clayey sandstone.

Some birds, of a lazy or unpatriotic disposition, build nests of twigs, moss, and feathers glued together, and fastened to the roof and walls of the caves by a gelatinous mucus, generally green or muddy-coloured. These birds keep to themselves and have their own caves, which is lucky, as their nests are of no value.

The marketable nests are of three qualities:—

1st class nests, which are pure white, and look as if they were made of thin threads of isinglass woven together. They resemble in shape the mud Swifts' nests one sees under eaves at home, but are smaller.

2nd class nests, which have feathers and other foreign matter mixed with the "isinglass."

3rd class nests, which are yellow in colour, and contain a good deal of dirt and foreign matter.

In addition to the above, what is called "refuse," that is, the clippings and cleanings of the nests, which have to be carefully cleaned and packed, bits of white "gelatine," which may occur in moss of twig nests, and the old nests which have been through the rains, is collected and sold.

During the long break of calm fine weather which usually occurs in October, between the monsoons, a party of convicts and Andamanese are sent out round the islands to clean the caves. This is a very important operation, as the nests which the birds last built during the preceding dry season, and in which they hatched out their young, are still in the caves, dirty and discoloured from the rain, etc. It is necessary to take all these away, and to scrape and clean the roof and walls of the caves, leaving a clean surface for the birds to rebuild on. If this was not done they would breed in the nests of the former year.

All the dirty nests are brought to me, and sold, as they are, for Rs. 2-8 per lb.

The birds arrive in November, but do not settle down to business till January, at the end of which month a party is sent out who make a clean sweep of all the nests built. As a rule, this crop of nests is small, and not of much value, and if there has been rain in December, is often discoloured and yellow from the droppings from the roofs of the caves.

The birds who have hitherto worked leisurely in their building, now begin to hurry up, and a second collection of nests is made at the end of February. These are usually large, thick, and of excellent quality.

The birds, resolved to have one more try, build again, and the next collection is made in April, but the quality of these varies. The nests are often thin, and very dry and brittle, though the color is good. It is the making of this third collection which I generally supervise, and I will now describe it in detail.

Bundles of torches, (for many of the caves are dark as night,) a couple of iron tridents, some clean liuen bags with long straps, a ladder of bamboos, some rope, and a large chest, securely locked, are the equipment: and taking these, with the two convict collectors, on board the "Ross," making a boat and an Andamanese canoe fast astern, I proceed south accompanied by a staff of 40 Andamanese.

The first thing the Andamanese do is to strip off every rag of clothing, and thank heaven they are away from civilisation for a fortnight!

Starting at 7 A.M. we reach the Cinque Islands at noon, but as the caves here, and on the next island "Passage," are small, and, being in serpentine, yield inferior nests, I don't go ashore always but send the collectors in a canoe, taking shots at them with the camera. In about an hour they return, and if the weather is very fine I go to the Brothers and collect tortoise-shell, and then return to Rutland Island. The caves here, and Jollyboys, and Malay Tapu yield few and inferior nests, but the scenery is lovely, the Labyrinth Islands, south of Port Mouat, being one of our show places. As Rutland Island rises to 1,400 feet, and all the country is more or less hilly, there are plenty of good views to be taken.

The calophylla and bullet wood trees covered with hoyas and orchids in blossom, make the beach very lovely from March till June, as the former trees, with two or three other species often in flower, hang over the sand, and the sea washes in under their branches, so that one can bathe in shade and surrounded with flowers.

The next place to go to is Port Campbell, on the west coast, about 20 miles north of Port Mouat. Here, the first thing that would strike you is the fearful damage done by the cyc'one of 1st November 1891, and as there are fine cliffs and headlands, and at the same time curious patches of wrecked forest, as if the wind had really gone mad (in one place a whole mangrove swamp has been torn up, and the trees laid flat), one can have a busy time with the cameras. I now unpack my 15" x 12" camera to the disgust of the Andamanese who have to carry it, and several views are taken which I may be tempted to send to your Exhibition next winter.

This is all done at high water, and when the tide has fallen we row round to the sea face of Mont

gomery Island, and scramble half-way up a cliff, then slide down a long slope of sandstone to the mouth of a cave. The water is waist deep, and the opening small, so look out if there is any surf on, as over the rough ground, if one trips, the consequences would be unpleasant. Once inside, the cave is found to be large and lofty, and the birds, knowing our errand, fly about wildly dashing themselves against the torches and in our faces, and chattering in what, if translated, would doubtless prove to be very bad language.

The trident is slid up the wall, and the nests, one by one, are carefully detached and put into the linen bags, where they must be neither crushed nor soiled, and on no account wetted with salt water. The yield from this cave is always a good one, and the nests are large and white. About four hours suffice to collect them all, and then we return to the "Ross" and pack them in the chest.

Leaving Port Campbell next day we steam up to Spike Island, cross through Homfray Strait to Strait Island on the east coast, 35 miles north of Port Blair, and anchor. There are some small caves here which are stripped of their nests, and the next day is spent at the South Button Island.

This is of volcanic origin, and full of fissures, which suit the birds admirably. It is only a few hundred feet across, and rises from deep water to a height of 60 feet. One can touch the cliffs from the deck of the "Ross," and looking down into the clear blue water, see the brilliantly-coloured coral fish in thousands. This island is second in importance of all our stopping places, and a whole day is taken up in making the collection, which is usually of the first quality.

And now for the last and most important place, "Méopong," at the north end of Stewart's Sound, 84 miles from Port Blair. All up the east coast of the Middle Andaman the scenery has been fine, as the hills which form the backbone of the islands rise to about 1,600 feet. Stewart's Sound itself is composed of mangrove swamps and low islands, but 5 miles to the south is a hill 1,500 feet high, and 10 miles to the north are the twin peaks of Saddle Hill 2,400 feet high. I know no lovelier view in the islands than Stewart's Sound at sunset, best seen as one leaves it by the southern entrance. We anchor in a little sandy bay "Chaka-mat-koito," (the village of jack-fruits,) and then have a three miles walk through the jungle to a limestone hill. In this are the caves, and it takes us two whole days to collect the nests. These caves are quite dark, and snakes, lizards, and bats live in them. How they were discovered so far from the sea I cannot say, but probably the flight of the birds was watched. The Andamanese take no interest in the subject, and of course could not communicate with the first collectors, who were probably Malays. These people would watch everywhere during the day season for the Swifts, and whenever a flock was seen would search in the neighbourhood till their building-place was found. Doubtless many caves exist in these islands, of which as yet we are ignorant.

The Andaman Islands have been known for a long time to the Malays who have been accustomed to come here for trepang, birds' nests, and slaves. So far back as 1600 the Andamanese were kidnapped as slaves by Arab and Malay traders, which fully accounts for their subsequent hostility to all comers. The Malays have maps of the islands, and names for all parts of them; indeed the word Andaman is supposed to be of Malay origin, they looking on the Andamanese as the Hanoumans, (as they pronounce it, Handoumans,) or monkey gods of the Ramáyana.

On arrival in Port Blair, the nests have to be cleaned and packed which must be done very carefully so as not to break, or soil them; all dirt and feathers being removed. They are then wrapped one on the other, and tied with twine till a circular bundle like a wheel is formed, weighing about 4lb.

The price of these nests varies. First class nests should be worth their weight in silver or about Rs. 145 per viss, but rarely fetch more than Rs. 130 per viss (3 lb. 10 oz.) Second class nests are worth Rs. 100

—Rs. 110 per viss; and third class nests about Rs. 75 per viss. One collection is worth about Rs. 1,400. The refuse from the cleaning is sold at Rs. 5—Rs.—7-8 per seer. The birds are now left alone to build for themselves, which they do hurriedly, hatch out their young, and are off "somewhere," with the first of the S. W. monsoon. These nests last built are small, discoloured with dirt, and often with spots of blood as if the bird was exhausted, and would be of very little value if taken.

Like isinglass, once thought so highly of, they are of no nutritious or tonic value. Their composition is unknown, but it is generally supposed to be a gelatinous secretion from the salivary glands of the birds.

I will conclude with a recipe for "Potage au nid d'hironde."—

For each nest allow one tea-cupful of chicken broth. Soak the nest for two hours in cold water, pull it apart and then drain, and boil in the chicken broth for ten minutes, until the nest is entirely dissolved. Season to taste, and serve.—*Journal of the Photographic Society of India.*

TEA PRUNERS.—The importance of really good cutlery for use on tea plantations cannot be over-estimated. Messrs. George Westenholme and Son, Limited, of Washington Works, Sheffield, who have given special attention to this branch of their industry, are manufacturing excellent tea pruners, the strength, durability, and finish of which are of the first order. The pruners are hand made and of the best crucible steel, matters of considerable importance.—*H. and C. Mail*, Oct. 14.

TREE TOMATOES FOR STEAMERS.—In converse with Mr. Nock at Peradeniya the subject of tree tomatoes was broached; and with reference to the statement published by a resident at Nuwara Eliya that if a remunerative demand existed he could supply the fruits in hundredweights, Mr. Nock said they ought to be in demand for passenger steamers. In his own case when proceeding to Britain he took a quantity on board which were much appreciated, eaten ripe as gooseberries are eaten. They lasted quite good as far as Malta, and Mr. Nock has no doubt that they would keep good for a whole voyage. We hope this statement will lead to experiment resulting in a large and steady demand for a fruit which is excellent for dessert, cooking and jelly, is easily and plentifully grown on our hills, up, as we have indicated, to Nuwara Eliya, where on a recent visit we saw plants put down as a shelter for a cabbage garden.

BOMBAY AND CEYLON MANGOES.—Though the mangoes of Bombay are highly prized by the epicure, they are not equal to those of Ceylon. Around the former place they grow in profusion, several varieties are raised, among which are the small round, the large round, the long cylindrical, the sweet and delicate, and the coarse fibrous mango. The fruits of the Bombay mango are of a peculiar pink and yellow colour, and are retailed at very high rates. The tree is large with a spreading habit, the leaves have a sweet resinous smell, and the fruit in shape resembles a short thick cucumber. The ripe fruit is very perishable, and when it begins to decay is very offensive. Like the apple, the number of varieties raised from the seed are very great. So highly are some of the best trees prized in India, that they are carefully guarded night and day through the fruiting season. [The above from the "Horticultural Times" takes us by surprise. That the grafted and highly cultivated Bombay mangoes should be inferior to those of Ceylon, which are but rarely grafted and still more rarely cultivated, is flattering to Ceylon, but surely it is a horticultural heresy?—*Ed. T.A.*]

GOVERNMENT QUINOLOGY.

Mr. D. Hooper, the Madras Government Quinologist writes as follows in his Report on the analytical work conducted in the laboratory during the year ending 31st March, 1892:—My visits to the Quinine Factory have not been so frequent as in former years, but several samples of bark have been sent in for analysis from the Dodabetta and Naduvatam plantations, and the products of manufacture have been constantly tested as to their purity. The sulphate of quinine has responded favourably to the chemical tests; it contained only a trifling amount of sulphate of cinchonidine, and its appearance and solubility were all that could be desired. The febrifuge has been made by the oil process, and has been somewhat lighter in colour than when the factory was first started. Some interesting barks have been analysed during the year, and the results are given in the following table. The majority of the barks are from hybrid trees, a number of which are grown at Naduvatam and are gradually replacing the poorer succirubras or red bark trees. It is difficult to tell the value of hybrid trees except by analysis, as the variable habit of these trees is accompanied by a variable alkaloidal composition, and some trees having the habit of a succirubra contain a good amount of quinine in their bark, while others with the appearance of an officialis sometimes contain a preponderance of the inferior alkaloids characteristic of the succirubra. Some of the hybrids were very rich in quinine, exceeding the amount found in the best crown barks, and knowing that these trees are faster growers and have a thicker bark, their cultivation is more profitable. Some of the better kinds of hybrids are being propagated by cuttings from analysed trees, and it will be interesting to observe the success of these experiments when the young plants are sufficiently developed. The following is a description of the different barks analysed:—

1. Hybrid bark marked "Magnifolia" from Naduvatam.
2. Bark from smooth-leaved officialis type of hybrid.
3. Magnifolia hybrid with pubescent leaves.
4. Officialis type of hybrid, 10 years old.
5. Officialis type of hybrid, 9 years, old.
6. Magnifolia hybrid from Dodabetta, 4 years old.
7. Officialis hybrid from Naduvatam.
8. Natural magnifolia bark, 20 years old.
9. Mixed hybrid thinnings from Chinamen's lines.
10. Hybrid, Naduvatam.
11. Succirubra hybrid.
12. Succirubra hybrid, 9 years old.
13. Crown bark from an old tree, Dodabetta.
14. Uritusinga, variety of *C. officialis*.

	Quinine.	Cinchonidine.	Quinidine.	Cinchonine.	Amorphous Alkaloids.	Total.	Sulphate of Quinine.
1 ...	5.82	1.2955	.60	8.26	7.83
2 ...	5.18	1.18	.23	.10	.45	7.14	6.97
3 ...	4.85	4.2042	.71	10.18	6.52
4 ...	3.18	2.0842	.48	6.16	4.23
5 ...	2.67	2.0456	.47	5.74	3.59
6 ...	2.45	1.1940	.32	4.36	3.30
7 ...	2.40	.93	.14	.29	.34	4.10	3.23
8 ...	3.28	1.91	.09	.34	.42	5.04	3.07
9 ...	2.28	1.98	...	1.40	.42	6.08	3.07
10 ...	2.26	.87	...	1.34	.52	4.99	3.04
11 ...	1.95	1.75	.04	.91	.61	5.26	2.62
12 ...	1.40	1.9588	.41	4.64	1.88
13 ...	5.75	1.15	.16	.27	.30	7.60	7.73
14 ...	4.21	1.6643	.51	6.81	5.66

These are only a selection of the barks analysed during the year. It will be seen that the sulphate of quinine ranges from 7.83 per cent in No. 1, to 1.88 per cent in No. 12, and the last named, with respect to its alkaloids, generally yields its maximum at this age. As an instance of the variation in the value of these trees No. 6 from a 4-year old tree contains more quinine than the sample No. 8 taken from a 20-year old tree, and this shows the importance of ascertaining the quality of a bark when it is young and preventing the mistake of cumbering the land with very poor trees. The average analysis of barks from some young plots has given quinine to be over 3 per cent, but as the harvesting was made from the poorer and smaller trees, the succeeding crops will be much richer. It is satisfactory to find such old trees, as represented by No. 13, yielding such rich bark, but it is only what should be expected if the trees are treated to manure. The estates are now being subjected to a course of systematic manuring and the effect is felt in the barks affording more alkaloids. If trees are allowed to grow for many years without their roots being artificially fertilised, the quinine in the bark is sure to deteriorate and the tree itself will show signs of decay. This rule does not only apply to the slow growing species of officialis, but also, and more emphatically, to the fast growing hybrids which are more exhausting to the soil.

Astringent Bark.—Two years ago I reported on the analysis of a large number of astringent barks from Indian trees, some of them never before analysed. Since then further opportunities have been given of examining other barks to ascertain the amount in them of tannic acid or other principle having a similar action. The bark of *Anogeissus latifolia* has hitherto been supposed to be one of the most astringent drugs, but I have recently found that a bark much richer in tannin, is derived from the *Bridelia montana*, a tree belonging to the natural order Euphorbiaceæ. This species of *Bridelia* is common on the ghats of the Nilgiris and in other parts of India. It is well known as a valuable astringent in Western India and is used by the Goanese in certain diseases. Some years ago in Orissa a case of poisoning was traced to the employment of this bark. The tanners of this country, however, do not seek after drugs very rich in tannin; as the quality of the tannin present appears to be the criterion of the value, and the bark of the Tangedu tree (*Cassia auriculata*.) which contains only 11 per cent of tannin, is used more than any other bark in south India. Of the other barks in this table, *Casuarina* bark is used in Madras as a dye and tan, and *Mirica Nagi* bark is largely used by Mahomedans and Hindus in the north in medicines where astringents are required. Some of the fig barks have been chemically investigated during the year, and as some of them contain tannin, they are included in the list:—

	Tannin.	Water extract.	Ash.	Colour with iron salts.
<i>Bridelia montana</i>	39.9	41.7	7.3	Blue-black.
<i>Acacia pynantha</i>	33.8	46.7	3.5	Do.
Do <i>decurrens</i>	33.4	44.8	3.2	Do.
<i>Kandellia Rheedii</i>	27.4	45.5	9.1	Do.
<i>Acacia melanoxylon</i>	26.8	54.2	4.1	Do.
<i>Macaranga tomentosa</i>	18.4	22.2	11.0	Do.
<i>Casuarina equisetifolia</i>	18.3	22.1	9.5	Do.
<i>Acacia dealbata</i>	17.8	32.1	5.3	Do.
<i>Mangifera Indica</i>	16.7	32.3	6.3	Do.
<i>Ficus racemosa</i>	14.1	20.6	12.2	Greenish.
<i>Mirica Nagi</i>	13.7	27.0	7.1	Blue-black.
<i>Diospyros embryopteris</i>	12.4	19.9	4.9	Do.
<i>Ficus Indica</i>	10.9	17.2	8.0	Greenish.
<i>Fleuggea lencopyrus</i>	10.3	20.5	3.5	Blue-black.
Do. <i>miserocarpa</i>	8.9	18.3	11.4	Do.
<i>Ficus gibbosa</i>	4.3	10.4	15.0	Greenish.
<i>Ouronligo orchioide</i> (root)	4.1	19.9	8.6	Do.
<i>Ficus religiosa</i>	3.8	12.3	11.7	Do.
Do. <i>hispida</i>	2.1	11.7	13.6	Do.

Wattle Barks.—The Australian acacias or wattles introduced in the hills many years ago have firmly established themselves, but nothing seems to be done, as in Australia, in collecting the bark as a commercial article. It is true that the common forms of wattle (*A. melanoxylon* and *A. dealbata*) are more plentiful on the hills than these species—*A. decurrens* and *A. pycnantha*—which yield rich tanning barks, but wherever the better species have been planted they have grown vigorously and well, and the bark is equally rich in tannin as that from trees growing in Australia. The price of good wattle bark is £10 per ton in the English market, and the market is supplied exclusively from Australia. A sample of bark from some *Acacia decurrens* grown on the Nilgiris was forwarded a few months ago to London for valuation. The reply stated that the sample of bark was in good condition and rich in tannin, but as buyers were in the habit of procuring their bark from a certain country, in regular quantities, there would be a prejudice in receiving it from a new source such as the East Indies, and there is nothing to guarantee their receiving a regular supply of the same quality. Tanners do not like changing the materials they employ, and English and Continental firms after obtaining wattle barks from the Australian Colonies for nearly a century are apt to look with suspicion upon other wattle barks. I have obtained the following results in analysing the barks of the Nilgiri grown acacias:—

<i>A. pycnantha</i>	33.8	per cent. tannin.
<i>A. decurrens</i>	33.4	„ „
<i>A. melanoxylon</i>	28.6	„ „
<i>A. dealbata</i>	17.8	„ „

The samples of *pycnantha* and *decurrens* were from a private estate near Dodabetta. The *melanoxylon* was from a good sized tree after it had been cut up in logs for firewood, and represents the strength of the bark found on the majority of the fuel used in Ootacamund. The *dealbata* was a fresh sample from some young bushes of the very common yellow-flowering species. All these have an astringent principle of the same chemical characteristics, which I feel assured is the same as that found in the trees grown in their own native country. I have also made extracts or “tannage” from these barks, preparations which hold the virtues in a concentrated form, and much better than the crude bark for exporting. There is a good market in Europe for well prepared wattle bark extract, and the demand has been on the increase during the last few years.—*M. Mail*, Nov. 4.

GOVERNMENT PLANTATIONS IN SELANGOR.

A memorandum for establishing Government Plantations in Selangor has been drawn up by Mr. E. A. Watson and appears in the last *Gazette*. Estimates of expenditure have been drawn up, of which we append the totals.

The State of Selangor contains a very large area of virgin forest suited to the cultivation of tropical products, especially coffee, which will not only yield large profits to the investors, but will be a source of steady and permanent revenue to the State. Coffee, however, is comparatively a long time in bringing in a return, which to a great extent makes capitalists, especially those knowing nothing of its cultivation, hesitate before venturing on what they consider to be a risky investment, whereas they might not hesitate to purchase at a good price an estate in bearing shewing good returns. Unless the State takes an active lead in the matter, I am afraid it will be a long time before planting will take the prominent place it should.

At present the State is chiefly dependent upon tin for its revenue, and at the present rate at which these alluvial deposits are being worked it is only, in my opinion, a question of time for the large tin fields to be exhausted. Should the Government commence planting operations on a comparatively large scale, I believe that in the course of a few years all

the fine upland grounds in the State will be converted into flourishing coffee districts, and the Government would never have any difficulty in getting any plantations taken off their hands at a good profit; the value of the remaining forest land would also be considerably enhanced. With carefully kept Government books recording expenditure and returns on the different estates, capitalists would have little hesitation in investing, while, on the other hand, they would be cautious in accepting figures given by private individuals, especially as the Government need never be anxious to part with their estates.

The labour and other conditions are so different from Ceylon and other Planting countries, that if planters do not fail entirely, the amount of money they throw away is so considerable that they, and others who may have joined in the venture, get disheartened, and the State gets a bad name as regards planting prospects.

I would suggest that a district be selected, and that the land be cut up into blocks, one mile long by half a mile wide, giving an area of 320 acres to each, and if possible every block should have a river frontage as, for coffee, water and especially water power is of great importance, and does not seem to have received sufficient attention in the estates already opened up. When the land is blocked out, I would recommend that in the meanwhile only alternate blocks be granted to planters, the Government reserving each alternate block; and, when all the available land in the district is taken up, it might then be advisable, should planters apply for these reserved blocks, to put up annually a certain number at public auction, as, if the district is a flourishing one, planters would not hesitate to pay \$50 an acre for good land adjoining their own property when no other land is available close by.

I would recommend that on all main ridges on the mountain ranges a Government reserve of, say, 10 chains be kept on each side; this does not apply to spurs branching off the main range.

When the land is blocked out, applicants might be allowed to take up any block, excepting those reserved, on the usual terms and paying survey fees.

Should any individual or company apply for the purchase of any Government Estate, the Government might consider the proposal and sell the estate on receiving, say, not less than 25 per cent over and above what the property has cost to plant and develop. This, I think, would attract capitalists, who might be inclined to invest in a property that they can see for themselves is an assured success and bringing in immediate returns.

A very important point, and one on which the greatest care and judgment should be exercised, is the selection of seed for planting. I attribute the hold the *Hemileia vastatrix*, or leaf disease, took on the coffee in Ceylon due to a great extent to the want of discretion on this point, as year after year seed was taken from young diseased trees, instead of importing good seed from picked trees from other countries; and in proof of this, I can say, from practical experience in Ceylon, that old coffee in other districts stood the disease and gave better crops than the young coffee in the newer districts; and from personal experience in the Straits I can state that seed imported from Liberia has always produced a superior class of tree of that obtained locally.

When one district is fairly started, the Government could then take up others. In fact, the Planting Department would practically prospect the land, and the intending investor would merely have to get a block plan, at a small cost, from the Survey Department and go over any block marked out, which he could take up on the usual terms.

I consider that, should this or some similar scheme be taken up by the Government, the State of Selangor will in the course of a few years be a very flourishing planting country.

I herewith enclose very carefully drawn out estimates of expenditure and returns for Liberian coffee, which I think will be found to be pretty accurate.

EXPENDITURE.		\$
1st year.—Opening and planting	300 ac.	21,050
2nd.—Do do	300 ac.	
Weeding and upkeep	300 ac.	25,300
3d.—Opening and planting	300 ac.	
Weeding and upkeep	600 ac.	31,600
4th.—Opening and planting	300 ac.	
Weeding and upkeep	900 ac.	
Plant for dealing with coffee		43,900
5th.—Felling and planting	300	
Cultivating	300 at \$60	
	300 at „ 20	
	600 at „ 15	43,000
6th.—Cultivating	900 at „ 60	
	600 at „ 25	
	300 at „ 15 and pulp-	
	inghouses, &c. 61,000	
7th.—	900 at „ 60	
	600 at „ 25	69,000
8 h.—	1,200 at „ 60	
	300 at „ 25	79,500
9th.—	1,500 at „ 70	105,000
10th.—	1,500 at „ 80	120,000
	Total	602,350

STATEMENT OF EXPENDITURE AND RETURNS.

Year.	Yield	Receipts.	Expend.	Cr. or Dr.	Balance.
1	21,050	—	21,050
2	25,300	—	46,350
3	31,600	—	77,950
4	43,900	—	121,850
5	900 cwt.	23,400	43,000	—	141,450
6	2,700	70,200	61,000	—	135,250
7	5,100	132,000	69,000	—	71,650
8	7,500	195,000	79,500	+	43,850
9	9,900	257,400	105,000	+	196,250
10	11,400	296,400	120,000	+	370,650

Yield calculated at 3 cwt. fifth year; 6 cwt. sixth year; 8 cwt. afterwards. Produce 78s in London, at 3s=\$26 per cwt.

This table shows that \$140,000 is required to bring into bearing 1,500 acres of Liberian Coffee. No return is taken until the fifth year. By the end of the eighth year the whole expenditure on the property is recovered and a profit of \$43,850 left. The expenditure is liberal, and the estimate of returns moderate, and I consider the table to be a safe estimate, under ordinary circumstances with good management and Indian labour.—*S. F. Press*, Oct. 31.

[Mr. Watson's proposal is in direct violation of all the principles of political economy. The business of Government is to provide all possible facilities of communication and for the provision of labour, but certainly not to plant estates in order to sell them. How could ordinary planters meet such competition? Mr. Watson is not right about fresh coffee seed, too; for seed was imported from various countries, including Liberia, into Ceylon, and the seedlings were scarcely above ground when they were attacked by leaf disease.—*Ed. T.A.*]

BAMBOO AND ITS USES.

A museum, and neither a small nor an uninteresting one, might well be formed for the single purpose of illustrating the innumerable and varied uses to which the Bamboo is put. Exterminate the Bamboo, and the poor Chinaman is deprived of his big sun hat, and the wealthier Chinaman of the soles of his shoes. And although as a rule one associates the Bamboo chiefly with the Chinese, yet it is hardly, if at all, less important to the natives of India, the Malays, the Dyaks of Borneo and the Japanese. The gracefulness and beauty of its growth render it one of the happiest subjects of the Japanese artist. And in a Japanese landscape what fitter frame to a view of the Peerless Mountain could be imagined than a cluster of slender Bamboos gracefully arching the foreground. Without Bamboos how many

screens, fans, and vases would present only a blank surface. Even many a Kensington drawing-room would be deprived of much of its decoration, and perhaps even of some of its furniture.

The Chinese cultivate it in plantations. They have a method of keeping the shoots cut down close to the ground for three years, not allowing them to grow till the fourth. These young shoots are boiled and eaten, as most writers say, 'like asparagus.' But besides serving as fresh vegetables, these shoots are preserved by different methods, being either candied or pickled. One of the medicines of Chinese physicians called *tabachir* is extracted from the Bamboo, being developed from a fluid secreted in the joints. But if the wonderful property claimed for the leaves acted as it ought, there would be no need for any more medicine. A charm against sickness or misfortune has only to be written on a Bamboo leaf which is to be burned and the ashes drunk mixed with tea. Whilst we are speaking of it as food and medicine, it may be mentioned that it is applied more directly and externally in the form of *bastinado* to offenders of the law, a form of *Bamboo Chow-chow* which has been the last meal of many a poor wretch who has perhaps also found in Bamboo the staff of a miserable life.

In some places Bamboo forms the only material in the construction of a house. The framework consists of poles lashed together with long strips of the outer fibre, the thatch is of the leaves, and the walls of matting, while for the floor the largest poles are split into narrow strips. This is the case in Borneo where also the same material is used for the construction of pathways round the faces of precipices, and of bridges spanning the gorges. Some of these native bridges are formed of a single Bamboo for a footway and a smaller one for a handrail,—truly the very simplification of a bridge. The tobacco pipe of these bridge-builders is a kind of large hubble-bubble formed of the same material as their houses and bridges.

More than thirteen centuries ago, in the year 550, a small hollow bamboo cane (so it is said) formed the packing case in which the first silkworms eggs were smuggled from China to Constantinople by two Persian monks in the service of the Emperor Justinian.

Some of the oldest Chinese books consisted simply of strips of Bamboo pared thin, upon which the writing was scratched. And to-day paper is made from the interior part of the stem beaten into a pulp. From this paper the thick sole of the Chinese shoes, previously spoken of, are made. From the fibre is made a very light material which not only the Chinaman but the foreign resident uses for summer clothing, the difference only being in the fashion of the garments.

The rain-coats which in wet weather make the coolies, and the sampan and jimricksha-men look like strange, big, bedraggled birds, are made simply of dried Bamboo leaves. Its use is as frequent afloat as ashore. Strong ropes and cables are made from the fibre, and masts from the poles. The shavings are used to stuff pillows and beds with, and the leaves serve as bedding for cattle. One species has so hard a surface that it can be used for a whetstone. On the busy wharves where steamers load or discharge the weight of heavy loads is distributed amongst a dozen or more coolies by an ingenious but simple arrangement of bamboo poles. In the same way large blocks of stone or granite are transported as rapidly as one can walk. Indeed the almost universal method of carrying burdens in China is to suspend them from either end of a bamboo carried across the shoulder. In this way pigs, poultry, and vegetables go to market, and in this way too the hawk and itinerant restaurant transport their stalls.

Perhaps one of the prettiest and certainly one of the simplest forms it takes is in the manufacture of a Japanese fan. A piece of bamboo about a foot long with a point in the middle is taken. One half of this forms the handle. The other half is split down to the point into numerous fine strips, which being spread out form the framework of the fan

upon which the paper is pasted. And frequently enough its only decoration will be a simple, boldly-drawn spray of bamboo. In front of nearly every tombstone in a Japanese cemetery may be seen a short length of bamboo, forming a very simple vase containing a small branch of green leaves or a few flowers. It would be tedious to do more than enumerate such miscellaneous articles which bamboo enters into the construction of, as handles for pens, brushes, and agricultural tools, holders for pens or joss sticks, fishing rods, water pipes, stems for tobacco pipes, carved tobacco boxes, mats, sedan-chairs, cages, stools, flutes, shopkeepers' measures, both of length and capacity, and a host of other things literally 'too numerous to mention.'

Regarding its use as fuel the following quaint lines from the book of Messer Marco Polo, the Venetian, may be of interest as a specimen of traveller's tales in the days when there was little fear of contradiction. 'The people cut the green canes, of which there are vast numbers, and set fire to a heap of them at once. After they have been awhile burning they burst asunder, and this makes such a loud report that you might hear it ten miles off. In fact, any one unused to this noise, who should hear it unexpectedly, might easily go into a swoon or die of fright. But those who are used to it care nothing about it. Hence those who are not used to it stuff their ears well with cotton, and wrap up their heads and faces with all the clothes they can muster; and so they get along until they have become used to the sound. . . . I tell you the truth, however, when I say that the first time you hear it nothing can be more alarming.'

In those climes where the bamboo does not flourish and where humanity boasts of a higher civilization, the mathematician proves with deep abstrusities of x and y that a cylinder is the strongest form a material can take. He simply recognises in the style of architecture which nature adopts not only in bamboos but in bones, a combination of strength and lightness which he clumsily endeavours to imitate in hollow rods for his clanking machines. But he nevertheless condescends to lean upon a yard of bamboo for a walking-stick.

EPSILON.

—China Mail.

COFFEE-PLANTING IN MADAGASCAR.

SIR,—The inclosed are extracts from a letter which I have just received from a young Swiss whom I knew at Maroantsetra, and who is beginning a coffee plantation in the neighbourhood of Tamatave. Did I not know him to be of unimpeachable veracity, I should hesitate to believe him. However, his statements are confirmed by two well-known British residents at Tamatave—Messrs. R. and B., of the New Oriental Bank, and Mr. W., a merchant. Writing under date on May 27, my informant says:

I will give you all the particulars I know about Liberia coffee. I have planted already 700 young plants, which I bought from Mons. D., who has a small coffee and cacao plantation. This gentleman is nearly the only one who has Liberia coffee. He has only about eighteen large trees, and, most unluckily, they are planted too close together—6ft. square; so only the outside trees are in properly good order. Everyone who sees these trees is astonished at the quantity of coffee they have borne. The trees are five years old; from 8ft. to 10ft. high; branches from the bottom to the top; the outside trees over 5 ft. in diameter, and covered with coffee. The proprietor is willing to bet £10, or more, that one of his corner trees will give 50 lb. of dry coffee in one year's time. And I believe it, and everyone who sees the trees does the same. Messrs W. and B. (alluded to above) have seen the trees, last Sunday, the day before yesterday, and you can ask them. . . . The trees are planted too close. They ought to be at least 8 ft. by 10 ft., or, better, 10 ft. by 10 ft. The inside trees are also covered with coffee; but, as they have not enough air, they have run up into height,

and don't look as well as the outside ones. . . . He also has some young trees, two years old next month; they are full of flowers and fruit, and will at least give from 1½ lb. to 2 lb. of dry coffee this year. . . . Mr. D. has already sold, from his few trees, over £40 worth of seed. . . .

When one remembers that land suitable for coffee and cacao can be got very cheap; that labour, although not plentiful, does not cost more than 16s per month at the worst of times; and that the climate of the east coast, although very hot, is not particularly unhealthy, while in the islands of the interior it is really enjoyable, one wonders that more Englishmen do not try their fortunes out here.

The political situation is still, and likely to continue, *tendue*, but that would not in any way affect planters.

While this was being written, a friend here informs me that, some time ago, "he sent some samples of Malagasy coffee to London, to be reported upon; and that he has just heard from home that three separate experts have valued it at 2s a pound!" As he says, "he supposes that this means the retail value; but, even so, it is extraordinary." Of course, we all drink it here, and find it deliciously fragrant and wholesome; and it is pretty dear, too. I have over 15,000 young coffee plants in my garden here; but they are all sold to go to a new plantation, about two days' journey east of this capital, the land here being two hard as a rule. If my first informant's figures are correct, and there seems to be no doubt about them, a plantation in Madagascar should give extraordinary returns. Taking 500 trees per acre, before the end of three years we should have from 750 lb. to 1,000 lb. per acre; while at the end of six years it might reach nearly 25,000 lb. per acre. This, at only 8d per pound, would give over £800 per acre. Surely this is the "biggest thing" in coffee planting any of us have ever heard of? Probably one of your numerous correspondents may be able to say whether it "beats the record" or not.

F. CORNWALLS MAUDE,

(Late Colonel Royal Artillery).

Antananarivo, Waterloo Day, 1892.

—Field, Aug. 6.

In a communication to the *Field* of August 6th last by Col. Cornwallis Maude, some statements are made and figures given in relation to the cultivation of Liberian coffee in Madagascar that, if correct (and there would seem no valid reason for doubt on this point) well deserve the attention of coffee planters and capitalists all over the world.

An analysis of the remarks of the Colonel himself and those of his young Swiss friend reveals the startling facts that an acre of Liberian coffee in the island of Madagascar, planted 10 feet by 10 feet apart, or say 500 plants to the acre, yields at two and a-half years old 1,000 lb., or over 9 cwt. per acre of dry coffee; and at the age of six years the yield per acre would be 223 cwt., or over 11 tons per acre.* This at 8d per lb., or £74 13s 4d per ton—which at present prices is a low quotation—means a return of £821 6s 8d per acre.

Col. Maude makes no mention of the probable yearly amount required for the cultivation of an acre of coffee in Madagascar, gathering of the crop, &c.; but judging from my experience of this work in India, I should say that a sum of about £35 per acre would be ample to meet all expenditure for a twelvemonth. This, then would leave us a net balance of £786 8s 8d on the year's working. The worthy Colonel may well exclaim "Surely this is the 'biggest thing' in coffee planting any of us have ever heard of."

Having an intimate acquaintance with nearly all the coffee-growing districts of Southern India, the following figures may be relied on:—Clearing and planting a coffee estate costs about £10 per acre for the first twelvemonths, and for the following five years, say, an average of £7 10s per acre per annum. The trees

* If clean coffee is meant, the statement is utterly incredible.—Ed. T.A.

are planted 6 ft. by 6 ft. apart, or 1,210 to the acre; 5 cwt. of dry coffee per acre for a maiden crop, *i.e.*, at two and-a-half years old, is considered a good crop, and from 7 cwt. to 10 cwt. per acre per annum for the following four seasons is thought to be an exorbitantly paying crop. I have known estates or portion of estates, yield at the rate of 1 ton to 30 cwt. per acre in a single season, but such are altogether exceptional returns.

In Southern India the trees are not allowed to exceed a height of 3½ ft. to 4 ft.; but according to Col. Maude's young friend, those in Madagascar are permitted to attain a height of from 8 ft. to 10 ft., which of course, makes a very great difference in the matter of crop.

Whilst engaged in coffee planting in India, and at the time when the coffee leaf disease was at its height, I had sent me from London a warden case of young Liberian coffee plants as an experiment, thinking it possible that they might resist the disease; but in this I was disappointed. When planted out in the spring they made a good start, and grew well throughout the south-west monsoon, but perished from the disease during the ensuing hot season, although no old trees suffering from the blight grew nearer to them than a couple of miles. Assuming Col. Maude's information to be correct, I would venture to give this advice to those of our countrymen who are contemplating coffee planting. Go not to India, Java, the Brazils, or Ceylon, but steer a straight course for the Island of Madagascar.*

J. LOWRIE.

—Field, Oct. 8.

A NEW SELANGOR COMPANY.

Our London correspondent writes under date Oct. 7: The Selangor Coffee Company, Limited, has just been registered at Somerset House, London, with a capital of £15,000. Its objects are:—To purchase or otherwise acquire any lands in the Straits Settlements, and to cultivate, manage, and develop the same; to superintend estate and properties in the Straits Settlements, and generally to undertake the business of estate agent; to plant grow, and produce coffee, tea, cinchona, cocoa, cardamoms and other natural products of any kind in the Straits Settlements, and to trade and deal in the same; to work mines or quarries, and to manufacture or otherwise deal in ores, metals, minerals, oils, precious and other stones, or products, and generally to carry on the business of mining in all its branches; to construct coffee curing mills, tea factories, roads, docks, wharves, tramways, ships, barges, &c.; to carry on the business of merchants, exporters, importers commission agents, shipping agents, shipowners, engineers, insurance and advertising agents. The liability of the members is limited. The first subscribers are:—

Henry Kerr Rutherford, managing director Ceylon Tea Plantations Co., Mincing Lane, E.C.

Wm. Herbert Anderson, managing director new Dimbula Co.

Henry Tod, director Ceylon Tea Plantations Co.

Alexander Wm. Martin, stockbroker, Thogmorton St., E.C.

D. A. W. Reid, managing director of the National Bank of India.

Frank Watkin, merchant, City.

Gustavus Arthur Talbot, director Ceylon Tea Plantations Co.

The qualification of a director is £100. Messrs. Henry Kerr Rutherford and William Herbert Anderson have been appointed the first directors of the company. The registered office is at 21, Mincing Lane, E.C.—*S. F. Press.*

GOVERNMENT PLANTATIONS v. PRIVATE ENTERPRISE.

Our planting friend writes:—It is strange that the day after my note on Mr. E. A. Watson's scheme for Government Plantations appeared in your columns, you should give the names of the first subscribers to and the first directors of "The Selangor Coffee Company Limited." A company of this description

* But see about a reliable labour supply.—*Ed. T. A.*

will do more towards opening up the State and bringing it to the fore than any number of Government or Government-propped plantations. All success to the "Selangor Coffee Company Limited." A bumper and no heeltaps. The names of Rutherford, Anderson, Tod and Talbot are a tower of strength, and are a sufficient guarantee that whatever is undertaken will be done thoroughly and done well. A further good omen is that all these men are money-makers. Not money-grubbers; but money-makers: for it may almost be said that everything they have touched for the past ten years or so has turned to gold. There is abundant evidence, apart from the formation of the Selangor Coffee Company, that men who have done well in Ceylon in recent years, are now beginning to think that the mercury of success has reached its highest point; and "fresh fields and pastures new" are eagerly being enquired for by those who wish to withdraw their money while prices are at their highest. To this end the ubiquitous Ceylon planter might have been found at any time during the past few months prospecting for land in Dutch Indies, in French Indies, in New Zealand, in New Hebrides, in British North Borneo, and heaven knows where besides. The opinion of your scribe is that the Malay Peninsula will be the first point of attack for this restless and pushing army; and, granted a measure of success to the Selangor Coffee Company, Limited, capital will pour into the country so fast as the country can take it.—*S. F. Press, Nov. 5.*

BARK AND DRUG REPORT.

(From the *Chemist and Druggist.*)

LONDON, Oct. 20.

CINCHONA.—At Tuesday's fortnightly auctions a fairly large quantity of bark was offered, the catalogues comprising:—

	Pkgs.	Pkgs.
Ceylon cinchona ...	884	of which 857 were sold
East Indian cinchona ...	297	do 239 do
Java cinchona ...	58	do 58 do
West African cinchona ...	235	do 235 do
South American (Calisaya) cinchona ...	755	do 545 do
Cuprea bark ...	664	do 51 do
	2,893	1,955

The assortment of bark was a fairly good one; red barks, as usual, formed the great bulk of the Ceylon supply, while among East Indian barks the yellow varieties predominated. Competition was pretty brisk throughout the sales, and almost the entire offerings (not counting Cuprea) sold at an average advance of about 5 per cent upon the previous sales—the unit being now from 1½d to 1½d per lb.

The following were the approximate quantities purchased by the principal buyers:—

	Lbs.
Agents for the Mannheim and Amsterdam works	159,184
Messrs. Howards & Sons	58,970
Agents for the Frankfurt o/M. and Stuttgart works	41,720
Agents for the Brunswick factory	30,832
Agents for the American and Italian works	20,463
Agents for the Auerbach works	14,782
Paris works	8,070
Sundry druggists, &c.	41,628
Total quantity sold	378,649
Bought in or withdrawn	105,837
Total quantity of bark offered	484,486

REMINISCENCES OF A TRAVANCORE PLANTER.

It is nearly twenty-two years ago since I, seated on the "knife-board" of a London bus, was informed by a sanguine friend the delights of coffee planting. It was, theoretically, a glorious life in a splendid climate, and with a moderate outlay a speedy fortune was a moral certainty. Soon after this eventful bus ride I retired with a gay and joyous heart from the dreary City office in which I was engaged; I borrowed a "Pope's Tamil Handbook" and studied the language; purchased books

on coffee planting, with wonderful estimates of crops and profits, and also a gun, and, finally, I set sail for the East. I am now a middle-aged man, whose gray hairs are becoming impertinently obtrusive, and that glittering mirage of a fortune is still as distinct from me as it was 20 years ago! Travancore was the happy hunting-ground I choose for the pursuit of Fortune. In those days planters were few and far between. Land was to be held at the upset price of one rupee per acre, and there was no competition at the auctions. Some time in the fifties, General Cullen, who was then British Resident in Travancore and a good botanist, opened small experimental gardens of coffee and spice trees on the Assambo Hills and in other places in the State. Most of these little gardens, after helping to make a beginning, and to start the idea of planting, have been abandoned; but even now in out-of-the-way nooks and corners of the jungles the traveller sees to his astonishment a few nutmeg and fruit trees planted long ago by the enterprising old General. Mr. Maltby, who succeeded General Cullen, conceived the idea of opening a tea, coffee and cinchona garden at Peermad, which he called "Maryville." It is still in existence, surrounding the iron-roofed Residency, though there is but little left of the coffee and cinchona, and the tea is of the China variety. It was planted in the days when a tea bush was simply a tea bush, and long before the planter vexed his soul about the quality of his *jat*.

These Residential efforts were from their nature tentative and amateurish, but they were soon followed by professional planting over large areas in Peermad. "The Hope" and "Woodlands" estates were planted in 1861 by Mr. Munro and General Stevenson respectively; "Stag Brook" in 1862 and "Twyford" and "Fairfield" in 1863. About the same time Messrs. Cox, Grant and Fraser, and other pioneers of Travancore planting, who had come over from Ceylon,* were busy in the South, and by the time I arrived on the scene the coffee-planting industry was fully established. Of course it was all coffee in those days for no one dreamed of planting any other product. There were fields upon fields and acres upon acres of glorious coffee trees, covered with dark green leaves unscathed by any taint of leaf-disease, glistening white with fragrant blossom in the Spring, and red with ripened berries in the Autumn. No wonder that the heart of the old planter waxed glad within him, and the young planter thought that he had but to plant his coffee seedling, and his fortune was assured. The industry developed with enormous rapidity. Thousands of acres of forest fell under the planter's axe, and applications for land poured in on the Government. The upset price was raised from Re. 1 per acre to R10, but competition was keen, and at the last auction—held, I think, in 1876—the average price was, if I remember aright, R22. Since then the Government has stopped all public sales, but why, I cannot say. The planter, one would think, is a person to be encouraged; he spends all, or almost all his money in the country, and draws not a cent out of it; he employs the natives of the country as writers, conductors, oanganis, maistries, coolies, not to mention the servants of his household, and enriches many of them so that they advance to the status of taxable citizens. Except in one particular I do not grumble at the Government. It has been kind to us in many ways, and it gives us grants for roads. It is our own fault if our private roads are in bad order; but who is to blame except the Government for a public road being almost impassable? There is one road I wot of, along which the whole traffic of this district passes, which a couple of months ago was a disgrace to civilisation. Foundation it had none, and its "surface," had disappeared into deep holes, or was swamped with mud, or covered with rocks and boulders. Years of correspondence with Government Officials failed to improve the state of that road. Its reported vileness was probably put down to "Planters' exaggeration."

* Mr. Cox did not go from Ceylon to Travancore, but had been for years resident there.—Ed. T.A.

In spite of carts being upset, and tea chests and boxes broken. That was two months ago. Now, it is as if a fairy's wand had passed over the whole of its once foul length, for it is a beautiful, hard firm and well-drained thoroughfare! Why? Because notice was received that H. E. the Governor was to pass along it. The D. P. W. was stirred to its innermost depths, and thousands of coolies were sent to embellish and beautify the slough. May Heaven bless His Excellency! The use of the road for once only in his lifetime has achieved more good than the protestations and petitions for years of us poor planters who use the road every day. And H. E. probably thinks it a very good road, which it is now. If it is allowed to relapse into its normal condition we might do worse than petition another Governor to come and visit us.

Looking back at the pioneers' far-away days it is wonderful to think what boys we all were. In this district there was hardly a man over 30. We had all the energy and hopefulness of youth, and a very bright future loomed before us. The young man of the present day seems a far more sober and serious being than we were. *Autres temps, autres mœurs*, I suppose. But they were good friends and merry companions, these old by-gone comrades, and it is sad to think what has become of many of them. I can count just fifty men who had come and gone in this district alone since I have been here. Of these I know for certain that eleven are dead, and probably many more who have wandered away beyond our ken have joined the great majority. For many years coffee flourished exceedingly, and extensions of estates were made on all sides. But the enemy was within our gates, and leaf-disease, slowly, insidiously but surely was sapping the industry to its core. War was waged against the foe; analytical chemists prescribed remedies; all sorts of experiments were made with various manures, and with different methods and times of pruning; volumes of correspondence were published on the subject in the planting journals. But it was all of no avail. The enemy was sometimes repulsed and seemed about to retire altogether, but it was only to advance again with redoubled vigour. The planter was teetering, and had to admit it. But he did not sit still with folded hands and bemoan his fate. If not utterly ruined, as he sometimes was, he cast about with characteristic pluck for some new product with which to retrieve his past disasters. His choice of products was limited, and the tea and cinchona were these most generally chosen. The latter thrived well, particularly on the High Range in the extreme North of Travancore, where the oldest trees were planted twelve years ago and yield of bark is from 500 to 900 lb. per acre. At lower elevations *Succinbra* was the variety principally grown, and the harvesting of the bark paid well for many years, till prices steadily dropping through over-production reached their present low level, at which cultivation of this variety hardly pays. There is still a good deal of coffee left in Travancore. Some men have stuck hold to it in spite of leaf-disease, and, cheered by present high prices, refuse to have anything to do with tea. Others, who when they gave up coffee and replanted their estates with tea, have several fields and patches of coffee still left on sheltered hill sides where the soil is good. These relics of the past represent the survival of the fittest, and yield good, though perhaps irregular, crops. But speaking generally of Travancore, King Coffee is dead, and Tea reigns in his stead. Peace to his ashes, and long life to his successor! TORUM.

—*M. Mail*, Nov. 2.

CASTOR OIL is made palatable by repeatedly treating it with hot water, and the addition of saccharin, until it tastes like a thin syrup. Then small quantities of the aldehyde of Ceylon cinnamon oil and some essence of vanilla are added until all traces of the scratching taste disappear. Its action is the same as that of the ordinary castor oil.—*Pharmaceutical Era*.

SOME FIBRE-YIELDING PLANTS.

THE COCONUT PALM,

(Cocos Nucifera.)

The coconut palm is at the present day cultivated largely in many parts of the world. It is extensively grown in tropical India, Burma, Ceylon, the Pacific Islands, and even in Africa.

It is a graceful tree with a cylindrical straight stem of about three feet in circumference, and generally attaining a height of from sixty to eighty feet. The long pinnate leaves, ten to fourteen feet in length, are formed in a crown on the top of the tree. When systematically cultivated the coconut is planted fifteen to twenty feet apart, and comes into bearing in from seven to ten years, gradually increasing in its production, and continues to thrive well for fifty to sixty years.

There are two kinds of fibres obtained from this palm, the one, the most important, from the husk of the fruits, and the other variety from the base of the leaf-stalk.

The first kind, which is obtained from the husks of the fruit, has a regular demand, and is put to a great many uses, in consequence of which certain coconut-growing districts carry on a thriving trade.

The fibre obtained from the husk is known as coir in commerce. Coir is obtained from the husks in various ways: of these two are very important, viz., one by crushing the husk in machinery, and the other by soaking it and crushing it by a hand process. The quality of the fibre obtained by the hand process is generally superfine to the other, and this in its turn depends to a great extent on the time at which the nuts are plucked, and their soaking or maceration in a green or fresh state before they dry up. The husking of the nuts themselves is very expeditiously done by those who are accustomed to the work, a single man with the help of pointed spike fixed to the ground husking from eight hundred to a thousand nuts per day.

The maceration is done in ponds or pits containing the water, or in enclosures in streams, or sometimes the sea. In each case the husk, divided into pieces, is thrown in and weighed down in the water, and in a month's time they get thoroughly soaked. Next the pieces are placed on a small wooden block, and are one by one struck with a short piece of heavy wood made round, till the soft cellular substance is removed and the fibre remains behind.

In the case of crushing by machinery, the husks are easily soaked or macerated in water before subjecting them to crushing. This system tends to produce a less elastic and springy fibre.

Coir was known in Europe as a commercial product from very early years, at least so far back as the sixteenth century, but a development in the manufacture of coir goods did not take place till after the great Exhibition of 1851. The specimens exhibited there drew the attention of many capitalists in England, who began gradually increasing the number of articles manufactured out of this product.

Europe takes in this fibre in two forms, one cleaned fibre and the other coir yarn. It should be mentioned that before the fibre is ready for export it has to be combed and sorted, for the husk of the coconuts contains fibres of various lengths and textures. In this process of sorting, we get the coarse fibres, the long and elastic fibres, and the short and woolly fibres. The other form of export coir yarn is largely made in Ceylon, Cochin and the Malabar Coast, and it forms a regular and thriving industry in some of the villages of these districts. Yarn is twisted by hand from the coir by drawing out to thick strings of fibre and twisting them: this is done in quite an expert manner by those who are practised to the work.

Coir and yarn from Cochin are considered to be superior to any produced in other countries, and hence always fetch good prices. This has been found out by investigations to be to a certain extent an anomaly of trade, for oftentimes good yarn exported from other countries are classed as Cochin.

The yield of coir per nut or tree has been variously estimated. Husks from forty middle-sized nuts yield on an average six pounds of coir, and when made into yarns thirty-five fathoms are generally made out of a pound of fibre.

In Ceylon, where coconuts are cultivated largely, and where a very flourishing trade in coconut fibres exists, a fine yarn is made, of which nearly fifty fathoms go to make a pound.

The fibres and yarns command very good prices in the London market. According to one of the latest reports, Cochin coir has been fetching £19 to £25 per ton good, £15 to £19 common; Cochin yarn £26 to £46, whilst Indian yarn fetched £21 to £23 good, £14 to £22 common.

Coir was first used in England for stuffing mattresses; later on, table mats, fancy baskets, bonnets, and a variety of other articles were manufactured out of it. The coir or fibre is made sufficiently fine for the loom and matting, both coloured and plain, of different textures, are made, whilst in combination with wool, fine hearth rugs and carpeting are made. The fibre is largely used in making brushes, brooms, &c.

The value of yarn in the manufacture of rope was long recognised, and is considered to be one of the best for cables, as it resists moisture and especially sea water to a considerable extent.

There are at the present day over 480,000 acres, more or less, under coconut cultivation in various parts of the world,* and the ever-increasing demand for the products of this tree makes its cultivation a profitable undertaking.—*Indian Textile Journal.*

VARIOUS NOTES.

VALUE OF THE INDIAN TEA INDUSTRY.—A correspondent writing to the *Englishman* points out that it has been estimated by the *Economist* that in tea alone in Northern India fifteen millions sterling has been invested. He computes that the Indian tea industry, not including Southern India, represents a capital of two hundred million of rupees. In Southern India the amount of money invested in planting property generally must be enormous, for it is well-known that one firm alone lost in the Sampaji Ghaut, a comparatively-speaking tiny District, even when it was at its best, not far off hundred thousand sterling. It would be most interesting to know just how much sterling money the various estates between Koppa and Comorin represent, and further what sum is annually distributed throughout the different districts by planters.

PLANTING ON THE NILGIRIS.—A friend writes me from the Nilgiris:—Owing to the drought during Sept., we had a very sharp attack of leaf disease—one of the worst known, from all accounts. But the late abundant rains have driven it off, and we are now getting a nice flush out. Crop, too, is ripening fast, giving a very fair quality bean. Unfortunately the leaf disease and drought have caused a lot of black coffee on the ends of the branches, one estate starting with 200 bushels of black before crop had actually begun. The drought and rain, too, brought out a fair blossom which will interfere greatly with all our work next year, rendering thorough pruning impossible and necessitating taking coolies off for picking when they ought to be cattle-manuring. Labour has been and is very scarce here this year, owing to the railway work both here and in Mysore. Canarese coolies are decidedly rare this year, and the local coolies being able to get 10 annas a day on the railway naturally go there in preference to doing estate work on Rs 6 to 8 a month. Consequently nearly all work is decidedly behindhand.—“Croppy,” in *Madras Times* of Nov. 5.

* We should think a million acres would be nearer the mark.

TEA IN PERAK.—From the Kuala Kangsar Monthly Report for September, in the *Perak Government Gazette*, we quote the following aragraph :—

On the 16th I visited the Cicely Tea Estate with the Acting Superintendent of Government Plantations. The lessees ask that their lease of this and the Hermitage Estate may be cancelled on the ground that they have been working them at a loss, there being no demand for the tea they have manufactured. The Cicely Estate is in better order now than when it was first taken over by them, and if they manufactured only rough cheap tea, for which they would obtain a ready sale amongst the Chinese miners, they would probably make it pay. They have, therefore, being allowed to give up the lease of the Hermitage Estate only, which was of very little use to them.

AGRICULTURAL CHEMISTS FOR INDIA.—Among the passengers by the P. & O. steamer "Kaiser-i-Hind" which left London on the 14th October, are, as we have already announced, Dr. Leather and Mr. S. H. Collins, who are coming out as agricultural chemists to make analyses for the Agricultural Department of India. One of these gentlemen will reside at Simla and one at Dehra; and we have learned that they have both had special experience in agricultural analysis, having spent some years as assistants in the laboratory of the Royal Agricultural Society of England under Dr. John A. Voelcker. Among the inquiries intended to be carried out will be a full and exhaustive analysis of the various Indian crops, cereals, pulse and straw and hay used as foddors; also the soils producing these crops, with a view of preparing a more just and reliable classification upon which the various land taxes shall be assessed. We believe this new department of agricultural investigation is one of the results of Dr. Voelcker's recent visit to India; and we should like to see something of the same kind established in Ceylon.

THE BRITISH NORTH BORNEO DEVELOPMENT CORPORATION (Limited) have issued a circular to their shareholders enclosing a report by their manager in North Borneo (Mr. Pryer) detailing the work accomplished to June 30. They say that Mr. Pryer's subsequent advices lead them to hope that by the end of the year he will have nearly 1,000 acres in all under cultivation—viz., about 300 acres in Liberian coffee, 200 acres in Manila hemp, and the rest spread amongst the various other products he is essaying the planting of, in order to find out what plant will best suit settlers to grow. A small sugar mill promises to be standing by that time, with an acreage of sufficient well-grown cane at hand to keep it at work; a large number (many thousands) of coco-nut and sago trees coming up, and a good many self-providing and rent (in kind or money) paying tenants seeking their own livelihood settled on the estate, whose number can be indefinitely increased if they can earn a living, of which Mr. Pryer has little doubt. There will also be the estate houses finished and furnished, roads made, planks sawn, growing plants of all kinds, &c.; in fact, as he says, "a rentable country and not merely a plantation of one or two particular things." The unsatisfactory results so far attending tobacco planting in North Borneo have reacted on the prosperity of Sandakan, and given so great a check to the value of the corporation's town concessions that they have had to devote their entire attention to planting. Manila hemp will be the first product to come in, and Mr. Pryer hopes to show a satisfactory profit on this cultivation in due course. Coffee in the fourth year should be giving good returns.—*London Times*, Oct. 15.

BRAZIL WOOD, although associated with the country of Brazil, grows quite extensively in Jamaica, as well as in other parts of tropical America (says Allan Eric in the *Drug Reporter*). As is well known, it is used to produce reds and browns, and decoctions of it are very extensively used in printing eslices. While Brazil wood is very abundant in Brazil, and is an important article of export from that country, most of that used in the United States comes from the West Indies. Whenever I saw the tree it was growing in mountainous or rocky localities, in dry places. It scarcely, if ever, grows to be more than twenty-five feet high. The leaves are bi-pinnate with many smooth, obtuse, oblong leaflets. The flowers are in panicles and have downy stalks. Like logwood and fustic, the heartwood alone is valuable. There is another wood, called Braziletto, which is found in Jamaica, but it is inferior to *Cesalpinia braziliensis* as a dyewood. Pernambuco wood is from another tree of the same species. This tree has a prickly trunk, with prickly pods and the flowers, which are red and yellow, possess a delicious perfume. The sap wood of this tree is extremely thick and the heart wood from which the dye is extracted composes only about one-third of the entire diameter of the trunk.

TEA IN TIBET.—A correspondent writes from Torchendo to the *N.-O. Herald* on 11th Sept :—

The tea crop is coming in and as many as 500 porters have arrived in a single day, each laden with loads of brick tea from Yachow, weighing from one to two cwts., according to the age and strength of the coole, man or woman. It is marvellous how they struggle over our mountain paths;—many are children of 8 to 10 years, who begin by carrying 40 to 50 catties. The journey takes about 25 days. From here on it is conveyed on the backs of yaks, and droves of these queer, short-legged, bushy-tailed oxen are now constantly arriving from the interior and helping to hock up our already overcrowded town more hopelessly than ever. But, at last, it is a satisfaction to find that beyond the frontier human muscle ceases to be cheaper than that of beasts of burden, with which it so painfully competes in China.

THE ARROWROOT grown and produced in Jamaica is almost, if not quite, equal to that of Bermuda, says a writer in an American paper. The arrowroot starch, as we know it here, comes from the tuberous roots or more correctly, root stalks of the *Maranta arundinacea*. The plant grows about 2 feet high has branching stems, ovate-lanceolate hairy leaves and panicles of white flowers. It bears a globular fruit about the size of a currant. The roots are often more than a foot long and are about as thick as a man's finger. They are jointed almost white, and are covered with large paper-like scales. These roots sometimes curve so that the points come up out of the earth, and thus form new plants. The roots are dug up when a year old, washed, carefully peeled, and reduced to a milky pulp. Mills for this purpose are used in some places, but in Jamaica the roots are usually reduced by beating in deep wooden troughs. The pulp is then mixed with much water, cleared of fibre by means of a sieve of coarse cloth or hair, and the starch is allowed to settle to the bottom. The water dissolves and so removes the greater part of the albumen and salts, while the starch quickly settles down as an insoluble powder. Successive washings are employed for further purification. The arrowroot is finally dried in the sun, great care being taken to exclude dust and insects. The careful peeling of the roots is of the greatest importance as the skin contains a resinous matter, which imparts a disagreeable flavour to arrowroot with which it is allowed to mix.

CEYLON TEA IN AMERICA.

The visit of Mr. Farr, of the [well-known firm of Messrs. Wattson & Farr of New York, to London, of which we are informed by our London letter by this mail, may, we hope, be of good augury for the future of the enterprise so energetically pushed on by Mr. Elwood May. With the apparent misunderstandings between the gentlemen last-named and Mr. Griminton, as the special Commissioner for Ceylon at the Chicago Exhibition, we are all now well-acquainted, and we have the fullest assurance that these have been fully removed and that the cordial co-operation which had been hoped for between those two gentlemen will not be hindered by anything that has taken place. We are told that Mr. Farr had expressed himself as confident that he will now be able to secure the monetary assistance which his firm consider to be necessary for the full carrying out of their schemes for the due representation of Ceylon tea at the Chicago Exhibition, and for the further prosecution of the enterprise with which their names and that of Mr. Elwood May have been so prominently associated. Confidence appears to have been felt by Mr. Farr that the Ceylon Tea Fund would give him sufficient assistance to warrant its being represented that the Company in which he is interested has the full recognition of the Planters' Association of Ceylon. It is this recognition that we know has all along been sought as being most desired by those who have been working in the interests of Ceylon in the United States, and when this has been fully obtained there would seem to be good reason for hoping that the work so energetically commenced may ere long have full fruition. Information that has reached us from London is to the effect that the shipments thence of Ceylon tea to America have largely increased within the last few months; and Messrs. Gow, Wilson and Stanton, a firm which deals so largely in Ceylon tea, we know to have strongly deprecated what they deem to have been the shortsightedness of our local public associations in not granting in the fullest sense to Mr. Elwood May the authorization of their names in his dealings with the American public. But our London letter above referred to gives us further items of intelligence that have a direct and most important bearing on the future of the enterprise with which our present remarks deal. It tells us of sundry parcels of our teas having been forwarded by a well-known company largely interested in Ceylon to New York, and of these having been submitted to the judgment of tea experts in that city. To the astonishment of the consignors these gentlemen assigned a lower place in their valuation to broken pekoe than they had given to the pekoes! This is a complete reversal of the customary judgment of the long-experienced London brokers, and we may well inquire as to the meaning of this singular decision. Then again, the New York brokers valued much of the Ceylon tea submitted to them at eightpence when the same break of tea was being sold at the Mincing Lane sales at one shilling and twopence. Here we have the astonishing discrepancy between the two prices of no less than six pence per pound, and this fact, added to that above stated, leads, we think, necessarily to the doubt as to whether our teas are likely to be fairly dealt with by those interested in the tea trade of America. It will be within the recollection of our readers that it was one of the complaints made by Mr. Elwood May that the tea broker and firms of New York had shown themselves to be inimical to the work he had undertaken. He stated while in London that those brokers and

firms felt that they could make more money out of the coarse teas of Japan and Java with which they were accustomed to deal than they could out of the finer and more expensive teas of Ceylon. We think we may see proof of the correctness of that statement in the information now supplied to us. Either the brokers and dealers consulted have shown themselves to be very ignorant of the value of our teas and the relative qualities of the different sorts, or else they have wilfully set themselves to bring about a depreciation of their value in the American market. However this may be, whether the cause of the decision given be due to ignorance or wilfulness, we can appreciate the difficulty that the New York traders have thrown in the way of the American Ceylon Tea Company, and the fact, should, we consider, make our public bodies more determined than ever to grant the fullest assistance towards breaking down the barriers that such a course of action is likely to oppose to our teas receiving full acceptance by the American public. We are glad to hear that Mr. Farr has stated it to be the intention of his company, if all his hopes are realized, to establish an outside store in Chicago which will be able to respond to all references made to it by our representative at the Exhibition to be held in that city.

NOTES FROM OUR LONDON LETTER.

LONDON, Oct. 28.

MR. FARR'S VISIT TO LONDON AND PUSHING CEYLON
TEA IN AMERICA.

We are just now having a visit in London from Mr. Farr, of the firm of Wattson & Farr, of New York. The name of this firm has been repeatedly mentioned as having given most valuable assistance, monetary and otherwise, to Mr. Elwood May and to the American Ceylon Tea Company that that gentleman represents. I have not been fortunate enough to meet Mr. Farr myself, but a friend who has done so tells me that the (Mr. Farr) has expressed himself very hopefully with regard to the future operation of the company mentioned above. He told my friend that he felt there was now every chance that the Ceylon Tea Fund would grant assistance, and in that sense become associated with and lend the *egis* of its name to the enterprise in which his firm has so largely engaged. Mr. Farr said that the sum wanted to enable them to continue the work so ably begun by Mr. Elwood May was £5,000, and that he had no doubt that, if the hopes he expressed with regard to the Ceylon Tea Fund were realized, this sum could be raised. It has always been understood by me—if my memory serves me rightly—that Messrs. Wattson & Farr would further adventure a similar sum if that outside aid were forthcoming. We hope therefore soon to hear that a decision favorable to Mr. Farr's hopes has been taken in Ceylon. Relieved as it has now been of responsibility for the Chicago Exhibition expenditure by the public step of late taken in the way of taxation, the Tea Fund might well be able to give liberal support to an enterprise from which so much may be confidently hoped to result. It has been mentioned to me that your Planters' Association has already made a recommendation of such a purport to your Tea Fund Committee, so little doubt is expressed here that that Committee will respond to it. Mr. Farr speaks most highly of Mr. Elwood May and of what that gentleman has already accomplished. Indeed he describes him as having "done wonders." Mr. Farr's presence in London has no direct connection with

the affairs of the Ceylon American Tea Company⁴ but is due to some negotiation arising out of the late failure of an important London firm. He is comparatively a young man, but seems to have favorably impressed all those who have come into contact with him since his arrival here. He speaks with much enthusiasm as to the prospect of pushing your teas at the Chicago Exhibition, and states it to be the intention of his firm to establish a store in that city for the purpose of supplying all wants that may arise out of your representative in the Great Show itself. We know that Mr. Grinton made special mention of the importance of having such an establishment when he addressed the members of the Ceylon Association on his last return from America, and we recollect, we think, that he further said he would himself aid such a scheme financially; so no doubt, he will be glad to hear of Messrs. Watson & Farr's resolution.

THE RENEWED ACTIVITY IN THE CHINA TEA TRADE.

During the week I have had a long conversation with a gentleman well qualified to inform me with respect to the causes which have led to a renewal of activity in the China tea trade. On my asking if he could account for this he replied:—"The fact is that the market is almost denuded of cheap teas from India and Ceylon. There is nothing to be bought now at the sales of those kinds below 6½d, and the result is that those traders who advertise their cheap blends of Ceylon and Indian with China are at their wits' end to keep within their advertised prices. They must either use almost exclusively China, or they must put their prices up. This last, of course, they are exceedingly unwilling to do. It would give a great blow to their trade, and so they are bidding freely for any China rubbish they can find offering. It would be much more sensible, in my opinion, if they took the bull by the horns and raised their retail prices so far as to enable them to keep up the standard of their blends to what it has hitherto been. Do I think that this putting into circulation a larger amount of China tea will improve the popularity of that of Ceylon? No, I cannot think this to be likely. The taste for the last variety is far too firmly established. What has to be dreaded, however, is the possible effect this present demand for China may have during next year. You see we cannot expect to receive any large quantity of Indian and Ceylon before next June, or possibly later. Therefore there seems every reason to expect that the present high rates will be maintained until that date. Possibly this fact may induce the China shippers to send home a large quantity of their cheaper teas, and we may have the market flooded with them. In that case a weaker demand will probably follow for Indian and Ceylon. You see men who advertised the finest tea the world produces at 1s 7d per lb. cannot possibly sell pure Ceylon of high quality at that price. Take off the fourpence duty and this is changed to one shilling and threepence, out of which all sorts of charges for storage and packing, and at least these profits, besides cost of transport to distant towns, has to be paid. Now a really fine Ceylon tea cannot be bought at the sales below a shilling the pound, and it stands to reason, therefore, that there must be a large use of inferior teas to make up. That is why these advertising people are now failing the pinch due to the absence of cheap Ceylon and Indian teas. Of course they are buying the only cheap teas available just now, and these come from China only. As I have said, there is no need for us to care about the present heavy sales of China, but it is the probable effect

on the course of next year's supplies that must be regarded with some anxiety? This view had not previously occurred to me, and I am not sufficiently up in such matters to offer any reliable suggestion based upon it; but as an outsider it occurs to me that the more you can send us at the present time of the cheaper teas, the less chance there will be of a renewed competition by China next year.

VALUATION OF CEYLON TEA IN NEW YORK.

Dealing with the foregoing topic reminds me of a further communication had by me this week on the subject of tea. A friend—well-known to yourselves—told me that he recently sent several samples of Ceylon tea to New York for valuation by the experts there. When the report from these were received my friend was exceedingly astonished to find that the broken pekoes had been valued by the New York referees at threepence per pound *below* the price they had quoted for the pekoes! This is quite a renewal of the judgments universally given in London, the broken pekoes always selling higher than the pekoes. Further, the New York valuation on a particular sample was eightpence per lb., whereas at the time this valuation was made the same teas were selling at the Mincing Lane auctions at 1s 2d! What can be concluded from such a report? The question to my mind is whether it is due to ignorance or to some malevolent desire to keep out Ceylon tea as far as possible. We all know that the New York brokers have all along been opposing Mr. May's efforts. Indeed, that gentleman told us when last in England that almost the hardest part of his work on behalf of Ceylon teas was to combat the opposition of the New York brokers. This was at the time confirmed by Mr. Delmege, who said at the meeting of the Ceylon Association reported to you that some years back his firm had endeavoured to introduce your teas into America, but that they could not induce the New York brokers to have anything to do with them, the fact being that they—or the dealers—could make much more profits out of the cheap Japan and Java teas they were accustomed to deal with than they could out of the finer Ceylon teas. As the result Messrs. Delmege had to wholly abandon their attempts on your behalf, and it has been left to Mr. Elwood May to at length obtain some footing in the States for your production. It is evident from what my friend told me that the opposition among the New York brokers and traders still exists. It is impossible except under such a supposition, to account for the extraordinary character of the report furnished to my friend.

CHINA VS. CEYLON TEA: A NEW BROCHURE.

While on the subject of tea it may be mentioned that there has just been published a *brochure* entitled "Theine versus Tannin," and a copy has been obtained by me of this to forward to you with this letter. This pamphlet is written by Mr. Stuart Cranston, of Glasgow, and purports to be a letter addressed to Mr. Goschen when Chancellor of the Exchequer. [As we extracted a lengthy notice of the pamphlet from the *H. and C. Mail* some time ago, we omit our correspondent's remarks.—Ed. T. A.]

It will be unnecessary for me to further allude to the contents of Mr. Cranston's pamphlet. After reading it I feel convinced that every argument it adduces has been fully met and threshed out before, and it is the general view here that its publication is only the "expiring kick" made by those interested in the doomed teas of China.

COMPARATIVE VALUE OF ANIMAL MANURES.

The application to the land of animal manure, either alone or mixed with vegetable substances, has from the earliest times been considered as the best means of producing fertility in the soil, or of restoring its productive powers when exhausted.

Of all what may be termed auxiliary manures at the command of the gardener, probably guano occupies the first and most important position. And although guano of the strength in nitrogen formerly obtained can scarcely be bought at the present time, yet the unshaken belief in this manurial agent entertained by many market gardeners may be explained by the fact that in certain cases they get as good a crop from it now as they did previously. The fact being, that in the majority of cases 8 to 10 per cent. of nitrogen is quite sufficient to apply in any manure at the ordinary rate, and the larger quantity formerly used was, in too many instances, wasted.

Guano, as is probably known, is composed of the excrements of sea-birds, which have accumulated in the course of time, in layers of greater or less depth, upon uninhabited islands and rocks. Good guano comes to us from those zones of the earth in which it never, or at least extremely seldom, rains, and from such islands as are sufficiently elevated to prevent the overflowing of sea-water; for if either happened, the best and most efficacious portions of the guano would be dissolved and washed away. If a dung-heap is suffered to lie without attention for only a few years with the sun shining upon it, the air driving through it, and the rain washing its goodness away, what will at last be left? Not much, beyond the carbonaceous and mineral substances which could not be dissolved or volatilised.

Such is the case with washed-out and bad guano, and this inferior article is now very frequently to be found in commerce, in the place of the rich guanos formerly to be purchased; therefore, gardeners should be on their guard when buying this fertiliser.

Enquiries are often made as to the value of poultry manure, and its comparison with other animal excrements. We have therefore given in the table below the quantities of four of the principal manurial constituents contained in cow-manure, pig-manure, and fowl-manure; each in its natural state and free from litter. The quantities are shown in pounds per ton of manure.

Selected Constituents in Three Animal Manures, in lbs. per Ton.

Constituents.	Cow Manure.	Pig Manure.	Fowl Manure.
	Lb.	Lb.	Lb.
Potash.....	7	2	24
Phosphoric acid ...	5	18	41
Lime.....	6	33	47
Nitrogen.....	9	13	87

The data thus given shows that of the three manures quoted, that produced by cows is by far the least valuable, except in the matter of potash; and it is generally so regarded. This may be explained by the large quantity of fertilising constituents withdrawn from the food by the milk yielded. It has been estimated that a milch cow will carry off from a meadow in the course of a year by the milk which she yields as much plant-food as is contained in 1½ ton of farm-yard manure.

The excrements of cows contain the smallest quantity of nitrogen, and the largest quantity of water, amongst the manures of which we have spoken. On this account they pass but slowly into putrefaction, and become less heated when lying in heaps; for heating is exclusively a result of the putrefactive fermentation, and keeps pace with this process. In addition to this, the substance of these excrements does not acquire a crumbling texture by lying or desiccation, but becomes saponaceous and compact; by which its distribution in the soil, as well as its decomposition and liquefaction are rendered more difficult. The slow but persistent action of this manure is thus explained at once.

Pig-manure varies in character probably more than that of any of our domestic animals, for pigs are of all creatures the most indiscriminate in their diet, and their excrements must, on that account, vary much, according to the kind of food they may happen in any particular case to obtain. Containing so much water and so little nitrogen, dung, like that from cows, but slowly undergoes decomposition in the soil, and is, therefore, regarded as one of the "cold manures."

Fowl-manure, like that of guano from sea-birds, is a powerful fertilising agent; it contains as much or more nitrogen than many of the commercial manures in the market, besides 1 per cent of potash, and 1.83 per cent of phosphoric acid. The dung of fowls contains not only the undigested food, but also in solid form the excretions of the kidneys, which in cattle are voided as urine, and are apt to be lost both by drainage and by rapid fermentation. Thus the richer food, and the fact that the dung of fowls is comparatively dry, explains the higher percentage of nitrogen, phosphoric acid, and potash in it. Care in its use is necessary, as also with guano and other of the strong manurial agents, or mischief may be done to the plants for which it is employed. If dissolved in water, it may advantageously be applied to all fruits trees, especially during the period of fruiting; also for Tomatos, Onions, Chrysanthemums, Fuchsias, Geraniums, &c. If fowl-manure is used for Vine borders, for which purpose it is admirably adapted, it should be mixed with equal quantities of charcoal-dust or cinder siftings.

Farmyard manure is particularly liable to fluctuations in its chemical composition, according to its preparation, and the amount of food and litter supplied to the animals. The following may, however, be taken as about the average composition per ton:—

Selected Constituents in 1 ton of Farmyard Manure.

	Lb.
Potash	11
Phosphoric acid	8
Lime	16
Nitrogen	12

It has been found that by far the larger part of these ingredients in farmyard manure are in an insoluble connection—that is to say, in a state in which plants cannot feed upon them until they have undergone further change.

For example, a portion of the nitrogen in farmyard manure exists as ready-formed ammonia—our sense of smell readily detects this fact—but a large proportion becomes only very gradually converted into ammonia, as the nitrogenous organic matter decomposes in the soil.

Thus, owing to the slow decomposition of farmyard or stable-manure, and the tardiness with which a large proportion of its nitrogen becomes available for the use of the growing crop, three or four times, or even more nitrogen, than in active artificial manures or fowl-dung, must be applied to produce the same effect upon the immediately succeeding crop. Stable-dung, however, possesses two very important properties—one mechanical and the other chemical.

By reason of its bulk and the quantity of organic matter it contains, it serves to render the soil more open and porous, and so to enable it not only to retain more water in a favourable condition, but also to absorb and retain more of the valuable constituents of the manure, and thus to arrest the passage of them in solution below the root-range of the plants. Further, by the gradual decomposition of the organic matter of the dung the pores of the soil become filled with carbonic acid, which probably serves to retard the oxidation of the ammonia into the more soluble form of nitric acid, in which it would be more liable to be washed out of the soil, and lost by damage. At the same time, the carbonic acid evolved in the decomposition of the stable-dung will, with the aid of moisture, serve to render the mineral resources of the soil more soluble.—J. J. WILLIS, Harpenden, *Gardeners' Chronicle*,

CELEBRATED TREES.

By A. H. DUNCAN.*

As the subject of Forestry seems to be one that attracts considerable attention in the columns of the *Farming World*, a reference to a few of the more famous trees now living may be of interest to some readers, and, as I have had the privilege of personal inspection of many of these, my remarks will doubtless be acceptable to those who prefer facts to fiction.

These trees may be classed thus:—

1st.—Those celebrated for their size.

2nd.—Those notorious for their extreme age; and

3rd.—Those that have acquired fame for some other reason.

Of those celebrated for their great size, I may begin by mentioning the Plane tree in the grounds of Kippendavie, near Dunblane, which, with a girth of 42 feet, and a height of 100 feet, is allowed to be the largest of its kind in Scotland; but, as most of my readers have probably seen this tree, I will say no more about it, but will pass on to what in France they consider their most gigantic trees. These grow in Normandy, and are two yews of the Haye-dé-Routot, in the Eure. The largest of these, although measuring 30 feet in circumference, is only 60 feet in height. Its hollow trunk has now been transformed into a chapel, but before this was done, it was capable of holding forty people, and eight musicians on one occasion played a piece therein. It is supposed to be 1500 years old. There is an oak tree at Guerbaville which, although only 250 years of age, has attained a height of 130 feet.

In England something better can be shown than this, and in the park at Welbeck Abbey, the seat of the Duke of Portland, there stands the celebrated Greendale oak, over 800 years of age, and measuring 33 feet in girth, while its branches cover an area of 2,700 square yards. But these are but as pigmies when we come to speak of the big trees of California, the "Giant-Sequoias." Those are divided into three lots, namely, the Mariposa grove, the Calaveras grove, and the King's River grove. In the Calaveras grove there are 27 trees of 250 feet or more in height, 4 of which are upwards of 300 feet, the highest being 325 feet. Of 300 trees that were measured in the Mariposa grove, the tallest was 272 feet, and in the King's River grove no single tree reached the height of 300 feet.

The celebrated "King of the Forest," when discovered by white men, was prostrate, already partly decayed, and the whole top burned away, consequently no one knows how high it was; and, although the accounts published at the time of its discovery speak of it as perhaps over 400 feet when living, these were merely guess work and not proved to be fact. I have stood inside the hollow trunk of the "King of the Forest," and have no hesitation in saying that it was the largest tree, in circumference, that I have ever seen. What the measurement was I now forget, but it must have been immense, from the fact that of the 2,675 giant-trees which are still left standing in California, the largest one is exactly 99 feet in circumference, and this is considerably smaller than the old "King" was.

My readers may fancy that, with the giant trees of California, my record of forest Kings has come to an end, but such is not the case, for in the deep dense bush of the Gippsland district of Victoria, in Australia, there are trees of the Eucalyptus species which would tower over the Sequoias were they placed alongside of one another. Many a time and oft have I lain down, rolled up in my rug, and camped for the night under these huge gum trees, which grow between the Yarra-yarra and the Watts rivers in Victoria, and, looking up 300 feet of clean and branchless barrels, have watched the possums gambolling and chasing each other, chattering as they frisked about in the light of the pale cold moon. And often, as I lay, have I thought that if one of these little creatures should happen to miss its footing, and come whirling through the air, down on the top of my devoted head, that it would have been a bad day for the possum, but an equally bad day for me

These huge trees, although tremendous in height, do not grow to anything like the same diameter as the Giants of California, 60 feet being an exceptional size in circumference for any of these to attain. But, although 300 feet is a very usual height for them to grow to, there are cases where they even exceed this, such as the one measured by Baron Von Mueller, at Neerim, on the Gippsland railway line, which proved to be 525 feet. The late Mr. William Ferguson, chief inspector of forests, has also left it on record that he measured a fallen tree from the butt to a point where the top had been broken off, and the length was 485 feet. With these trees, the tallest in the world, I will conclude the first part of my paper, and proceed, secondly, to consider those notorious for their extreme age, and of course, I mean by this, the trees whose correct age we actually are acquainted with, and not those like the Gaints of California, which, according to some, may or may not be 2000 years old, as no one really knows their age.

In the first place there is a vine, at Hampton Court, which was planted 150 years ago, and which is supposed to be the oldest vine in the world. It is upwards of 150 feet long, its stem being 32 inches in circumference, and in a good season, it yields more than 3000 bunches of grapes, weighing in the whole nearly one ton. They are of the finest black Hamburg kind, and are reserved chiefly for the Queen's table.

The oldest rosebush in the world is at Hilderheim, in Hanover. It was planted by Charlemagne, and, consequently, is over 1000 years of age. The Emperor planted it in commemoration of a visit made to him by the Ambassador of the Caliph Haroun-al-Raschid, but why he should have commemorated this important event in so singular a manner has not been handed down to posterity by any historian. Such a visitation, in the present day, would be commemorated by a succession of sham fights, dinner parties, and unlimited speechifying, and not in the humble way adopted by Charlemagne. There are various trees in public parks and in private grounds which are said to be from 1000 to 1500 years of age, such as the "Parliamentary Oak" in Clipstone Park, London, which is believed to be 1500 years old, and "Tasso's Tree," the famous oak under which the celebrated poet spent the greater part of the day during the last year of his life, when he had retired to the convent of Sant Onofrio, and which tree was blown down only recently, had also a great age attributed to it; the Cedars of Lebanon also, a few of which are still standing, we know existed at the commencement of the Christian era, but the oldest historical tree in the world, the one whose age is distinctly recorded in the traditions of the sacred annals of Ceylon, the planting of which, in the year 288 B. C., was one of the greatest events in connection with the Buddhist religion, is the celebrated "Bo Tree," which is growing amongst the ruins of Anuradhapura, carefully guarded by the priests and worshipped by pilgrims who come annually from all parts of the east to do homage to the "Invincible, powerful, all glorious Bo Tree." Compared with its age, 2180 years, the historical trees of England and Scotland, which are looked upon with veneration, are mere saplings; and the very Cedars of Lebanon, and the most ancient of continental trees, are far younger than this remarkable tree. It received the same homage 2000 years ago as it does now, and age after age the annals of Ceylon record the works each succeeding monarch has executed for its preservation, works which, although in many instances very old and crumbling away, can still be seen and recognised at the present day. Should such a calamity happen as the death of the great "Bo Tree" of Anuradhapura, it would spread consternation not only throughout Ceylon, but over India, Siam, and China. I have stood beneath the spreading branches of the "sacred pre-eminent Bo Tree," the appearance of which quite bears out its enormous age, and have examined the numerous ancient and remarkable structures that have been from time to time erected in connection with it, and are still standing as evidence of its long continued existence, and it seemed to me as if indeed the prophecy at the time it was planted

* Formerly of Rangala, Ceylon—Ed. T.A.

(that it would continue and flourish for ever), was likely to come true. I have also in my possession several leaves of the sacred Bo Tree, which are specially valuable from the fact that they can only be got by stealth or at great personal risk, as the priests refuse to allow any such degradation as plucking leaves from the tree which obtained its sacred character from the fact that it sprang from a branch of the Bo Tree at Magadha, under which the great Gautama was reclining when he attained Buddhahood.

We now come to the third class of celebrated trees, namely, those that have acquired fame for some other reason than that of extreme height or old age. Of this class, perhaps, fruit trees have gained the greatest notoriety for the extraordinary crops they are capable of producing.

In Malta and Naples 15,000 oranges have frequently been picked from a single tree, and one case is recorded of a tree in the Sandwich Islands which bore 20,000 oranges, whilst in two instances in Southern Europe 38,000 were picked from one tree.

There is an apple tree, near the homestead of Bungamero Estate, in Australia, the property of the late Mr. Hugh Glass, which, when 45 years old, measured 6 feet 6 inches round the trunk at 4 feet from the ground, and yielded 3 tons of apples. This tree is growing in a grass paddock, has never been pruned, and is yet perfectly healthy.

I read the other day of a monster Maréchal Niel rose at Warminster, which was planted on April 16th, 1888, and which made, the first year after planting, shoots 25 feet long, and produced 200 roses before it had been planted twelve months. Next year its shoots reached to the length of 30 feet, and the number of blooms amounted in 1890 to 2000. The plant covers at the present time an area of 450 square feet, and is carrying flower-buds and blooms of more than 3000 in number. As these remarks were published in several gardening journals, and never contradicted, I presume they are correct, and therefore include them amongst my own personal observations on celebrated trees.

No doubt many of my readers who have visited Archacarry, the principal seat of Cameron of Lochiel, have been surprised at the double row of beeches, the outer boughs of which trail in the swiftly flowing Arkaig, and wondered why they were thus planted. The circumstances attending the setting of these were as follows:—Just before the rising of '45, Lochiel received a quantity of young trees for planting round Archacarry; when the summons came for the clan to join the standard of Prince Charlie, the plants were hurriedly consigned to trenches, to await more peaceful times. But the men whose duty it was to have planted them out "came back to Lochaber no more," and so the plants struggled on in the trenches as best they could, and there they stand to this day, so closely crowded that a man can scarcely squeeze through between some of them.

As certain trees are famous for their height, and others for their age, so there are some also which have gained notoriety from the enormous size of their leaves, as for instance the Inaja palm of the Amazon country, whose leaves reach a length of 30 feet, and a breadth of 10 to 12 feet. The leaves of the Talipot palm of Ceylon are also very large, being frequently 20 feet by 18 feet, and are used by the Sinhalese in building their residences. Indeed, I have myself often resided in huts made entirely of talipot leaves, and on one occasion had a stable built of them, in which my racehorses were quartered, when in training, on a private racecourse in the Medamahanuweara district of Ceylon.

Before closing this paper I must say a word about the well-known Banyan tree, the sacred fig-tree of India. One could hardly call this a single tree as, owing to its peculiar mode of growth, it is rather to be considered as an aggregate. The branches keep dropping off shoots, which take root, and then the branches, continuing to grow outwards, drop other roots, until, in course of time, the area covered by these trees is marvellous. I have seen many very famous ones, which cover large areas of ground, but the largest known one is probably that in the Royal Gardens, Calcutta. Planted in 1782, it now

covers an acre and a quarter of ground, although much injured by cyclones.

It is needless for me to say that there are many trees entitled to a place in a paper such as this is, but, wishing to give only particulars of such as I have personal knowledge of, or am convinced of the correctness of my information about them, I have abstained from mentioning many that I would otherwise have gladly referred to. I am sure that there are readers of the *Farming World* who could supplement my paper by giving information concerning some of the more celebrated trees that they have visited, and which it has not been my privilege to see, and I need hardly say how pleased I, for one, would be to read any remarks that they would kindly forward for publication in the columns of the *Farming World*.

PLANTING NOTES.

The *Grocers' Journal* of 21st Oct. discusses the question "Is tea being over-produced." Quoting statistics it says that from them it would not appear that there is a plethora just yet of tea from India or Ceylon; and adds:—We feel, looking at solid fact and at consumptive agencies, and putting aside the possible loss or gain for the maintenance of markets at their present level to certain sections or individuals, that any attempt to curtail production would be far from beneficial to the consumers here, who have learnt to rely so much upon the products of our Asiatic Empire that any material cessation of supplies from thence must be exceedingly prejudicial to their pockets. And it is clear that it would re-act on the Indian and Cingalese planters themselves in the long run, because it is a fact, which is known to most of those who watch with interest this mighty trade, that China is beginning to feel that though it is still alive, it must soon die if it does not improve, and that consequently she is straining every nerve, even going so far as to adopt modern methods and machinery, and taking instruction from her masters in the Kangra Valley, in her anxiety to bear once more in Europe her old figure and regain the prestige and the profit which has been wrested from her. Tea production once fail in India, and all the wit of the Celestial tea-gardeners will be set to work to increase their export; and as "the finest tea the world produces" can still be obtained from the land of the Great Mogul, it would be wise in those whose interests are antagonistic to hers not to open a door which may be closed upon themselves.

The *Scientific American* draws attention afresh to the danger in planting Croton oil trees among tea bushes.

Here is a tea joke:—"What do you think of this story of tea in South Carolina?" "It is true, of course. You can't spell South Carolina without it." In this respect Travancore scores over Assam, Ceylon, Wynaad and even China, yet, paradoxical though this may seem, not over the Celestial Empire.

Here is another joke, from the city of the coming World's Fair:—Customer (in restaurant)—"Have you any crisp green lettuce?" Waiter—"Yes, sir. Perfectly fresh, sir." Customer—"And some fresh berries?" Waiter—"Some brought in today, sir." Customer—"And some nice green tea?" Waiter—"Yes, sir. I got some just picked this morning, sir."

At a meeting of the Peermad Planters' Association on the 27th October, it was resolved to guarantee the amount demanded to insure the telegraph line being continued to that district from Kottayam, and the Travancore Government has also guaranteed a considerable sum. Competition now is so great and planting has become so much more of a business than it was in the days of coffee, when the planter could, "like the fine old English gentleman," etc., that the telegraph is almost indispensable, and if that of Travancore is connected with the Periar works it will doubtless pay handsomely. The only other item of interest settled, was sending a sample case of tea from the various estates to the Chicago Exhibition and all efforts in this direction to advertise Travancore tea is of importance. Planters in Ceylon invariably, col-

lectively get a better average, and yet the Travancore tea is equally good, and certainly has as much attention paid to its manufacture but the big companies in Ceylon have got the name and (all credit to them) have advertised themselves so much, that many people have been forced to believe that there is but one tea and that Ceylon. CHOPPY.

—*Madras Times*, Nov. 12.

BADULLA PLANTING REPORT.

Nov. 12th.

After a fortnight's fine weather, which has been rather a trial to those who planted with the first rains in October, we are having true north-east rains. The 11th was the heaviest rains we have had for years at this part of the district, the rain-gauge showing 6.60 as the result of some three hours' rain. Several coolies have been killed, and the wash has been something dreadful. I have never known streams so high, and the damage done by slips and wash has been very great. On the 8th there was a very distinct shock of earthquake felt in the district and it seemed to be moving from south to north. We had a very successful breakfast to Mr. Fisher on the 4th, almost the whole district being present. The compliment to Mr. Fisher was well deserved, for he has done a great deal to the district during the past few years, both for planting and native interests; and the province now is in a very different condition from what it was when he took it over. We shall all miss him both in his official and private capacities. Tea is flushing very well indeed, and prices are so good at present that we should all do well this year. The higher coffee in the district is looking well, but there is very little crop set for the coming spring crop; and they are commencing to show up in hollows. Autumn crops are coming in well, and the quality is excellent, there being practically no light at all. Prices for this product are most remunerative, and the pity is there is so little left. The prices realized for Uva teas are very noticeable, there is hardly a factory in the district that does not rank with the best marks, and in the last sale to hand every break was well over the shilling, two or three being much higher. Uva teas will run Boga-wantalawa very close this year for first place. Yields also this season promise very well, and we are all ahead of last year.

GOLD PROSPECTING IN MYSORE.

Mysore, having an area of some 27,000 square miles, and there being little known of the geology of the greater part of the country, and less still of its gold-yielding capabilities, the prospector has pretty well to trust to his own intelligence as to the most likely ground on which to begin operations. The *Gazetteer* of the province has a brief allusion to gold in the Bettamangala Taluq, Kolar district; the low flat hills near Ooscottah are said by Dr. Heyne to be gold bearing; Huliur Durga, according to the *Gazetteer* yields a little gold; while from the Administration Reports of the Province the gold-prospector will find that in the Shimoga district a certain amount of revenue was derived by the State from the farming out of the right to wash for gold in certain streams of that district. An inspection of the localities would reveal to him certain well-marked and similar features in all of them; low hills showing little signs of vegetation, an absence of boulders and *tors* which are conspicuous on other hills in Mysore, the taluqs on the hill-sides consisting of angular fragments of slaty rock of a dark green of inky blue colour. In the water-courses below the alluvium he will find the bed-rock, where exposed to the action of the weather, soft and of light yellow colour, showing a schistose structure (splitting into layers) and having a greasy feel; below the action of the weather, this schistose rock is harder and tougher and of a distinct green or dark blue tinge. Later on he will learn to identify this rock as

a chlorite or talcose-schist—the great gold-bearing rock of Mysore. The eye can recognise the schistose hills of Mysore with unfailling accuracy, and once familiar with their general characteristics, a close inspection is unnecessary; they can be distinguished by sight from long distances. Mysore is traversed from end to end in every direction by good roads, and the Government bungalows, maintained at State expense, are situated, at convenient distances from each other throughout the Province so that, provided with a good bullock coach one can traverse the country in any direction in comparative comfort. Draught-bullocks are not necessary, every village having a supply which can be had at three annas per mile per pair. An acquaintance with colloquial Canarese is essential; if not a servant that speaks English and Canarese to act as interpreter is indispensable, as scattered all over the country and within a mile or two of each other are villages of cultivators who are acquainted with the features of the neighbourhood, and from whom by judicious questioning much information can be derived and much unnecessary tramping saved.

A steel crow-bar, small pestle and mortar for pounding specimens, a hammer and a gold washing dish make up the stock-in-trade of the gold prospector. The washing dish should be of wood and can be readily made by any carpenter, a pattern dish being procurable from the village jeweller, as they are commonly used for washing the "sweeping" of the goldsmith's shop for the recovery of the waste gold in the manufacture of jewellery. The gold-washing dish used by the natives of Mysore is called *halagay*, i.e. plauk—in fact, it is a circular piece of wood, fifteen inches in diameter and three inches thick, scooped out to resemble a shallow dish. This makes a capital "panning off" dish, quite equal to the Australian miners' "tin dish" for ordinary purposes and superior to it for testing purposes, as the graining of the wood detains particles of gold which could not be recovered in the tin dish. With a small supply of tinned stores packed away in his bullock coach and the prospecting plant above enumerated, the gold-seeker is sufficiently equipped for his undertaking. Having settled on the tract of country to be examined, he sends to the *a mildar* (revenue official) of the railway station from whence he means to make his start, to have bullocks stationed along the route he means to travel, giving the probable date of his departure from the railway station. A *shadaree* or tariff is sent him, showing the intermediate stages and distances of posting-stations, with sums to be paid at each for hire of bullocks. Having arrived at the headquarters of the district he means to prospect it, is as well to call on the Deputy Commissioner to state the object of the journey and obtain all the information available as to the most likely localities. There is always an amount of unofficial information to be obtained in this way, and it is surprising how much is known of old mines and gold-washing grounds, and yet how little of this information finds its way into official records. A letter from the Deputy Commissioner to the *a mildar* of the taluq or revenue division in which the locality to be examined occurs, smoothes the way wonderfully. In India little can be done without the aid of the Government. Let it be known that the *Sircar* has given permission, and all things are easy. Arrived at the scene of operations the first thing to be done is to obtain the confidence of the village *sonnar* (goldsmith). Most Indian villages, however small, have their gold or silversmith. If there is one in the village visited, be sure the next will have, and a word to the *a mildar* will quickly bring him to your presence. Judicious questioning with a small present for his trouble and he will conduct you to the best gold-washing streams in the neighbourhood. If it is old mines you are in search of, take with you the village goldsmith, the *thotu* (village watchman) and make for the nearest hills. When there ask if any *goonees* (pits, shafts) or *gweeces* (caves, drives) are to be found, and examine all such; little seems to be known by the natives of the nature of these workings. In low or flat ground a slight depression in the surface, with perhaps a more vigorous

growth of shrubs on the margin, is all that testifies to what is perhaps the mouth of a shaft of considerable depth. The shafts have no uniformity of shape, the old mines appearing to have followed down the rich shoots of gold in all their windings and zig-zagging, so that timbering in the modern sense of the word was impossible. The walls (foot and hanging) are kept apart by blocks of reef allowed to remain unworked, and where the reef has proved so rich as to make it worth-while taking all out, large blocks of stone from elsewhere have been inserted and all the rich quartz taken out. The depth to which these old pits descend is very great. On the Mysore Mine at Kolar, old workings have been found extending to 310 ft. below the surface. In other parts of Mysore soundings to a depth of 185 ft. have not reached the bottom of some of these old mines now partially filled with water. In addition to the shafts, adits and drives (tunnels) were known to the old workers. They generally occur in high ground on the side of a hill where the reef has been exposed by a land-slip or from other causes. Here the reef has been followed along its course for long distances, and tunnels a quarter of a mile long have been discovered in the Mysore Province. Of these tunnels and pits the natives know little. Local names such as *Jalgar-gunni* (gold-washer pit), *Hon-dhona* (golden well), *Thungsala-guvve* (mint caves) give some indication of the nature of the workings, but it is only by close and frequent questioning that the existence of such pits is discovered, as the ignorant natives believe that these old works are the shrine of some malignant spirit that will punish those who point them out to the sacrilegious. The existence of works of this character is a sure sign to the prospector that he has hit on likely ground, and so far, not a spot has been found in Mysore giving indications of being auriferous where these old mines are wanting. It is difficult at these old mines to find visible gold in any of the quartz remaining unworked, or in the *debris* surrounding the shaft. Perhaps, after making numerous tests a few specks of yellow, in the dish, may reward him. The natives were careful and patient workers, and it is only worthless stone that has been rejected at the surface; down below, now and again, the portion of the quartz-love left to support the sides may be found rich. A few ounces of quartz crushed up the mortar and then panned off in the wooden dish gives ample evidence of the character and worth of the stone.

If the existence of old workings is not known or is denied by the natives then the prospector must ask to be taken to the washing grounds of the *jalgars*. A sandy water course draining the adjacent hills is generally pointed out. This contains water only during the rains, and it is only during the rainy season that the *jalgars* carry on their operations. It is well for the prospector to carry with him several water-pots filled with water to enable him to carry on his tests. It is no use attempting to test the bed of the watercourse, as several feet of sand and coarse gravel generally cover the bottom. Should a portion of the bed rock be exposed in any part here, the loose sand should be scraped off and thrown away, and the crevices in the rock carefully swept out and the resulting handful or two of sand washed in the dish. Any gold that may be in the sand will be most likely to be found in the sweepings from the rock crevices, as the great weight of the gold makes it work its way below the lighter sand and lodge in the crevices of the bed-rock. If no portion of the bed-rock can be conveniently got at, then a little of the surface earth should be swept up on a pathway or any other hard surface on the neighbouring fields. A handful or two will suffice to test in the dish. Should the alluvium prove to be auriferous it will be time to look about for the reefs from which the gold must necessarily have come. It has been stated that the gold exists in the alluvium where no reefs have been found, and it is thought that either the gold comes from the schistose rocks about and not from quartz-rocks or that it has been washed down from long distances. In Mysore the prospector may be sure that if he finds gold in the alluvium the quartz-reefs are not far off. If the

specks in his dish resulting from the washing of the scraping from the bed-rock or pathway are very small and light, he may assume the reef is some little way off; if the specks are heavy then the reefs are in the neighbourhood. Quartz reefs which stand up prominently and whose course can be traced by wall-like ridges running over the surface of the country for miles, may be at once abandoned as worthless. In such reefs the quartz is hard and white, or perhaps stained here and there with brown iron rust; it breaks off into large blocks having saccharoid appearance and is *hungry looking*, in miner's parlance. The auriferous quartz of Mysore is seamy, *i. e.*, the quartz appears to have been deposited in layers of varying thickness from an inch or two to a few lines. Between the layers a dark-coloured mineral is apparent, and in these seams much of the gold is found. Frequently the whole mass of quartz has a blue-black appearance with darker lines to mark the layers; included pieces of the chlorite and talcose schists which form the adjacent ground will also be seen entangled in the reef. A patchy out-crop here with another out-crop some yards off and only slightly above the surface ground is the usual indication of this class of quartz reef. Below the surface a compact mass of hard dark-coloured quartz cutting through the schistose rocks will be found. It is not always that an out-crop yielding gold can be hit on, but such out-crop are not uncommon and sometimes an out-crop may be found showing gold to the eye, (the gold is best seen by dipping the sample in water). Near to the reef any portion of the adjacent earth should give a speck or so of gold.

Satisfied of the gold-bearing capabilities of the locality examined to secure the land for mining purposes, the prospector must mark off the block required (restricted by the Government to one square mile) pointing out the boundaries to the Revenue authorities, and sending in a plan of the ground to the Chief Secretary to the Mysore Government. The application has to be accompanied by a deposit of R2,000. The plan can be best prepared with the aid of the village map, a copy of which is always with the village clerk. This plan shows the boundaries of the various "holdings" of private individuals and Government lands, and also gives the assessment to be paid on each holding. Private lands must be purchased from the holders by the gold seeker; Government lands can be had free on payment of the assessment which for wastelands is 8 annas an acre. The plan and assessment statement prepared from the village map must accompany the application for the block. The rights of way, rights to water-courses, and grazing rights, are not to be interfered with, and the surface right of the ryots must be acquired by the applicant. A lease of the mining rights for 30 years is granted by the Mysore Government on payment of the usual land tax and a royalty of 5 per cent on the gross yield of gold. Such briefly is the manner in which lands are prospected and acquired for mining purposes. No regular survey (geological or mining has yet been undertaken by the Government. Dr. Bruce Foote, Superintendent of the Geological Survey of India has made a sketch map of the country showing roughly the limits of the best known auriferous tracts, but much remains to be done before the mineral wealth of the Mysore Province can be even approximately estimated. Large tracts of country have yet to be examined, while careful survey of even known auriferous tracts has not yet been thought of.—*Indian Agriculturist*.

VARIOUS NOTES.

TO DESTROY ANTS.—A correspondent in the *New York Observer* says the following has worked like magic; 1 spoonful tartar emetic, 1 spoonful of sugar, mixed into a thin syrup. As it evaporates, or is carried off, add ingredients as needed. For ants on the lawn, a spoonful of Paris green cut with alcohol and made into syrup with sugar and water can be placed on pieces of glass or crockery.—*Pharmaceutical Era*.

YELLOW COMPLEXION FROM EATING PAPAWA.—The *Singapore Free Press* of 1st Nov. says:—

We read in the *Java Bode* that the military surgeon Dr. Jacobs, relates in the last number of the medical periodical there, three cases of persons whose skin became yellow by eating papayas. The first was a European lady with a fine, white skin and a healthy complexion. She was accustomed to eat a papaya after tiffin and also after supper. The second is the commander of a man-of-war, who used to eat papaya every day, and the third a gentleman of Italian origin who daily for the last three years had been in the habit of eating these fruits. The lady gradually lost her yellow complexion by no longer eating the fruit, the marine-officer regained his normal complexion on leaving for Europe, but he resumed his yellow tint on returning to India and on again eating the fruit. The Italian still continues to eat his daily and to be yellow. The conclusion Dr. Jacobs arrives at is that the papaya contains some colouring matter which reacts on the skin.

VOLEATILE CONSTITUENTS OF CINNAMON.—Schimmel and Co., in their October report, claim that the result of Weber's examination of cinnamon leaf oil (*ante*, p. 6) is in full accord with their experiments with oil distilled by themselves. They further state that the product formerly known as cinnamon root oil likewise originates from cinnamon leaves, but that it shows a rather different composition. Safrol is present besides eugenol, whilst cinnamic aldehyde is replaced by benzoic aldehyde, and terpenes are present in larger proportion. The oil from cinnamon bark contains a large amount of cinnamic aldehyde and 6 to 8 per cent. of eugenol. The presence of safrol has not yet been established, though it probably does occur. In an examination of the terpenes of Ceylon cinnamon oil of their own distillation, Messrs. Schimmel recognised phellandrene. It is noted as a peculiarity of *Cinnamomum zeylanicum* that it contains quite different volatile constituents in its roots, leaves, and bark; camphor being most prominent in the root oil, eugenol in that from the leaves, and cinnamic aldehyde in the oil from the bark.—*Pharmaceutical Journal*, Oct. 29.

BOILER PITTING CURED BY GRAPHITE AND OIL.—In the *American Machinist* of July 28th, Mr. T. T. Parker has a very interesting column article regarding pitting in boilers. Besides some clever theories, he has this to say from a practical point of view: "A boiler of the porcupine persuasion pitting was found in the mud drum. Acting under advice, the drum was cleaned and scraped, after which it was painted with graphite mixed with cylinder oil. Measurements of the depths of the pits were taken, and six months after they were found no deeper, and no new ones had shown up. Other parties have since tried this experiment in mud drums, but it is too early as yet to give the result. However, knowing the character of plumbago, if the interior of a boiler could be painted with it in such a way that it would stay it may be this would prove a remedy. I am satisfied also that the person doing so would kill two birds with one stone, as the scale could be easily detached. In a pair of cylindrical boilers 42x28 occasional applications of cylinder oil (mineral) and plumbago has kept back corrosion on a trial of six months. Boilers were new when plumbago was used. The boilers which the new ones replaced were thrown out rotten from corrosion. The feed was mine water, as nothing else could be had." In addition to Mr. Parker's remarks we add that Messrs. Harig, Hoop & Co., Louisville, Ky., after experiencing more or less trouble from rust and scale in the mud drums of their boilers, applied with great success graphited oil, purchased from the Joseph Dixon Crucible Company, Jersey City. The mud drums were cleaned out and the graphited oil applied with swab, brush or anything handy to the joints and parts where the water enters the drums. Every four or six weeks this process is repeated with the most gratifying results.

COFFEE LEAF DISEASE IN JAVA.—The *Singapore Free Press* of 1st Nov. says:—Soutabaya reports as to the coffee leaf disease are somewhat contradictory. Nevertheless the *Handelsblad* assures us that numbers of gardens belonging to the Government as well as to private individuals have suffered very much from this sickness. Perhaps the approaching West monsoon will do something to stay the disease, otherwise the prospect of a good coffee crop is very doubtful. An agreeable prospect for the gentlemen coffee planters and the Government's exchequer.

THE GOLD PRODUCTION OF THE WORLD.—Year by year the gold production of the world is (says the *London Times*) increasing, and the result for 1891 were the largest on record. In round numbers, the production for the last five years was as follows:—1887, 5,097,600oz.; 1888, 5,251,000ozs 1889, 5,641,000oz.; 1890, 5,538,000oz.; and 1891, 6,033,000oz. For the first time for many years there was a slight-set back in 1890. A noticeable feature of recent years has been the development of the Witwatersrand Goldfields. The production of these fields has been as follows:—1887, 34,897z.; 1888, 230,917z.; 1889, 379,733oz.; 1890, 494,801oz.; and 1891, 729,213oz. Adding in 1891 the output of other Transvaal goldfields, which amounted to about 107,000oz., the total production of the Transvaal for 1891 reaches 836,250oz. For the current year it is expected that the production will quite reach 1,250,000oz. In 1888 the Transvaal only produced 4½ per cent. of the world's yield, but in 1891 the proportion had risen to 13·8 per cent. and this year it is tolerably certain to reach 21 per cent. The following was the production in 1890 for the countries named:—United States about 1,586,500oz.; Australia, 1,469,200oz.; and Russia, 1,019,000oz. As the return for these countries has not altered to any large extent, the Transvaal will probably take the third place for the current year and very likely the second place in 1893. Mining in the Transvaal has not yet reached its culminating point, as new mines are being constantly opened and old ones still further developed.

ANALYSIS OF THE BANANA.—W. M. Doherty, Assistant Government Analyst, New South Wales, has undertaken the analysis of the banana fruit, basing his investigations on the Cavendish or Fiji variety (*Musa Cavendishii*), which is the kind in chief demand in Australia. In his report, read before the Australian Association for the Advancement of Science, he gave the results of the analysis of picked specimens divested of their skins. These proved that, far from the fruit being a perfect food for man, as frequently claimed, the small quantity of albuminoids present indicates it as being insufficiently nutritious. To obtain the quantity (4·2 ounces) of flesh-forming substances required by the average man under normal conditions, fifteen pounds weight of the fruit would need to be consumed daily, and this would contain nine pints of water. The banana is therefore described as a very unevenly balanced food, not suited alone for the diet of man, but an excellent and wholesome addition to a diet rich in nitrogenous substances. In nutritive properties it bears a resemblance to the potato, as shown by the following results of a comparison analysis:—

	Cavendish	
	Banana.	Potato.
Water	75 71	75 77
Albuminoids	1 71	1 79
Total carbonaceous matter (non-nitrogenous)	20 13	20 72
Woody fibre	1 74	0 75
Ash	0 71	0 77

Chemical News, lxxvi, 187).—*Pharmaceutical Journal*, Oct. 29.

ADVANTAGES OF CEYLON TO BRITISH MANUFACTURERS.

By MR. JOHN FERGUSON OF THE "CEYLON OBSERVER."

The Colony of Ceylon is now recognised as the best school in the world for the training of the tropical agriculturist or planter of sub-tropical products, such as coconuts, palmyra, or any of the palm family, coffee, cacao, tea, sugar, cinnamon, cinchona bark, tobacco, cardamoms, nutmegs, etc.

It is well that British manufacturers should know that every improvement in machinery bearing on sub-tropical plantation work is eagerly canvassed by Ceylon planters, and discussed in the press. All motors—electric, steam, gas, water-turbines, etc., etc.—rolling, drying, sifting, pumping, pulping, hydraulic machines; also improvements in furnishing, tropical clothing, tinned fruit products, etc.; experiments with new seeds, plants, etc., and all novelties in hardware, implements, building, labour-saving, etc.

To show the position attained by Ceylon as a plantation colony, it may be mentioned that the export of tea, which, so recently as 1886, was under eight million pounds, was, in 1891, over sixty-eight million pounds, and will in 1892 approximate to eighty million pounds, while ultimately it may reach to one hundred and fifty millions—making Ceylon the greatest tea growing country in the world.

Of coconut palm trees there are over fifty millions planted in the island, the exported produce being valued at over twelve millions of rupees apart from home consumption. The island also produces the finest cocoa, cinnamon, and cardamoms.

The mining of plumbago has developed greatly of recent years, so that the export has quadrupled in ten years, being now close on 400,000 cwt. a year.

Precious stones and gems are dug for, and exported to the value of £20,000 to £40,000 every year.

The advertisements suitable for the Ceylon papers include all machinery, electric motors, gas, steam, wind, and water engines, agricultural implements, and machinery connected with the production of tea.

—*Fame.*

PLANTERS AND THE TRAVANCORE STATE.

A communication received from a Peermaad correspondent suggests reflections upon the past, the present and the future of planting in the Travancore State. Our correspondent enters upon comparisons with Ceylon, and probably the remark will be generally approved that "what Travancore wants, is more advertising." Ceylon has given itself bold advertisement for some time past, and has reaped a rich reward. But the secret of its success does not live in this alone. Planters' interests are better looked after in Ceylon than in Travancore, or indeed in India; and more encouragement is given for the investment of capital. There is a Planting Member of Council in Ceylon; there is none yet in India. In Ceylon there are fine roads, while in Travancore there are not. All these points are of importance; and it is unquestionable that in Travancore, and in the whole of Southern India up to the present time, the planting community has not received from Government the consideration that it merits, from the capital that it represents and the labour that it employs. It must be remembered, too, that where the State takes an interest in a community, the feeling usually becomes reciprocal, and thus tends to the benefit of all concerned. Alluding now to affairs in the Travancore State, we may remark that the Government there is not unmindful of Planters' interests. Indeed, a considerable amount of praise might be bestowed upon its treatment of planters. Yet the fact remains that the good which planters do to the country is not fully realised. Every year half-a-dozen young capitalists are coming into the country. Unless they see their way to get land, and good means of transport for their produce they are scarcely likely to prefer Travancore to Ceylon. Nevertheless, the sale of forest land has been stopped. No sales of such land have taken place for some fifteen years, though miles and miles of forest is left,

which is absolutely valueless except as a nursery for elephants. During the year there have certainly been one or two sales of land of sorts, but these have been unimportant; and the question arises, "When the old lands are all planted, what is to be done if no more land is sold?" Travancore is in many ways exceptionally well-suited to the production of tea, and probably there is no place where the present inclination to increase the industry is so strong. But if the State places obstacles in the way of sales of suitable land, the extension of the planting industry cannot go on very long; and the natural resources of the country cannot be properly developed.

The history of the last decade in Travancore is one of growth of tea-planting, and partial decay of coffee planting. Ten years ago Mr. Parker's estate of Penuhurst, in the Peermaad district, was the only real tea estate in Travancore; at a rate the only one which shipped tea regularly to London. The total export from Travancore will, this year, be certainly 10 millions, most of it of a very desirable quality. Some of the yields in Peermaad were very large. Mr. Acworth's place, Arnakalle, gave in 1891 just 60,000 lb. at an average of 10J. whilst Bon Ami with a yield of considerably over 100,000 lb. was but a fraction below, and in all the districts the price was kept up nearly at this level. The yield on Arnakalle is said to have been abnormal, giving rather over than under a thousand pounds an acre. But many estates give an average of over five hundred, and the total, an average yield of just above 400 lb. an acre for all tea in bearing, which compares very favourably with Ceylon. This year in sympathy with every tea-producing country in the East, the crops have been below estimates, but it is to be hoped that the heavy rains which have been falling recently will benefit the yield of the latter months. Coffee, unfortunately, is now very nearly a thing of the past in Peermaad; the only three estates which can be called Coffee Estates, and are by their size really worthy of the name are Tinnyford, Paycarnum and Chenukara, and both the latter places lie on the banks of the Periyar river at a much lower elevation than the generality of the others. Of course, most other places have nice little sheltered bits, which are nursed, and amply repay the care thus bestowed on them; but they are seldom 50 acres in all, and can therefore hardly be called Coffee Estates, especially as there is generally treble or quadruple the amount of tea on the same places. There can be no doubt that in the best and most sheltered places, given good soil, and various other advantages thrown in, high cultivation in the broadest sense of the word is necessary to obtain a continuance of even fair crops of Coffee, whilst if these are wanted, and the land is cold or exposed, it is but lost labour. Still with present prices, it is worth the effort to keep any tree alive that will bear, and this, we believe, generally done. Cinchons, of course, flourishes best in the Northern ranges at and near Davycoolum, where they have been growing the finer kinds, and have kept along well, even through the awful prices which have been ruling. In Peermaad over to the South there is still a very great amount of Sacciraba growing luxuriantly, and forming in parts regular forests. But these are left alone very much, in hopes of better days, nearly all the bark which is taken now being from trees which had to be rooted out of tea. Cinchona no doubt stops tea flushing very much, and if it is thick, says 6 or 7 feet apart, tea will do nothing. But it fairly kills Coffee in a very short time.

From what we have said it will be seen that the prospects of tea are excellent, that coffee promises a fair return under favourable conditions, and that cinchona flourishes, though of late years prices have fallen so much as to counteract to a very great extent the advantages of healthy growth. There is enough in this statement to warrant the Travancore Government making some slight effort to encourage the planting industry. There is a good deal, too, in a suggestion which has been put before us, that a Planting Member of the Travancore Legislative

Council would be useful. With a similar Member in Madras, and with a combined effort on the part of Planters in this Presidency and in the Native States of Southern India to obtain recognition as a community, and to get progress aided rather than impeded, Travancore would, doubtless come in for some share of the improvement that would result. Good roads, just laws impartially administered, and the withdrawal of unreasonable restriction upon sales of land would do much to give Travancore a chance of asserting its claim to be regarded as one of the most important planting districts of Southern India. We would advise local Associations to take up the question of a planting member, and subsequently to urge, through the gentleman appointed to this responsible position, the needs of the district, and the desirability of giving the planting industry all reasonable encouragement. Lord Wenlock has held out encouragement to planters in the Madras Presidency, and the inquiries now being made, as mentioned in the report of the Nilgiri Planters' Association published on another page, are tolerably sure to result in the appointment of a planting member. It would be good news, indeed, if Travancore decided to follow suit.—*Madras Times*, Nov. 11.

MANURES AND THEIR APPLICATION.

By PROFESSOR H. E. SHELTON.

[Professor Shelton is an Agricultural Instructor imported by the Queensland Government from the United States. In addressing the Conference of Sugar Planters at Mackay, he gave utterance to much useful matter mixed with sentiments in regard to commercial fertilizers as extreme in one direction of the doctrines of M. Ville on the other. No doubt cattle manure is excellent but it is costly to apply and sometimes hard, or impossible to obtain. Such is the case on most of our tea estates, which are certainly benefited by applications of bones, castor cake and perhaps some salts of potash.—*Ed. T.A.*]

Mr. Shelton said:—Mr. Chairman and gentlemen, the subject of manures seems to be one of considerable interest in this district. During my short stay here questions relating to fertilizers have been raised by planters more than I have heard in the same time in other parts of the colony. I put this as a compliment, I admit, or not. It may argue increased intelligence or increased interest in the question. It may also be that your soils need it. On second thoughts I may say that I have a bad throat and may likely have to cut short my remarks at any time. I just say this lest it be thought that the difficulty lies higher than the throat. Thus in manures—I mean by this the subject in its most limited sense—Mr. McLean has said that water is a great fertilizer. So it is and so is sunlight and heat not ordinarily regarded as manures, and what we have to do is to try and define this term 'manures' in one sentence which will give a definition which will hold water. It is commonly said that manures are anything which will increase fertility. We could then add heat, water, and the others. The definition best given was by Joseph Harris, and he gives: "It is anything that added to the soil increases its fertility within a given climate." And this seems to be, on the whole satisfactory. I thus take the subject in its limited sense—I mean those things the farmer takes to increase the fertility of his land. I would call attention to this writing on the board, which, I may say, is not Greek or Choctaw, but is a list of the fourteen elements—namely, oxygen, hydrogen, carbon, nitrogen, potash, phosphoric acid, lime, and others. These are the fourteen elements which have been found in plants, some invariably but not all so. The only ones the farmer has to consider are nitrogen, potash, phosphoric acid, and lime, and we might draw the line through the last as it seldom appears. Then the elements for the farmer are nitrogen, phosphoric acid, and potash, putting them in their order of importance. Before

touching upon these elements it is important to hold in mind certain facts with regard to the soils we treat. Every practical farmer knows we can add to the fertility of soil by cultivation. We depend not only upon the chemical condition of the soil, but upon other conditions than the knowledge of the elements contained therein. Take the great boulders on your hill-sides. They contain a large proportion of valuable elements, but in their form cannot be utilised. Take a strong clay land—it is right enough if something was not wanting. That is, an improvement in the physical condition of the soil, and we improve it by ploughing and deep tillage, and by summer fallowing. Let us bear in mind that fertility is not only from the three elements but because it has been made possible for the plants to get hold of them. Let me give you another illustration. There is the deep volcanic soil of the Bundaberg district. The soil has a great reputation for the production of cane, and gives good crops. If you analyse the soil it does not contain extreme quantities of potash, phosphoric acid, and nitrogen. The source of the strength of the lsis scrub is this: Take it in your hand and squeeze it and if it is dry it all runs through your fingers. It is in the condition of an impalpable powder. It has been worked up and ground into a condition that it is instantly available to the plant. You have there, also, a depth of 10, 20, or 30 feet, so that the plant can send down its roots to a great depth. Thus soils may be physically perfect and chemically worthless, or chemically perfect and physically worthless. We may take the hardest soils and pulverise them by drainage and sub-soiling. The object is to improve generally all soils physically. This leads us to another fact. Men who have had chemical analyses of their soils taken have often found that the physical condition of soil may be worthless, though it contains excellent chemical properties. The ordinary chemical analysis, unless there is a knowledge also of the physical conditions, is of little value. This subject of the physical and chemical relations of soils has an important relation to the general subject of manures. Put them on stiff or undrained soil and they count for little. If you put manures on such land, and the ground is hilly, the water rushes down, the manures are carried away and count for very little. But put them into well drained land and you will quickly get the best results from the application. It is thus sufficient to show that we can easily explain the chief principle of values in the use of fertilizers. There are a lot of peculiar facts about manures which no one can explain. The English farmer always puts bone dust to his turnip crop. Theoretically we should apply it to the grains rich in this element. Manure rich in nitrogen, again, the farmer puts to grass and cereals while leguminous crops always get mineral manures. Then, too, we may get in the rich scrub lands a soil which cannot be artificially made by combining nitrogen, potash and phosphoric acid, etc. And if we take the same quantities of these elements and manufacture a soil containing exactly these things, excellent though it looks, yet we should get three crops from the first soil and nothing from that made by chemistry. We can make soils that will give results—we may admit that from the outset. As far as the farmer is concerned, the main sorts of manures are the manures which give the best results all round, and those to him are the good old ones of farm refuse and barn yard manures. All experience goes to show that. Experience shows that commercial fertilizers are often severe and thus unsuitable. They eventually bring loss and serious loss to the man who applies them and they cannot pay their way on the whole. They have a peculiar effect on the soil. If you try sulphate of ammonia you get great crops, for a time, but afterwards you can get no results as the land seems to be over stimulated. Like the old toper who takes his three nips a day and four or five on Sunday, and then on Monday thinks he must take six, and then they don't have the same effect as the three, although I do not speak from personal experience but only as an analogy, so it is with the

land. I have a little girl and she is an enthusiastic gardener, and had tried sulphate of ammonia and nitrogen but afterwards found out that where before three doses had been given she would now have to give five or six. Thus the last state of the garden was worse than the first. Another sort of manure is barn yard manure. None other could give better results than this at present. Barn yard is the farmers' manure and is a most valuable one as it gives back to the soil what it takes from it. But you may think that your land is constantly wanting something in excess of this. You may say such is not strictly true; the bulk of the cane grows from the air. The average of the waste when we take the three tons of sugar from the cane will be five or six tone of megass, leaves, tops, etc., probably sufficient to pay for what has been taken out of the soil. Sir John Bennett Lawes, who stands head and shoulders above all agricultural experimenters, has been growing wheat on the same land for 40 years. For the first 20 years he got 16½ bushels and for the second 20 a good deal less, or an average over the whole time of about 10 to 11 bushels. There were sufficient elements or enough of nitrogen, potash and phosphoric acid broken down to supply these crops. It was a useful experiment but bad farming all the same. In another plot Sir J. B. Lawes grew his crop one year and summer fallowed the next. He got as much wheat from the one year's crop as he had got from the two in the other way. One good crop in two years is certainly better than two poor crops in two seedings. We learn from this—and I want to say this as far as I can see and give my impressions—your soils will crumble down and work up enough to make up for the necessary loss from your fields. If bagass and the tops and the other waste could be put back on the fields and simply the sugar carried off my impression is that the soil would be improved from year to year. Some of you are now deciding it in a practical way but my impression is that there would not be much loss if the waste products were put back. Supposing then we want to make our manures. There is this difficulty with planters. It is difficult to see how you can get on without cattle. Stock manure must be used in some of its forms, either as cattle or horses. If you take care of this, take the filter press cake and other refuse and add it to the manures of the farm, the question is how shall we use them to get the best results. The climate is most severe on the soil and on the manure we put upon it. The burning sun, great moisture, and the heavy rains are very severe on them. Our soils are deficient in nitrogen because they are always being cooked by the burning sun, and washed by tropical rains. If we loosen up our soils the sun and the rain will have much less effect, but if we loosen up the manure we find it wastes its substance and loses its properties. If we stir up a manure heap we find in the centre it has a white fungus, like so much sawdust. (Mr. Dunne: Is the steam escaping the ammonia being lost?) Keep water on it but don't let it leach, back up the heap and cover it if possible, but don't get too high a pile. Now about composting and saving wastes. This is a most important matter. If we have got a good pile of rich stuff (and you can usually tell the value by the odor except in the case of nitrates and one or two other things that do not smell) and get all of the odds and ends and put them on next to your cane and it will give it a quick start and make a fast crop. If you want a greater quantity of manure made then you can increase the pile by covering it over with six inches of earth. Don't use sand it might as well be not covered at all, but cover with three, four, or six inches of soil which is rich in humus. You will then nearly double the size of your manure pile and conserve what would have gone to waste in the manure. The next question will be how to apply the manure. The old rule was to put the manure in the fields in small heaps and farmer John said the heaps held the nitrogen. Farmer John is usually right, but this time he was wrong. He now spreads it all over the fields. An excellent machine has been made in the States which a man drives along and spreads the manure evenly over about 15ft. The objection to leaving it in piles

is that more or less of the manure sinks into the ground. With the help I had to employ I could not get anyone to dig out the bottoms of the heaps and you could tell where the heaps had been over the field by the more vigorous growth at those places, the soil absorbing as it did a good deal of the valuable constituents of the heaps of manure. The best thing to do is to cart your manure to the ground as quickly as possible. It has been shown that the earth has a tendency to seize upon the ammonia as fast as made. About ploughing in manures the general practice is to be condemned. If you plough them in you bury them at the bottom of the furrow in lumps. The manure will not ferment and will give next to no results the first season. Get the manure so that the earth can be worked up with it thoroughly. This is the rule and simply harrowing will do the thing as quickly as possible. Roots will always find the manure. They go wherever the food is. There is another branch of the subject which should not be left out, that of green manuring. Many a man has taken an old worn out farm abandoned by its former owner, and by judiciously cultivating certain crops such as the bean, the pea and the clover, and ploughing them in and following them by putting in crops which are not specially exhausting has raised a poor hungry farm to a condition of extreme fertility. Green manures will do this. Farmers, however, often made mistakes. They plant such crops as rape, rye and others, and plough them in and get a benefit therefrom. They at once jump to the conclusion that they have added to the fertility of the soil, but they have probably done nothing of the kind, but they have only altered the soil physically by loosening it. Take lucerne, clover, peas, beans, and plough in the whole of the crops at a certain stage and you add immensely to the soil. These crops have the property of taking nitrogen from the atmosphere and it is thus conveyed to the soil. You will see now why careful cropping goes for so much, simply because it takes nitrogen out of the atmosphere. It is a subject of tremendous importance is that of green manure. In the Southern States the farmers have found that the great problem is to get nitrogen into the soil and nothing will do it so well as by the cow pea. The cow pea will do more in the way of furnishing this rare element than any other crop generally available to planters. Get the pea, sow it broadcast and let it grow itself. Let it rot on the ground sooner than plough it too soon. It is better never to plough in a green crop than to plough it in before everything is ready for it. The following is another means of improving the soil. I had hoped this morning that Mr. Coyue would have opened the subject with a discussion on fallowing. The additional effect of fallowing besides putting the land in excellent condition is to kill the grass and weeds out. It is worth while to remember these things in Queensland. A second class of fertilisers are the chemical or commercial fertilisers. These are those which are commercially valuable or have a position in the market. I have given an opinion against using them, but I do not wish it to be understood that they could not be made useful upon every plantation or farm. Frequently you have need of some manure to give the crop a quick start and you have the phosphates. But I have no sympathy with the idea that commercial fertilisers will revolutionize agriculture. The whole subject is gradually working itself out and in my opinion the most that can be said of the commercial fertilisers is that the time is near when the man who uses them only will have to give up agriculture altogether. The man who neglects to attend ordinary sources of manure, the refuse, waste in the fields and expects to get on with commercial fertilisers will have crops and he will be in a position to harvest them by himself. This reminds one of the old story about the Scotch Laird. He was out with his gardner and looking proudly over his field, said, alluding to the commercial fertiliser he used, "Well Sandy, and we'll soon be able to manure a' this land with the fill of one of your vest pockets." "Ay," said Sandy, "an' ye'll tak' the hale crap hame in tither pocket, I'm thinkin'." And so with the man who uses nothing

but commercial fertilisers, he will soon put his crop in his 'vest-pocket.' Commercial fertilisers are valuable for the nitrogen, phosphoric acid and potash they contain and not for the many other things, as iron, lime, etc., which are quoted often by people who have them for sale. You probably ask which is most valuable but it is a question I cannot answer. It depends upon the crop. As a general thing we want nitrogen but there are many limitations in cane growing as you will find out. If you give large applications of nitrogenous manures you will get a cane with a rank growth but you will have a cane crop which will make a lot of trouble in the sugar house. If you apply phosphoric acid you will not always get an increased growth but you will get an early crop; you will bring it to early maturity. If the land is poor then it will be well to do with a proportion of nitrogen. If you use potash it seems to depend upon the condition of the soil. It is very uncertain as to the results in manuring as it will often give much trouble and no one will get better results from it. On the whole they are found to be most beneficial when least depended upon, the favorites for moderate use being nitrogen and ammonia. About the application of these fertilisers, it is always better to apply a good many small quantities than one good feed at a time. Let the plant send up its plate as often as it likes, but don't give it enough to disgust it at once. This means more expense and the planter must exercise his judgment in the number of applications he can afford to give. A few years ago, it was customary to apply a ton or so to the acre. Now they give 2 or 3 cwt. to the acre and they get much better results. These fertilisers should be put on the top of the ground as close as possible to the plant without touching it. It is generally said that all manures wash down, but the principle is that if the manure goes down, the plant's roots go after it, so that if the bone dust is put two or three inches down it will not matter, because the roots will go after the manures in whatever position they are placed. It is quite enough to sprinkle over the surface with a little light soil. Another subject which I might touch upon is the application of manures to orchards and fields. The orchards are permanent but the field crops are not. The orchard being permanent we must manure it with something that is permanent to the soil. However this subject and that of manuring by irrigation cannot be touched upon now as I have to speak tonight and have already occupied your time long enough. I will therefore conclude by thanking you Mr. Chairman and friends for your attention.

Mr. H. D. Penderson asked which was the best way to prepare a manure heap. Should a pit be dug 5 ft. deep or so for the cattle to go on.

Mr. Shelton said: Don't prepare the manure in a pit, or the cattle tread in the edges and you get a very nasty hole. Simply remove the surface soil for a few inches, put down your manure and let the cattle and hogs go on it.

Mr. Shelton further said he would not put the manure direct to the roots unless the manure was thoroughly rotted. The principle in forming a farm-yard manure heap was not to let it rot rapidly as of meat waste by the escape of the nitrogen with the ammonia as shown by the strong smell, hence the advisableness of covering with a layer of soil.

In reply to Mr. Stevens, he said that the trash itself he thought would be a better manure than the ashes.

Mr. Dunne said there were three green crops which could be used here: Corn, Sorghum and Sweet-potato. Were the potato vines a good green crop to grow?

Mr. Shelton said he did not think the vine was much good but it still had some value, say to put the product of 10 acres on one. Potato vine was heavy on the soil. On heavy clay soils he would plough in sorghum and corn, but he would not do so on light soils.

In reply to Mr. Paget, he said he did not think the manure-sprayer could be applied to an ordinary drag. He thought the price of the wagon and spreader in the

States, was about £25. He thought the Strawsoniser would be suitable for bone dust and manures; it costs about £40. It does its work well and is good if the work required from it is sufficient.

In reply to Mr. Stevens, he said that there was really no waste from the manure blowing away, in spreading with the spreader.

Mr. McDonald stated that in Trinidad he had experimented with five different manures, at a place he was on in Trinidad, blood-manure, Sulphates, yard-manure, guano and a mineral manure and found the best results from guano and yard manure. He found the best method to apply guano was 5 cwt. to the acre $\frac{1}{2}$ at a time the second application to be made when the cane formed the first point as after that the cane deteriorated and formed molasses. The guano he used was the Peruvian. He thought it better to feed stock on the ground than fallow it.

Mr. Shelton said the fallowing deprived the grubs of food and starved them out.

Mr. McDonald said green megass was a bad manure to use; he thought it injured the land the juice in it doing harm rather than good. Lime he found was beneficial on the whole as it prevented souring.

Mr. Stevens said they were making a compost at Homebush of megass and the filter press cake, etc.

Mr. Shelton said the filter press cake was an excellent manure. In reply to Mr. McDonald he said that the manure when spread out on the soil dried quickly and did not ferment as moisture was required to produce fermentation. The ground would seize on the ammonia and thus there would be no waste.

In reply to Mr. Man as to how to use green manures, Mr. Shelton said Messrs. Young of Fairymead were experimenting with 200 acres of cow pea and we would presently have the result of their experiments. Barn yard manure should not be applied direct to the plant but piled above it and thus the valuable elements would sink down and be followed by the roots of the plant. In reply to Mr. Penderson he said that bone manure would be better if the bones were crushed before being boiled or used in a refinery as all the elements except the phosphoric acid would be boiled out. The best way to use them would be to puddle a piece of ground, put them alternate layers 6 in. deep of farm yard manure and bones the whole to be covered and kept moist and to remain for 6 or 8 months. The bones would then fall to pieces under the hammer.—*Sugar Journal and Tropical Cultivator.*

MANUFACTURING INDUSTRIES OF THE MADRAS PRESIDENCY.

Of all the indigenous manufactures of the Madras Presidency, weaving continued to be the chief one during the year 1891-92 among the population outside the agricultural classes. Although it is difficult to give the exact number of looms at work, they are steadily on the decrease, being run out of the market by the competition of cheap machine-made foreign goods, and the decline during the year has been more marked in consequence of the distress which prevailed. To add to the difficulties under which Native weavers labour, large mills worked by machinery have been started during the last decade in several districts of the Presidency. There are four of these spinning and weaving mills at the town of Madras, three in the Tinnevely district, and one each in Malabar, Bellary and Coimbatore. The quantity of cotton worked at these mills was estimated at over 230,800 cwts. Besides these mills the Basel German Mission in the Malabar and Canara districts have extensive weaving establishments, at which excellent cloths are manufactured in large quantities annually. The quantity manufactured by the Mission Establishments during 1891-92 was 263,600 yards, valued at Rs. 50,000. There were also 38 cotton presses at work in the Presidency, of which 14 were in the black cotton soil districts of the Dekkan, 11 in

Coimbatore, 10 in Tinnevely, 2 in Trichinopoly and 1 in Kristna. The aggregate quantity of cotton cleaned and pressed into bales at these presses for export was about 790,100 cwts., valued at R1,75,75,000. Next to cotton come works for onring coffee, of which 28 works were maintained during the year, viz., 15 in Malabar and South Canara, 11 in Madura, and 2 in Coimbatore; 125,400 cwts. of coffee were cured at these works, the value of the article being estimated at R66,00,000. Amongst the other large works in the Presidency are the four Sugar Factories in South Arcot owned by Messrs. Parry and Co., one Hemp Factory at Chittivalsa, in the Vizagapatam district, owned by Messrs. Arbuthnot and Co., and a Cement Factory at Madras owned by the same firm, and several Brick and Tile Factories in South Canara. Of the last those worked by the Basel Mission have earned a name for themselves, and the demand for the machine-made tiles manufactured has been greatly on the increase both within and outside the district. No statistics are available of the quantities exported by land, but 7,669,800, valued at R3,21,800, were exported by sea during the year, against 6,880,700, valued at R3,02,300 in the previous year. The manufacture of indigo and the tanning of hides and skins are also carried out to a large extent in several districts of the Presidency.—*Madras Times*, Nov. 14.

GOVERNMENT ENCOURAGEMENT OF PLANTING IN PROTECTED NATIVE STATES.

A PROPOSAL.

We copied in our issue of the 3rd instant a "Scheme for Government Plantations in the State of Selangor," which bears the signature of Mr. E. A. Watson, and is "published for general information, by order," in the *Government Gazette* of that State for the 28th October. The argument is this:—Selangor contains a very large area of virgin forest suited for cultivation of tropical products generally, and coffee in particular. The planting of coffee would bring in large profits to the planters and steady permanent revenue to the State treasury. The deduction to be drawn is an obvious one—the planting of coffee should be encouraged and fostered by the Government of the State in every conceivable legitimate way, to the manifest advantage both of the individual and of the public as represented by the State.

Should it be thought that we are proceeding too rapidly, and that the dictum as to the suitability of Selangor for coffee has to be proved, we may at once point to the success of the small coffee estates already opened in Selangor and in the neighbouring State of Perak; to the example of Ceylon, and the statements of veteran Ceylon planters that the climate and the soil of the Malay States are, if anything, more favorable for their culture than those of the Island. Hear what Sir Græme Elphinstone says, speaking with the authority of years of practical experience: "The quality of the strong, deep soil is very suitable; the climate is superior to that of Ceylon, being free from the incessant squalls and heavy rainfall, with a complete absence of sunshine, sometimes for ten days or a fortnight, which is a frequent experience in Ceylon in both monsoons, and has a most prejudicial effect upon the yield and the vigour of coffee and tea."

We trust we have carried our readers so far with us, and now proceed to examine the means proposed by Mr. Watson to secure the desired object. Stated briefly, his proposal is that Government should establish, not experimental gardens, but one or more *bona fide* coffee estates—in fact that Government should play the part which have been played by some one in every new country, of the pioneer and the experimentalist, and publish for the benefit of succeeding planters the full results of its operations, with complete records of expenditure and returns. In the old country and in Crown Colonies of the severe type, and among Government officials of the ancient style and the school of *laissez*

faire, such a proposal for Government initiative—or interference as it would be termed—would call forth howls of warning and deprecation; but there are manifest signs that the views as to the part which a Government should play are year by year broadening and extending, and we would strongly urge on the local powers that be the advisability of giving serious consideration to the present proposition, and of not pushing it aside on general grounds of the impolicy of State interference and initiative. Surely such a disposition of Government surplus balances is preferable to investment in Indian or Ceylon 4 per cents? The capital sum required is not large, the risk not great, and the returns, with ordinary care and prudence, are certain, so far as certainly can be predicated in such matters, to be remunerative, if not handsome, directly, while the agricultural interests of the State—always of great importance and, in the long run, probably ranking above mining—would be stimulated, encouraged and developed.

Estate estimates are strange things, and we have known of some elaborate and detailed schemes, with full allowances for unforeseen contingencies, death rates and so forth, which on paper shewed the *impossibility* of avoiding handsome returns, but which when put to the practical test have proved fallacious. The estimates and returns accompanying this scheme have been prepared by an expert, and most certainly appear to be drawn on the basis of liberal expenditure and moderate returns. They shew that to bring into bearing 1,500 acres of Liberian coffee in Selangor, \$140,000 are required; that by the end of the eighth year the whole expenditure would be recovered and a profit of \$43,850 be attained. Once the experiment is proved and results published, there would be no longer necessity for Government to pose as a planter; and Mr. Watson calculates that successful Government estates could be disposed of to capitalists at "not less than 25 per cent over and above what the property has cost to plant and develop."

One word more. Government undertakings are not uniformly successful nor economically managed. To work such a scheme as that proposed it would be necessary to employ, not planters who have proved a failure elsewhere, or gentlemanly amateurs, but *bona fide* planters, with youth, energy and, above all, a good record of practical experience.

There are two sides to every question, and there may be strong arguments against Mr. Watson's proposal. All we maintain is that it deserves consideration, and we shall gladly open our columns to correspondence on the subject.—*Pinang Gazette*, Nov. 8.

THE FRUIT GROWING MOVEMENT.

BY THE APOSTLE OF FRUIT CULTURE.

It is well that the public should bear in mind the following facts:—

1. That the *Horticultural Times* is the official organ of the fruit-growing movement.

2. That after ten years persistent advocacy by its originator it has, at last, the gratification of seeing its principles attracting the attention of all classes of the community.

3. That our "improved System of Culture for Profit"—two of the leading features of which were the substitution of the pyramid for the standard tree, and the cultivation only of special varieties—has now been adopted by the horticultural world as the only system by which fruit culture can be made to pay.

4. That we have been the means of having horticultural education incorporated in Board Schools in rural districts by the County Councils, besides securing the first government grant ever made in this country for the advancement of horticulture.

5. We planned and established the first horticultural college in England.

ABOUT FRUIT TREES.

We find that lime, wood ashes, and old iron, put round the roots of declining trees, have a very beneficial effect. These fertilizers restore the trees to a healthy condition, and also greatly improve the fruit

in quality: about half a bushel of mixed lime and ashes to each, and dig it in with a hoe some six feet around the trunk, and put the old iron immediately around the base of each. The trees put forth with renewed vigour, bloom abundantly, and yielded a good crop of fruit. An excellent wash for trees may be made thus: Heat an ounce of salsoda to redness in an iron pot, and dissolve it in one gallon of water, and while warm apply it on the trunk. After one application the moss and old bark will drop off and the trunk will be quite smooth. This wash has quite recuperative properties, making old trees bear anew. We have tried soft soap as a wash with good results, and also a coating of lime in the spring season, which is a fine specific for old trees.

CLEAR POTASH AS A FRUIT MANURE.

We have used within the last few years a good deal of potash in connection with the trees in our orchard, usually buying it by the cask for this purpose. We simply break the potash into small pieces, not larger than egg size, using about eight pounds to an average sized tree, scattering it upon the ground about the tree in a circle extending half-way from the trunk to the extremity of the branches. When this is done in the autumn or early spring, the rains and snow dissolve the potash, which will be absorbed and spread through the soil, thus bringing the fertilising properties directly to the small roots of the trees, without the slightest injury to the vegetation. The future crops will show remarkable results, both in quantity and quality of the fruit. In 1889 our trees bore, as did everybody's that year, a heavy crop of apples; and, again last year, we have had, what few others had, a crop nearly as large as the previous year, which proved of a remarkable fine quality both in appearance and freedom from decay. This we attribute to the free use of potash on the soil about the trees, proving clearly that potash is a fertilizer essential to the growth of fruit. One pear tree which for a long time had small and imperfect fruit, the spring following the application of potash produced pears of extraordinary size, and singularly free from blemish. We esteem potash as admirably adapted to all kinds of fruits, large and small.

[Of course what answers for apples and pears in Europe will equally benefit oranges, peaches, plums and other fruit grown in Ceylon.—*Ed. T.A.*]

ORCHARD HOUSES.

Every year we feel more convinced that the orchard house, as a rule, is not managed in such a manner as will produce the most amount of fruit. Our ideal house is a span-roofed house with a path running round the inside about four feet from the sides of the house. This will allow a row of plants, or trees rather, round the sides of the house in pots, and a centre bed of trees in pots; by good culture as fine fruit may be grown on pot trees as those planted out. When the crop is cleared from the trees, they may be given all air possible, and eventually placed outside. Such a house is very suitable for growing a crop of tomatoes after the trees are turned out. Good plants should have been grown or made ready as soon as the house is ready for them, when they will soon begin to fruit. By this means two crops may be obtained in the year, without any waste time.—*Horticultural Times*.

FIBROUS PLANTS AND THEIR TREATMENT.

A factory has been established in High Street, Lambeth, under the supervision of Mr. Taylor Burrows, late of Lisle, for the treatment of various fibrous plants. Samples of these plants of every species can be submitted for carefully-supervised trial, and if the present machines or processes prove unsuitable in some little detail or other, the defect will be discovered and remedied. In like manner advice will be given as to the best machines and methods of treating fibrous plants, and the opportunity will be afforded of studying the various processes of production, and of acquiring a knowledge of the most scientific methods of preparing fibres. In fact the present

enterprise promises to develop into an important public technical school, for it is proposed to establish branches in textile manufacturing and cognate centres. From a still wider point of view the fibre factory may be regarded as an exhibition and a permanent institution for perfecting machinery and process relating to the treatment of fibre-bearing plants of every description.

The various processes to be carried at the model-fibre factory comprise the rapid retting and ungumming of fibrous plants: automatic breaking, scutching, combing, and hackling: spinning into simple or mixed yarns; cottonising and woolenising fibres to imitate fine cotton or wool, suitable for the manufacture of various mixed and cheap fabrics as well as for fine and costly goods; bleaching and dyeing the same and the rapid drying of fibres by means of cold air. The factory consists of a spacious warehouse and store room for machines and samples, with offices annexed; and a large machinery and operating room, with a laboratory and an engine and boiler house. The chief feature in the operating room is a new machine for dealing more particularly with leaf plants, such as phormium tenax, aloes, agavas, palms, and the like.

"We saw," says a writer in *The Times*, who describes the factory, "some phormium tenax put through this machine with great success, and with rapidity and simplicity. Another machine is a scutcher for hemp, flax, reha, and, in fact, all stem fibres. In this we saw some reha stems from France easily decorticated without previous soaking or steaming. The wood was well taken out and the fibre left ready for ungumming and subsequent treatment. In the plants thus treated the fibre is got out mechanically, and is then treated according to requirement, by ungumming, bleaching, and preparing for spinning. There is also a spinning machine in order to test the various fibres in this respect, and to see how they are likely to meet the requirements of a commercial article. Another important improvement is also being introduced at this factory, and that is the rapid retting of flax. The usual method of retting is to soak the flax in water for about three weeks. By the new process this will be effected in about a couple of hours. This quick action is brought about by submitting the flax to the intermittent influence of heat and moisture, which is stated to be very effective, and in no way to act prejudicially upon the fibre."—*H. and C. Mail*.

MR. MAXWELL ON COCONUT BEETLES.

The resident of Selangor issues the following notification about what he calls cocoon-nut trees; but probably he means coconut trees:—

No. 185.—THE COCONUT-TREE BORER (BEETLE).—District Officers are instructed to use their influence with the native owners of cocoon-nut plantations in order to induce them to clean their trees periodically and rid them of beetles. The palms should be ascended once every month or six weeks. The lowest leaves, if showing signs of drying up, should be chopped off and the trunk cleared of any old leaf-stumps and of ants'-nests, etc., which the latter may have harboured. At the same time the top shoot should be carefully examined. If they are of a yellowish, sickly colour the beetle is probably the cause. There is no difficulty in finding the whole, as an accumulation of short loose fibre marks the spot. This fibre should be removed and a wooden or metal probe pushed into the hole (one of the side-ribs separated from a frond will answer the purpose.) The beetle is soon transfixed and pulled out. A little sand should be thrown into the whole.

The above is the system employed on the Malabar Coast where the removal of beetle is one of the ordinary routine operations of the coconut-growers. A single toddy-drawer will there clean from fifty to one hundred full-grown trees in a day.

The insertion of a little kerosine oil into the hole may be usefully tried, Kerosine oil if mixed with an equal proportion of milk form an emulsion which can then be diluted with water to any desired extent.—*Straits Times*.

SIR WALTER HELY-HUTCHINSON ON THE COCOA* BEETLE.

(The following notice has been published in Grenada.)

The attention of cultivators of cocoa is drawn to the fact that at the present season the Cocoa Beetle is in its mature state, and that the females are depositing their eggs on the cocoa trees.

The female beetles are capable of depositing hundreds of eggs.

Each egg, thus deposited, may, and probably will, produce a grub (worm).

Each grub (worm) is capable of destroying the branch of the cocoa-tree on which the egg is laid.

As the number of grubs will probably be considerable, unless steps be taken to check the laying of the eggs, it will be seen that the present is the time to destroy as many of the beetles as possible.

There is no cause for alarm, for the remedy is simple, and only requires united action to ensure success.

The beetles are easily captured, especially in the early morning, when they may be caught by the hand on the cocoa trees.

Cultivators of cocoa are therefore strongly urged to examine their trees, or to cause them to be examined, every morning; and to use every effort to capture and destroy the beetles.

The beetles may be easily recognized. The female is about one inch long, the male is smaller. The beetles are black, with faint white markings. Orders have been given for the public exhibition of specimens at every police station and at every school house in the island.

In addition to the above measures, it is very desirable that as far as possible, all prunings, and rotten wood of every description, should be removed from the plantations and burnt.

This notice has been drawn up after consultation with, and with the advice of, Mr. D. Morris, F.L.S., the Assistant Director of the Royal Gardens at Kew. Mr. Morris has been in consultation with the members of the Cocoa Commission, and has himself, since he has been in Grenada, been studying the habits of the Beetle.

VARIOUS NOTES.

MR. CLEMENTS MARKHAM AND CINCHONA.—In reviewing "A History of Peru," by Mr. Clements Markham, the *Athenæum* of 29th Oct. says:—

In 1860 he again visited the interior of Peru, for the purpose of transporting cinchona plants to India; and his success in that undertaking is shown by the rapid increase of plantations in the East, and the heavy fall in the price of quinine. This result, so detrimental to the trade of Peru and Bolivia, was fully anticipated; and in the republic which he loves so well the expediency of his assassination was freely discussed, his escape being chiefly due to the indolence of the natives and to the fact that "what's everybody's business is nobody's business," as the Irish peasant said of the unpopular landlord. Seeing that the British Minister had recently been riddled with bullets in his own house at Lima and in broad daylight, with hardly a protest from our Government, it was not likely that much fuss would be made over a mere traveller; and, moreover, open violence would have been superfluous, for a well-flavoured *picante*, a glass of *chicha* or a cup of excellent Yungas coffee would have sufficed.

We were not aware before that Mr. Markham had so incurred the anger of the Peruvians. Ceylon planters ought to cherish feelings of gratitude towards Mr. Markham; for certainly cinchona was the salvation of Ceylon in the interregnum between coffee and tea. But the grand benefit has been to suffering humanity.

* Evidently not the palm in this case but the chocolate plant.—Ed. T.A.

CEYLON TEA AND PRODUCE COMPANIES.—We publish on page 408 a list of Ceylon tea and other produce companies registered in England, as framed by Mr. H. K. Rutherford. Judged by dividends on ordinary shares, the most prosperous companies in the list are the Scottish Ceylon with 18 per cent against it and the Ceylon Tea Plantations with 15. Then come three companies each of which divided 10 per cent: Ceylon Land and Produce; Standard Tea, and the Kelani Valley Tea Association. The New Dimbula Company divided 8 per cent. A dividend of 7½ per cent is opposite the Ceylon Investment Estates Association, and 6½ against the name of the Dukwari Ceylon Tea, with 6 per cent in the case of the Spring Valley and 5 for the Scottish Trust and Loan and the Colombo Commercial Companies. The Uva Coffee divided 3½ per cent, while two companies, the Oriental Bank Estate and the Lanka Plantations, each show a dividend of 2½ per cent. The most important Company of all judged by the amount of its property (over 9,000 acres in tea out of a total acreage of 16,791) gave only 1½ per cent on ordinary shares, the preference shares taking 5 per cent. In the case of the Madulsima Coffee there is a *Nil* opposite ordinary shares, while preference took 8 per cent. Opposite the Hunasgeria Tea there is an unqualified *Nil*. There are blanks opposite five new companies. Judged by acreage under tea the Ceylon Tea Plantations stands second in the list with 7,362 acres, the United Planters coming next with 5,193, and as the fourth in rank, the Oriental Bank Estates with 4,421 acres. For other interesting details we refer to the tables.

A GORGEOUS FLOWER is that of *Brownia coccinea*, a specimen of which was lately sent from the Peradeniya Botanic Gardens to a lady in Colombo who had purchased a plant and had written to ask what the flower was like. The one in question was a huge mass of brilliant red petals, looking at a little distance something like a gigantic rhododendron. The Dictionary of Botany gives the following information:—

BROWNIA.—A genus of small evergreen trees belonging to the *Leguminosæ* and to that section having regular corollas. The species are peculiar to Venezuela, New Grenada, and some portions of central America, one of them being also found in Trinidad. The leaves are alternate, equally pinnate, and from one to one and a-half foot long, with from four to twelve pairs of entire leaflets. The flowers are rose-coloured or crimson, and disposed in dense terminal or axillary sessile heads. The pods are compressed scimitar-shaped, often covered with rusty pubescence, and contain many seeds. It would be difficult to point out a more beautiful genus of stove-plants than this, and few tropical plant-houses of any pretensions are without some of them. *B. grandiceps* has long pinnate leaves with about twelve pairs of leaflets and axillary or terminal flower-heads eight inches in diameter; the flowers are pink, very numerous, and arranged in tiers as it were round a conical axis, the outer ones expanding first, followed by the others until all are open, when the flower-head is not unlike that of a *Rhododendron*. The leaves droop during the day so as almost to hide the flowers from view; but they have been seen to rise up in the evening and remain erect all the night; the flowers are thus exposed to the falling dew, but the leaves drooping again during the day, protect the flowers from the heat of the sun. This species is a native of Venezuela, where it is called Rosa del Monte or Palo de Cruz, and was introduced to England in 1828. Altogether there are six species in cultivation, some of them with bright scarlet flowers, as in *B. coccinea*, which was the first known in our gardens. The genus is named in honour of Patrick Browne, who wrote a history of Jamaica.

H. K. RUTHERFORD 21, Mincing Lane, E.C.

MR. JOHN BROWN ON THE PRESENT CONDITION OF CEYLON COFFEE.

We presume it will be admitted that few men could be better qualified to judge of the present condition of the few coffee trees yet remaining in Ceylon than is Mr. John Brown of the Colombo Commercial and Uva and Spring Valley Companies. This gentleman has but recently returned to England after a stay in this island of a good many months; and as the representative of the three Companies mentioned he must have had every opportunity of forming a judgment of the state of things upon the several estates owned by them upon which some fields of coffee yet remain. It is understood that by a process of gradual elimination every "shuck" tree has been got rid of, each of those remaining being apparently in full health and vigour. Mr. Brown, it appears, has stated since his arrival at home that he never saw fields of coffee looking more promising than did those under his observation while recently in Ceylon. Even in the palmiest days when coffee was king in the island, there could not be seen, according to Mr. Brown, trees looking in better heart or promising more fairly. Alas that such appearance should be delusive! Fine and healthy as these yet remaining fields appear, and promising as is the appearance of blossom and of the subsequent fruiting, but few of the berries produced will ripen upon the trees. They fall off immaturity, and the crop returns are most heart-breaking. We may recognise in this fact, perhaps, the justness of the assertion frequently made by experts that the soil and climate of Ceylon are both of them better adapted to the production of a leaf than to that of a fruit crop. In the case of the Uva estates visited by Mr. Brown he found the coffee trees covered with verdure; and had the putting forth of this been the ultimate purpose of their planting we should hear nothing of the continuance of the distressing effect of *Hemileia vastatrix* upon the coffee cultivation of the island. And, yet what has always been termed the "leaf disease" appears to have had little or no effect upon the production of foliage at the present time. Indeed this is stated to be luxuriant. Failure now only occurs when the time for fruiting arrives; and it would be interesting to consider whether, since so far as any affection of the leaf is concerned, the effects of the disease appear to have passed away, a little longer period of patience and waiting may not witness a similar beneficial change as regards the fruit-bearing of the trees. It used to be common in the days when *Hemileia vastatrix* was at the height of its virulence to see whole fields left utterly leafless. No such sight, according to Mr. Brown, is now to be seen. He has stated that nothing could be finer than the condition of the trees when he saw them from a leaf-producing point of view. Here we have a distinct amelioration upon former common conditions. Is it hopeless to expect that the trees, having so far recovered from the weakening effect of the disease from which they so long suffered as to produce full crops of leaf, may in time become so far further recuperated as to be able to bear their crops of berries until maturity be reached? We do not pretend to predict whether such a hope, if entertained, will ever be justified; but it would seem to be certain that to some extent the

trees have slowly recovered from the effects of the disease. If we could pass through one or more seasons without experiencing a recurrence of further outbreaks of this, we can see no assignable reason why in time strength may not be so further obtained as to enable the full function of the trees to be performed? At all events it would be unwise, in the face of all present evidence, to decide that the day may not ultimately return when an acre of coffee may yield crop rivalling that of our former experiences.

NOTES FROM OUR LONDON LETTER.

LONDON, Nov. 4.

THE CEYLON TEA FUND COMMITTEE'S GRANT TO THE AMERICAN CEYLON TEA CO.

We understand that a telegram has been received by Mr. Farr, of Messrs. Watson & Farr of New York, to whose presence in London my latest letter made reference, intimating that your Tea Fund Committee had resolved upon voting to the American Ceylon Tea Company a grant of ninety chests of tea. Mr. Farr, it appears, is greatly pleased at the receipt of this intelligence, because it gives him what he and those connected with him in the States have so greatly desired, an official recognition of their status by the leading planting body of Ceylon. Mr. May and Messrs. Watson & Farr had, we believe, asked that

A CONCESSION OF £1,000

should be made to them for two succeeding years by your Planters' Association, but it was replied to them that the resolution before referred to was taken before their letter of detailed application was received. Mr. Farr, who is a man of between 30 and 35 years of age we should say, thinks that he may well be pleased with the aid now voted by your planting community, and he believes it will enable him to obtain all the further aid he requires here and in America. It may be concluded from the fact that Mr. Farr leaves today upon his return journey to New York that he has been able to make all arrangements with respect to aid obtainable on this side before the receipt of the telegram from Ceylon, and it is possible that he had secured promises in advance the performance of which was contingent upon his obtaining the help now guaranteed to him from Ceylon.

MR. MAY AND PUSHING CEYLON TEA IN AMERICA.

When speaking relative to what Mr. Elwood May has already accomplished in America with regard to the introduction of Ceylon tea, Mr. Farr remarked that perhaps no man had ever succeeded as Mr. May had done in getting services rendered for nothing. "Nothing for nothing" is a customary saying; but Mr. May, according to Mr. Farr, has succeeded in proving an exception to the rule of it. Probably Mr. May, as a man of considerable independent means made by some lucky ventures and added to by marriage to a lady of considerable means, was in a more likely position to effect this than the generality of businessmen could be. He occupies a good social position in New York, and is liberal in the exercise of hospitality, so that he can place matters before businessmen from a platform which a more needy man could not possibly occupy.

VALUATIONS OF CEYLON TEA IN NEW YORK.

I was mentioning the fact of recent valuations of your teas in New York to several Ceylon men this week. These held that the facts narrated in my last letter fully justify Mr. May in his assertion that it would be no use attempting to effect the

introduction of Ceylon tea into America through the ordinary channels, and that it would be necessary to "go round" them. Mr. May was certainly right when he said to me:—"You don't know my countrymen, sir. If you did you would see that you can't deal with them as you do with Britishers. My people are peculiar, you see." It is very certain to my mind that Mr. May knows what he should do far better than anyone here or in Ceylon can do or suggest. Every day seems to bring to light some fact demonstrating that in view you have an agent who does not require any dictation as to his methods of working. As he has said he *knows* his countrymen, and he knows, I suspect, how to humbug them for their good. To do so may be somewhat critical, but it seems to be the only way of working successfully in approaching Brother Jonathan, who—he may say what he likes—hates all Britishers and everything they produce in opposition to him. But certain things he must have, and so is willing to take them if he can obtain nothing of equal quality elsewhere.

THE NEW BROCHURE ON CHINA *vs.* CEYLON TEA.

The pamphlet sent you by the last mail entitled "*Theine vs. Tannin*" has been the subject of a good deal of conversation in various circles since its issue. The dealers and others interested in China teas of course welcome it warmly, and predict that it will have much effect in remaking a taste for China tea. This, however, is much to be doubted; for it is hardly likely that the work will reach the hands of any large number of consumers, its circulation being certain to be almost entirely confined to those who make their living by dealing with tea. And with such the interests they have acquired of a promising character are likely to weigh much more than any abstract questions as to quality or healthfulness. Besides this, the fact is now established that, rightly or wrongly, the public at large will have *strong* teas, whether the strength be due to the presence of an extra quantity of tannin or not. That this is so is evidenced by the prices attached to a table of analyses of different qualities of tea drawn up, we hear, by Mr. John Hughes. This shows that tannin rules the markets, for the rate of price obtained follows the amount of tannin existing in the various samples. That there are many whose digestive organs cannot stand the strong teas of India and Ceylon there is no manner of doubt, though if these would only drink first infusions and those of not longer than three minutes' duration, there is every reason for the belief that they would not suffer from after ill-effects however much of tannin may be yielded by analysis of the tea they consume.

CEYLON TEA: AN EXPLANATION BY THE WIFE OF A CEYLON TEA PLANTER.

Modern Society has recently published a considerable amount of correspondence dealing with the foregoing topic, and in its issue for the 29th Oct. there appeared the following—

"The wife of a Ceylon Tea Planter" writes:—"A copy of your valuable paper, *Modern Society*, dated Oct. 1st, having come into my hands, I note particularly the remarks of a correspondent in reply to an article from 'Alice' of the 17th ult. Will you allow me to say that if 'Alice' and all your readers will try the Ceylon and Indian teas they will find them perfectly pure and unadulterated. The tea after being plucked from the trees is prepared entirely by machinery, and no colouring matter is used, and 'Alice' will find it only necessary first to warm the teapot with a little boiling water, which she should pour away, then put in the tea and add boiling water. Care should be taken not to allow the tea to stand too

long on the leaves to draw out the tannin, which is most injurious."

THE FALLING-OFF IN THE QUALITY OF CEYLON TEA.

Speaking with an expert this week he told me he thought it must be conceded that the quality of the Ceylon teas now received was distinctly below the average of those upon which the public taste for them had been educated. He attributed this falling-off to the larger proportion of low-grown teas now reaching us from Ceylon. In his opinion these were decidedly inferior in every way to the teas grown at higher elevations, and he feared that the increasing yield of these would be likely to somewhat damage the public estimation of Ceylon tea. He also thought that the large receipt of such growths had done a good deal to depress prices, and deemed that it would be worthy the while of dealers in packeted teas to name on the labels the elevation at which these were grown. He regarded this matter so seriously that he even went so far as to say that efforts should be made to check the extension of your cultivation of:

TEA IN THE LOWCOUNTRY.

and that your Government should refuse to sell land in districts so situated unless a guarantee be given that they should not be devoted to tea planting. It is, of course, out of the question that I can offer you advice in such a matter; but really the opinion expressed relative to the evil result apparent from the indiscriminate offering for sale of high and low grown teas is so strong, that it would probably be well to give some consideration to the matter.

THE TEA-GROWING INDUSTRY IN BRITISH INDIA.

It quotes particulars as to thirty-four companies engaged in the pursuit, and states that of these six paid no dividend whatever in 1891, while the average result of twenty-eight dividend-paying concerns was a return of 7.44 per cent, representing the mean between the maximum 17 per cent of the Brahmapoetra and 2 per cent of Noakachara. In 1890 twenty-seven companies sent to market 23,824,328 lb. of prepared tea, gathered from 55,752 acres. The gross price realized was 11 91d per lb. against a cost of 9.33d, leaving a profit of 2.58d. In the year following, 1891, thirty-five companies sent 31,300,259 lb. to market, gathered from 69,566 acres. The average price realized was 9.84d against a total cost of 8.29d, leaving a profit of 1.55d. The difference between the two years was probably on a rough calculation about £100,000, or about 3 per cent on the capital all round. A comparative statement given shows that in 1890 24 companies paid an average dividend of 8.69 per cent, three companies paying nil. In 1891 28 companies paid 7.44 per cent, seven companies paying nil. The article states that there are about sixty tea companies working in India in tea cultivation, and that the sterling capital of these aggregates 5½ millions, with a debenture liability of three-quarters of a million, and owning a cultivated area of about 125,000 acres. The average production in 1890 of 27 companies was 448 lb. per acre, and in 1891 for 35 companies 450 lb. The editor of the *Capitalist* remarks that "the unevenness of results is one of the most important points to be investigated in the search for a judicious purchase." He remarks further that the prospects for 1892 are much brighter, although there will be a short field, and he adds "the rapid increase of production in Ceylon has now come to a standstill." Your readers will probably find the few figures above quoted of considerable interest to them,

NOTES ON PRODUCE AND FINANCE.

INDIAN AND CEYLON TEA IN NEW YORK.—There is a trade exhibition held in New York at which the agents of the Ceylon and Indian tea companies have attractive pavilions. Natives are in attendance to sound the praises of Ceylon tea, and to furnish visitors with a cup of the beverage. Of course, the Ceylon people are pushing ahead in a well-organised and effective manner.

TEA IN NATAL.—Natal tea planters are going ahead. Natal mail advices say that the 1892-93 tea season of that colony had just been opened. The rains of August and September had done a great amount of good to the crop, and the prospects of a good season were decidedly satisfactory. A total yield of 560,000 lb. is expected. This would show a considerable advance on the out-turn for 1890-91.

INVESTMENT IN TEA SHARES.—As pointed out in more than one financial paper, investors might with advantage to themselves turn their attention to Indian tea companies. "Wiry Leaf" writes in the *Financial News*:—"I have been reading Messrs. Hawes' report on Indian and Ceylon tea in your *Produce Market* column of the 28th inst., and it does not take much foresight to see the effect such an advance in prices as is there indicated must have on the profits made this season by some of the Indian tea companies. Somewhere about Christmas, 1891, I tipped Eastern Assam Company shares at 15s. I am now buying them at £2 12s 6d. I will now tip British Indian Tea Company £1 10s—should be worth £3 in six months. The position of this company is this:—Formed about twenty-five years since with a capital of £240,000: nearly in liquidation about ten years later; saved by the energy of the present chairman and a few friends raising £11,000 debentures; £20 shares now reduced to £5 value 30s., stands—debentures about £11,000; shares at market value £18,000, or, in all, £29,000. A dividend of 3s, honestly earned, was paid in 1891: none last; year debt after paying debenture interest, about £150; and, I think, this year, with the market in this strong position, a dividend of 5s may fairly be looked for. Many tea companies pay 6 per cent and 10 per cent, as per list published by Mr. Martin, 27, Throgmorton Street; but unfortunately (for them) the public seem to prefer building societies, mines, breweries, &c., run and directed by fat guinea-pigs and hungry M.P.'s, of which none of these companies that I know of can boast. The two companies named and several others, as Assam Company and Jorehaut Company, which are cheap at present prices, are quoted in the Official List." In an article on "Indian Tea Companies," in the *Capitalist*, a London financial paper, the writer says, referring to the table published by the Indian Share Exchange, 126, Bishopsgate Street:—"The 1892 Indian crop, though of excellent quality, is considered certain to give a short yield, owing to unfavourable weather conditions, while the rapid increase of production in Ceylon has now come to a standstill. Prices for both descriptions of tea have accordingly advanced very much. So far as can be foreseen at this moment, the working results of the 1892 crop are likely to show a considerable improvement over 1891. The low prices ruling for the past two years in the selling markets have given a great stimulus to the trade both in this country and especially abroad, and there is a tolerable certainty that consumption will go on expanding gradually from year to year, and that even increased crops will be readily absorbed. All these considerations help to recommend the present time as opportune for investments in shares, with excellent promise of remunerative returns."

MIENG OR LAO TEA.—The last number of the *Keo Bulletin* contains some interesting facts about the "mieng," or chewing tea of Laos, in Siam, which has proved to be the leaves of the Assam tea-plant (*Camellia theifera*). The leaves are steamed, then tied in bundles, and buried in the ground for about fifteen days. They are chewed by men, especially when hard at work rowing or poling on the rivers. Mr. Stringer, Acting Vice-Consul at Chiengmai, in a report on the culture and use of Mieng or Lao

tea says:—"In gathering the leaves only the young ones are taken, and the upper portion of the leaf is nipped off with the fingers, about a quarter of the leaf being left attached to the tree. If the whole leaf is picked, the young branches from which the leaves are picked off die. Each handful of leaves as it is gathered is tied tightly together. The picking takes place in the early morning, and about mid-day the leaves are steamed. This process takes place in a shed built for the purpose, and provided with one or more furnaces. The furnace consists of a hole in the ground, and over this is placed an earthen pot or chatty containing water. The 'mieng,' tied in small bundles or handfuls, is placed in a wooden cylinder, about 24 in. in height and 15 in. in diameter. At the bottom of the cylinder is a network of small strips of bamboo. This cylinder is suspended over the earthen pot, and round the edge of the pot is placed a wet cloth so that all the steam may pass up through the cylinder. When the 'mieng' has been thoroughly steamed, which is ascertained by its having sunk down to a certain point in the cylinder, it is left to cool and then taken out and retied, as the bundles have decreased in size, and it is then ready for use. If, however, the 'mieng' is to be kept for any length of time, it is placed in small pits dug in the ground and lined with large leaves, and it is then well trodden down to press out as much of the liquor as possible. It is then covered up with leaves and large stones are placed in the top, and it is left thus buried for about fifteen days. I am informed that 'mieng' which has been pressed and buried in this way will keep for two years. If the 'mieng' is required for immediate consumption it is not necessary to bury it, but it is packed in large baskets, and large stones are placed on it to press out the liquor. The liquor which is left in the pot after steaming the 'mieng,' and which is of a dark reddish-brown colour, is used as an article of food by the Laos and Siamese. The habit of chewing 'mieng' is almost universal among the Laos, and to the men engaged in hard work, such as poling or rowing boats, a quid of 'mieng' seems to be almost indispensable. It appears to have the same effect upon the nerves as that of drinking tea. The price of the prepared article at the village which I visited was one rupee (1s 3d) for twelve packages, a package containing ten bundles or handfuls. In Chiengmai from seven to ten packages are sold for one rupee."

JAVA TEA.—Messrs. Hawes and Co. say in their report:—"It is satisfactory after so long a time of depression in this department to be able to report an improvement both in the quality and values of Java teas. During the past month a great rise has taken place in all grades of Indian and Ceylon, especially in the common and good common teas. Similar grades of China have also risen, but, like Javas, not to the same extent as their competitors, the two latter having at present marked advances of only 3d to 1d per lb. No good common Indian or Ceylon leaf teas are to be had under 7d to 7½d per lb.—and little at these figures—or of Chinas under 6½d per lb. This fact made those who are responsible for the low-priced blends at 1s to 1s 2d per lb. look about for something under these quotations, and the cheapness of good common leaf Javas, as compared with similar grades of other growths, was soon recognised, some of which were still hanging on the market, without enquiry, at about 5½d to 5¾d per lb. Active competition to secure these parcels made sellers firm, and there is nothing now under 6d to 6½d per lb. The quantity offered during the past month totalled 5,175 packages, of which 4,576 packages were of "direct import," as against 2,786 packages in September. The general quality of the late arrivals has shown improvement, some very useful invoices having sold from the Tjiboengeer, Tjomas, Perawatote and Sinagar Estates. With the reduced exports from other parts, and the demand for lower-priced teas, we may fairly expect a better enquiry and a firmer market for Java teas for sometime forward."

THE ALLYNUGGER TEA COMPANY, LIMITED.—The prospectus has been issued of the above company. The

capital is £120,000, in 5,000 six per cent cumulative preference shares of £10, and 7,000 ordinary shares of £10. The company is formed to take over the Allynugger and Chatlapore plantation in Sylhet, and other properties. The directors are Messrs. Thomas MoMeekin, W. L. Watson, and Sir Alexander Wilson.—*H. and C. Mail*, Nov. 4.

THE AMSTERDAM CINCHONA AUCTIONS.

Amsterdam, Nov. 3.

At today's auctions, 3,761 bales of Java bark were sold, leaving about a quarter of the supply undisposed of. The market was a trifle easier, the average unit being $6\frac{1}{2}$ cents (equal to not quite $1\frac{1}{4}$ d per lb.) Manufacturing bark in chips, quills, and shavings sold at 9 to 66 cents (equal to $1\frac{1}{2}$ d to 12 d per lb.); ditto root at 17 to 41 cents (equal to 3d to $7\frac{1}{4}$ d per lb.); manufacturing bark in quills and chips at 18 to 54 cents (equal to $7\frac{1}{4}$ d to 10 d per lb.); and ditto root at 9 cents (equal to $1\frac{1}{2}$ d per lb.) The principal buyers were the Anebach, Brunswick, Frankfort-on-Maine, and Mannheim factories.—*Chemist and Druggist*.

TEA TRADERS' TALK.

The variation in new season's tea as compared one year with another, indicates of how little value is the established trade grading as an indication of quality. This is particularly true of China teas. Superior Formosa, for instance, may mean one thing this year, another last, and so on through all the gradings. In Japans there is a closer adherence to grade. Good medium is pretty nearly the same thing from year to year. This variation cannot be overcome, except when a careful selection is made by experts, who match the style of leaf and cup quality, and place thereon a private brand. Tastes differ just as much with tea brokers as consumers. If all the shippers in China should get together, examine each lot of tea and grade according to an established standard recognized and adhered to at every shipping port, then reliance might be placed upon invoice or line grades.

Tea and coffee are like all other vegetable products, influenced temperature, climate, soil and methods of curing. The first two are beyond man's control, and hence uniformity of tea from any one district is not to be expected, and can only be secured by a careful comparison and grading.

It is amusing to note how experts differ as to the value of tea. We had three values placed on a sample of fancy Formosa by three experts, there being a difference of 25 cents per pound between two of the estimates.

A broker distributed a sample into seven parts, and upon each part the expert placed a different value.

An English salesman of high repute made repeated tests of tea, naming the district in China where grown and its value, viz., 32 cents. The tea was a Japan Oongou, which cost 18 cents in the auction room.

Every retail grocer should draw teas and familiarize himself with style of leaf and flavour, and become so expert as to be able to match teas and keep grades uniform. This should be carried on with the aid and assistance of an expert buyer of large experience and one in whom confidence can be placed. Then it will be possible to maintain any established grade.—*American Grocer*, Oct. 12.

RAMIE AND ITS CULTURE.

The following communication, recently published in the *Pacific Rural Press*, will be read with interest, as it contains much valuable information:—

To the Editor: In writing this article on the very important subject of ramie for this country, and the great State of California in particular, at your request, please pardon me if I confine myself, in a homely way, closely to the important information on the subject closest to the people's interest. I shall endeavour to give the most important facts in the fewest and plainest words possible to make it understood, interesting and most useful.

Ramie is a species of nettle, but thornless. There are three different varieties all suitable for this climate; but they vary in excellence in the market from two to four cents a pound, the best, which I recommend, being worth six cents a pound here in the rough as it comes from the decorticators, dried and baled.

Decortication of itself is of a very simple nature, being to strip or peel the bark from the wood, to knock out the inner wood, which must be done as fast as leafed and cut, or on the same day of cutting. It can be done to play by flail, treading with horses, or flax break, and shaken out; or more properly in these days, with a machine run by horse or steam power, and with four to six men working two acres a day easily. One machine will run through 120 acres in two months, and keep a gang of men busy all the summer through. Ramie will grow in about that time if well supplied with water, irrigation or natural moisture.

Ramie should be cut green when about four or five feet high, and when it first begins to brown at the bottom of the stalks. Ramie will not rot like flax or hemp, and thus must be broken green before the gum or glue sets to the stalk. It should be run from the decorticator on an endless wire carrier through a drier and baled at the exit for shipping to the factory, where it is, by a process, ungummed and prepared for carding and spinning. It is excellent to knit or weave into goods of superior quality, pure or mixed with wool for cassimeres, woollen and worsted fabrics.

Ramie fibre is of a very firm texture and of uneven length, from two to six inches. It is a flat, hollow ribbon, and thus takes dyes in all shades of the brightest colors, as well as for black silk. It is not of such a glossy nature as common silk, but partakes more of what is called dead silk in black, which all ladies know is most desired in expensive goods. Silk is wound off the cocoons from 80 to 1,000 yards long and doubled in the winding seven strands, while ramie, being short, must be carded and spun like raw silk or broken silk, and therefore is not mixed with line silk in the way sometimes spoken of, but after made into thread is used to mix in the body, the strongest parts needed, for the warp or filling, and sometimes for the body of the goods when silk may be used for the raised glossy figures of flowers, giving a beautiful contrast and exquisite shading. In wool mixtures it can be cut or graded to the even lengths and carded and spun as a completed mixture, benefiting the wool by its superior strength, gloss and finish, the wool making the nap and warmth, the ramie alone being porous and cool for summer wear.

Ramie fibre being smooth, tough and strong like silk, makes a splendid worsted line of goods pure, such as fancy braids, binding, linings and dress goods, or mixed with long wool in the more expensive and intricate varieties of cassimeres and worsteds, upholstery, plush and other goods. In tapestry and curtain goods and rugs, it cannot be excelled by Oriental importations, as it is most durable and fast in colors. For fish lines, nets, hammocks, yacht sails and any uses exposed to moisture, where strength and durability are desirable, it is not to be equalled.

Ramie is not adapted to be worked on linen, hemp, cotton or jute machinery. It is estimated that some \$30,000,000 to \$70,000,000 worth of worsted alone, and of wool and woollen goods worth many more million dollars, are imported into the United States annually. Ramie fibre that can be grown in this country can take the place of this and excel in durability and fine finish, besides for all other purposes in ramie goods, pure, mixed silk and other ways, I have no doubt, to amount to much more.

There is no end or limit to the possibilities, apparently, to the uses to which it can be put. Why should we not hasten to reap the direct benefit, as well as the incidental impetus it would give to all other enterprises, employments and home markets?

Ramie is now grown in China, Japan, India, Mexico, Cuba, Hawaii, Samoa, West Indies, Guatemala, Columbia and Brazil, and in the United States in Alabama, Louisiana, Texas, California, Washington and Oregon in small quantities. It is also grown in South France, Italy and Hungary, and is worth in China \$100 to \$200 per ton cleaned by hand. This is done there by scraping the pellicle off the outside of the stalk, cut green, then peeling the bark, and with a bamboo stick rubbing out the mucilaginous gummy matter over a log, and repeated washing and drying on scaffolds or roofs or their houses. For export it is only partially ungummed. For their hand-weaving they strip this partially ungummed fibre into threads as long as possible, containing, of course, thousands of fibres, which they fasten, stick or tie together end to end, making long threads in imitation of silk, which they weave into goods, then boil and bleach out and color in the piece. This primitive way of working, which can only be done with the cheapest of labor, has deceived most of our experiments into the belief that the fibre was long as the stalk, like flax and hemp, and of course prevented success in our working it to manufacture by machinery. But now that we have scientifically investigated the fibres before we undertook to build machinery, and found out just what was wanted, it was easy enough to solve the difficulty, which of course, "was in a decorticator" (if a decorticator was to do, or could do, the whole business), which never has or never will be done economically by one. But when only decortication was wanted by a decorticator (see Webster), and we had a simple way to treat or finish it afterward, success was attained. The farmer is not bothered with the ungumming, which is the difficult part of the work.

AS TO PLANTING.

It can be done in various ways, but I have had early and extended experience in nursery and farming, as well as machinery and manufacturing, so looking to the end that the greatest success and efficiency might be attained, I will suggest this plan. After properly moistening, plow and pulverize your ground well and deep, roll smooth, mark out as for corn, but make the rows six feet apart, plant in the furrows from one to three feet apart, drop like potatoes, and cover like corn—or you can stick the roots, butt down, slanting sideways, two or three inches deep and cover the top about one inch, or let it come almost or quite to the surface, if the ground is not mellow and sandy and is moist to the surface, or is liable to bake. Cultivate well between the rows until the sprouts are up two or three feet high, when layer out to cover the ground in a bed four feet wide, leaving a space two feet wide between the beds to cultivate, from which you can procure roots that spread out into these spaces to replant or sell without disturbing the beds. You will find it will pay you for some years to come to raise roots to sell as a little demand will absorb all now on hand, and I have no doubt the price will double or treble before the rush is supplied.

The first crop after layering can be cut with a sickle by hand and all the poor or branchy shoots can be layered to fill up any vacancies or cut into cuttings and planted like grape-vine cuttings.

Now these two-foot paths can be kept open and used for cultivation, or, after the four-foot beds have become solid, can be allowed to spread full.

I advise this plan as a four-foot bed can be grown solid thick sooner than six feet, and after that can be easily extended. When roots become plentiful and cheap you can plant thickly all over the ground at first planting, if you choose, but with roots \$3 a piece, as at first in New Orleans, it could not be afforded. Although one planting lasts for a life-time it is supposed that five cents would be high, but two or three cents is reasonable, and \$21.63 per thousand is very reasonable, delivered in good order, the

purchaser running no risk in shipping at all. Two thousand five hundred, six feet by three apart, or 7,500, six feet by one apart, makes the first cost enough on a large scale, and with layering and cuttings will soon cover the beds.

If planted this spring a scattering crop can be cut in the fall from the layers, and the next season three or four fair crops can be expected, and the next year your most sanguine hopes ought to be realized. Anyone purchasing larger amounts or where possible, can have my personal attention as to soil, preparation and care, I will contract to buy all you will raise from roots purchased of me, for five or ten years, at six cents a pound, in bales delivered in San Francisco, Los Angeles, San Bernardino, Sacramento, Tulare or Bakersfield, Cal.; El Paso, Dallas or Galveston, Tex.; New Orleans, La.; or Mobile, Ala.; Atlanta, Ga., or Jacksonville, Fla.; Salem, Or.; or Seattle, Wash. I will also agree to furnish decorticators at a reasonable cost; now \$700 to \$800 for two acres a day, and give freely all necessary information and assistance possible personally; deposit a forfeit of \$50,000 for every two thousand acres planted from roots purchased from me and paid for, or leave that amount approved, due on the same at 8 per cent interest and accept notes payable in fibre; build manufactory and buy your crop for five or ten years at 6 cents a pound, paying cash 90 days for the name, each crop delivered as above.

Ramie is not a noxious weed, does not spread over the country by seed, is not hard to eradicate, dies with drought, flood, or plowing out to sell the roots or replant. As to its injury or drain on the soil I must say that has been over-estimated, as the comparisons have been made with grain and fruit that grow and ripen, grain, wood, fruit, seed or pits, which make the greater drain and from the surface. The ripening of seed or pits, hardening of stem or wood, is much more exhaustive of the soil than the first or green part of the growth. Ramie should be compared with alfalfa more properly, but has some very important advantages over that also. While alfalfa roots deep and draws its substance not mainly from the surface, but deep down in the subsoil and far into subterranean depths for moisture, it does not materially exhaust the surface, though in cutting green it is all removed, stalk, leaves and all sold or used, hardly if ever, returned even in manure if fed on the place; yet, if ripened for seed, it exhausts the soil much more, while with ramie the roots also go down deep, not only one tap root, but many, each stalk supplying its own, every joint or piece supplying them if detached from the mother roots. Ramie is always properly cut green, all the leaves, about two-fifths of the whole weight, being stripped and left on the field; the wood and juice is separated and burned in dryers, and the ashes can be returned with little trouble, so that nothing but the pure fibre need be taken permanently away.

Now if an old overgrown stalk should be cut, weighed and burned to estimate the loss, the result multiplied by the number supposed to be on an acre, it might be that "fifty tons per acre" might be estimated, which would give a very erroneous impression from the real facts, I think the leaves and wood being returned might add to the soil, together with irrigation and the air, all, or nearly all, removed in the fibre, and possibly more in some cases at least. Something is taken from the air and water, and more brought up from the subsoil, or below. At any rate, I have seen as fine stalks on ten, fifteen and twenty-year-old grown patches of ramie (that I have been told have not been fertilized and not much watered) as I could wish to raise. About five tons green stalks can be expected off an acre each cutting, making a thousand or more pounds of fibre, or three to four thousand pounds in a season of three or four cuts.

Ramie fibre must not be bleached before used in the factory, as it needs a different treatment for different uses, and you must not be deceived by long, fine bleached or unbleached samples, as there is no practicability in them. Ramie is not ungummed if

long, and cannot be used in that condition except by hand, and then must be prepared, while green and fresh by hand. We want no hand work, and cannot compete with foreign labor in that way. So do not be deceived by gaudy showings.

Bales of it have been made and shipped from the south, twelve to twenty years ago, and found unsaleable for profit to this country, and spoiled for their uses in Europe, by hand or otherwise. We want plain, practical working material.

It must be thoroughly and economically ungummed, and then it is as free and pure as wool, camel's hair or alpaca, and cut to even lengths, or separated into two, four and six-inch lengths, will card and spin as readily by machinery, and if properly done is full of strength and gloss. The farmer, except for curiosity or satisfaction, does not need to be a manufacturing expert to pass on the machinery or fibre. He simply, necessarily wants to be satisfied that he can put into bales and sell the raw material, and roots maybe, enough for several years to pay him for planting, raising and marketing, as well or better than anything else he can raise, and that he will get a better market for his other products, and be able to buy a superior article of goods for less money than is possible without it. If he can make \$180 or \$240 per acre on a large number of acres for several or many years, and never less than \$50 clear, or double or quadruple his market, and that at home instead of the chances abroad; get his goods for less than half or one-fourth of the price he now pays; get a genuine, durable article that will wear four times the length of time the adulterated article he now pays a big price for, builds up his country, makes his property valuable, I think it is worth a little effort and faith, even if there is a good deal of work, and may be some few mishaps to start with.

—*Planters' Monthly.*

S. H. SLAUGHT.

THE ORANGE IN JAPAN.

[Report by Consul Smithers of Osaka and Hiogo, prepared from information obtained from the Governor of the Hiogo Ken and from facts furnished by Mr. H. E. Amore, an English gentleman engaged in exporting young trees to California.]

VARIETIES.

There are many varieties of the orange found in Japan, of which the most profitable are the Oonshiu, Hira-Mikan, Koji, Kinkan and Natsu-Mikan. In the prefecture of Osaka the location of the orange trees is about 3 miles distant from the sea, at an elevation of 2,016 feet, and at Arita-Gun, in the Province of Kii, they are located from half a mile to three miles from the sea, at an elevation of 610 to 800 feet.

A southerly exposure is best for the trees and the best soil a sandy loam with gravel about 3 feet from the surface. Hilly and rolling land is preferable for the "Oonshiu" and "Hira-Mikan" varieties.

The minimum temperature is 36° F.; maximum 95° and average 65°.

THE OONSHIU

is in every respect the best variety. The tree, or more properly, the bush, grows to the height of 10 or 12 feet and covers a space 22 or 23 feet in diameter, or 70 feet in circumference. It branches close to the ground, and, not being pruned, the weight of the fruit causes the lower branches to lie on the ground completely covering the trunk. They are extremely prolific, and as the fruit is not thinned out when small, it does not often attain a size of over 3 or 3½ inches in diameter, and the majority not over 2½. Like all other fruits, they are picked by the Japanese when green (unripe) and sour, as early as the 1st of October, and are gathered and packed by December, when they are stored, keeping so well as to be found in the market as late as the end of May. The fruit of the Oonshiu is flattened at the poles, the rind peels off very easily and the segments part as readily.

When the orange is cut horizontally, the juice is so abundant that it runs over freely. They are

practically seedless; out of 200 only 2 were found to have seeds. Their flavor is very pleasant—sweet, but not too sweet—and is much liked by foreigners in Japan and China.

THE "HIRA" MIKAN,

sometimes called "Kishin" Mikan, or "Kino-Kuni" Mikan, is a smaller fruit than the Oonshiu, and though it has a few seeds it is desirable. The tree goes to the height of 30 feet, is an immense bearer and is as hardy as the Oonshiu.

THE "KIN-KAN,"

kuowu in China as the "Kumquat," or golden orange, grows to the height of 16 feet and is very prolific. There are two kinds, the "Maru-mi" (round fruit) and the "Naga-mi," or long fruit. It contains 4 or 5 seeds and is palatable, eaten raw, rind and all, but its chief use is as a preserve in syrup or crystallized. It has long been popular both in Japan and China, when treated in this way.

HOW PROPAGATED.

The orange tree is propagated in Japan by grafting on sour stock, "Citrus Trifoliata," or native wild orange, which is so extremely hardy that it does not appear to suffer with cold. It grows to the height of 25 to 30 feet. The fruit is perfectly round, somewhat larger than a billiard ball and full of seeds. The stock for grafting is propagated from these seeds. The young trees are transplanted each spring and after two years are ready for grafting. The leaf is trifoliate, like the clover. The tree is very thorny and it is deciduous; the sap falls in the winter and does not rise until late in the spring, and it is to this that the extreme hardness of trees grafted on this stock may be attributed. The Japanese do not appear to give the same attention to the cultivation of orange trees as in California and Florida, allowing vegetables and corn to grow between the trees, which are planted so closely together that the branches often interlock.

The irrigation which takes place only in the dry season is done by pails and the liquid manure is distributed with dippers by hand.

There are no nicely laid out groves as in the United States, but irrigation patches and many trees are planted on the hillsides in terraces the same way as rice and other products.

INSECTS.

No attention is paid to insects beyond burning the chrysalis or beetles. The "scale" is injurious in some parts and almost unknown in others as may be seen by the smooth-skinned oranges from Arita.

NURSERIES.

The principal ones are about 12 miles from the sea and the trees are protected in the winter till the third year with coarse straw matting roughly tied around, the idea being to preserve the young growth and not because they fear injury to the matured branches. As the Japanese see no beauty in an upright tree, but rather prefer them crooked or dwarfed, the young trees are not staked or trained.

One reason for preferring the low tree is that they can pick the fruit without ladders, and another is that the branches keep the ground cool and more moist than if exposed to the sun.

As the tree is not a rapid grower, although it produces fruit at an early stage, it would not be a difficult or expensive thing to cover them with a light framework and awning during the cold weather in parts of the United States where the climate is temperate rather than to be deprived of so valuable and ornamental a tree.

THE MARKET PRICE OF THE OONSHIU.

Fruit in Japan is from 2 to 5 silver yen per 1,000 according to size and quality, and considerable shipments are made to San Francisco, but, owing to their being packed in air tight boxes often arrive in bad condition.—Agricultural Department, Washington, D. C. Consular report, December, 1890. No. 708.—*Florida Dispatch,*

CARDAMOMS.

Zingiberaceous planters are frequently met with in the tropical forest. Large specimens of *Elettaria*, particularly *Elettaria speciosa* form a constant constitution of the underbush—for instance, upon Java. The leaves of the *Elettaria* often reach an enormous length, up to 15 and 20 feet, and for this reason serve as a magnificent ornament of the forest.

Elettaria cardamomum white et maton is indigenous to Ceylon, but not to Java. Its cultivation is carried on in a number of districts, the total amount of the harvest of 1891 being estimated at 443,000 pounds.

In British India cardamoms are cultivated chiefly in Coorg and Mysore 2,500 to 5,000 feet above sea level. Some of the Mysore plantations have an extent of 1,000 acres. The cultivation was first commenced in 1871 by a few coffee planters.

Upon Ceylon the Dutch collected cardamoms about the middle of the eighteenth century. At that time the export amounted to 7,000 to 8,000 pounds. Subsequently it fell off considerably amounting to only 5,500 pounds in 1813. Some years ago the cultivation was started in nearly all districts below the level of 4,000 feet, which resulted, of course, in over-production and a great decrease in value of the product. In 1887 to 1888 there were under cardamom cultivation 4,572 acres. The production amounted to 250,000 pounds from regular plantations, and 100,000 from the so-called kampong cultivation (crude country farming).

There are three kinds of cardamoms to be found in Ceylon; the indigenous, the Malabar, and the Mysore. All three are probably only varieties of one and the same species.

"Malabar" cardamom has a pale green "indigenous" a red stem of dark color near the bottom. The fruit of the "indigenous" cardamom (in Sinhalese, "ensal") is known in commerce as "Ceylon natives," and less esteemed than the "Malabar" (called "rota ensal.") The former is longer than the latter. The Mysore variety is more robust than the others. It grows at higher altitudes, is more hardy, and has larger, not velvety, leaves.

Good soil and moisture are the chief requisites for a successful cultivation. Tropical valleys are the most favorable localities. Some shade appears to be necessary, and the excess of winds must be guarded against.

Cardamoms ripen very irregularly. When growing in stiff loam and exposed to too much rain, the plant grows vigorously, but bears no fruit.

When the plantation is started in the forest, the undergrowth is first removed and the forest thinned out so as to still preserve the requisite amount of shade. The soil is drained by suitable trenches where required, and all weeds carefully removed.

Planting is usually done in rows, so far as the remaining trees permit. In good soil plants are set at distances of 7 feet. Propagation is made mostly by planting pieces of the tuberous rhizome, rarely by seeds. A special part of the plantation is usually reserved for propagating purposes. The plants raised there are taken completely out of the ground, and the root divided into the several tuberous sections, which are either planted at once or first developed in a nursery and then transplanted. Plants raised from seeds, of course, require a longer time before they bear fruit, but the seed method has the advantage that the planter is always sure of the variety, while he has no such assurance when he has to buy pieces of rhizome in the market, particularly from natives.

The pieces of rhizome are laid immediately under the surface of the soil. After three or four years the plants produce fruit, but a full harvest is not obtained until the fifth year. They continue bearing for six or seven years and sometimes longer. The usual yield of an acre of five-year-old plants is estimated at 300 pounds. The plants flower throughout the whole year. Fruit and flower are always seen on the plant at the same time. But the harvesting is confined to the time between the end of August and the beginning of the next April, more particularly to the last three months of the year.

The capsules are collected when they become firm, but before they have become entirely yellow, in which latter condition they are apt to burst on drying. Fully ripe fruit separate easily from the stem, those nearly ripe do not. A coolie can gather as much as 12 to 15 pounds per day. Four pound fresh capsules furnish one pound of dry.

In order to impart a yellow straw color to the capsules, they are subjected to a so-called "curing" process. They are first placed for a short time into cold, and then for a minute into boiling water, next they are exposed to the sun, three hours during the morning, and two during the afternoon, which bleaches them. In some mills of Colombo the fruits are sometimes treated with sulphur fumes. When the fruit is picked the stems still adhering are broken off.—*Montreal Pharmaceutical Journal.*

AN IMMENSE POULTRY FARM.

Americans are not noted for doing anything on a small scale. Even the poultry farms are the largest of any in the world. Except in Egypt, artificial hatching is carried on more extensively than in any other country. Mr. Ross A. Smith, of Charleston, S. C., gives an account of a visit to the largest poultry farm in this country, or in any other, under one management.

The owner is Dr. T. A. Greene, of Boston, but the farm is located at Long Island, New Hampshire, and is known as the Roxmont Poultry Farm. It consists of 1,300 acres; 200 are under cultivation to raise feed for poultry kept on the place, and thirty-five carloads are purchased besides.

Fifteen thousand hens and four thousand ducks are the average number, and 120,000 chickens and ducks are hatched annually by seventeen incubators of 640-egg capacity each, and they are kept in operation all the time.

One laying house 1000 x 25 feet and 600 houses 6 x 8, incubator, house 70 x 40, two stoves and cellar. When all the incubators are located the upper stories are used as nurseries for chickens just hatched, up to eight days old.

One hundred tons of coal is annually used to heat the buildings and furnish power to grind and cook feed. Ten thousand ducks and 45,000 broilers are marketed annually, and the daily shipment of eggs averages 220 dozen. The Roxmont farm represents a capital of \$120,000, and netted a profit the first year of \$6,000, with a fair prospect of doubling it this year.

Here is an instance where capital invested in poultry, properly managed in a business way, pays. As a rule, poultry on a large scale has not been a profitable investment for its owner, but it has been a lack of management or mismanagement, undertaken by an inexperienced person. We are glad to present this statement to our readers, for we know it is authentic. Knowing Mr. Smith personally and of his public career for several years, we can vouch for the correctness of this statement. I wish we had one capitalist in Florida who had sand enough to back such an enterprise. If it can be made profitable in frozen New Hampshire, it certainly can be in our almost perfect climate in Florida.

This is practical poultry culture, with the fancy left out. Eggs and meat are the objects sought after. The varieties are not mentioned, but no doubt a cross is used. As the fowls are raised for market, principally eggs, I should say are secondary to a meat supply, and broilers are the most prominent.

E. W. AMSDEN.

—*Florida Dispatch.*

[Like banana and orange growing, poultry rearing on a large scale requires to have a good market close at hand. That and cheap grain exist in America.—Ed. T.A.]

HINTS AND HELPS.

TO REMOVE PAINT STAINS FROM FLOORS.—Soak them with benzine or turpentine for a short time, then rub with emery paper or pulverized pumice stone,

HOW TO MAKE HENS LAY EGGS.—Provide them with clean quarters. See that they get at least one meal a day of food in which there is red pepper, and do not go near the nests till sundown.

TO CLEAN OILCLOTH.—Never use soap in scrubbing oilcloth nor a hard scrub brush, but use a soft brush and then wipe with a wet cloth. Once in a while apply a coat of copal varnish to keep it looking new.

TO REMOVE SCORCHES FROM LINEN.—Scorchs may be removed from linen by spreading over them the juice of two onions and half an ounce of white soap. To remove rust or ink stains spread the stain with a paste of lemon juice and salt and lay in the sunlight. Of course this applies to white linens only.

TO OBTAIN OIL OF ROSE GERANIUM.—Fill a wide-mouthed bottle with fresh rose geranium leaves that have been gathered when dry, and pour in as much perfectly pure glycerine as the bottle will hold. Cork it securely and keep in a warm place for several weeks, then it will be ready for use. It is good for the bath, also for rough or chapped skin.

HOW TO CARE FOR SHOES.—A little linsed or sweet oil well rubbed into the leather about once a week prevents the leather cracking. Whenever you have the misfortune to wet your feet, don't despair. Fill your shoes with oats, which will help absorb the moisture and preserve their shape. When nearly dry rub with oil, and the next day your shoes will look as well, and mayhap better, than before their wetting. The oats may be dried and saved to the next time. Above all things else don't neglect the heels. At the first evidence of so-called "running over" have them repaired.

TO PRESS SEAMS TAILOR FASHION.—The pressing board needed is about twenty-six inches long and shaped like a shirt board, perhaps two and one-half inches wide at the small end and three and one-half at the large end. It has rounded edges and is thick enough not to need padding or covering. Press thick cloth with a firm, hard stroke, letting the iron remain on the goods if necessary. If unlined cloth or flannel is being pressed the iron must not stand on it, for a mark would be left on the right side. The flat sides of the board are used to press the waist seams, the long edges are for the sleeve seams and the round ends for the armhole seams. In doing these last the board is braced between the knees, one end resting on the floor. All this pressing is done holding the board in the lap. But the special knack is to press all seams above the waist line down and below the waist line up. This keeps out wrinkles.

LEMON JELLY CAKE.—Two cups of sugar, half cup of butter, two teaspoonfuls of cream tartar, one cup of milk, one teaspoonful soda, three cups of flour. Bake in five layers, use juice; yellow rind grated, of one lemon, mix with water and boil till it thickens.

PINEAPPLE JELLY.—Soak half a box of gelatine an hour in a cup of cold water and stir in a cup of sugar. Add a little more than half a cup of the liquor drained from a can of pineapple, and half a pint of boiling water. Strain, stir in a cupful of the pineapple chopped fine, turn into a mold and set on ice.

LEMON CUSTARD PIE.—Grate the rind of one lemon and squeeze the juice on one teaspoonful of sugar and a tablespoonful of flour, mixed together. Beat to a froth the yolks of three eggs, and stir into them one cupful of new milk, then mix in the sugar, flour and juice, and bake in a plate lined with paste.—*Florida Dispatch.*

ENORMOUS PRUNE YIELD.

On the Briggs orchard, Visalia, Cal., three trees of the French prune variety yielded a total product of 2,813 pounds, the average per tree being 937.66 pounds.

The *Visalia Delta*, says: With sixty-four trees to the acre this would give a yield of 60,910 pounds, or 80½ tons. As 2.65 pounds of fresh prunes are required to make one pound dried, one acre would produce 23,362 pounds ready for market, and at 11 cents per pound, the present selling price, the gross value of the yield of a single acre would reach the sum of \$2,569.82;

at 2½ cents per pound on the ground, for which they could be sold today, the price of an acre's product would be \$574.05.

In the Briggs orchard there are twelve acres of prune trees of different ages and several experienced orchardists estimate the average yield at 600 pounds per tree. There are 64 trees to each acre, which would make 38,400 pounds to the acre, the value which at 2½ cents per pound on the ground—the price at which prunes are now selling here—would be \$960 per acre, a net profit (after allowing for every possible expense and loss) of more than \$900 per acre. If dried at the orchard and sold the value of the crop per acre would be \$1,593.90, and for the twelve acres the enormous sum of \$19,126.80 would be realized.—*American Grocer*, Oct. 12.

VARIOUS NOTES.

TEA IN FOOCHOW.—The *Foochow Daily Echo* of 15th Oct. says:—

We hear that the activity in the tea market during the latter part of last month led to wired orders being sent up country to prepare more, and that the answer came back "Too late, no more to be got. Sacks of old tea have been used as fuel to boil rice." We give this information, which is not derived from Hong-men, Brokers or Tea-boys, for what it may be worth. It is thought that there are still some 20,000 chests to arrive, which is not likely to be added to, on account of the demand having sprung up so late.

A BLEND OF COFFEE AND COCOA.—In noticing a food exposition at New Haven, the *American Grocer* writes:—

The space occupied by the Clark Coffee Co., is a centre of attraction. The decorations are tasteful, and their effect heightened by the brilliant red of the handsome packages containing Cocoa-Coffee, which we noticed in many of the New Haven stores. People tested the merits of the goods at the exposition, going away pleased with this new blend of coffee and the cocoa bean.

Soyer, the famous French chef, was, we believe, the first to combine coffee and chocolate, the compound being named by him "choca."

FORESTRY IN BURMAH.—From the official reports on forest administration in Upper and Lower Burma during the past fiscal year, it appears that the most important work done in the upper province was the reservation of forests, the total area reserved during the year being 1,059 square miles, including the most valuable teak-producing areas in the country. The total area of protected forests is 16,461 square miles. The experimental cultivation of eucalyptus and English fruit trees has not been successful. The experience of recent years in Upper Burma teaches that, with few exceptions, the forests have been much overworked and that it will be a long time before they reach the normal condition of productivity. The drought of last year had the effect of largely decreasing the export of teak, for the rivers were so low that between 40,000 and 50,000 tons remained stranded and could not be got down to the sea. The reports from various parts of the country show that forests of all kinds have been wastefully worked—the rubber forests by the Kachin chiefs and the Shan forests, where the chiefs entered into improvident agreements with speculators. But the Government did not think it prudent to interfere at present with the Shans. The exports of teak last year from Rangoon and Moulmein amounted to 161,967 tons, valued at more than 117 lakhs of rupees. Of this less than one-third went to Europe, the remainder going to India. The exports of teak from Siam at one time threatened to come into rivalry with the Burma teak, but they have fallen off, and last year no Siam teak went to India. The Moulmein teak all descends the Salween and its tributaries, while that in Rangoon reaches the sea by the Irrawady and the Sittang. The net revenue from forest administration to Lower Burma last year was nearly 16 lakhs of rupees, and in the upper province nearly ten lakhs.—*London Times*.

BLEACHING AND BLEACHING AGENTS.

(Being one of the series of Marsh Lectures, delivered by Mr. C. Driberg, Oct. 15th, 1892.)

Bleaching is a very ancient art, as passages referring to it in the earlier sacred and profane writers fully testify. It had probably reached a high degree of excellence among the inhabitants of the first Assyrian Empire, and was certainly practised in Egypt long before the commencement of written history.

In Scripture we have special mention of "fine linen, white and clean." Herodotus tells us that the Babyonians wore "white cloaks"; and Athenæus makes mention of "Shining fine linen" as opposed to that which was "raw" or unbleached. At this early period and for many centuries afterwards, the operations of washing, fulling and bleaching were not distinctly separated. The common system of washing followed by drying in the sun adopted by the ancients, by frequent repetition, decolourised the raw materials of textile fabrics, and thus must no doubt have taught them the art of natural bleaching. Washing or steeping in ammoniacal or alkaline lyes, or milk of lime, followed by exposure to the sun, formed the chief basis of their system, while woollens, then as now, were treated with soap and Fuller's earth, potter's clay or like argillaceous deposits.

[The use of lyes—like that of "washing soda" in modern times—results in the formation of a soap with the resinous and fatty substances naturally inherent in vegetable fibres or communicated to them in the process of weaving; while Fuller's earth and similar natural deposits have the property of extracting, by absorption, the fatty substances present in wool.]

We read that in the time of Vespasian (about 60 A.D.) and undoubtedly long before it, cloths were "sulphured," and according to Pliny, "sulphuring" was often had recourse to in ordinary washing as well as in the bleaching process.

Bleaching continued to be practised with no essential change of its principles, until the discovery of chlorine. In the last century Holland had a reputation for bleaching; the process passed next to Ireland and Scotland, and thence to England.

The first step towards the modern or chemical system of bleaching was the investigations of Berthollet on chlorine in 1784.

The knowledge of the use of chlorine as a bleacher was soon after brought to Great Britain and practically applied in Aberdeen, and about the same time in Glasgow, from whence it reached the Manchester manufacturers. After this a number of patents were taken out for various bleaching liquors and powders consisting of compounds or mixtures containing chlorine, till the new and "continuous process of bleaching," as it is called, was introduced and patented about 1828.

The term bleaching is generally understood to mean the process of decolourising cloth, but the word may, and is also applied to the whitening of other substances as well, as we shall see later. In this paper, therefore, the signification of the term will extend not only to the decolourizing of textile fabrics and solid bodies alone, but also to the bleaching or removal of the natural colours of any substance.

And first, I shall notice what is known as the "natural method" of bleaching, where exposure to light, air and moisture forms the leading part of the process.

The simplest form of natural bleaching is to spread out the cloth to be bleached on a grass

field called a "bleaching green" or to hang it out on lines in the open, and to continue sprinkling it with water several times a day. After being exposed for a considerable time to the action of air, light and moisture, the cloth is rendered white. The process is necessarily tedious, and occupies much valuable land (not to speak of time), and it is for this reason that in past days much of the cloth to be bleached was sent over from England to Holland. A particular kind of cloth which was regularly sent to Holland received on that account the name of "Holland"; and another kind of linen which, owing to its fineness, was spread on the better grass-fields or lawns, received the appellation of "Lawn."

Let us now enquire into the chemistry of this the simplest form of bleaching. Till comparatively recent times it was thought that the only agent in the natural mode of bleaching was resident in the sun's rays. Chemical change, both of combination and decomposition, but more particularly the latter, can be effected by the action of light, and many instances of this may be cited. Such change is chiefly produced by certain invisible rays which accompany the luminous rays of the sun, though the latter also under certain circumstances exert similar powers. The chemically acting rays are sometimes called "actinic" rays, and the peculiar agency or principle associated with light and heat in the sun's rays, and upon which their chemical power depends is known as actinism. This power was first discovered by M. Berard in 1812. It is essential to the growth and development of all the higher orders of plants, and to the existence of healthy animal life. But the discovery of the substance called *ozone*, which possesses powerful bleaching properties, and which in greater or less quantities exists in the atmosphere of country districts, led to the opinion now held by chemists that the bleaching which takes place when cloth is moistened and exposed to the air is mainly due to the *ozone* present in the atmosphere, and this is proved by the fact that in town districts, where little or no *ozone* exists, cloth is never able to be bleached perfectly white.

Ozone, which is a gas, was discovered by Schönbein of Basle, and when first identified was supposed to be a new elementary principle analogous to chlorine, but is now known to be *oxygen* in a second or allotropic state—*oxygenized oxygen* as it is sometimes called—in which it exhibits increased activity and new properties. Roscoe describes *ozone* as *oxygen* in a condensed state, being $1\frac{1}{2}$ times as heavy as *oxygen*; that is, 3 volumes of *oxygen* condense into 2 volumes of *ozone*. Thus the molecular formula of *oxygen* being O_2 , that of *ozone* would be represented by O_3 .

Ozone can be prepared artificially by hanging a piece of phosphorus in a bottle filled with moist air, or by the action of strong sulphuric acid on permanganate of potash (a substance which in the form of a solution is familiar as "Condy's Fluid"). *Ozone* is, however, largely produced in Nature by electric discharges which occur during thunderstorms, and the credit of purifying the air commonly attributed to "thunder and lightning" must be given to *ozone*. This same substance is of the utmost importance in the plant economy as helping to form the higher compounds of nitrogen for the nutrition of plants. *Ozone* derives its name from the strong and peculiar metallic odour which characterizes it. Of course its artificial preparation is of no practical value, and in fact it would be almost impossible to perceive it in a room full of people. Besides, as I have indicated, it is the free

ozone in Nature, and not artificially prepared ozone that is of importance in the bleaching process. But, how does *ozone* act as a bleaching agent? Let me first state that ozone bleaches by oxidation. Now change of colour is a very common accompaniment of chemical change. This is of the utmost importance in chemical tests as all students of practical chemistry will know—the mere application of heat is sometimes sufficient to produce a loss of colour, instance the case of sulphate of copper or bluestone. In the same manner oxidation nearly always produces change of colour (as in the conversion of ferrous into ferric oxide), and so the oxidation by ozone of the colouring matter (that is the coloured substance diffused throughout the tissues of the material to be bleached), tends to produce a change or rather a loss of colour and to whiten the material. Why, it may be asked, is it that the oxygen of the air, constituting as it does one-fifth of the whole atmosphere—why is it that this oxygen does not readily oxidise all oxidisable substances? Well, oxygen does oxidise a good many substances, as those who have studied the “weathering” of rocks know; but there are a good many other substances which are not easily or not at all oxidisable by the normal form of oxygen, but require the more active form of “oxygenated oxygen” or ozone before oxidation, *i.e.*, combination with oxygen can take place.

Again, the question may suggest itself, why is ozone a more active oxidiser than ordinary oxygen? The answer to this question is: In consequence of the readiness with which the molecule of ozone gives away a part of its oxygen and reverts to the normal molecule of oxygen. For reasons, which I will not attempt to explain here, there are some substances which are stable and others which are unstable; that is to say, some have a character of permanency and others have a tendency to decompose or change their chemical condition. Ozone is one of these unstable bodies, and as I said before, has a tendency to revert to the normal and stable condition of oxygen, whenever circumstances favour the change. This may be better understood by saying that the 3rd atom of oxygen in ozone or O_3 is not firmly held in the molecule, and has therefore a tendency to break away and join some other substance and to oxidize it, leaving behind two atoms of oxygen which form the normal oxygen molecule. (I am going into this explanation rather fully since it applies also to the case of other bleaching agents.)

A molecule is the smallest particle of any substance that can exist in a free state, and a molecule is made up of more than one atom; for instance, the molecules of Hydrogen, Nitrogen, and Oxygen each consist of two atoms, and they are therefore represented by the molecular formula H_2 , N_2 and O_2 —the figures indicating the number of atoms in the molecule. Ozone, as I said, consists of three atoms of oxygen, and is represented by the formula O_3 . Now when ozone, for the reasons mentioned, tends to be reduced to O_2 (normal oxygen), one atom of oxygen or O becomes separated, but as we have seen, one atom of oxygen cannot exist in a free state but must become united either to another atom of oxygen or to another atom of some other element or to a group of other dissimilar atoms. And it is this readiness of the atom of oxygen that has been liberated by ozone on its conversion to common oxygen, it is this readiness to combine with other substances that makes ozone such an active oxidising agent, that is such a powerful bleaching agent,

for when ozone oxidises a vegetable colour it bleaches it. The condition of an element the moment it is liberated from a compound is known as the “nascent state,” (which is in reality only a transient state), and it is the fact that ozone sets free “nascent oxygen” that makes it a more active chemical agent than ordinary oxygen, and stamps its character as a powerful oxidizer and bleacher. The natural process of bleaching is also taken advantage of for the decolorizing of oils.

Another chemical agent that bleaches by oxidation is Hydrogen peroxide. The molec. formula of this substance is H_2O_2 , and it may be said to be water, which is H_2O , with an additional atom of oxygen, hence it has been called “oxygenated water.”

Hydrogen peroxide was discovered by M. Thenard in 1818, and may be prepared among other ways by the action of Hydrochloric acid upon Barium dioxide: when pure H_2O_2 is a thickish liquid. In its chemical properties it closely resembles ozone: and as ozone tends to give up one atom of oxygen and revert to common oxygen, so H_2O_2 tends also to give up one atom of oxygen and become water. Here again it is the nascent oxygen that is the active agent which oxidises and bleaches vegetable colouring matters. In the arts peroxide of oxygen is used to restore the lights of paintings that have become darkened by sulphuretted hydrogen. There is another curious use to which it is put. Though it is no secret that the art of dyeing is made use of by some vain people, it is not, I think, commonly known that they sometimes avail themselves of the opposite art of bleaching! A weak solution of peroxide of hydrogen is sold by hair-dressers for transforming the darker shades of golden tresses into the lighter flaxen tints.

The third and most important bleaching agent is chlorine, as such or in the form of “bleaching powder.” It is the chlorine present in bleaching powder which is the active agent in bleaching, and if we understand the manner in which chlorine acts, we shall be in a position to follow the bleaching action of its compounds.

The element chlorine which is a gas was discovered by Scheele in 1774. It is not found free in Nature, but many of its compounds occur—the most familiar being sodium chloride, common salt. Chlorine can be prepared from common salt by beating it with sulphuric acid or oil of vitriol, but is generally prepared in the laboratory by the action of Hydrochloric acid (also called muriatic acid or spirits of salt) on a black powdery substance called manganese dioxide. Chlorine is a greenish yellow gas, whence its name, possessing a disagreeable and peculiar smell. The gas when present in any quantity causes violent irritation and excessive coughing. The most remarkable property of chlorine is its affinity for hydrogen with which it combines to form hydrochloric acid. Now water as before stated is chemically represented as H_2O , and the bleaching action of chlorine depends upon its power of combining with the hydrogen in water and liberating the oxygen. Chlorine without water cannot bleach, and water without chlorine cannot bleach, but the two together, forming what is known as “wet-chlorine” exerts a bleaching action.

Here we again have nascent oxygen whose powers of oxidation and bleaching we are already acquainted with. Chlorine may be termed an “indirect bleacher,” because of itself it cannot bleach—it cannot oxidise because it has no oxygen to give—but it is able by its attraction

for hydrogen to induce water to part with its oxygen which in the nascent state is able to bleach as well as disinfect, that is to convert colouring matters and many offensive gases and vapours into colourless and inodorous substances.

We next come to "bleaching powder" which has acquired the erroneous name—that has stuck to it—of "chloride of lime." Bleaching powder is in reality a compound of calcium chloride and calcium hypochlorite with the formula CaCl_2 , CaCl_2O_2 . It is prepared on a large scale by passing chlorine gas into chambers on the floors of which a layer of slaked lime about 2 inches thick is spread—the gas is all absorbed and bleaching powder formed, *i. e.*, slaked lime and chlorine give bleaching powder and water. In all processes of bleaching by means of "bleaching powder," the material to be bleached has first to be "sour" or dipped in an acid solution. This is a very important operation as I shall show you presently. In the early days of bleaching "sour milk" was used in carrying out this operation, owing to the lactic acid it contained, but it was afterwards found that a stronger acid, namely sulphuric acid, reduced the time required for bleaching by one half. Now, what is the importance of this "souring"? Well, in bleaching powders we see that we have chlorine, but the chlorine is, as it were, locked up; and we must somehow set it free. The setting free of chlorine is brought about by the action of the acid. When sulphuric acid comes in contact with bleaching powder the calcium hypochlorite is first acted upon and hypochlorous acid formed; next the calcium chloride is acted up and hydrochloric acid formed; and these two acids reach upon each other to form chlorine and water.

Thus by the use of an acid, or by the process of "souring" the bleaching powder is decomposed and finally yields the bleaching agent, namely chlorine, whose action in combination with water as "wet chlorine" we have already seen; and goods to be bleached by bleaching powder must be dipped in a solution of it as well as in a dilute solution of acid; it does not matter which operation is carried out first, the only essential being that the bleaching powder and the acid should meet together in the material and liberate within its tissues the chlorine which in conjunction with water does the bleaching work. Chlorine as gas or as bleaching powder is also used for bleaching paper materials such as old rags, paper pulp as well as cotton waste. Printed paper as books, engravings, maps &c. that have been stained or discoloured may also be whitened by the use of dilute solutions of bleaching powder. Again, chlorine is useful in the process of bleaching sponges, and as dilute bleaching powder solution, for whitening straw.

Another bleaching agent that is worthy of some note is sulphur dioxide or sulphurous acid gas. It is used in the bleaching of silks, woollens, straw, &c.

The gas, which is produced when sulphur is burnt in air or oxygen, has the peculiar suffocating odour of burning brimstone, and possesses the power of extinguishing flame, on which account it has been used with success in the putting out of chimney fires.

When silk is required to be very white, as for gloves, stockings, &c., the goods are cautiously submitted for two or three hours to the action of the fumes of burning sulphur, or they are sometimes immersed in a solution of the gas. Woollen goods and fleeces are sulphured in sealed

rooms in which sulphur is left to burn. In the process of removing printed paper, such as engravings, maps, books, &c., the articles are exposed to sulphur fumes after being slightly moistened. In bleaching straw goods sulphuring is done in a "sulphur chamber" or stove. Sulphuring is a method of sophistication employed almost universally where fruit drying and preserving are carried on wholesale. The object of sulphuring fruit is to brighten the colour of the fruit, and to secure it from the attacks of insects. The operation has, however, been condemned as being more or less prejudicial to the health of the consumers. Not long ago another objectionable mode of sophistication was brought to light, namely the colouring of "green peas" by means of sulphate of iron or green vitriol, and this imposture was traced out owing to symptoms of poisoning following the consumption of the adulterated articles. In Ceylon sulphuring is known to be used in the bleaching of cardamoms, and it is to be hoped it will not go further and extend itself to other products whose value is ruled by outward appearance as well as other qualities such as cocoa.*

And how does sulphur bleach? Sulphur in burning takes up two atoms of oxygen from the air, forming sulphurous acid gas, SO_2 which is the bleaching agent under consideration. The fumes may be used or a solution of the gas in water is sometimes conveniently employed, for one volume of water dissolves about 30 volumes of the gas at the ordinary temperature. Now sulphur dioxide, to use the shorter name, SO_2 in bleaching, acts in a manner exactly opposite to that in which chlorine acts, inasmuch as it either directly removes oxygen from the colouring matter present, or it does so indirectly in the presence of water by itself removing the O from water and allowing the Hydrogen to rob the colouring matter of some of its oxygen. With the oxygen it takes to itself SO_2 unites to form a higher oxide SO_3 .

Thus the bleaching action of SO_2 is a "de-oxidising" or "reducing" action, (since it takes away oxygen), while the bleaching action of chlorine as well as of ozone and peroxide of hydrogen is an oxidising action.

Sulphur dioxide does not entirely destroy colour, as chlorine does by oxidation, but by its reducing action produces a loss of colour which in a sense is not permanent, for dilute acid or alkaline solutions tend to restore the lost colour. Flowers bleached by sulphur dioxide regain their colour when dipped into dilute acid. Again, new woollen goods or garments, such as flannels, blankets, &c., though almost colourless when new return to their natural yellow after repeated washing, for the washing soda which may be used, or the potash or soda present in the soap employed, helps to destroy the colourless compound formed in the texture of the wool during sulphuring and resuscitates the original colour.

The last bleaching agent of any importance is chromic acid in the anhydrous form, represented chemically as CO_3 and also called chromium trioxide. It is prepared by the action of sulphuric acid on bichromate of potash. Chromic acid is thus got as red needle-shaped crystals, soluble in water. Now this chromium trioxide is easily reduced to the sesqui-oxide C_2O_3 in the

* In preparing the "uncoated ginger" of Jamaica for medicinal use, the fresh rhizomes after being scraped, washed and dried, are afterwards bleached by being subjected to the fumes of burning sulphur, or immersed in a chlorinated bath.

presence of organic matter and in the change oxygen is energetically evolved. The ease with which chromic acid parts with some of its oxygen and becomes reduced to the green sesqui-oxide, constitutes its value as a bleaching agent—bleaching as it does by oxidation. It is largely employed in the arts in calico printing, bleaching of textile fabrics, tallow, oils, &c. Chromic acid has, however, rather fallen into disuse, at any rate so far as textile fabrics are concerned.

I may here mention that there are many chemicals which have the property of extracting and precipitating colouring matters, such as sulphuric acid in the case of oils, phosphoric acid in sugar refining and the like, but here there is no true chemical bleaching action. Again, chlorate and manganates, which easily part with their oxygen, have also been proposed as bleaching agents, but have never been accepted with favour.

I have thus endeavoured to bring before your notice, in as general a manner as possible, the most important bleaching agents, and to explain the manner in which they exert their bleaching action. There are of course many modern patent preparations that have been offered to the public as "bleachers," but these, if their composition be made known will most probably be found in every case to owe their action as such to one or other of the chemical agents I have mentioned. Here for instance is the description of a preparation made known within the last few months, and called

OZONINE.—A new product, called ozonine, appears to be destined to render service in the bleaching industries. In the proportion of 15 grains to a quart of water, the product acts energetically upon fibres, wood, straw, cork, and paper, as well as upon solutions of gum and upon soap, and the effect of the bleaching is identical in acid and alkaline solutions. The product is obtained in the following manner:—125 parts of resin are dissolved in 200 parts of oil of turpentine, and to this is added a solution of 25 parts of hydrate of potassa in 40 parts of water and 90 parts of peroxide of hydrogen. The jelly obtained, on exposure to the light, changes in two or three days into a clear fluid, to which the name of ozonine has been given.

And this brings the consideration of my subject to a close, and I trust it has proved of some little interest to you. A knowledge of the science of such processes as bleaching, whether in this case it will merely help you to understand the action of the sun and air upon the linen laid upon the grass or hung upon the line, or whether it will go further and aid you in discovering the best means of bringing into a more marketable form our fibres and paper-making materials, oils, and wax, and other substances that are capable of being bleached by any one of the agents I have indicated, and whose action I have attempted to explain, I say such knowledge is never useless, and if I have been instrumental in adding in the smallest degree to your stock of technical knowledge, I shall be perfectly satisfied with myself this evening.

THE TEA ROLLER PATENT CASE. LEAVE TO APPEAL TO PRIVY COUNCIL REFUSED.

Today (Nov. 25th.) Chief Justice Bunside delivered the following judgment in the tea roller patent case, *Jackson v. Brown* and the Colombo Commercial Co., refusing the defendants' application for a certificate preparatory to the hearing of the case in review and to leave being granted to appeal to the Privy Council. Mr. Justice Lawrie concurred.

This was an application by the defendants praying for a certificate under the 781st sect. of the Civil Procedure Code for hearing in review previous to appeal to Her Majesty in Council. The plaintiff showed cause against the granting of the certificate. The action is in the District Court of Colombo by the plaintiff against the defendants' alleging an infringement of a patent and the prayer was for (1) an injunction to restrain the infringement; (2) for an account of all gains and profits derived by defendants from importing into use and sale of infringement of plaintiff's patent and a decree for the amount of such gains or profits accruing from such infringement; (3) for costs; and (4) for further relief. The defendants traversed the infringement, and at the trial on the merits in the Court below the learned District Judge dismissed the plaintiff's action with costs on his finding of fact that the defendants had not infringed the plaintiff's patent, and the plaintiff appealed to this Court. On the appeal the District Judge's finding of fact was reversed and the judgment of the Court below was set aside, this Court holding on the facts that there had been an infringement by defendants of the plaintiff's patent. The following is

THE DECREEAL ORDER

which the defendants desire to appeal from:—"It is ordered and decreed that the decree made in this action by the District Court of Colombo and dated the 2nd day of May 1892 be and the same is hereby set aside, and in lieu thereof it is decreed and declared that the plaintiff is entitled to, and it is accordingly ordered that the said District Court do issue an injunction restraining the first defendant and the second defendant company or their servants, agents, or workmen severally from importing into, using, selling or procuring to be imported, used or sold in Ceylon, any tea leaf rolling machine possessing the arrangement of transmitting motion to the top rolling surface through the case or jacket surrounding it as described in the plaint and in the specification therein mentioned and claimed by the plaintiff as novel and original, and further from infringing the plaintiff's grant of exclusive privilege and invention, in manner aforesaid, and it is also further ordered and decreed that the case be and the same is hereby remitted to the said District Court in order that the District Judge may deal with the plaintiff's prayer for an account of all gains and profits derived by each of the defendants from the importing into use and sale in Ceylon of tea leaf rolling machines infringing as aforesaid, imported into Ceylon or used or sold here by the defendants or either of them or by any person or persons by the order or for the use of the defendants or either of them, and that thereafter the defendants be severally ordered to pay to the plaintiff the amount of the gains and profits so derived by them, and it is also further ordered and decreed that the defendants do pay the plaintiff the costs of this appeal." By the Courts Ordinance and by the provisions of the C. P. Code cl. 63.

THE POWER OF THIS COURT TO GRANT LEAVE

to appeal to the Privy Council is restricted to cases in which an appeal is sought against a party or parties to a civil action—(1) a final judgment, decree or sentence or against any rule or order made in any such civil suit or action having the effect of a final or definitive judgment decree or sentence. And by sect. 42 sub-sect. 2 of the Courts Ordinance every such judgment, decree, sentence, or order shall be given or pronounced for or in respect of a sum or matter at issue above the amount or value of Rs. 5,000, or shall (2) involve directly or indirectly the title to property or to some civil right, exceeding the value of Rs. 5,000. It is not possible to read the Courts Ordinance and the Civil Code on this subject together without, I admit, encountering some if not considerable confusion; but I think it is clear that both provisions contemplate that the judgment to be appealed against must satisfy the material requirements, which I have just quoted. But whether it is the judgment in review which is the matter of appeal or the judgment reviewed

is certainly not clear and both Ordinances leaves it quite open that it may be both judgments. The 42nd section of the Courts Ordinance refers to

THE DESIRE IN THE FIRST PLACE TO APPEAL against the judgment at first pronounced, and the first proviso declares that before any "such appeal" shall be "so brought" such judgment shall &c. The plain meaning of this is that whatever occurs subsequently that is the judgment to be appealed against. Then the second proviso refers to "such judgment &c. in review" clearly referring to the judgment in review which under the latter part of the previous proviso the Court had had authority to pronounce, and it is to that judgment in review only that the provision as to value, finality &c. attaches; and it is the third proviso which gives direct authority to appeal against such judgment. But when we come to the Code we find that precisely as in the Courts Ordinance it refers to the right to appeal to Her Majesty against any final judgment, decree &c., and the desire to appeal against such judgment. It is therefore the original judgment against which the desire must exist to appeal, and it is this judgment by section 780 that he must apply by petition to have brought in at review, and against which he must state his grounds of appeal, and he must pray for a certificate that as regards amount or value or nature, the case fulfils the requirements of section 42 which I have just quoted, or that it is otherwise a fit one for appeal to Her Majesty in Council. I will dispose of this latter exception directly. Here then by the Code with regard to the original judgment, as by the Courts Ordinance with regard to the judgment in review,

FINALITY AND VALUE

are essential ingredients; and that this was distinctly contemplated is made clear by the subsequent 782nd section which declares that the judgment decree or sentence of the Supreme Court after such hearing in review shall be pronounced in accordance with the rules hereinbefore prescribed for the judgment and decree on appeal. And then comes section 783 which says the person feeling aggrieved by such judgment in review shall if he desires to appeal therefrom, apply &c. I do not think therefore it possible to successfully contend that no conditions attach to the judgment at first pronounced, and that every such judgment must be heard in review if desire to appeal is asserted. The question therefore for us to decide is—does this judgment or decree in question come within the category of those above enumerated and against which only we are empowered to grant a certificate that it may be heard in review previous to appeal to Her Majesty in Council. I have most carefully considered it without any reference to my own feeling or inclinations except so far as they would naturally lead me to grant leave, if I thought we had the power to do so, and I can arrive at no other conclusion than that we have

NO POWER TO GRANT THE CERTIFICATE

asked for. In disposing of the question it is proper to deal with the provisions of the Code as to the value of the judgment. Till that point is settled it is immaterial whether the judgment, decree or order be final or not. And this brings us to decide at once whether the judgment is given or pronounced for or in respect of a sum or matter at issue above the amount or value of Rs.5,000. For myself I have no hesitation in saying it is not. It is on the contrary as yet and so far only a judgment given and pronounced upon the bare question of fact of infringement or no infringement, and involves no definite sum or matter at issue of any definite value save and except the costs of appeal. Then does it involve directly or indirectly the title to property or to a civil right exceeding the value of Rs.5,000? It was not denied at the hearing that upon the face of the proceedings it was not easy to gather what was the value of the property, the right to which was affected by the judgment but it was suggested that this Court might order information to be obtained by enquiry

in accordance with some dictum based on circumstances only which is to be found in the older authorities of this Court, in which it was assumed that a money value could be attached to a decree for a divorce upon a fiction as to the value of every marriage. It is scarcely necessary to say that these dicta are of little or no value in the light of decided authorities by which we must be governed. Lord Selborne laid down the rule in *Allan v. Pratt*, 57 L. C. P. C. that the judgment is to be looked at as it affects the interests of the party who is prejudiced by it, and who seeks to retrieve himself from it by appeal. If there is to be a limit of value at all, that seems evidently the right principle on which to measure it, and looking at this case upon that principle I cannot see how it can be but that the value of any right or property affected by it exceeds Rs.5,000. Coming to the question as to the finality of the judgment, I am also of opinion that the partial decision of the action by our decree is not final so as to bring it within the category of judgments or orders upon which we are permitted to allow an appeal.

THERE CAN BE BUT ONE FINAL DECREE

in an action and this is certainly not the final decree. No final decree can be made till the District Court has adjudicated on the matter remitted to it and which involves the decision of the general question of costs. As the decree in respect of which the certificate in review now stands, it is final on a question of fact, but not final regarding the object of the suit, viz. damages for the infringement of the plaintiff's patent. I am now brought to the words to which I had promised to refer and which find place in the order with respect to the original judgment, but are not to be found in the Courts Ordinance or in the Code, in relation to the judgment in review, viz. "Or that it is otherwise a fit one for appeal to Her Majesty in Council." Beyond the fact that these words have been taken from the Indian Code I cannot find any authority as to their intent and meaning. I am disposed to think that they have found their way into our law rather through inadvertency than from any deliberate intention to confer on a single judge of this Court

AN UNLIMITED DISCRETION

to grant a certificate in any case in which one judge of this Court may consider a fit one for appeal. Looking at the source from which the words come I think they must be construed to refer to those cases peculiar to India in which the particular laws and customs and social life of the people often call on her local courts to decide large questions involving not merely rights of property but of personal status and of caste affecting at once Imperial interests and rule, and as well, the interpretation of many systems of law. I have carefully examined the reports of all the cases dealt with by the Privy Council for the last 30 or 40 years and I can find none on which an appeal has been taken by leave of the local courts on principles analogous to this case. The defendants have the right to go to the Privy Council for

SPECIAL LEAVE

to appeal and looking to the practice of the Council not to grant special leave in those cases in which the Court below have improperly granted leave which has been set aside. I feel it the safer course and move in the interests of the defendants to refuse a certificate, and so leave them free to go to the Privy Council for special leave which will certainly be granted if we are wrong, without the prejudice against granting special leave, if without authority we grant leave improperly. I would add that my brother Lawrie whilst concurring in this judgment, has had some difficulty in arriving at the conclusion that it is requisite that the judgment sought to be appealed from should, in the first instance, and before a certificate is granted, disclose the money value referred to in the Ordinance. His opinion was that it was only the judgment in review to which the value qualification applied, and in agreeing with this judgment he has done so more in deference to the

strong opinion which, as head of the court, I have expressed. And I may say with regard to the Inventions Ordinance which contains a clause giving a right of appeal to the Privy Council, that clause requires that the appeal shall be governed by the same rules as those laid down in the charter. The charter has since been repealed and the terms of it re-enacted in section 42 of the Courts Ordinance, so that our judgment applies as well to the right of appeal as given by the Inventions Ordinance.

GEIKIELITE AND BADDELEYITE, TWO NEW MINERAL SPECIES.

Various pebbles were lately brought to this country by Mr. Joseph Baddeley, who has been acting as manager of a Gem and Mining Company in Ceylon. They had been picked up by him in the neighbourhood of Rakwana (Rackwanné) at various times, and had then attracted his special attention by reason of their high specific gravity. Their real nature not being evident on inspection, Mr. Baddeley, when invalid brought them home to England for identification.

One kind of pebble, kindly analyzed for him by Mr. Caudet, was found to be essentially a tantalate of yttrium.

Pebbles of another kind were taken to the Museum of Practical Geology in Jermyn-Street for examination. The external characters being found by Mr. Pringle insufficient for the determination of the species, the pebbles were handed over to Mr. Allan Dick for chemical investigation. Quantitative analysis proved the mineral to be essentially magnesium titanate ($MgTiO_3$) and chemically analogous to Perovskite, calcium titanate ($CaTiO_3$). To this interesting new species Mr. Dick, in a paper read before Mineralogical Society in June, gave the name Geikielite, in honour of Sir Archibald Geikie, F.R.S., Director-General of the Geological Survey, in whose laboratory the analysis had been made.

As described by Mr. Dick, Geikielite has a specific gravity 3.98 its hardness (6.5) is between that of quartz and felspar. It has a perfect cleavage, with a splendid metallic lustre, and an imperfect cleavage nearly at right angles to the former. The pebbles themselves show no remains of crystal-faces, are bluish-black in colour, and opaque; but thin cleavage-flakes, when seen in the microscope have a peculiar purplish red tint, and in convergent polarized light show a uniaxial figure, of which the axis is just outside the field of vision. When digested with hot strong hydrochloric acid the finely powdered mineral is slowly decomposed, and the titanate acid separates out. In strong hydrofluoric acid complete solution takes place in a few hours. The mineral is infusible with the blowpipe; fused with microcosmic salt it gives the characteristic reaction of titanate acid notwithstanding the presence of a small proportion of oxide of iron.

Shortly after Mr. Dick's paper had been read, Mr. Baddeley courteously offered to allow me to select a single pebble for the British Museum Collection out of his small store of the mineral, the remaining ones being required by him for sending as samples to be used by searchers in Ceylon. But this store, small though it was consisted of more than one kind of pebble, the close similarity of aspect being due to friction against a bit of graphitic which was with them. On this heterogeneity being pointed out, Mr. Baddeley allowed me to take not only the promised pebble of Geikielite, but also those three pebbles which, not being Geikielite, were useless as samples of that mineral. One of the three fragments proved to be garnet, a second was ilmenite—both of them common minerals—but the third, a fragment of a crystal still retaining some of its faces, presented characters which give it unusual interest.

The fragment, which weighs just over three grams, is black and opaque, and has the general aspect of columbite; its extremely high specific gravity (6.02) and its hardness (6.5) are also suggestive of that mineral

In microscopic fragments it transmits light and is dichroic, changing from a greenish yellow to brown with the plane of polarization of the light; the fragments, when examined in convergent polarized light, show a biaxial figure, the apparent axial angle being large (near 70°); the character of the double refraction is negative. There is only one well-developed zone of crystal-faces remaining on the fragment; it consists of two rectangular pairs of parallel faces (pinacoids) and of four prism faces (m), the faces of one pinacoid (a) being much larger than those of the other (b); the angle am , as determined by means of reflection, is about 44° , but the images of the signal are multiple and wanting in definition; the dispersion of the optic axes indicates that the system of crystallization is mono-symmetric. Two other faces form a re-entrant edge parallel to the larger pinacoid, and inclined to the edges of the well-developed zone, but whether this is really due to twinning or not is far from evident.

The above set of external characters suggested that the fragment does not belong to any of the known species and it became necessary to determine its chemical behaviour, but on account of the necessity of preserving the natural faces of what might possibly be an unique fragment, this was a process demanding great caution; fortunately, the behaviour was such that it was practicable to determine the precise chemical nature of the mineral without interference with the crystal faces, or, indeed, any appreciable destruction of material. It will be sufficient to state here the result, namely that the material is no other than crystallized zirconia; the technical details relative to both this mineral and Geikielite will be given in the next number of the *Mineralogical Magazine*. It is remarkable that, notwithstanding the wide prevalence of zircon itself (silicate of zirconium) the natural occurrence of the oxide of zirconium has not previously been noticed. For this new species I beg to suggest the name Baddeleyite, in recognition of the services of Mr. Baddeley to mineralogical science; but for his close scrutiny of the mineral products of Rakwana, the existence of the above remarkable species would doubtless have long remained unknown. L. FLETCHER.

—*Nature*, Oct. 27.

[This is interesting; and we trust a full account of the researches of Mr. Baddeley and others will be published.—Ed. T.A.]

SECRETS ABOUT TEA.

INTERESTING FACTS AND SUGGESTIONS TO LOVERS OF GOOD TEA—AMERICANS DRINK THE WORST AND CHEAPEST—PAYING \$1,000 FOR FIVE POUNDS OF CEYLON TEA.

Tea drinkers will be interested in an interview a Mail and Expressman recently held with Mr. S. Elwood May, president of the great Ceylon Planters' Tea Company, at No 110 Fifth avenue, in this city. He is a tea expert, and said:

THE PERFECT TEA.

"The perfect tea does not please at first, for two or three reasons. Too strong; or, rather, you use too much of it. Excellent fault, when you find it out and adapt your making of it. Too strong in another sense; that is, you steep it too long and get the tannin. You want the tea without the tannin. Stop, then, between tea and tannin. This applies to all sorts of tea. Hotel and restaurant tea is steeped by the hour, and nobody wants a second cup of it. Tea at home, as a rule, is steeped too long; it is tea and tannin; puckery; wrong in strength; it is tea, strong, not of tea, but of tannin.

THE FAMOUS CEYLON TEA.

"The tea of Ceylon has two strengths: that of tea which is delicate, fine, inspiring, and that of tannin, puckery, harsh, unpleasant, bitter. One is a beautiful amber; the other is dark and forbidding. All tea has these two strengths. A proper steeping extracts the better and leaves the worse. Japan and China teas, at their best, are crasse compared with that of Ceylon, which is new to your taste. This newness

is 'herby.' Why not? Is not tea an herb? Would you have it metallic? Excuse the herby taste for a week; you will, find it outgrowing excuse. Your taste is righting itself.

AMERICANS DRINK THE WORST TEA.

"The worst tea in the world are sold to this country. English Breakfast tea is a name invented to bungbug with; there is no such tea. American teas are weighted and colored; some of them steeped and the leaves 'manufactured' over again. It is useless to say they are poisons—people do not die of them. Taste is perverted. Give it time to recover. Drink the herby tea for a week, but be sure that you follow directions in making it."

This is a fair introduction of tea—pure, clean, fine tea—an attempt to get it made right, steeped right and judged deliberately, with some allowance for taste, misled by long habit.

CULTIVATE A TASTE FOR FINE TEA.

Is it worth your while to reform your taste in the trifle of tea? In a week you will know. Let us send you a sample. A primer goes with it with clear and full instructions for steeping. As often happens, they need it most who least suspect it. You shall say you never knew the comfort, the cheer, the power of it. And the tea would be cheap if the price were double.

\$1,000 FOR FIVE POUNDS OF TEA.

Mr. May related this interesting incident:—"As I was sitting in my private office one morning, not long ago, I heard a well-bred woman's voice in the outer office asking our native Ceylon servant if the company could furnish her with Golden Tip Ceylon tea, worth \$200 a pound. I was not long in presenting myself, and informed her that the last sale of Golden Tip Ceylon tea brought at public auction \$183 in London and was brought by an English lord, that it would be impossible to say when the next parcel would be offered, and that only five to eight pounds came to the London market at a time, and that only occasionally. There must have been some of the curiosity I felt as to what she could want with such costly tea depicted on my countenance, for after a short pause she said: "I would gladly purchase five pounds at \$200 a pound, as I am going to give a tea. I am constantly going abroad, and always proclaim, when provoked to do so, that we Americans have the best of everything. I should like to feel that we had entertained our friends in America with tea at \$200 a pound, for I recently read of the sale of tea you speak of in London at \$183." I was so carried away with her national pride, that I forthwith offered, if she would permit me, to send her some of our best Bud tea, with my compliments. After her departure my mind turned to other whims that rich Americans had indulged in, and I concluded that nowhere are there so many people willing to spend fabulous sums for the gratification of their pride and fancies."—*New York Mail and Express.*

REMINISCENCES OF A TRAVANCORE

PLANTER.—II.

The first tea bushes that I saw in Travancore were some planted in the garden of Mr. John Grant's hospitable bungalow at Mahendragherry, on the Assamboo Hills, where an old friend and myself arrived fresh from home in the beginning of 1871. I did not pay much attention to them, as my mind was at that time full of coffee; but, so far as I remember, there were two varieties, planted on each side of a garden path, one being Assam indigenous, and the other Assam hybrid. There were, I think, only a few bushes, and they were allowed to grow up to their natural height. No use was made of their leaves, and they were less objects of economy than curiosity, though I believe in later years their seeds were found particularly useful, and these few trees are the ancestors of many tea estates in Assamboo. Whether these were the first tea bushes planted in Travancore I cannot say for certain, but I fancy those planted by Mr. Maltby at the Peermaad Residency are older, though the latter, as I said in my former article, are of

very inferior *jat*. When I went to Peermaad at the end of 1871 there were patches of China or China hybrid tea round every bungalow. But little use was made of it, and though occasionally some hold man made experiments in tea manufacture, making his "boys" roll the leaf, and firing it in the common chatty or the domestic frying pan, the result was not altogether pleasing. The bot, might sip his home-made tea with a smack of pleasure and try to deceive himself into a sense of enjoyment, but his guest was not so amenable. He would not like that tea; he even, with great politeness suggested comparisons between its flavour and that of nauseous drugs, and the result was that these little flickering attempts at tea-making always died out, and domestic tea came up to the hills in packets with the other stores. One estate, which had a few acres of tea planted on grass-land, was hold enough to make a whole break of tea and ship it to the London market. But the result was very disappointing. The Brokers wrote disparaging—not to say insulting—remarks on the shipment; the price obtained was unprofitable, and the experiment was not repeated. Some samples from the 'Mary Ville' garden near the Peermaad Residency were favourably reported on by the London Brokers, but I do not think this resulted in any tea being shipped home, the tea from this little experimental garden being sold annually at Alleppy, where cardamoms and other Travancore Sircar produce are disposed of.

I believe the first tea clearing in Travancore for which forest land was felled, and the produce of which has regularly gone to the London market was planted on the Penhurst Estate in the Peermaad District in 1877. The manager had at the time 100 acres of coffee, but, owing to leaf-disease and heavy monsoons, was having a bad time of it. Every Spring the trees looked beautiful. They were covered with dark green leaves, the blossoms came and set, and a big crop seemed too great a certainty to bet on. Then the South-West Monsoon came raging and threshing among the trees; the dire red fungus ate away the leaves; the branches died back, and held out, as if in derision, their bare black tips; and the immature berries, weary of the rain and wind and leaf-disease, were lying on the ground in bushels. Some stuck to their posts on the branches, and swelled and ripened into pickable cherry, but these were, if possible, more disappointing than their fallen friends. They were comely to the eye, but there was no coffee inside them—nothing but a black smelling mass of sodden rot. Ruin seemed advancing on that manager by leaps and bounds. He tried manuring; but it was of no use—the manure might affect the soil, but not the weather or the climate. Then he considered deeply, and argued with himself thus:—"If China tea grown on grass-land does well; why should not a good *jat* grown on forest-land do better?" There was no debate on the question, which was carried *nem. con.* Several maunds of good Assam hybrid seed were ordered from the Nilgiris; down went twenty-five acres of forest, and in the monsoon of 1877 the seedlings were planted. No Royal children were more anxiously watched than were those young plants in their early struggles for existence. But they well repaid all the care and anxiety bestowed on them. There was no doubt about their growth; they seemed determined to show the poor weather-beaten coffee in the adjoining field that they, at any rate, had found a congenial home, and by the time they were eighteen months old many of them were over six feet high. So far it had all been easy work and plain sailing, but after they had been topped, and a new growth of young leaves were ready to pluck, the difficulties of manufacture loomed large on the manager, and his efforts at making those leaves into tea were crude and peculiar. There were no tea-planting neighbours to go to for help and information, and the assistance derived from books, though very good in its way, was of less value than a little practical tuition would have been. However, one day he plucked some leaves; his coolies rolled them with their hands and made them up into pretty little cones, and then left them to ferment. This

was at mid-day, and the hook said they ought to be left to ferment till they attained a "bright copper colour." About every ten minutes the manager went to look at them, but he could see no trace of anything approaching "copper colour," only a nasty olive green, which kept getting darker and darker. It was still the same when the day waned, so he left those little cones with his blessing till the following morning. He was up early the next day, and hurried to his primitive little glass-built tea house. He did hope that long-delayed "copper colour" had come by that time, and with trembling finger lifted the corner of the black that covered the cones. But, alas! his nose was assailed by a horrid sour smell, and his gaze fastened on a revolting sight of black rotten putrefaction, and all that first attempt at tea-making had to be thrown into the manure pit.

They are very funny to look back upon, those old experimental days, and it is wonderful to think what difficulties ignorance managed to introduce into what is really a very simple process. But experience, though dearly bought, came at last, and thanks to this, and also very greatly to kindly-given hints from tea-planting friends from other Districts, good marketable tea at length found its way from Travancore to Mincing Lane. About 1883 tea planting began to be general throughout Travancore, but it was carried on gradually though steadily. There was no violent rush to plant up large acreages with borrowed money and mortgaged title-deeds. The Travancore planter, as a rule, prefers to keep these in his safe, and to go steadily and cautiously ahead as far and as fast only as his means permit. But the industry has now grown from small beginnings to goodly proportions, and is still increasing. The following is about the acreage under tea in each District in Travancore:—Ashambo, 1,500 acres; Punnudi District, 1,180 acres; Northern District 2,260 acres; Peermaad 3,400 acres; High Range 600 acres or a total of nearly 9,000 acres. Of this a large percentage is not as yet in bearing; but when the whole arrives at maturity, the tea exported from Travancore will probably exceed three million pounds annually. The yield varies exceedingly as it is affected by soil, climate and elevation. Individual fields have given as much as 1,100 lb. of made tea per acre, while it is difficult to persuade others, where the soil is poor, or the situation exposed, to rise to a greater effort than 300 lb. Still judging from what the older tea produces, it is safe to estimate an annual average yield of 400 lb. per acre over the whole of Travancore when all the tea now planted comes into full bearing. The climate closely approaches that of Ceylon, and tea thrives at all elevations, from nearly sea-level to the breezy heights of the High Range, about 5,000 feet above the sea, a finer flavour at the higher elevations compensating for a smaller yield than is obtained lower down. The cost of production is small. With an estate in good order and yielding 400 lb. per acre, tea is placed on board ship for under 4 annas per lb., and unless the market be hopelessly demoralised, this leaves a good margin of pr. fit. Prices have lately been very bad, though they are now showing signs of a welcome rise. But though the good old days when we were sure of 1s a lb. and were rather angry if we didn't get 1s 2d, seem to have gone for ever, we can still show a satisfactory result in the annual balance sheet. O clever inventors have been vying with each other in introducing machinery to lessen the cost of labour; and low exchange which means drawing more rupees against our produce with which to pay our coolies, is almost our salvation. I have heard it said that if the rate of exchange rose, prices would follow suit. It may be so, I don't pretend to understand these things. But, personally, I should be sorry to see the experiment tried, and would prefer letting sleeping dogs lie, and leaving things as they are. In many possible ignorance, the price of tea seems to me to be much more a question of supply and demand than of the different values of sovereigns and rupees.

I must conclude with a tribute to the character of my brother-planters, among whom I have spent so many years of my life. A planter, if you come

to consider him, is really a most talented person. He must know something of almost everything—building, engineering, book-keeping—and the more he knows of the subjects the better—besides all the details of planting and manufacture. He must be able to speak the language of the people he works among, and have tact and temper to manage them properly. Where will you find a more hospitable, generous, kind-hearted body of men, more united in trying to attain any desired object, or more ready to forget their little private differences—which, alas! must arise in any community—and stand shoulder to shoulder in repelling any infringement of their rights? Who are keener sportsmen, pleasanter companions, better friends? Twenty-one years is a big slice out of one's life. I might, perhaps, have turned them to better advantage elsewhere. But, on the other hand, I might have done far worse, and if I had the power I would gladly live all those twenty-one years over again among the planters of Travancore. TOTUM.

—*M. Mail*, Nov. 14.

COTTON-SPINNING IN JAPAN.—The cotton-spinning industry in Japan had a period of extraordinary activity during the first half of the current year. The mills in that period produced 41,000,000 lb. of yarn against 44,000,000 during the whole of 1891 and 42,000,000 during the whole of 1890 and the total production of the year is expected to reach a hundred million pounds. Of the ten largest mills only two paid dividends under 10 per cent. for the six months, while others paid 25, 20, 19, 18, 15, 12, and 10 per cent. The explanation of this sudden prosperity is said to be a succession of good rice crops, accompanied by high prices for grain and a great improvement in silk culture and the prices in foreign countries for Japanese silk. The agricultural classes have profited by these and have more money to spend in purchasing yarns. The main advantage of the Japanese cotton spinner is the low price of labour, which is only 6d a day for men and 3d for women; the great obstacle to permanent success is defective organization. The cotton industry in Japan does not depend on protection. There is a small revenue duty on imported yarns and on imported raw cotton, while the mills receive no Government assistance, but are wholly the outcome of private enterprise.—*Times Weekly Edition*, Oct. 28.

CHINESE GINGER.—The Superintendent of the Botanical Department, Hong Kong, writing to the Royal Gardens, Kew expresses his belief that Chinese ginger is much more succulent than West Indian ginger—so much that it is impossible to dry the rhizomes sufficiently to render them fit for export in the usual commercial form,—or, if it had been otherwise, dried ginger would have been exported from China long ago. So far as he has been able to learn, preserved ginger is made at Canton and Hong Kong only. The Imperial Chinese customs returns for last year show that in junks alone the quantity of fresh ginger exported from Canton to Hong Kong was over 6,000 piculs (a picul is 133 lb.). Preserved ginger is manufactured in Hong Kong to a large extent for export to the United States. "Preserved ginger as understood by us, is not made in Swatow. What is preserved there is made for native consumption, to be used medicinally or for cooking, and is exported largely to the Straits Settlements, and never to Hong Kong. This is kind of ginger is called Ng Mai Keung." This is an *Alpinia*, but it does not resemble the Canton ginger, and is not preserved in syrup. The rhizomes of true ginger, *Alpinia* and *Curcuma*, are all classed generically by the Chinese under the name Keung.—*Grocer*.

OUR PLUMBAGO AND GEM MINING INDUSTRIES.

Apparently it must be concluded that to a very great extent the two industries mentioned in the above heading will hereafter be closely allied. As pursued by itself, the second of the two has not hitherto promised to result in much success to the several companies formed locally and at home for the sole purpose of pursuing it; but to judge from what our London Correspondent has written us by this mail, there seems to be at least a fair prospect that a better result may ere long be attained by the Ceylon Gemming and Mining Estates Syndicate formed and promoted chiefly by Mr. Henry Saunders. It will be within the memory of our readers that this Syndicate went to a very considerable expense in sending out an expert, Mr. Barrington Brown, to examine and report on the various properties proposed to be acquired by the Syndicate; and that upon receipt of that gentleman's report steps were taken to secure a very considerable amount of land in several localities. That report was withheld from publication pending the conclusion of certain negotiations entered into with respect to some of the properties it was proposed to acquire. These having now been brought to a successful issue, the report mentioned has been made public, and we are in receipt of a copy of it by the last mail. Mr. Barrington Brown would appear,—to judge from that document—to have carried out the work entrusted to him with much thoroughness; and, on the whole, the tenor of the report was decidedly encouraging to the syndicate, which upon its receipt commenced early operations, the sending out of two practical miners and a quantity of machinery. Although but little has of late been heard of the work performed by the men and the machinery at their disposal, we now learn that time has by no means been wasted. At the present moment active operations are in progress with plumbago pits situate about twenty miles inland from Bontota; but the ore as yet obtained from these has been too mixed with grit to be commercially very valuable. A prospect is held out, however, that ere long the output from the pits will be sixty tons monthly, and of greatly improved quality; and the syndicate has reason for feeling certain that when this amount of yield has been attained capitalists will come forward with the cash necessary to work the other and more valuable properties at Dambetence obtained either by purchase or on lease from their former proprietors. So far as we can form an opinion nothing seems to stand in the way of a prosperous future for the syndicate, but the want of the money to develop properties acquired by it. It started, we believe, with a capital sum of £10,000 subscribed by the few gentlemen composing it. Of this sum £2,000 was absorbed by the expenses attending Mr. Barrington Brown's investigations. The machinery sent out, and the charges for its transport and erection probably cost an additional like sum; and these expenses, added to what had to be paid for the properties secured, reduced the balance of capital available for working and development to a wholly incommensurate amount. Still much progress has been made; and if the prospect mentioned above of turning out sixty tons of plumbago *per mensem* can be realized, there should be little

or no difficulty in obtaining the further moneys required for extended development. This, indeed, we understand to have been promised should such a stage of advancement be reached; and there is some hope, therefore, that both industries may in the future be placed upon a satisfactory basis. Difficulties we know have been experienced with regard to associated gem mining which are not attendant upon the raising of plumbago. Our London Letter, however, mentions a recent invention which, should it fulfil all that it promises, will go far towards overcoming one of the most important of these. The separation of the gems from the *illan* (associated débris of pebbles, &c.) on anything like a large scale has hitherto presented obstacles, as it had to be done by hand, and the operation of course placed much temptation to theft in the way of the natives employed upon it. A description of the new mechanical separator will be found in our London Letter, a stream of water, we learn from our Correspondent's description, being so arranged that the gravity of the gems causes their separation from the gravel under conditions which prevent any attempt at robbery being made. The Syndicate hopes to be able to send out some of these separators, should that branch of its enterprise which deals with plumbago prove to be sufficiently remunerative. In that case we may yet see some measure of success attend the efforts made at gem mining on a large scale. All that is necessary to secure this end is, in the opinion of the Syndicate, adequate capital. Should plumbago be raised in sufficient quantity to enable this to be obtained, both industries may be found hereafter to be flourishing side by side with each other. The leading gems of Ceylon, we may remind our readers, are generally composed of the higher forms of corundum, with which mineral the diamond is associated in India, although this most precious of all stones has never been found in Ceylon. Sapphires and especially good rubies come next to the diamond in value; and our readers may like to see what is said about these and other varieties of corundum in Dana's great work on Mineralogy, of which a copy has just arrived to our order. After quoting names and synonyms and showing the forms of crystallization, the more popular matter runs thus:—

VAR.—There are three subdivisions of the species prominently recognized in the arts, and until early in this century regarded as distinct species; but which actually differ only in purity and state of crystallization or structure. Haüy first (in 1805) formally united them under the name here accepted for the species, though the fact that adamantine spar and sapphire were alike in crystallization did not escape the early crystallographer Romé de Lisle, and led him to suggest their identity.

Var. 1. **SAPPHIRE, RUBY.**—Includes the purer kinds of fine colors, transparent to translucent, useful as gems. Stones are named according to their colors: *Sapphire* blue; true *Ruby*, or *Oriental Ruby*, red; *O. Topas*, yellow; *O. Emerald*, green; *O. Amethyst*, purple. A variety having a stellate opalescence when viewed in the direction of the vertical axis of the crystal, is the *Asteriated sapphire* or *Star Sapphire* (*Asteria* of Pliny). The ruby sapphire was probably included under the *ἰσθαλί* of Theophrastus, and the *Carbunculus* and *Lychnis* of Pliny. The blue sapphire (Ceylon) was called *Salamstein* by Werner.

Barklyite is a more or less opaque magenta-colored ruby from Victoria, cf. Liversidge, Min. N. S. W., 198, 1888. *Chlorosapphir* is a deep green variety occurring in bombs of a "sanidine-gneiss" enclosed in an ancient trachytic tufa at Königswinter on the Rhine, cf. Polig. Ber. nied. Ges. May 7, 1888.

2. **CORUNDUM.**—Includes the kind of dark or dull colors and not transparent, colors light blue to gray, brown, and black. The original adamantine spar from India has a dark grayish smoky-brown tint,

but greenish or bluish by transmitted light, when translucent, and either in distinct crystals, often large, or cleavable-massive. It is ground and used as a polishing material, and being purer, is superior in this respect to emery. It was thus employed in ancient times, both in India and Europe. The "Armenian stone" is supposed by King to have been corundum rather than emery.

3. **EMERY.** *Schmirgel Germ.*—Includes granular corundum, of black or grayish black color, and contains magnetite or hematite intimately mixed. Sometimes associated with iron spinel or hercynite. Feels and looks much like a black fine-grained iron ore, which it was long considered to be. There are gradations from the evenly fine-grained emery to kinds in which the corundum is in distinct crystals. This last is the case with part of that at Chester, Massachusetts. The specific gravity varies rather widely, $G. = 3.75-4.31$ Smith.

Comp.—Alumina, $Al_2O_3 =$ Oxygen 47.1, aluminium 52.9 = 100. The crystallized varieties are essentially pure; analyses of emery show more or less impurity, chiefly magnetite.

For analyses, etc., see J. L. Smith, *Am. J. Sc.*, 10, 354, 1850, 11, 53, 1851, 42, 83, 1866, and 5th Ed., p. 139.

PR., ETC.—B.B. unaltered; slowly dissolved in borax and salt of phosphorus to a clear glass, which is colorless when free from iron; not acted upon by soda. The finely pulverized mineral, after long heating with cobalt solution, gives a beautiful blue color. Not acted upon by acids, but converted into a soluble compound by fusion with potassium bisulphate.

Obs.—Usually occurs in crystalline rocks, as granular limestone or dolomite, gneiss, granite, mica slate, chlorite slate. The associated minerals often include some species of the chlorite group, as prochlorite, corundophilite, margarite, also tourmaline, spinel, cyanite, diaspore, and a series of aluminous minerals, in part produced from its alteration. Occasionally found in ejected masses enclosed in younger volcanic rocks, as at Königswinter, Niedermendig, etc. Rarely observed as a contact-mineral. The fine sapphires are usually obtained from the beds of rivers, either in modified hexagonal prisms or in rolled masses, accompanied by grains of magnetite, and several kinds of gems, as spinel, etc. The emery of Asia Minor, Dr. Smith states, occurs in granular limestone.

The best rubies come from the mines in Upper Burma, north of Mandalay, in an area covering 25 to 30 square miles, of which Mogok is the centre. Also found in the marble hills of Sagyin, 16 miles north of Mandalay. The rubies occur *in situ* in crystalline limestone, also in the soil of the hillsides and in gem-bearing gravel. All the crystallized varieties of the species occur here; the spinel ruby is a common associate. A ruby weighing 304 carats is said to have been found here in 1890. Rubies and sapphires have also been reported from other localities, and the massive varieties are common especially in the crystalline rocks of Southern India. Ruby mines have also been worked at Jagdalak, 32 miles east of Kabul, Afghanistan. Some fine sapphires were obtained in 1882 from the Zanskar range of the Kashmir Himalayas near the village Machel in Padar, and since then mining has been carried on there with some success (Mallet, *Min. India*; La Touche, *Rec. G. Surv. India*, 23, 59, 1890). Blue sapphires are brought from Ceylon, often as rolled pebbles, but also as well-preserved crystals. Corundum occurs in the Carnatic on the Malabar coast, on the Chantibun hills in Siam, and elsewhere in the East Indies; also near Canton, China. At St. Gothard, it occurs of a red or blue tinge in dolomite, and near Mozzo in Piedmont, in white compact feldspar. Adamantine spar is met with in large coarse, hexagonal pyramids in Gellivara, Sweden.

Emery is found in large boulders at Naxos, Nicaria, and Samos of the Grecian islands; also in Asa Minor, 12 m. E. of Ephesus, near Gumuchdagh, where it was discovered *in situ* by Dr. J. Lawrence Smith associated with margarite, chloritoid, pyrite, calcite, etc.; and also at Kulah, Adula, and Manser, the last 24 m. N. of Smyrna; also with the

nacrite (?) of Cumberland, England. Other localities are in Bohemia, near Petschan; in the Ural, near Ekaterinburg; and in the Ilmen mountains, not far from Miask; in the gold-washings northeast of Zlatoust as small crystals (called *soimonite* after Senator Soimonov) in barsovite (Kk. *Min. Russl.*, 1. 30, 2, 80.) Corundum, sapphires, and less often rubies occur in rolled pebbles in the diamond gravels on the Cudegong river, at Mudgee and other points in New South Wales.

In N. America, in *Maine*, at Greenwood, in cryst. in mica schist, with beryl, zircon, lepidolite, rare. In *Massachusetts*, at Chester, corundum and emery in a large vein, consisting mainly of emery and magnetite, associated with diaspore, ripidolite margarite, etc.; the corundum occasionally in blue pyramidal crystals. In *Connecticut*, at W. Farms, near Litchfield, in pale blue crystals; at Norwich, with sillimanite, rare. In *New York*, at Warwick, bluish and pink, with spinel, and often in its cavities; Amity, white, blue, reddish crystals, with spinel and rutile in gran. limestone. Emery with magnetite and green spinel (hercynite) in Westchester Co. in Cortlandt township, near Cruger's Station and elsewhere (*Am. J. Sc.* 33, 194, 1887.) In *New Jersey*, at Newton blue crystals in gran. limestone, with grass-green hornblende, mica, tourmaline, rare; at Vernon, near State line, red crystals, often several inches long. In *Pennsylvania*, in Delaware Co. in Aston, near Village Green, in large crystals; at Mineral Hill, in loose cryst.; in Chester Co., at Unionville, abundant in crystals, some masses weighing 4,000 lb., and crystals occasionally 4 in. long with tourmaline, margarite, and albite; in large crystals loose in the soil at Shimersville, Lehigh Co. In *Virginia* in the mica schists of Bull Mt. Patrick Co.

Common at many points along a belt extending from Virginia across western North and South Carolina and Georgia to Dudleyville, Alabama; especially in Madison, Buncombe, Haywood, Jackson, Macon Clay and Gaston counties in North Carolina. The localities in which most work has been done are the Culsagee mine, Corundum hill, near Franklin, Macon Co., N. C., and 26 miles S.E. of this at Laurel Creek, Ga. The corundum occurs in beds in chrysolite (and serpentine) and hornblende gneiss, associated with a species of the chlorite group, also spinel, etc., and here as elsewhere with many minerals resulting from its alteration. (Cf. Shepard, *Am. J. Sc.* 4, 109, 175 1872; also Genth, l. c.) Fine pink crystals of corundum occur at Hiawassee, Towns Co., Georgia.

In *Colorado*, in small blue crystals in mica schist near Salida, Chaffee Co. Gem sapphires are found near Helena, Montana, in gold-washings and in bars in the Missouri river, especially the Eldorado bar. In *California*, in Los Angeles Co., in the drift of San Francisquito Pass. In *Canada*, at Burgess, Ontario, red and blue crystals.

ALT.—Corundum undergoes extensive alteration, a series of aluminous minerals being the result. The commonest change is to the potash mica damourite, also to spinel, cyanite, fibrolite, zoisite, margarite, and other species. Cf. Genth, *Am. Phil. Soc.* 13, 361, 1873; *ibid* 20, 381, 1882; *Am. J., Sc.*, 39, 47, 1890.

ARTIF.—Formed by decomposing potash alum by charcoal (Gandin); in crystals by exposing to a high heat 4 pts. of borax and 1 of alumina (Ebelmen); by subjecting in a carbon vessel aluminium to the action of boric acid, the process yielding large rhombohedral plates (Deville & Caron); by addition to the last of chromium fluoride in varying amounts, affording the red sapphire or blue sapphire, or a fine green kind; by action of aluminium chloride on lime (Danbrée.) Again by the fusion of alumina and minimum in siliceous earthen crucibles, yielding a fusible lead aluminate which was subsequently decomposed by the silica, setting free the alumina in hexagonal crystals of considerable size (Frémy and Fell); under varying conditions rubies, sapphires, etc., being obtained. Also by the decomposition of aluminium chloride by magnesium and water vapor at a high temperature in a sealed tube (Mennier.) f. Fouqué-Lévy, *Synth. Min.*, 218-224; 1882; Bourgeois. *Reprod. Min.*, 62, 1884.

NOTES FROM OUR LONDON LETTER.

LONDON Nov. 11.

After what I have recently written you as to expressions of complete content spoken by Mr. Farr before leaving London with the prospects now before the American Ceylon Tea Company as the result of the grant of tea made to it by your Tea Fund Committee it was a most serious and disagreeable surprise to me to be shown a letter just received from that gentleman in which he states that the company mentioned is without a farthing of money to carry on its work, and that unless some can be immediately obtained the Company must proceed to early liquidation. When last writing you my doubts were expressed as to

WHAT MR. FARR HAD BEEN ABLE TO ACCOMPLISH in a monetary way before leaving London, and my supposition was stated that he had concluded all his arrangements beforehand conditionally on news as to the grant above referred to being received. We can only surmise now that he had been too hopeful when he spoke as he did to my informant. His letter shown to me does not attempt to explain the discrepancy between his former hopeful view and that he now presses upon our notice. It remarks that Ceylon tea is now on the very "threshold of success" in America but that it cannot advance without immediate financial aid. Already his firm has made very large advances, and he writes that it is

NOT DISPOSED TO PROCEED FURTHER

though it is willing to hold back from any attempt to recover the sum the Company is indebted to it. That indebtedness, Mr. Farr further writes, is the sole debt of the Company, and he thinks that with comparatively slight aid the "threshold" mentioned may be crossed and future success secured. For this end he proposes to issue

£10,000 OF ADDITIONAL SHARES

at par, the selling price of which is to be five shillings per £1 of stock. No doubt it is necessary to hold out some strong allurements to probable investors in this transatlantic scheme, but the price mentioned appear to be rather a startling one. Still it is evident that money must be had somehow or other. Mr. Farr also wrote that he had cabled Mr. Grinlinton as to his pressing needs, and he probably relies much on that gentleman's well-known persuasive powers towards reaching the pockets of planters and merchants in Ceylon. He also declares himself to be confident that he can duplicate every subscription promised in India and Ceylon by a similar contribution in America. Now it seems that

WHAT IS DEEMED REQUISITE

is a cash realization of £2,500. Half of this would be £1,250; and if that sum can be obtained here and in Ceylon, Mr. Farr guarantees the whole demand being secured. You see it is not a heavy pull upon the purses of the numerous people interested in Ceylon tea that is asked for. Mr. Farr has represented his case to

THE CEYLON ASSOCIATION IN LONDON;

and we hear it is in contemplation to call a meeting of the Tea Committee of that body to consider how help can be given to the American Company. All of us here would regret to see this come to grief after so much has already been accomplished; and we hope that the deliberation of the Committee when it meets will decide upon some course which, in conjunction with what you may do in Ceylon, will avert so fatal a retrograde movement with respect to the prospects of a market for your tea in America. The position is decidedly largely connected with

THE FORTHCOMING SHOW AT CHICAGO.

Your representation there must be most injuriously affected if, just at the moment before its opening, it becomes known that your teas have secured so little of success in America that their representative Company has smashed up! What can be done to avert this? we are all asking. The strait is just as annoying as was that Mr. Grinlinton found himself to be in with regard to the funds necessary for the carrying out of his own work; but in this case we can have no taxation to fall back upon such as he has induced the planters of Ceylon to voluntarily submit to. I shall send you early intelligence as to what decision the Committee of the Ceylon Association in London may arrive at. There is no time to be lost if the Company is to be placed in a sound position before the Exhibition at Chicago opens, and most of us consider it to be vital to your island interests that this should by some means or other be done. We hear it said that probably £500 of the shares proposed to be issued could be disposed of here in London. If this should be the case we can hardly suppose that there would be any insuperable difficulty in obtaining a subscription of the balance of £750 in Ceylon; but all efforts towards this end here must await the meeting referred to of the Association's Tea Committee.

THE "ORCHILLA."

It is unknown to me if the orchilla referred to in the subjoined extract is identical with the orchilla weed which is an export from Ceylon. I rather fancy that it is; and in that case the information given in the extract will be of interest to many of your readers.

THE ORCHILLA.—Three interesting reports from United States Consuls, in Lower California, Cape Verd, and Ecuador, dealing with the orchilla lichen and its economical value, have recently been published simultaneously by the Washington State Department. It grows on rocks on the coast of the Canary and Cape Verd Islands, Sardinia, Minorca, and elsewhere, and in some places is described as a manure shrub rather than a lichen. It yields the archil of commerce, which gives a rich and extremely beautiful purple tincture. It was extensively used by dyers when, in 1853, the discovery of the orchilla in America and on the Galapagos Islands is said to have created a commercial sensation in Europe, because of its superiority over any lichen in use prior to that time. In 1872 a ship's captain discovered it in Lower California, and after a few years a certain Mr. Hale succeeded in obtaining a concession from the Mexican Government of the entire orchilla lands on the Pacific coast of that State—a belt six miles broad and comprising nearly eight degrees of latitude. About 3,000 men were employed in the industry; but since the Congo Free State has become the main source of supply the California industry has languished. In the Cape Verd Islands it is plentiful, but difficult to obtain, for it grows on the sides of precipices where it is shaded from the sun the greater part of the day. The export amounts to about 120 tons, and goes mainly to Lisbon. In Ecuador it is gathered by hand, put in the sun to dry and cure, and is then pressed into bales. The demand at present is small. It is used in Europe, especially the Galapagos variety, because of the delicate colour, lustre, and tone that it gives to silk.

THE SEPARATION OF PRECIOUS STONES FROM THEIR MATRIX,

I this week sought an interview with Mr. Henry Saunders, who, it had been told me, would be able to afford me full information with respect to it. That gentleman was kind enough to furnish me with very full particulars, and communication of these to yourselves will doubtless be possessed of interest. You are aware that one of the greatest

difficulties experienced with regard to associated gem mining in Ceylon has been the necessity of having all material excavated picked over by natives, who are of course exposed to much temptation to fraudulently conceal gems found by them when doing this. The invention is intended to overcome this difficulty. It is due to the cleverness of Mr. W. S. Lockart, a member of the Institution of Civil Engineers. The machine designed by this gentleman has a hopper into which is poured the material brought up from the pits. A series of sieves first divides the different sized pieces of quartz or gravel for the purpose of facilitating the further operations. After this is done the gravel is allowed to drop into a tube—which in the instance of the machine now on exhibition is of glass for the purpose of showing the operation in progress. At the entrance to the tube the gravel is met by a stream of water falling, from a height of 18 inches only. This fall is said to be quite sufficient for the purpose, and by its power the quartz particles are forced out of an opening midway down the tube, the whole of the gravel being put into a strong gurgitation during its passage down the tube by the force of the water. But although this force is adequate to deal with the quartz or other pebbles, it is insufficient to affect the greater specific gravity of the gems. It results that, while the quartz is forced out of the tube, the gems fall through the remaining portion of it into a locked receptacle at the bottom. Mr. Saunders told me that he saw a quantity of Ceylon gravel experimented with in this machine. A number of rough gems of different kinds, together with a few nuggets of gold, had been well mixed up in the gravel before it was put into the machine. When the mixture reached the glass tube the effect of the water was seen in it to be what looked like a violent boiling, the particles being strongly agitated and tossed up and down. On reaching the circular slot all the gravel was worked out of it, and the gems and gold could be seen falling through the bottom part of the tube into the receptacle at its base. Not one of the gems dealt with missed falling into this, all those inserted being found in the box. If this invention should prove to be capable of being worked on a large scale all your gemmers will have to do is to guard the security of the stuff excavated until raised to the surface for treatment by it, and one of the greatest difficulties as yet experienced will have been overcome. Negotiations are in progress with the inventor for the despatch of some of these machines to Ceylon, but we believe these cannot at present be completed owing to the uncertainty of the position of

THE CEYLON GEM AND MINING ESTATES SYNDICATE.

In conversation relative to the last matter Mr. Saunders obliged me with many details respecting it. The expenses incurred by the Syndicate in sending out Mr. Barrington Brown in the first place, the despatch to Ceylon of the two practical miners at present working there, the acquirement of land and provision of machinery, have nearly exhausted the capital at first subscribed by the members who formed the Syndicate. It is now necessary, therefore, to raise further capital. The copy of the last report that I send you with this will explain pretty fully how this necessity has arisen. Mr. Saunders tells me that at the present time the miners sent out are working on plumbago pits about twenty miles inland from Bentota. As yet these pits have not been sunk deep enough to insure a good outturn, about 15 tons of plumbago per month having been only as yet obtained, and that too much mixed with grit to

be of good commercial quality. All reports received, however, promise better things, and it is confidently expected that sixty tons per month will ere long be raised. This would pay well, and Mr. Saunders has reason for believing that as soon as that quantity has been secured for three months in succession, ample capital for further extension will be forthcoming. What it is desired to do is to work the old pits secured by the Syndicate at Nambapanie in Dumbara. There are known to contain a large supply of plumbago, but the late proprietors had, we believe, to abandon them because the mines could not be ventilated. Mr. Barrington Brown is of opinion that all difficulty in this respect can be overcome by driving a ventilating gallery, the cost of which will be £2,300; and if means should become available this work will be carried out. The question now before the syndicate is whether a reconstruction of it should not at once be proceeded with; but the prospects of doing this successfully are largely dependent on increased yield being obtained from the pits now being worked. If ultimately the Nambapanie properties can be re-opened the search for gems in their neighbourhood would be resumed, and then Mr. Lockhart's invention will receive thorough trial. It is already exciting much curiosity among the Burma mining companies and those working in South Africa and Australia, though only an experimental machine has as yet been constructed.

MR. BARRINGTON BROWN'S REPORT.

Mr. Saunders further told me that the report made by Mr. Barrington Brown to the Syndicate had been kept private until arrangements had been concluded with respects to certain properties the management desired to secure. These are now complete, and a copy of Mr. Brown's report was given to me. I am uncertain whether you have ever received one of these, so it may be advisable to send you a copy with this; you will observe that it is of a hopeful character.

NOTES ON PRODUCE AND FINANCE.

THE PURITY OF TEA.—A report has been supplied from the Commissioners of Customs, on the examination made by their analyst under the 30th section of the Sale of Food and Drugs Act, 1875, of imported teas before they are taken out of bond. Of the 412 samples of tea procured by the officers of local authorities from retailers during the year, not one was found to be adulterated. This certainly would not have been the case a few years ago, when the import of China tea was on a larger scale.

TEA IN MAURITIUS.—The success of the Ceylon tea-planting industry has filled other Colonists with a desire to emulate it. The planters of Mauritius are turning their attention to tea. The *Kew Bulletin* says:—"We have the pleasure of recording the fact that tea of very good quality has been grown in Mauritius, and a total weight of 865 pounds has been manufactured since January last. This, it is true, is only a small beginning, but if the island produced only sufficient tea for its own consumption it could very well support one or two small estates on hilly land in the interior, not required for other cultivation." The following remarks on tea were written by Mr. John Horne, F.L.S., late Director of Gardens and Forests, in a report on the agricultural resources of Mauritius, published in 1836:—"The tea shrub grows well in the higher lying parts of Mauritius. So far as the climate is concerned the growth of this shrub in most parts of the island that are situated at an elevation of more than 800 feet above the level of the sea is proved beyond a doubt. It has long since been introduced and planted at several places; but what has to be proved is the quality of the tea which the Mauritian grown leaf will produce. Then, whether the yield will be sufficient

to give a profit on the expense of cultivating the shrub picking its leaves, preparing them into tea, as well as other expenses incident to the cultivation of the shrub and the preparation of the leaves for the market, in such a condition as to compete favourably with teas from Ceylon, India, China, Java, &c. There is at present growing in the borders, &c., of the nursery gardens at Curepipe, a number of plants that would yield a sufficient quantity of leaves to test their quality when prepared into tea. So far, then, that test could be applied at once. The wants are appliances to cure the leaf, and a tea maker or curer. If these problems are satisfactorily solved there is not the least doubt that tea will take a place, perhaps, of no small importance, among the products of the colony."

UGANDA AND ITS PRODUCE.—Captain Lugard, at the invitation of the London Chamber of Commerce, gave an address on Saturday at the Cannon Street Hotel on "Uganda: Its abandonment or retention considered from a commercial point of view." He referred to the importance of the cultivation of tea and coffee, and said that cotton had been successfully planted in one district. If they could extend the cultivation of cotton, Lancashire would soon be independent of other markets. The country had capabilities of commercial development, and what was really needed was railway extension. England, he said, was pledged to protect Uganda and to remain in it, and a great disgrace would rest upon this nation if we abandoned a helpless people.

THE CHICORY DODGE.—As an instance of the difficulty surrounding the coffee and chicory question, the public analyst of East Sussex, in his quarterly report alluding to the adulteration of coffee, points out that in the cheap tins the proportion of added mixture is often from 40 to 60 per cent (in one instance 70), and some of them really ought to be labelled "Chicory mixed with coffee." Even at the low prices paid, he says, buyers are losers of the true dietetic value belonging to pure coffee.

THE TRADE RETURNS.—The Board of Trade returns for October do not give signs of improving trade. The decrease of both of imports and exports continues, and so far as they effect the home trade of the country, they may be regarded as confirming the impression which pervades all the great centres of industry in the kingdom, that the winter will be a bad one. According to the return issued on Monday, we find that there was a decrease in the imports for the month of £2,146,971, and for the ten months of £1,468,484. The export trade shows the same results. With the exception of living animals and food and drink there is a decrease under every head, both for the month and ten months. With regard to the import of dutiable articles, we notice a falling off in the imports of tea to the amount of 4,561,543 lb., and in coffee of 10,477 cwt.—*H. and C. Mail*, Nov. 11.

THE CASTLEREAGH TEA CO., OF CEYLON.

The first general meeting of this Company was, according to notice, held at the Company's offices, Colombo, at 3 p.m. today. Present:—Messrs. V. A. Julius, W. Moir, and J. H. Starey (Directors), W. H. Bailey, F. H. Wiggin, G. C. Trask, F. C. Roles, R. Reid, Dr. J. B. Spence; and by proxy, Messrs. C. L. Martin, A. H. Dingwall, B. Bremner. Mr. John H. Starey having been called to the chair, the notice of meeting was read by the Acting Secretary, Mr. A. C. Courtney.

The CHAIRMAN stated that the business before the meeting was mainly formal as it was requisite by the statute for the Directors to retire within a year of the registration of the Company. Unfortunately this did not admit of accounts for the full year being presented, but the full accounts of expenditure and crops for 13 months to 31st Dec. 1892 would be submitted as early as practicable in 1893, probably before the end of January. In view of the exceptional season and general shortness of tea crops in Dikoya the position of the company might be regarded as satisfactory, though far less so than

was anticipated when the estimates were framed. The directors had that day received from the superintendent of the estate a letter confirmatory of the reduced estimates he had submitted about August last, and on this basis a rough estimate of results had been computed. There was necessarily at this time much room for doubt as to the ultimate results, but if the crop of 110,000 lb. tea should be realized, if the present price of about 57 cents should be obtained for the portion of the crop yet to be sold, the directors hoped to be in the position to recommend a dividend in January of like amount to the interim dividend paid in August, viz., 4 per cent. The estate as is well-known, is not at maturity and the weather has been very unfavorable for quantity and quality. Referring to the prospects of coffee crop:—the season is very late, and as usual with crop only on suckers it is difficult to estimate. The statement with reference to prospects of dividend was based upon the expectation of a crop of 200 bus.—Before proceeding to the election of directors the chairman would be pleased to answer any questions.

It was then proposed by Mr. W. H. BAILEY and seconded by Dr. J. B. SPENCE:—That Messrs. Starey, Moir and Julius be re-elected Directors; which was carried unanimously.

The CHAIRMAN stated that this concluded the business of the meeting and while heartily thanking the gentlemen present for their attendance and for re-electing the present Board said, that it seemed desirable not to change the directors before the first year's accounts could be submitted. There would be another meeting in a short time when he would be quite willing to retire.

A vote of thanks duly acknowledged terminated the proceedings.

AN EX-CYLON PLANTER IN AUSTRALIA.

A REMARKABLE CONTRAST—CLOSE OF THE SHEARING SEASON—A FINE SIGHT—SHEARING VERSUS GATHERING COFFEE—AMUSEMENTS OF THE WOOL SHEARERS—RACES AND BETTING—AUSTRALIAN POLO—"WALERS" IN CEYLON.

The Barrier, N. S. W., Oct. 26th, 1892.

The contrast of the present surroundings with those six months ago is remarkable. It is not only the change from cold winter's snow to budding spring as in Europe, but it is the wilderness blossoming as the rose, the dry dust wastes transformed into grassy swards spangled with wild flowers over which the stock roam happy and glad. Not only does this mean more money to the owner, but it gladdens the eye. The whole aspect, formerly so dreary, so dispiriting, now becomes an actual "thing of beauty," but alas! not a "joy for ever." If it would only last. Many an "if" comes in our thoughts in this life. If Ceylon had this climate what a paradise! The chief fault of Ceylon is the relaxing tendency of the climate and consequent waste of tissue and drain of secretions formed and supported by blood supply. There is no tonic like bitter cold, and those who live in countries where bitter cold is experienced at one time of the year are indeed fortunate, as they do not require a "change." Our bitter cold is all over now. Spring is far advanced. Shearing is a thing of the past, and the once busy scene of operations is deserted save by the half wild cats and the few miserable "killing sheep" doomed to slaughter. The shearers and rouseabouts all received their cheques and departed red-hot for a big spree, and their money, no doubt, is long ago spent. Matters are very quiet now. The sheep have to be distributed properly in their different paddocks. Here and there a "wooly one" turns up who eluded the musterers; but there are very few, and it speaks much of the care with which these enormous paddocks are gone over, that out of close on 50,000 (fifty thousand) sheep so very few were missed. All the wool-bales are not off yet, but only a few remain. It was a fine sight one day during shearing when work was stopped for want of rain to see the boss, boss of the shed, wool-classer, and a visitor, start off in the big

waggonette with 6 horses, all with rifles or guns, to shoot the kangaroo or turkey, and at the same time visit one or two camps on the run. All the hands turned out to see the start. The wool-presser came past and said to me: "Ah that looks like good times. Grand sight! six in hand, is n't it?" And so it was. I wondered when I would be able to drive 6 in hand 20 miles without smashing a gate. Shearing differs from gathering coffee-crop in this that there is no immediate hurry. If rain comes work stops. Of course the longer shearing lasts the longer you have to pay the rouseabout at 25s a week, and that is important. One evening some of us from the house went to look on at a "Buck-Ball" at the shed. Huge "slush-lamps" flared and flickered, lighting up the shed and casting strange shadows behind the variously groned men, sitting on wool bales or lying amongst greasy "combing." At one time there would be a set-to with the gloves between one from the house and a shearer, and the various hits provoked applause. Then they would start songs and they would go round for a time in great variety. Then clog-dances or step-dances to the music of an accordion would take up the attention of the audience. Then a great contest at the "Straight-pull-up," or what the Scotch call the "Sweetree": some good hard tussles took place. Then the accordion began dreamy languishing strains, and huge shearers in greasy soiled moleskins and heavy boots, rough boundary-riders, and smart "pickers-up," all waltzed slowly round, swaying gently and revolving in the same spot;—it was too ridiculous. We came away having enjoyed the evening on the whole. What a mixed crew you see at a station during shearing. There was a doctor here one year as cook to the shearers, and I have heard of an ex-colonel and his son as boundary-riders. They are a cheery good-natured lot, but the reverse of thrifty.

We had some races, too, on the fine racecourse near, and great was the betting among the men. A little mare "Podge" has carried everything before her and great things are prophesied of her. After the preliminary canter the boss asks "Is all your stuff up?" (meaning "Are your bets made?")—and away he goes with the horses and jockeys round to the starting point. "A flying start! They're off!" "The gray's leading." "Wait till little Podge comes to the hill." And afterwards I have to pass the various transfers of small sums which result from the betting.

Then polo was a favourite game. We generally played it on Saturday afternoons. The rapidly changing groups of keen riders and smart ponies, the shouts, the clouds of dust, the waving of clubs, and then the breathing time, when a huddled group of men and panting ponies formed a contrast to the dashing activity seen during the play. Now a club is broken, now a rider has to dismount for his dropped club, now a scrimmage forms, now a bold rider dashes away taking the ball with him right from goal to goal. These are all born riders (I don't include myself—a new chum) and they guide their steeds better than the polo players at Colombo or Bangalore. It is a fine game, and the better the riders the safer the game. A duffer on a hard-mouthed brute of a pony will make sad havoc among good players. My own efforts have not been distinguished for much brilliancy yet, but I suppose that will come in time. I begin to see what the horses are like now, and it is really wonderful how well-bred the ordinary station horses are. I raise a hornets' nest about my ears sometimes by twitting the others about the "fiddle-heads" Australians send over to India and Ceylon. Of course there are many well-bred ones, but the general rule is that the better the breeding the worse the breaking in of the nags sent to Ceylon and India. They are better off in India than in Ceylon; because a planter can get castis from military remount depots; but in Ceylon, where there is little or no military demand, the horse-market is not what it should be. I could procure very suitable nags for friends in Ceylon; but the buyers must take the risk of the journey. You can buy for £18 what would fetch R400 to R600 in Colombo. I don't mean a big raking weight-carrier but a nice bit of blood, young

and well-broken. A lot of those fiddle-headed ewe-necked "walers" that you see in Ceylon are ugly outcasts who have left their country for their country's good. ABERDONENSIS.

PLANTING NOTES FROM PEERMAAD.

(FROM A CORRESPONDENT.)

His Excellency's visit has turned the eyes of the outside world to this little State, which is apt to be rather overlooked, not being able yet to keep itself continually before the world as do some of the others. This probably influences the tea interests, more than anything else, in the matter of keeping its light hidden under a bushel. Let us hope that the Chicago Exhibition will give it a good help forward. The Peermaad Planters' Association are pushing forward the matter of roads very strongly before the Government, and the Southern districts are preparing an address to present to His Excellency at Trivandrum, setting forth their wants. It was a matter of regret to all the planters in this district that owing to the uncertainty of the date of His Excellency's arrival from the shooting camp, and the limited space of time of his stay at the Residency, no address of welcome should be presented before he descended to the plains. I believe that this is the first time in history that a Governor of Madras has honoured this district by a visit, though Lord Canning came to the Periyar Project which, though in the Periyar Valley, cannot be considered as part of the Periyar planting district. This aforesaid Periyar Project is not an unmixed benefit to the Peermaad Planter, as coolies under advance have a knack of getting off the estates, under the plea of buying provisions at the huge bazaar there. And unscrupulous maistries and petty contractors persuade them with all the guile of a recruiting sergeant to stay there. The difficulty, of course, in getting them back is very great, there being no Civil Court within 50 miles or so. And many Estates, especially those near these works, suffer in consequence to some extent. It lies of course with Travancore only to help Planters in that way, by establishing guard houses on the routes approaching the works, and by Civil Courts, which would be accessible, and I believe then that the men could be brought to hand; but so far, nothing has been done.

Considering that in Travancore planters have been to a great extent self-taught, the result shown by the sales list of tea is very creditable. The coffee crop is now ripening slowly, but surely; the heavy burst of rain, which all came from the South-West accompanied by mist and wind, did much damage, and knocked off (on all the places outside the Periyar Valley) a great deal of crop. Probably the wily coffee thief is now awakening and preparing for his campaign, but the law as to theft of this description is very good and clear, and a great help to planters, the only thing being that Subordinate Magistrates do not use the powers given them as they might do.—*M. Times*, Nov. 18.

A PRIVATE QUININE FACTORY.

In our review of the Administration Report of the Government Cinchona Plantations and Quinine Factory for the year ending 31st March last, we remarked that it was our belief that the day was not far distant when the quinine manufactory operations carried on at Naduvatum would prove of real benefit to the cinchona industry of Southern India. The work accomplished at that factory under the supervision of Mr. M. A. Lawson has proved a most important fact, viz., that quinine can be made in this country and show a very handsome profit on the manufacture. Much of course depends on the manner in which the bark is treated; but under scientific management it has now been placed beyond a doubt that there is ample scope for a factory to be started by private enterprise which would repay investors a good return on the capital sunk in it. Five thousand

pounds sterling properly expended would, we understand, be sufficient to erect, equip and maintain for one year a factory of twice the extent of the one at Naduvatum—this, of course, would not include the cost of the purchase of bark. Such a factory would be able to grind up one ton of bark *per diem*, or says, 300 tons per annum. Naturally the amount of quinine and febrifuge manufactured would depend upon the quality of the bark; it would not pay to treat the Red bark, but the Crown and Ledger barks would pay handsomely. Should a factory be started, there should be no lack of bark to work upon. The Wynsad, North Travancore and the Nilgiris still have several thousand acres under cinchona cultivation, and within five years or so the output could be doubled, if necessary. What the Government of Madras has done, can be done by private individuals, and with this extra advantage, that whereas Mr. Lawson's hands are tied when he wishes to dispose of his sulphate of quinine, the private quinine maker will be able to place it in whatever market he likes. A very good demand for sulphate and febrifuge ought to spring up almost at the very doors of the factory, and a private Company in a short while should have in its hands the supply of the entire consumption of this drug in India, Burma and the East. During the last official year 144,500 lb. 4 oz. of bark gave an output of 4,425 lb. 4 oz. of quinine and 3,174 lb. at the Naduvatum Factory so that, presuming the bark to be of the same average quality, 300 tons should give an output of over 20,000 lb. of quinine, and some 15,000 lb. of febrifuge in the course of the year. We have been unable to ascertain the annual consumption of quinine in this country, but Messrs. W. E. Smith & Co., of Madras, inform us that they dispose of as much as seven thousand ounces in the course of a year. Whatever the total consumption here may be, there is no doubt that it is much below what it should be, and though hitherto the attempts to popularise this medicine have not met with much success, it is to be hoped that they will be preserved in, and should a private factory be started the efforts of Government to make this drug more widely known will be supplemented by private enterprise. It is almost needless for us to add that although a factory can be started for £5,000 the enterprise must be conducted with the strictest regard to economy to ensure success. We should be glad to see the matter taken in hand as we feel convinced that not only would it be profitable to the investor, but it would give an impetus to the cinchona industry which is sorely needed, and would in time probably lead to the complete rehabilitation of cinchona cultivation in Southern India.—*M. Mail*, Nov. 22.

BOTANICAL GARDENS IN JAVA.

The following account of these Gardens is taken from one by Dr Treub, the present Director; it appeared originally in the "Revue des Deux Mondes," and later, as a translation, in the "Chautauquan."

"The number of Botanical Gardens situated within the tropical zone is much greater than is generally supposed. It is necessary to say, however, that not all are Botanical Gardens, in the proper sense of the word, but rather limited agricultural stations or gardens of acclimatization. Some among them merit the name of great scientific establishments, and, holding the first rank in this list, are the gardens of Calcutta, and those on the Islands of Ceylon and Java. We propose briefly to trace the history of the last of these three, and to show by a study of its organization, how a new era is beginning for such institutions and that they are destined to play a steadily increasing part in the evolution of vegetable life.

On the 29th of October, 1815, a squadron, quitting the roadstead of Texel, in the north of Holland, set sail for the East Indies. It was taking to Java the commissioners-general to whom the sovereign of Holland had confided the office of taking back from England in his name the Government of

the Netherlandish Indies. Guided by large views, the new King had added to the number of Commissioners a distinguished naturalist, Reinwardt, a professor of the Athenæum of Amsterdam, in order to establish upon a solid basis the study of the marvellous nature which forms the wealth of the Dutch possessions in southern Asia.

The squadron did not reach the Strait of Sunda until the last of April of the following year. The passengers were delighted after their long and dreary voyage, to sail among the charming islands set as so many emeralds in the narrow silvery bands into which they divided the strait; and to breathe in the sweet perfumes wafted from the shores. They might well have desired to remain there and to put off the task awaiting them, for the future held many vexations.

Buitenzorg, situated about twenty-six miles from Batavia, in latitude 6°35' south, longitude 106°53' east, upon one of the long northern slopes of Mount Salak, a charming site enjoying a beautiful and healthful climate, was selected as the site of a Botanical Garden. Work upon it was commenced with 50 native laborers under the direction of two head gardeners, one of whom had followed the same calling in Holland, while the other had been brought up in the Royal Gardens of Kew. It would have been difficult to find in all Java a place better adapted to an undertaking of this kind, because, thanks to especial conditions, Buitenzorg added to its other advantages that of not being visited by the dry monsoon.

It is evident that a period of drought almost continuous for four or five months, as is common in the Island of Java would be suitable for only a very small part of plant life. Even the climate of Batavia, where an absence of heavy rains for two or three months is not of rare occurrence, would be much less adapted to a botanical garden than that of Buitenzorg, where they complain of it as an unfavourable year if in the midst of the dry season, so-called, there occur three consecutive weeks without rain. These frequent and heavy rains have a double advantage for the garden: first, Buitenzorg is indebted to them for its luxuriant vegetation which grows continuously; and in the second place the rains cause a lowering of the mean temperature which renders possible the culture of many plants of the virgin forests of the mountains, although Buitenzorg is situated at an altitude of only about nine hundred feet. In order to give an idea of how much water falls yearly on an average upon this Sans Souci of Java it will be sufficient to say that here the rainfall measures about one hundred and seventy-five inches, while in Holland, one of the most rainy countries in Europe, it reaches only about twenty-five inches.

At first no regular plan was decreed for the management of the garden. The archives contain no indication of any rules whatever regarding it. It is only known that its founder, Reinwardt, made numerous expeditions into the surrounding country for plants. The first Catalogue of the "State Botanical Garden," the name officially adopted, published some months after the departure of Reinwardt, contains an enumeration of nine hundred and twelve species. Reinwardt returned to Europe in 1822, in order to occupy a chair in the University of Leyden. During the succeeding years there were several changes in the management of the garden and its experienced varying degrees of fortune. Finally, in 1830, J. E. Teysmann was named chief gardener. This man, who had had only the education of a Primary School, received a half century later a testimonial, as remarkable as it was rare of the esteem in which he was held by the whole scientific world. Besides the Diplomas of Honour given him and the felicitations sent from all parts of the world, there was presented to him an Album in which more than one hundred Botanists, among them Darwin and Candolle, prescuted him their respects; and this Album upon its gold plate bore the following inscription: "To the most distinguished and indefatigable J. E. Teysmann, who has spent half of his life-time in the exploration of the botanical treasures of the Indian Archipelago, from his admir-

ing colleagues." It was under the management of this man that the garden became a scientific institution of State, with a Director and a special budget and an entire independence of the Viceroy. Let us now rapidly glance over its actual organization.

The Institution comprises three distinct Departments. First, there is the Botanical Garden, properly so called, in the centre of the town, occupying an area of about eighty acres. It is crossed by a large and beautiful walk called the Walk of the Kanaries, after the native name of the trees which border it, beautiful specimens of the *Canarium commune*, frequently reaching a height of ninety feet. Over this walk which runs along by the side of an artificial lake containing a little Island, pass daily numberless carriages and pedestrians. Leading out from it in every direction, numerous paths penetrate to all parts of the grounds. Plants of the same family are found grouped together, or occupying one of the entire divisions marked out by the paths. At one corner of each such plot is to be found a notice of the species which it incloses; and each species is represented by two plants, one of which bears a label giving its scientific name, its common name, and usually its special characteristics. His attention being attracted to the great number of climbing plants in the tropical regions, Teysmann conceived the happy idea of giving them a special place in the garden, where each might be surrounded with its natural conditions; and this department now offers a vast field for interesting observations. The total number of herbaceous plants comprised is about nine thousand.

In the middle of the garden is found a series of nurseries where young plants are cultivated partly under shelter, which protects them from the heat of the sun and from injury by the heavy rains. Some plants demand particular care, notably certain species of ferns and of the *Aracca* and of the orchid family. These are placed in buildings, resembling the hot houses of Europe, but with this difference that here they serve to keep the plants cool, instead of procuring for them a higher temperature. The garden has its own carpenters for executing such constructions—a little detail, which, however, will serve to give an idea of the scale upon which it is organized.

The native *personnel* is composed of a hundred individuals, among whom are three possessed of a special botanical knowledge, much more profound than one would expect to find among the Malays. This force works under the supervision of the Gardener-in-Chief and his Assistant.

The agricultural garden, the second department comprised in the Institution, situated about a mile from the centre of Buitenzorg, occupies more than one hundred and fifty acres. The local arrangement and the distribution of the plants at once indicate an object exclusively practical. All is laid out in regular order here; the roads and the paths cross each other at right angles, the plots which they set off are nearly all of the same size, the plants in each plot are of the same species and of the same age. While in the scientific garden each species had only two representatives, it has here on an average one hundred. But here the limitations are placed on the kinds of plants, which must be such as are or may become useful to agriculture or to colonial industries. There are to be found the different species and varieties of the coffee tree, of the tea plant, sugar cane, caoutchouc and gutta-percha trees, the *Erythroxylon Coca*, which furnishes cocaine, the trees which produce tannin and oils, plants used for fodder, etc. A special part of the garden is reserved for medicinal plants. A chief gardener conducts the work which is carried on by a force of seventy native workers.

The third garden is located at quite a distance from Buitenzorg, upon the slope of the neighbouring volcano, Gedeh. With an area of seventy acres, situated at an altitude of 5,000 feet, it possesses a climate which is marvellously adapted to the cultivation of the flora indigenous to mountains as well as to that of Australia and Japan. A force of a dozen natives work here under the direction of a European gardener. These three gardens which together constitute the State Botanical Garden

occupy an area of more than three hundred acres.

The Museum built opposite the first garden described, is a building about one hundred and fifty feet long and comprises a large central hall and two wings. On the lower floor the hall contains cupboards running all along its walls and glass cases through the centre, in which are kept the botanical collections. Some of the specimens are dried and some are preserved in alcohol. A gallery running the whole length of the upper hall is exclusively occupied by the herbarium. The pressed plants are not kept in portfolios as in Europe but in tin boxes in order the better to protect them against insects and mould, the great enemies of such collections in tropical countries. The number of such boxes exceeds twelve hundred, and each box contains one hundred specimens. One of the wings of the building is used as a Museum, and the other for a Library which contains five thousand volumes.

There are three Laboratories connected with the gardens to which a fourth is soon to be added, for the *personnel* is to be increased by the addition of two new officers, a Botanist and a Chemist, to whom will fall the special task of furnishing by long and patient researches, scientific information to those asking it, regarding the useful plants of the tropics. Behind the Museum in a special building is the Medical Laboratory where a Pharmacist makes researches into the nature of alkaloids and other curious and useful substances found in tropical plants. Of the other two Laboratories, placed behind the nurseries, one is reserved for the use of scholars who come from beyond the seas to study in this place. The room is lighted by five windows, in each of which is a large work-table. Cupboards against the wall contain all the necessary implements. There is in it, besides a small collection of the books which are needed, always at hand, in order to save the trouble of going to consult them in the regular Library. It is now proposed also, in order to facilitate the work of the visitor, to place here an herbarium composed entirely of the plants cultivated in the garden, in order that a rapid identification can be made in any doubtful case without being obliged to have recourse to the general herbarium. The arrangement of this building is simple, and presents the two great advantages of plenty of light and plenty of room. The last point is a very essential one in a warm country where one can endure no crowding, especially in work requiring close research. The third Laboratory is devoted to the use of the Director of the Garden. Close to these buildings are the offices and a photographic and lithographic gallery. All of these well-equipped buildings show the interest taken in the enterprise both by the Netherlandish Indies and by the mother country.

The Government of the Indies has authorized the Director of the Garden to distribute gratuitously the seeds and plants of useful vegetables. In 1838 fourteen hundred packages of seeds and cuttings and young plants were scattered through all parts of the Archipelago. It is especially the garden of agriculture which has been able to supply all of these demands; but it forms only one part of this scientific organization, and would very badly meet the requirements were it alone. The following statements will give a proof of this. When the remarkable anæsthetic properties of cocaine were discovered, it was only necessary to have recourse to the two plants of the *Erythroxylon Coca* in the botanical garden to make preparations for a large supply of the article. Enough seeds were gathered from these trees to set out a small plantation in the agricultural garden. When a year later a learned *savant* called the attention of the Dutch government to the necessity of the culture of the plant in Java, they were able to reply to him that the seeds gathered from the plants in the agricultural garden had already been planted by the thousands. The tree for a long time known as the producer of gitta percha has been in such demand and was so rapidly destroyed in order to obtain the juice that it was believed to be exterminated and it was even impossible to obtain seeds that it might be propagated again. In the plot devoted to the order *Sapotaceæ* in the Buitenzorg garden

were found two trees aged about thirty years which produce yearly a great quantity of seeds. It was from these that a young plantation was started in the Garden of agriculture, and thus the great number of young trees were obtained which were required for the vast plantation established a number of years ago, by the Dutch Government, under the auspices of the Garden. The camphor tree of Sumatra, a tree of great value, is exceedingly difficult to grow, first, because it bears very few seeds, and second, because these seeds very soon lose their germinating power, often being found worthless after a very short voyage. With particular care Teysmann succeeded in raising the trees at Buitenzorg. In 1885 the plants began to fructify, and now the garden possesses a young plantation of the camphor trees and a great number of plants can be distributed from there during the next rainy season.

The researches made up to this time into the pathology and the physiology of plants have not been very extensive, and yet they have been such as to tax the powers of the present *personnel*. Upon the arrival of the two new functionaries to be set apart exclusively for this kind of work, the force will be strong enough to meet fully all such demands.

Every one interested in natural history knows that Zoology owes a great part of its recent rapid development to the founding of various Zoological "Stations" (establishments in places where the species to be studied occur naturally). Of still greater importance in the development of the science of botany, are such great botanical "Stations" as this one at Buitenzorg, destined to be in the near future."

It is interesting to compare what is said of these gardens by Dr. Trimen, Director of Botanic Gardens in Ceylon. He visited them in 1891, and in his Report he states his experience as follows:—

"The Dutch botanical establishment at Buitenzorg is maintained entirely on a scientific basis.

"The Director has the control of all the six departments into which the institution is divided, as follows:—1, the Herbarium, Library and Museum; 2, the Botanical Laboratory; 3, the Experimental Garden and Laboratory for Agricultural Chemistry; 4, the Pharmacological Laboratory; 5, the Botanic Gardens; 6, the Photographic Institution. Each of these departments is under the immediate management of a highly-trained scientific or technical chief from Holland, and most of these have also an assistant. There is thus a very large staff of Europeans. The Laboratories, Library, &c. are completely stocked, and kept fully up to the time, and everything is provided for close investigation and original research in all branches of botanical study. Many students are thus attracted from Europe, and the Laboratories afford accommodation for a considerable number of workers. A valuable serial publication, the "Annales du Jardin Buitenzorg," is issued at intervals, devoted to scientific botany, and another one, "Teijsmannia," occupied with economic and garden subjects

"The Botanic Gardens themselves at Buitenzorg occupy between 60 and 70 acres, at an elevation of about 800 feet, with a fine soil and abundant water, and are well protected by a high iron railing and a barbed wire fence. Nearly the whole is occupied by a classified arboretum, each Natural Order being isolated by a road or path. The collection is extremely rich, and every species is elaborately labelled with upright labels made of the very hard wood of *Eusideroxyton*, which is never attacked by termites. The whole is now much too crowded, and cannot be said to be of much beauty, but is of course extremely convenient for scientific study. Connected with Buitenzorg is a small Hill-garden at Tijbodas, 4,700 feet, also under a European Superintendent, where is also a house for the Director and a Laboratory and accommodation for four students.

"The experimental Garden (Cultuur-tuin) is about two miles from the main garden, and is 200 acres in extent, but is not all at present occupied. It is laid out in square plots, each devoted to one product; large labels at each corner give the name, date of sowing, or planting, and other information. Here are

very many plants of great interest. Though a large distribution of seeds and plants is made to planters and others, no charge is made for anything.

"On the whole, I was filled with surprise and admiration at the completeness of Buitenzorg as a centre for botanical work; the only weak side seemed to be the Herbarium, which is by no means kept up on a par with the rest of the means of study,"

A TALK ON MANURES.

[By Professor Shelton before the Bundaberg Agricultural Conference, and reprinted from the Bundaberg Mail.]

Professor Shelton said the subject put down was "A Talk on Manures," and it was not a misnomer as there would be nothing technical about it, but the practical view of the matter. It was the question how to improve soils, and how to make cheap manures. The ground they tilled was not a simple depository of substances that went to make up vegetation crops, &c. The ground was much more than that. The ground was a great laboratory. A constant round of chemical changes went on in it. They (the farmers) were all the time thinking and planning that if they knew the deficiencies of the soil they could put into it what it required. That was a great mistake. They could employ an analyst to test their soils and pay him £10 10s. for the experiment, but it would be simply waste of money. A soil could be made that was chemically equal to the natural soil, but they couldn't get out of it what was in the natural soil. There were a lot of things required to make up the nutrition of plants. The common notion was that if they knew what vegetation took out of the ground, they could put back into it what was taken out. That was an error. He had noticed in reading the debates which took place in Bundaberg at the meeting of the Agricultural Society that that belief was current here. His saying that it was a mistake looked like a condemnation, and a sweeping charge, but he did not wish to put it like that—he only wished to correct them. They wanted to know the composition of the soil, and of the commodity grown. A chemical analysis of the soil was very good as far as it went, but if they had it they would be no nearer a solution of what they wanted; they would be no nearer the mark as how to restore fertility to the soil at a paying cost. What was it that made a soil good or bad. Several things. If the Burnett River overflowed its banks it would destroy the crops, and impoverish the ground. Yet there were the same properties in the ground, but they would no longer grow profitable crops. The same soils have the same composition and may be fertile yet not payable for growing crops. The chemical condition of the soil was the only one that had to be considered in the great question of fertility. They might have a soil that would no longer produce crops profitably. They might perhaps go and put 400lb. of bone dust on each acre, and they would immediately get good crops. In that 400lb. there was 100lb. of phosphoric acid, and the application of that had made already a crop from a failure to a success. In America it was a common thing to use gypsum about 100lb. to the acre. In that quantity there was lime also. It was good for lucerne, or clover, but not for everything. After the application of these manures the chemical analysis of the soil would show nothing out of the ordinary. Chemistry was one thing and farming another. The old idea that chemistry could come in and give an analysis as to what to put in for the crop which was to grow on it, and also make an application of the manures useful to the ground, was useless. It had been proved by scores of scientific men. It was something like the "vespotic" Scotchman. The story went that a Scotch gardener was walking out one day with his lordship. The latter said "Sandy, the time is coming when we shall be enabled to manure a whole paddock with your vespotic," "and" said Sandy, "you will be able to take the crop home in the other vespotic." (Laughter.) There are such peculiar changes in

the soil that an analysis would not be of service in trying to apply, what the land was supposed to want. Using fertilisers in all cases was not altogether successful. An analysis of the soil was certainly useful to a man who knew what chemistry was and how to use it, but how many farmers understood it? Chemistry came in handy when it came as natural causes. The use of potash to their ground, if they could afford to use it, might prove beneficial. If the soil were absolutely wanting, too, chemistry would be of practical utility. Unless they understood the chemistry of farming they would get into a quagmire. All vegetation was supposed to contain the following thirteen things:—Oxygen, nitrogen, hydrogen, carbon, phosphates, sulphates, chlorine, silicon, iron, manganese, magnesium, sodium and potash. All these alums were found in vegetation and were naturally provided for its growth. All the man could apply in the way of manure numbered four—namely, nitrogen, phosphorus, potash and lime. The air and earth formed the others. The most important fertilisers that ever have been found are those materials taken directly from the farm and the plantation. While they talk of those four manurial forms, they all try to put them in the soil. Humus was something that came from decayed vegetables or animals and formed in the earth. It was in itself a food for plants and also acted on the elements and made plant food. That was one of the inconsistencies which they experienced. Then it was held that the soil contained a lot of little animalculæ which had the power to produce nitrates in the soil. That was another inconsistency, which was given to show how complex was the question. Nitrates should be good to the soil. The application of water to the plant, it was well known had a powerful effect on its growth. It was altogether a fascinating question the matter of applying manure to the ground. Take for instance, stable or cattle manure or anything that came from animals. The composition consisted of the four alums mentioned and a mixture of some of the other 14 gases, etc. They might have manure good in weight and the right color which would make them believe it to be a perfect fertiliser, yet it might not be worth hauling to the field. Manure to be valuable must come from something valuable. Horses fed on one thing might produce ten times better manure than if fed on anything else. For himself he (Professor Shelton) would sooner have manure made from the decomposition of lucerne than ten times as much coming from the decomposition of cane tops. Lucerne contained a lot of nitrogen. Manures get their value out of the substances from which they are made. English farmers knew these things on account of the keen competition which went on amongst them—each one trying to be better than his neighbor. Cotton seed was enormously rich in nitrogen. It seemed that all the numerous nitrogenous seeds went to Europe mostly to England and the English Isles. It seemed to be the focus into which all those seeds were gathered. The soil when taken from the cotton seed or linseed, left the nitrogen behind, and that was most valuable for their soil. The colonial farmer wasted his manure as a rule, or allowed it to waste its nitrogen and become valueless. Oftentimes he had seen the stable manure piled up against the walls of the stable, and the rain from the eaves of the roof pouring down through. The water carried off all its good qualities. If it were kept in a compact mass it would still hold its value; and if it was to be of use it must be protected from, and not receive the rain or soakages from buildings. How might they apply these fertilisers to the best advantage? He had noticed in going around the district a lot of cane tops and megass on the land. They were not valueless, however, when allowed to rot there was a lot of acid in them. It took a long time to decompose even when in the ground. If any of the common nitrates were used with them there would no doubt be a good result. Lime, for instance, would be a good thing to mix with them, and it would cause a speedy decomposition. Their scrub lands around

here, though, were in a splendid natural physical condition, and perhaps if the cane waste were used to too great an extent the soil might be depreciated. To place manures in the land in heaps was obsolete, a thing of the past. There could be no use in the heaps until the oxygen got to it. The old notion when the manure was spread and gave out a rank odor in the field was that it was indicative of waste. The farmer then said let us put it into heaps. The odor was not really ammonia, as they supposed, unless it was stirred up. What did escape was in infinitesimal quantity of ammonia and several other gases. The knowledge of this has effected the process of farming of to-day. The manure was now spread on the field, and the rain beat it into the earth. There was no waste practically, it was "of the earth, earthy." It didn't matter how long it laid, if for six years. Another good lesson had sprung from this knowledge. The best method was now found to be to plough the land, spread the manure over it, and then go over it with a light plough or harrow. There were of course objections to it, as everyone must work according to his requirements. The methods of ploughing it in to a depth of six inches below the ground was one to be avoided, because the manure remained a solid mass in the bottom of the furrows practically untouched. The roots of a plant could not get through it as it became a green, festering mass, and was useless for the purpose intended. The land then takes two or three ploughings to co-operate with it. If it could be worked in, it would have been beneficial throughout the land—the young plant would have got the use of it—whereas it doesn't. One of its great functions is that it must be used so as to give the young plant a quick start. Among old English and Scotch farmers, where the pennies are of value, every grower knows what this is. Now every grower knows what a quick start is to a plant. All experienced farmers study little things. Yet this was not a little thing, for to give a quick growth meant no trouble about its after growth. It is astonishing, he said, how a young plant will go after the manure. For the matter of that it strikes one forcibly the strange affinity both young and old plants have for manure. They will send down their arms like outposts with all the avidity of a hungry rapacious traveller. Where the food is there the root will be always. Only the other day he was digging up a portion of his garden which he manured about six months ago and distant about three or four feet from a poinciana. It never occurred to him that that would be affected in any way. But he noticed in time that its phloxes were dried up with the slightest drought. Examination proved that the whole garden was a mass of poinciana roots. It had, so to speak, sent its skirmishers out in the direction of the manure and practically taken possession of the flower garden. They had eaten out every particle of the nitrogen. They ought not to lose sight of the great difference in manures necessary for different plants. One variety of plant life is benefited by one, another by another entirely different, and so on. For example, the orchard requires manure different entirely from that necessary for sugar or maize. There are different classes of crops and plants with different desires. Farmers need this fact brought to their attention continually. Some require something that acts quickly and is easily dissolved and easily accessible to the plant. Take broken bones for instance. Under an orange tree there may be nothing the first year or two, but it may be fruit bearing for the next. Again, he repeated they must adopt for different plants and crops different manures. Speaking of commercial fertilisers he continued, the most important were the nitrates. They exist under certain forms, the commonest of which is obtained from the arid regions of South America. Thousands of lives have been lost to get possession of them; they had made the fortunes of millions, and in late years England as usual had taken the great bulk. This, however, was only one of a series. Sulphate of ammonia was another obtained from the refuse of gas works, and here he would not let the opportunity pass of saying

that a great quantity of this invaluable preparation was going to waste. Even in the gas works of Brisbane they allowed the liquor to run to waste in the river. In Sydney they now utilised it as a manure. He reckoned it was one of the most valuable manures next to ammonia. Phosphates of lime he also reckoned a highly valuable fertiliser. Lime, he said, acts in two ways. It is a source of fertility to the lands that need it. Again, it was favourable to the soil and makes heavy clayey soil loose and friable, and, again, it puts soil in a condition to be used by plants. He had heard of two or three hundred loads being put to the acre. Some argued it must be used in large quantities. Some even favor it being put on the land and not altogether because the plant needs the lime. That lime does wonders to the soil English farmers know well, even in their cold slow English climate. Even in this sun-baked land our soils have another source of dissipation by what plants can get hold of them. There was a need of thinking twice before they put some of the old adages into practice. Referring to potash, or wood ashes, he said it was an element generally deficient in the soils of Queensland. In some soils where potash exists if you taste it you burn your tongue, but where it is deficient such is not the case. Most soils were deficient in this element. On the other hand along the coast the mangrove gets hold of a lot of it and generally contains a lot of it. It would therefore be wise on their part to burn down the mangrove and they would get the same results. Potash was largely obtained from certain mines in Germany. In a salt running district they discovered a great ruin of cyanide. It only contains a small amount of potash, however, 12 per cent. probably, besides a proportion of sodium, lime, etc. It is useful where soils need the use of this element. The nitrate is better when applied in connection with farmyard manure. All commercial fertilisers should be applied with others to supply this humus. The nitrates are quick in action, but do not last any great time. If applied injudiciously you get a tremendous growth of rank vegetation the first year, and nothing perhaps the next year. Just like an old toper. It acts as a kind of whip and spur to the soil. They urge things on, and then leave exhaustion. Unless renewed you have this debauching influence. There is such a thing as debauch in manures. The phosphates on the other hand are slow in action, but last longer. Every rain carries it into the soil, and the roots go after it like a race-horse. Bonedust decomposes slowly and can't be washed down. It remains on the land a long time. It is therefore best to use a good deal of phosphate, and here he added, the finer the phosphate is broken up the better. Bonedust contains in addition a good deal of nitrogen. It may be interesting to use the bones that are found round about our slaughter-houses in the back hand. They might be made available by every farmer. It is not necessary for a farmer to have a mill; with a hammer he might pound down bones to a degree, but another plan was to gather the bones and put them in a pit, say a layer of bones then a layer of horse manure, another layer of each and so on, keeping moist for 8 or 10 months, in which time the whole will soften and rot away, then they are in good condition for the plant to get hold of. In the case of all commercial fertilisers the best practice is to apply small doses and often. The successful manurers know this. To throw it in largely is to waste much of it, as it gets carried away. With the phosphates Sir John Bennett Lawes applied 200 lb. of nitrate of soda, with 200 lb. phosphate of lime; a pretty heavy dose. It is generally best to apply near the surface and work in with the hoe or rake. Pine apples, cane and plants generally feed near the surface. Most of their food is six or eight inches in the ground. Keep it where the roots are. It is nevertheless possible to get along without any manure and some present may have tried it. An old adage says cultivation is manure. The following process is a wasteful one. In Southern Europe he had read that crops of barley had been grown for 2000 years in certain parts of Greece. The plan adopted is tilling this year

thoroughly and growing a light crop the next. In the East of New York State the farmers plough freely one year and plant rye, then change the crop. On the former they get from eight to twelve bushels to the acre. Sir John Bennett Lawes who was the most practical agriculturist of the age, and who might be called the king of agriculturists, and besides whose experience all others were as child's play, had grown wheat for forty years on the same land. For 20 years he got 16½ bushels to the acre, and for the last 20, well, he was not quite sure. [Mr. McLean: 12 bushels.] "Yes, 12 to the acre and that would very likely go on for ever." That soil, he said, is crumbled down and decomposed to furnish food for that quantity. It is for the farmer to determine whether it is profitable or will not be. From J. B. Lawes' experiments he was sure where he added 14 tons of farm yard manure he got 30 bushels, and he gives a table showing what can be done in farming by the use of phosphates and the other is mere scouring. Sir J. B. Lawes in these experiments wished to see the strength of the soil. It is useless to think of applying great doses of nitrogen to cane as it will give great growth of stalks with a low density, and that is not what is wanted. You must use largely phosphoric acid, the chief fertiliser for the cane crop. Generally 23 parts of phosphoric to about 6 of nitrogen and seven of potash. The phosphoric must equal or be considerably more than the combined results of nitrogen and potash. He apologised for the great length at which he had spoken, but the subject was a great big one and after all he had only been able to touch on a few of the most salient points.—*Sugar Journal and Tropical Cultivator.*

THE NILGIRIS.

COFFEE.

What has become of the N. W. monsoon, is a question which planters are asking one another with increasing earnestness, and there is no doubt that the failure up to date of the usual rains has already done serious damage. On Monday and Tuesday there were heavy showers in the evening, and the weather generally has been more cloudy, but steady rain is what is wanted for a bit. On every side one hears that coffee has stopped ripening, and that black cherry is coming on at an alarming rate, while there is no doubt that a continuance of the present state of things will result in a terrible falling off in quality in the latter part of the crops. Quality last season was very bad, and the year before not much better, but with a good S.W., and early rains, it did seem as if Nilgiri coffee would this season regain its usual good standard, and as far as picking has gone, this hope has been confirmed. However, a failure of the N.E. monsoon is never without bad results, and it is to be feared that, later on, these results will show themselves in shrivelled and light-beans.

Prospects for next season are, at present, very uncertain. Wood is ripening far too rapidly under the influence of the unseasonably dry weather, and this probably means too early blossoms is most cases. Many estates are having sprinkling of blossom out now, otherwise coffee generally is looking well. A vicious go of leaf disease has mostly passed of without doing much damage, or rather, the generally improved cultivation which now obtains, enables the trees to resist their old enemy more effectually. 'Bug,' both black and green, though there are few estates to be found without a touch of one or the other, is comparatively harmless at present, and not a few mean look forward to a bumper next season, in spite of present want of rain.

TEA, ETC.

Tea, of course, though looking as usual as if it didn't care a rap what the weather was, is not flushing very well, and cold nights are not conducive to tender leaf. By the way, apropos of nothing, why do not the population of the Nilgiris generally show an interest in the proposed amendments of the Land Acquisition Act. There is no doubt that eventually the Nilgiri Railway will be extended to Ooty and thence to Gudalore, so that a good deal of property will be interfered with.—*South of India Observer.*

Correspondence.

To the Editor.

ADULTERATION OF INDIAN BONE MEAL.

Analytical Laboratory, 79, Mark Lane,

London, E.C., Nov. 4.

SIR,—I enclose you a newspaper cutting containing an account (only an abstract) of a trial in which I was called to give evidence as the analyst who had detected the adulteration of Indian bone meal with calc-spar or crushed coral.

You will remember that on the 21st of February 1891 I addressed a communication to the Planters' Association directing the attention of planters to this new and clever form of adulteration, with a view of cautioning all purchasers of Madras meal.

This letter was afterwards published in the Ceylon papers and copied into some of the Indian papers, so that I hope an effectual check has been put upon the fraud. The particular cargo referred to in this trial aimed as long since as the spring of 1891 and had therefore been waiting purchase a considerable time.

You will notice that by the verdict the sellers have to refund the money paid and will have the adulterated bone dust thrown again on their hands.

—Yours faithfully,
JOHN HUGHES.
[The case is a very important one and the verdict of the jury is satisfactory; but what is the meaning of Madras bone meal going to Britain generally from Ceylon?—Ed. T.A.]

(Before Mr. Justice WRIGHT and a Special Jury,
Sitting at Guildhall.)

M'CARNE v. CULVERWELL AND Co.

This was an action brought by Mr. Thomas M'Carne, a broker, carrying on business at Billiter Street, to recover the sum of £143 odd paid for 383 bags of Madras bone meal under a contract of April 8 last, and which turned out to be adulterated with fifteen per cent. of crushed coral. Mr. Leese, Q.C., and Mr. Lyon appeared for the plaintiff, and Mr. Green, Q.C., for the defendants.

Mr. Leese, in opening the case, stated that Madras bone meal was ground bones, which came mainly from Ceylon, and was used for purposes of manure. On April 8 the plaintiff, having a buyer for this kind of manure, entered into a contract with the defendants for the purchase of 383 bags of bone meal, on the "Clan Cameron" vessel. Between the date of the contract and the delivery Mr. Montgomery, the plaintiff's buyer, ascertained that certain shipments brought by the Clan line of ships were not pure bone meal, and he applied for samples. These were furnished, and when analysed they were found to contain fifteen per cent. of crushed coral. Plaintiff paid for the purchase on April 23, prior to receiving the report of the analysts, and when he received that report he communicated with the defendants, who replied, "We have nothing to do with your buyer's complaints; the meal was sold on its merits, and a sample handed to you." Under these circumstances proceedings were taken.

Evidence was then given on behalf of the plaintiff, the effect of which was that the bone meal in question was not a good merchantable article, owing to the adulteration, and that no sample was given with the contract, though a sample of the same shipment was furnished to the plaintiff for another buyer about a fortnight previously. It was further stated that it was not usual for brokers to have the bone meal analysed.

Mr. Greere, for the defence, said that some time in March last the defendants had a cargo of stuff by the "Clan Cameron" from India, known as Madras bone meal. Of that cargo plaintiff purchased half at £4 per ton, having had a

sample of it, the defendants refusing to guarantee it to be anything more than according to sample. The delivery was made on March 23rd, and on April 8th plaintiff purchased the remainder of the cargo at £3 17s 6d., and therefore the plaintiff was bound by his contract.

Evidence was then given which showed that Madras bone meal was well known in the market to be impure, and the price was considerably less than of any other bone meal. Madras bone meal was the only bone meal coming from India that was adulterated.

Counsel having summed up on both sides. Mr. Justice Wright remarked that the case was one of considerable importance to commercial men. When persons reduced their bargains to writing, as all business men should do, that writing alone was to be looked at to see what the contract was. The contract was to supply 383 bags of "bone meal" and the sole question for the jury was whether what was sold was in an ordinary mercantile sense commercially bone meal. In coming to their conclusion they must look only at the contract, and take no notice of the prior contract which was sold by sample. The jury, without retiring, returned a verdict for the plaintiff.

INSECT ENEMIES OF ROSES.

Colombo, Nov. 8th.

SIR,—I am nearly driven to despair in my attempt to grow fine roses by some insect which eats the tender shoots as they appear. I have applied flour of sulphur constantly but every shower of rain washes it off and the destruction at once goes on. Can you or any practical horticulturist help me?—Yours faithfully,
ROSE.

[Picking the insects off at night is the best remedy. Carbolic soap spray is also good.—Ed. T.A.]

LOW GROWN TEA.

SIR,—The latest tea "crank" (*Anglice* expert) who has been victimizing your good-natured London correspondent attributes the now notorious falling-off in the quality of Ceylon tea to the greater proportion of low-grown than formerly when the public taste was being educated. Is that borne out by facts or figures? You will be able to tell us if it is so. My own impression is that when the average of Ceylon tea was about 1/6 there was a larger proportion of low-grown tea than at any time during the present year. X.

EXCEPTIONAL AND AVERAGE YIELD OF LIBERIAN COFFEE.

Kalutara, Nov. 15th

DEAR SIR,—With reference to the estimate of crop on an individual specimen of Liberian coffee in Madagascar I can quite believe the quantity picked would turn out equal to the estimate, as 71 measures clean coffee was picked from one tree on this estate in a year, or considerably over 2 bushels, and I picked $\frac{1}{2}$ bushel from a four-year old tree at a single picking! These exceptions prove nothing however as the adjoining area of Liberian coffee never gave 10 cwt. an acre. I should think that 6 was about the average crop it gave till removed in favour of tea.—Yours faithfully,
L. D.

LARGE EXPORT OF CARDAMOMS!

Angroowelle, Teldeniya, Nov. 19.

DEAR "OBSERVER,"—Was not that a mistake in your export table of 65,000 odd of cardamoms shipped between mails? The s.s. "Assaye" was put down as taking away over 59,000 lb. This

large export startled us oardamom planters, and a neighbour largely interested in this product wrote to Colombo about it. The reply that came back was: "The *Observer* is wrong; the 'Assaye' took away 3,795 lb. only." If a mistake has been made, it would be as well to deduct the overplus from the total export, or perhaps it will have a tendency to bear the market.—Yours faithfully,

RICHARD BURKE.

[The figures we published were so given in the Chamber of Commerce Price Current; but on inquiry we learn that by a clerical error 187,386 lb. of tea were added to 3,795 of oardamoms. This will be corrected in the next circular.—Ed. T.A.]

VARIOUS NOTES.

INDIAN PATENTS.—No. 82 of 1892—Samuel Cleland Davidson of Sirrocco, Works Belfast, Ireland, Merchant, for "improvements in the means or apparatus for transmitting rotary motion from one shaft to another shaft revolving at right-angles thereto." (Filed 11th October 1892.) No. 134 of 1892—Hamor Lockwood, Chemical Manufacturer, Chapel Walks, Cross Street, Manchester, England, for "improvements in or connected with the purification of sewage and other foul waters." (Filed 11th October 1892).—*Indian Engineer*.

AMERICAN TEXTILE INDUSTRIES.—A recent bulletin issued by the United States Census Office deals with the textile industries of the country. The statistics show that while during the last ten years the number of factories remained stationary, the amount of capital invested was nearly doubled. The growth is greatest in the silk industry, the product of which more than doubled in the decade cotton coming next with an increase of more than a third, and woolen with less than a third. But in actual value of the product the woolen industry stands first with a production, in 1890, valued at about 338 million dollars, cotton coming next with 268, and silk third with 87 million dollars. The total product of the three in 1880 was 500 million dollars, and in 1890 693 millions, an increase which is said to be without parallel in any other country in ten years. It is curious that the sum paid for dyeing and finishing all these textiles in 1890 was less than for the much smaller production in 1880, but this is ascribed to the great improvement in methods and reduction in cost. On the other hand, the average annual wages increased in all the industries by about a fourth.—*London Times Weekly Edition*, Nov. 4.

THE FINANCES OF JAMAICA.—The report of the Collector-General of Jamaica for the year ended March 31st, 1892, can hardly be considered highly satisfactory by those interested in the Colony. The imports amounted to 1,759,890*l.*, which shows a decrease of 400,000*l.* in round figures, while the exports, which totalled 1,628,777*l.*, showed a falling off of over 180,000*l.* The revenue from import duties for the year aggregated to 319,782*l.*, or 13 per cent. less than the amount yield from this source in the previous year, while the internal revenue of the Colony—316,940*l.*—showed a diminution of nearly 20,000*l.* The shipping returns also fell away considerably; but the bright side of the picture is to be found in the agricultural industry. During the year 1,100 acres were added to the area under coffee in the Colony, while, although the acreage of sugar-cane, oom, tobacco, and ginger remained practically stationary, the cultivation of ground products and of guinea grass showed a good increase. But, taken on the whole, the position in Jamaica at the moment is such that friends of the Colony might well wish to see an early and substantial improvement.—*Colonies and India*.

PRACTICAL AGRICULTURE.

Mr. T. W. Armstrong, Manager of the Markham Grant in the Eastern Dun, has published a small pamphlet, bearing on practical agriculture, for the use of cultivators in preparing their lands for sowing. The little treatise can be had both in Hindi and Urdu and being cast in simple language, is made intelligible to the meanest intellect. The suggestions given will be acceptable to both Hindu and Mussulman cultivators, as to suit followers of either faith are mentioned; while the parallels drawn from the common events of every-day life will make the descriptions easily understood by the Indian Hodge. The work is eminently practical, but is based on scientific principles; and is evidently the production of a farmer who knows what he is writing about.

The section about ploughing directs that it be done deeply, and that the earth be not merely scratched; that the ploughed land should be left as light and open as possible, to admit of the greatest atmospheric influence; and special reference is made to the proper soils for growing sugar, rice, wheat, and potatoes. Suggestions are given for the proper succession of crops, and the proper times for allowing the land to lie fallow, points so much neglected by the ordinary *kashikar*: and the correct manner of preparing, manuring, and sowing the various crops. A good deal is said about manures, the proper way for collecting and preserving them, and how they are to be introduced into the soils; in a village with mixed inhabitants nothing should be lost, from old bricks to chaff; the good use to which bone ash can be put is specially referred to, and how well it fertilizes potatoes, tobacco, and the better classes of crops. Instructions are given for the selection of a lime soil for sugar-cane, and the proper mode of planting it in trenches; for the preparation of land in trenches for potatoes, the best method for manuring, and the necessary ridging and watering after the shoots reach the proper height. The various requirements for sowing rice, tobacco, gram, peas, and wheat are dwelt on in full detail.

This simple treatise concludes with some account of the results obtained from good ploughing and manuring; from the proper succession of crops, and allowing the land to lie fallow every few years. We recommend this little work to all those who wish to introduce scientific agriculture in a practical manner to their cultivators, in a way to be readily understood by the most ignorant.—*Pioneer*.

TEA PESTS.

Read correspondence with Messrs. Hemingway & Company of London and New York in reference to the use of London Purple against Tea pests. This preparation has been very extensively tried with excellent results in America, and more recently in England, for insect pests of various kinds attacking fruit trees, potatoes, &c. In an article in the journal of the Royal Agricultural Society of England (part II. Vol. III. 3rd Series) for June last. On the methods of preventing and checking the attacks of Insects and Fungi, by Charles Whitehead, F.L.S., F.C.S., arsenical insecticides are noticed as been recommended by Professors Riley and Lintner, "and many other United States entomologists of high standing. They have been tried in England for two seasons, but not largely, as the fruit growers are rather afraid of their poisonous qualities. Where they have been applied with care and thoroughness, the results have been decidedly satisfactory, but it must be borne in mind that if washes made with them are too strong, they will burn up the foliage and blossoms; therefore great care and accuracy are necessary in preparing them." Of London Purple Mr. Whitehead, quoting Dr. Pickard says, that "in America the efficacy of London Purple is established, and it is generally preferred because of its cheapness, better diffusibility, and visibility on the foliage. London Purple seems also to injure the plants less than Paris Green." Mr. Whitenead de-

votes several pages of his valuable paper to London Purple, and describes and illustrates the various forms of spraying machines and nozzles used for diffusing it in fine spray over affected plants.

The manufacturers of the London Purple responded very liberally to a suggestion made by the Society, and have forwarded a quantity of their preparation, and an American spraying machine fitted with Climax nozzles, for trial on tea gardens. A supply of the "Purple" and the pump have been forwarded to Kurseong for exhibition and trial at the Agri-Horticultural show in progress there. The pump is shown in a wood-cut in Mr. Whitehead's paper; the body, plunger and other parts are made of brass and gun-metal, and though it is small and very portable, it is "capable of being worked to a pressure of 100 lb. on the square inch with a moderate amount of hand power, though 50 to 60 lb. pressure is sufficient. It sends a fine mist to a height of 20 feet, and a single stream from 40 to 50 feet." It should be possible with a portable light pump of such power, for a couple of men to go over a considerable area in the course of a day. This may be practically settled by the Kurseong Show Committee.—*Agricultural and Horticultural Society of India.*

INDIAN FIBRES.

The officer in charge, Department of Land Records and Agriculture, Bengal, forwarded copies of correspondence with the Collector of Mozufferpore, and sample of fibre prepared at the request of Mr D'Oyley by Raja Krist Indra Roy Bahadour of Balehar, Rajshahy, Mr. D'Oyley mentions the Indian name of the plant furnishing this fibre as *Bariara*, but was at the time unable to say whether it is the *Sida rhomboidea* or *S. lanceolata*, (of Roxburgh). It is probably one of the varieties of *S. rhombifolia* (Linn) which includes Roxburgh's *rhomboidea*. The *Bariara* fibre has been noticed or reported on from time to time for a great many years, and valuations have also been made. Valuations of small samples of new products are not reliable. It is different with well known articles, but an unknown article has to be tested in various ways and under different conditions, the loss of weight in manufacture noted, and its adaptability for any purpose ascertained. In the case of fibre about 1 cwt. at least, is required to get reliable data for rope making purposes alone, and, if the fibre appears suitable for finer purposes, at least as much more is necessary for practical trial. In no case is any ordinary fibre worth the trouble involved in such trials, unless it can either be obtained wild in large quantities, or can be grown to give a good weight of fibre per acre cheaply.

The Deputy Commissioner, Akola, forwarded specimens of two plants yielding fibre named respectively *Baru* and *Ambara*, and requested to know their botanical names. They were identified as *Crotalaria juncea* (Linn.), or sun hemp, and *Hibiscus Cannabinus* (Linn.) Ambari hemp respectively; both are well known commercial fibres.—*Agricultural and Horticultural Society of India.*

HOW TO MAKE COFFEE.

A host of correspondents have been beseeching us these many weeks past to give them a recipe for making coffee. On the principle of every man thinking his own geese swans, I believe that we make as good coffee in our house as is to be met with in most middle-class families, where the master and mistress know something about cookery; and I will tell you in a very few words how our coffee is made. We allow a tablespoonful and a half for each breakfast cup and we use the best coffee that we can get. Formerly we had a coffee mill and ground the so-called beans, which are really the seeds of the coffee berry at home; but now we are content to use good colonial coffee, with a very small modicum of chicory in it. To make the delicious beverage we use that simple percolator, of block tin which, to my precise knowledge, I have seen used for fifty years. In the

upper cylinder of the percolator, we place the coffee, we close the top with a perforated block tin disc to prevent the aroma from escaping during the process of infusion and the water from falling with a rush on the coffee, then we pour in a sufficiency of boiling water, and the infusion percolates into the lower cylinder, and is in due time poured out from the spout strong, and clear as a bell. That is all. Stay, my cook tells me that the percolator must be kept from boiling again, which would be fatal to its flavour and its clearness; but it must be placed on a "hot plate," to prevent the contingency of its becoming tepid. Lukewarm coffee is an abomination, on which only tortured dumb animals and miscreants, guilty of the hideous offence of breach of promise of marriage ought to be fed.

In case you should think our coffee recipe too rough and ready, I have given you on the other side a number of recipes culled from long acknowledged authorities on the subject. As I say, there are a hundred and one ways of making coffee, but I have found ours not only palatable to ourselves, but to our friends. In the morning at breakfast we drink *café au lait*—one part of coffee to three parts of boiling milk. After lunch and after dinner, and altogether against the advice of my medical attendant, I drink black coffee without milk and with a little sugar. At luncheon I take *no petit vert* with my coffee; after dinner, I have a liqueur glass of green chartreuse with my *café noir*, and it does me good. My medical attendant may go to Hong-Kong; and I have not the slightest doubt that when he dines at the Esculapian Club he never fails to take his *petit vert* with his coffee. I remember dining once with no less than nine doctors; they all ate turtle soup, they all took curry, they all drank champagne and port afterwards, they all had liqueurs with their *demi tasse*, and they all smoked.

It is amusing to read what some old culinary authorities have to say about coffee. Worthy Dr. Kitcheuer, in his "Cock's Oracle" (1827), observes that coffee, as used on the Continent, serves the double purpose of an agreeable tonic and an exhilarating beverage, without the unpleasant effects of wine; but, as drunk in England, it debilitates the stomach and produces nausea, being usually made from bad coffee served up tepid and muddy, and drowned in a deluge of water, sometimes deserving the title given to it in "The Petition Against Coffee" (1874), "a black, base, thick, nasty, bitter, stinking, puddle water." For making coffee, the doctor recommended—sixty five years ago, you will remember—the use of the "German filter," which was only a simple percolator, and he adds that at least four shillings a pound must be paid for the coffee, and that at least an ounce should be allowed for two breakfast cups. As to making coffee in the ordinary coffee pot, the old fashioned mode of boiling and clearing the liquid, it is simply abominable. I have read one recipe where you are told that before you make your coffee you should put it into a basin and break into it an egg, white, yolk, shell and all. This compost being put into the pot, it is to be boiled up three times. It will then, says the prescriber of this nastiness, be as clear as amber, and "the egg will give it a rich taste." Sometimes the dried skin of sole and cod fish scraped, washed, and dried, and cut in pieces an inch square were used for settling the coffee, and isinglass was another favourite clearer. We had a cook once who maintained that the only possible way of clearing coffee was to throw a live coal into the pot after its final boil. That cook, I hope, came to a bad end.—*Sala's Journal.*

RECIPES.

SOYER'S METHOD.—Choose the coffee of a very nice brown colour, but not black (which would denote that it was burnt, and impart a bitter flavour); grind it at home if possible, as you may then depend upon the quality; if ground in any quantity, keep it in a jar hermetically sealed. To make a pint put two ounces into a stewpan, or small iron or tin saucepan

which set dry upon a moderate fire, stirring the coffee with a wooden spoon until it is quite hot through, but not in the least burnt; should the fire be very fierce, warm it by degrees, taking it off every now and then until hot (which would not be more than two minutes), then pour over a pint of boiling water, cover close, and let it stand by the side of the fire (but not to boil) for five minutes, then strain it through a cloth or a piece of thick gauze, rinse out the saucepan, pour the coffee (which will be quite clear) back into it, place it upon the fire, when nearly boiling serve with hot milk if for breakfast, but with a drop of cold milk or cream if for dinner.

COFFEE, FRENCH FASHION.—To a pint of coffee, made as before directed, add a pint of boiling milk, warm both together until nearly boiling, and serve. The French never use it any other way for breakfast.—*Soyer*.

WHITE COFFEE.—Put two ounces of unground coffee, slightly roasted, into a clean stewpan, which set upon a moderate fire, slowly warming the coffee through, shaking the stewpan round half a minute; when very hot, which you will perceive by the smoke arising from it, pour over half a pint of boiling water, cover the stewpan well, and let it infuse by the side of the fire for fifteen minutes, then add half a pint of boiling hot milk, pass the coffee through a small, fine sieve into the coffee pot or jug, and serve with white sugar candy or crystalized sugar. It is, as you will perceive, a great novelty, and an agreeable change; but if by neglect you let the coffee get black, or the least burnt, do not attempt to make use of it; it should only be sufficiently charred to break easily into a mortar if required.—*Soyer*.

COFFEE MADE WITH A FILTER.—To make a quart. First put a pint of boiling water through the filter to warm it, which again pour away, then put a quarter of a pound of ground coffee upon the filter, upon which put the presser lightly, and the grating; pour over half a pint of boiling water let it drain three or four minutes, then pour over a pint and a half more boiling water; when well passed through, pour it into a clean stewpan, which set at the corner of the fire until a light scum arises, but not boiling; pour it again through the filter, and when well-drained through, pour it into the coffee pot and serve with hot milk or a little cream separately.—*Soyer*.

ANOTHER WAY, MORE ECONOMICAL.—Proceed as in the last, but drain the coffee through once only, and serve, after which pour another quart of boiling water over the coffee grounds, which, when drained through reserve, and boil up for the next coffee you make, using it instead of water, and an ounce less coffee.

COFFEE.—The simplest, the easiest, and most effectual means to produce well-made coffee is to procure a percolator. Put the coffee in the well, place the perforated presser upon it, and then pour in the boiling water gently and gradually, until the quantity required is completed; put the lid on the percolator, and set it by the fire to run through. By strict attention to the foregoing instructions excellent coffee will be produced in a few minutes—the proportions of coffee and water being, one ounce of coffee to a large breakfast-cup of water. This is Francatelli's way.

INDIAN MILITARY WAY OF MAKING COFFEE.—Beat up an egg with a little water; mix it with four ounces of fresh-roasted ground coffee; then pour one quart or three pints of water upon it, and boil for five minutes; let it settle a few minutes to clear, or strain through napkin, flannel, or muslin bag. If this be done, it requires heating again; or, instead of clearing with an egg, pour a little cold water into the pot before taking it off the fire. It may be made this way on the night previous to marching; the cleared part poured off, bottled and corked, if made treble strong, and will keep strong for many days.—*Riddell's "Indian Domestic Economy."*

COFFEE, BURNT (The French "Gloria").—This coffee should be served in small cups, and be made as strong and clear as possible, and sweetened almost to a syrup. At the last moment a little brandy should

be poured gently over it on a spoon, fire set to it, and when the spirit is partly consumed, the flame blown out, and the coffee drunk quite hot. Allow a cupful for each person.—*Cassell's Cookery Book*.

COFFEE, ESSENCE of, to prepare.—Pour a breakfast cupful of boiling milk over a dessert-spoonful of the essence of coffee, and stir the mixture until it is smoothly blended. It is a good plan to keep the essence of coffee in the house when any one is in the habit of leaving early in the morning. With it a comforting cup of coffee may be made with very little trouble in a short time. Sufficient, three dessert-spoonfuls for a breakfast-cupful.—*Cassell's Cookery Book*.

THE SUPERIORITY OF INDIAN TEA.—Sir John Muir, Birt., at a recent function dilated to a great extent on the superiority of Indian tea over any other, and facetiously told how by a series of experiments he got Lady Muir to use nothing else at home. Sir John evidently holds a different opinion from that of Mr. Stuart Oranston, who in a recently-published pamphlet gives, as the result of the analysis of experts, apart from his own knowledge, his vote in favour of China tea, telling us that it contains a much lower percentage of tannin than the Indian and Ceylon plant.—*Glasgow Evening News*, Oct. 27.

CEYLON MANUAL OF CHEMICAL ANALYSES :

A HANDBOOK OF ANALYSES CONNECTED WITH
THE INDUSTRIES AND PUBLIC HEALTH OF
CEYLON FOR PLANTERS, COMMERCIAL
MEN, AGRICULTURAL STUDENTS,
AND MEMBERS OF LOCAL
BOARDS.

By M. COCHRAN, M.A., F.C.S.,

*Professor of Chemistry in the Ceylon Medical College,
City Analyst to the Municipality of Colombo, Member
of the Ceylon Branch of the Royal Asiatic Society.*

PREFACE.

THE following pages contain a record of analytical work connected with the various industrial enterprises and with the public health of Ceylon. A large portion of the work is necessarily devoted to agri-horticultural enterprises, these forming the chief industries of the island.

The work, in great part, may, therefore, be regarded as a contribution to the agricultural chemistry of Ceylon; and, as such, it is hoped that it will have an interest for planters, commercial men, and students of agriculture. I have, by way of illustration and comparison of Ceylon resources and products with those of other countries, drawn largely on the work of others, laying under contribution the best authorities within my reach on the subjects treated of. I trust this has added to the value of the Manual; and that the book, as a whole, may be regarded as a step towards the supplying of a felt-want, both on account of the comparatively full information supplied on some subjects, and by drawing attention to the lack of information on others, thus indicating lines of future investigation. Amongst

the subjects still requiring analytical treatment may be mentioned paddy and coconut soils, the annual rainfall, grasses, trees useful for shade or fruit bearing, Ceylon-grown cereals and food stuffs. The chemical examination of clays useful to the potter and cement manufacturer is likewise a desideratum. The mineral resources the island have received but little attention from a chemical point of view. For want of time and of skilled assistance, I have been unable to undertake any investigations purely from motives of scientific interest; hence the mineral analyses undertaken, as distinct from analyses of soils, are confined to surface rocks occurring on estates, plumbago and clay. A short chapter on precious stones and gems has been compiled from the work of others. The value of precious stones is based on their physical properties rather than upon their chemical composition; still the latter subject is of sufficient interest to justify the insertion of several analyses of precious stones and gems.

The direct bearing that the food and water supplies and the disposal of town refuse have on the public health, required the introduction of many analyses which will have an interest for all who are concerned for the public health. In this department further investigations are much to be desired.

Colombo, September, 1892.

CHAPTER I.—SOILS AND ROCKS.

PRACTICAL UTILITY OF SOIL ANALYSIS—FAILURE IN SPECIAL INSTANCES TO DETECT THE CAUSES OF INFERTILITY—DIRECTIONS FOR SAMPLING SOILS FOR ANALYSIS—ANALYSIS OF INFERTILE PADDY SOIL—ANALYSIS OF BURMA RICE SOIL—ANALYSIS OF JAPAN RICE SOILS—COFFEE AND TEA SOILS—DOLOSBAGE SOILS—MATALE SOILS—SOMBREORUM MANURE—DIMBULA, MASKELIYA, MATALE, AND VARIOUS OTHER SOILS—SOUTH COORG SOILS—BURNT SOIL—FIJI SOIL—CLASSIFICATION OF CEYLON COFFEE AND TEA SOILS—ROCKS AND STONES ON HILL COUNTRY ESTATES IN CEYLON.

As the cultivation of the soil is the most important of the industries of Ceylon, it is appro-

appropriate that I should begin this Handbook with analyses which represent the composition of Ceylon soils, so far as this has been determined.

Much has been said for and against the practical utility of soil analysis. When first the principles of chemistry were brought to bear upon the cultivation of the soil, it was confidently expected that methods of agriculture would assume the nature of an exact science. The cultivator had but to get his soil and a crop, such as he meant to raise, analysed, and he would see at a glance what constituents it was necessary for him to add to the soils in the shape of manure. Cases, however, occurred in which soils which yielded good results on analysis, were nevertheless found to be much less fertile than others which appeared to be lacking in a due proportion of available elements of plant food. Such instances still occur of failure on the part of the agricultural chemist to account for the infertility of a soil by the analysis of a sample thereof. Thus the planters of Ceylon have had before them the case in which the late Dr. Voelcker analysed a sample of soil taken from a patch of land on which coffee trees were dying out; but was unable to discover any peculiarity in the composition of the soil to account for the failure. The three most important elements of plant food—nitrogen, phosphoric acid, and potash—were found in proportions considerably above the average for Ceylon coffee soils, while no actively injurious substance was discovered. While frankly admitting, then, that present methods of soil analysis may fail, in certain cases, to detect a deficiency of available plant food, the solvents used in the laboratory being different from those at work in the soil, chemical analysis may nevertheless be generally trusted to detect an absolute deficiency of plant food in the soil, to discover the presence of injurious substances, and to give a general indication of the resources of the soil. The utility of soil analysis is also greatly increased, when a number of carefully selected samples of soils known to be fertile for any particular product have been analysed, so as to afford a standard with which to compare other soils on which it is intended to raise the same kind of crop, or which have disappointed the hopes of the cultivator. Care should, of course, be taken that the sample selected for analysis is representative. The following are the instructions issued by the Royal Agricultural Society for the collection of samples of soil for analysis:—

"Have a wooden box made 6 inches long and 6 inches wide and from 9 to 12 inches deep, according to the depth of the soil and subsoil in the field. Mark out in the field a space of about 12 inches square; dig round in a slanting direction a trench so as to leave undisturbed a block of soil with its subsoil from 9 to 12 inches deep; trim this block or plan of the field so as to make it fit into the wooden box; invert the open box over it, press down firmly, then pass a spade under the box and lift it up, gently turn over the box and nail on the lid. The soil will then be received in the exact position in which it is found in the field.

"In the case of very light sandy and porous soils the wooden box may be at once inverted over the soil and forced down by pressure and then dug out.

"When the soil is evidently of unequal character, separate samples should be taken of the different qualities and examined separately, as an indiscriminate mixing could only by chance result in yielding an average composition of the whole field."

Professor Church, formerly of the Royal Agricultural College, Cirencester, recommends the following method of sampling:—

"Where the soil of a field is uniformly and distinctly marked out from the subsoil, three or four parcels of earth may be taken from different parts of an acre. The surface vegetation and accidental foreign matter are first cleared from the selected spots; then a trench is dug down to the subsoil, so as to leave a square block 12 or 18 inches square of the surface soil intact; from this, vertical slices are cut until 5 kilograms or 10 lb. of each have been obtained. This material is then placed on a piece of sacking in a wheelbarrow. The same operations are repeated on the other selected spots, and from the united quantities of soil thus obtained, after thorough mixing with the spade, a final sample of about 4 or 5 kilograms (8 to 10 lb.) is taken. This should be transported to the Laboratory in a wooden box, not in a closed metallic or glass vessel. A sample of the subsoil may be obtained from the spots opened in the above operations, the depth to which the subsoil is excavated being at least equal to that of the soil.

When the surface soil shows any kind of inequality to exist in the texture, color, or other character of the surface soil, it will be necessary to take a number of representative specimens from places which resemble one another closely, and to mix them together. Then a second series of samples is secured from other places in the field, differing from those first selected; but also resembling one another. Of course, if three sorts of soil exist alongside of one another, a third series of samples will be required."

Much has already been done by the Ceylon Planters' Association in getting unmanured representative coffee, now mostly tea, soils analysed by Mr. John Hughes; but scarcely anything has been done for the paddy soils of the island, by way of determining the composition of fertile and infertile soils.

The following is an analysis of infertile paddy soil from the Walaganwala paddy fields. This was a soil on which the paddy plant grew well enough to a certain stage; but was unable to mature its seed. The air-dried soil yielded the following results:—

Analysis of Infertile Paddy Soil.

	per cent
Moisture	2.500
* Organic matter	6.460
Soluble in standard	
Hydrochloric acid	
Silica	.590
Iron protoxide	.836
Iron peroxide	3.526
Alumina	5.640
Lime	.126
Magnesia	.115
Potash	.077
Soda	.028
Phosphoric acid	.034
Sulphuric acid	.056
Chlorine	.012
Quartz and	
† Insoluble silicates }	80.000
	100.000

* Containing nitrogen

.129

† Containing silica

72.000

This analysis represents the composition of the soil which passed through a sieve having 10 meshes to the lineal inch. The sieve kept back 8.1 per

cent of gravel, nearly pure quartz, and .654 per cent of organic matter in the shape of roots, seeds, &c. The soil was of a free sandy nature, containing a very large proportion of insoluble siliceous matter. By a fusion analysis, the 80 parts of insoluble siliceous matter were found to contain 72 parts of silica leaving only about 8 per cent of basic substances as the future resources of the soil.

The element of plant food on which this soil appears to be especially deficient is phosphoric acid. I therefore took special pains in the determination of this ingredient. I made two determinations of the phosphoric acid soluble in hydrochloric acid with closely concordant results, obtaining only .034 per cent. A third determination of the phosphoric acid, in which the solvent used was nitric acid, yielded .045 per cent. This deficiency of phosphoric acid accounts for the paddy not yielding seed, as this ingredient of plant food is by far the most abundant of the mineral constituents of rice grain, and even in the husk it is present in greater proportion than potash or lime, as may be seen from a glance at the following analyses:—

Analysis of Rice Ash.

	Ash of Grain. * Average of different chemists.	Ash of Grain. (Muspratt.)	Ash of Husk. (Muspratt.)
Phosphoric acid	55.00	53.36	1.86
Potash	23.70	18.48	1.60
Soda	4.00	10.67	1.58
Lime	3.15	1.27	1.01
Magnesia	12.10	11.69	1.96
Oxide of iron	trace	.45	.54
Sulphuric acid0592
Chlorine	trace	.27	...
Silica	2.00	3.35	89.71
	100.00	99.54	99.18

On the other hand the whole amount of mineral matter in rice grain is so very small, viz., in dried rice .9 per cent, and in naked rice .3 per cent compared with other cereals, e.g., wheat, different kinds, from 1.7 to 3.02 per cent., oats 2.4 to 3.8, peas 2.4, beans 3.1, that paddy might be expected to succeed on land in which cereals richer in mineral ingredients would starve. This is just a case in which the analytical chemist would be materially assisted by a table of analyses of soils from fertile paddy lands to which he could refer. When compared with good paddy soils of other countries which have been analysed, the soil of the Walaganwala paddy fields must be pronounced very deficient in phosphoric acid.

The soil also contained .836 per cent of protoxide of iron, an ingredient generally regarded as unfavorable to plant growth; but the amount of this ingredient is rather less than the average of six determinations of the same in coffee soils.

The portion of the above soil not required for analysis was divided into four equal parts of somewhat less than 2 lb. each. These were placed in four pots. One was left unmanured, one was manured with sufficient bone dust to add .111 per cent of phosphoric acid to the soil, so that it

now had as much phosphoric acid as a good coffee soil. To the third pot of earth sufficient slaked lime was added to increase the lime by .260 per cent. The fourth pot was manured with a little dry cow dung. Four seeds of paddy were planted in each pot on the 19th of January. The pots were placed in the back verandah of my bungalow with northern exposure and were watered daily. From their position they could only get the benefit of the direct rays of the sun for a short time in the afternoon, a circumstance which was no doubt adverse to the natural development of the plants; but, if placed on the compound, the plants would have been liable to be cropped by animals.

The average time taken for the first three seeds in each pot to germinate and appear above ground was, in the soil treated with lime, 9 days; in the unmanured soil, 12 days; in the soil manured with bone dust 15 days; in the soil manured with cow dung, the first two seeds took 14 and 27 days respectively. On the 26th of May I measured the growth from the ground to the tips of the blades.

The results with other data are tabulated below:—

Length of straw from ground to lowest seed.	Number of Seeds in each ear.	Date when in ear.	Mean length.	Greatest length.	
14	2	June 1	3ft. 0 1/2 in.	3ft. 0 1/2 in.	Manured with Bone dust.
12	2	May 2	2ft. 9 1/2 in.	2ft. 9 1/2 in.	Not manured.
7	1	May 26	2ft. 7 1/2 in.	2ft. 7 1/2 in.	Manured with cow dung.
...	Treated with lime.

None of the seeds was well filled, and some were mere leaves. Although the paddy manured with bone dust had the greatest number of seeds, these were not quite equal in quality to those grown in the unmanured soil, and in the soil manured with cow dung. The sickliest plants were those in the soil treated with lime, although these were the first to germinate. These last came to nothing. The blades were short, of a very light green, evidently very deficient in chlorophyll. The blades of the paddy manured with bone dust were of a rich dark green, and those of the unmanured paddy were but little inferior. It is evident that, as grown to a great extent in the shade, the paddy has little if at all benefited by the phosphoric acid in the bone dust, but had profited somewhat by the nitrogen in the same. I cannot, however, infer from this experiment the comparative inutility of bone dust for the paddy crop; but simply that, having been added to the soil at the time of planting, this insoluble or rather very slowly soluble form of phosphate had not had time to be decomposed, and rendered

* From Johnston and Cameron's "Agricultural Chemistry."

available for plant food. Had the bone dust been in the soil for a season before planting, or had a more readily assimilable form of phosphate been used, and had the conditions of growth been more natural, I have no doubt the result would have been more markedly in favor of the phosphatic manure.

Although I cannot refer to the analyses of any Ceylon soils fertile for the paddy crop, I am able to quote from the "Journal of the Chemical Society" analyses of two Burma rice soils from Syrian near Rangoon. The analyses are by the late Dr. R. Romanis, Government Chemical Examiner at Rangoon, who says that in any one district "the valuation of the soil by the amount of phosphoric acid present corresponds pretty well with the settlement officer's valuation. Comparing two districts with each other, it was found that soil in one district, comparatively poor in phosphoric acid, might yield as large crops as soil in the other district which was richer in phosphoric acid; but it could generally be explained by the fact that, whereas in the latter, where the holdings were larger, the grain was sown broadcast, in the former the rice was grown in nurseries and planted out by hand. The conclusions drawn from these investigations by Romanis are that, climate and situation being equal, the value of the soil for paddy cultivation depends on the phosphoric acid in it, and that the planting out system is far superior to the broadcast system of cultivation.

The following are the two analyses referred to. Both are alluvial soils from the delta of the Irrawaddy. No. 2 was virgin soil.

Analyses of Burma Paddy Soils.

Japan Rice Soil and Ordinary Arable Soils.

Professor O. Kellner, Agricultural Chemist at the College of Tokio, Japan, gives analyses, shewing the chemical composition of the soil of the rice field as compared with the ordinary arable soil at the Experimental Farm of the College.

Comparison of the chemical composition of

ordinary arable soil with soil of rich field on Experimental Farm, Tokio. (Kellner)

	Dry Field.		Rice Field	
	Soil.	Subsoil.	Soil.	Subsoil.
Hygroscopic water	15.49	18.69	14.30	12.84
Loss on ignition	20.01	14.90	22.30	18.79
Humus	7.90	7.17	9.96	8.86
Nitrogen	.80	.60	.489	.799
Combined water	11.31	7.13	11.850	9.130

The soils of both fields dried at 100°C. and extracted with cold hydrochloric acid Sp. Gr. 1.15, gave the results shewn in the following table:—

	Dry Field.		Rice Field.	
	Soil.	Subsoil.	Soil.	Subsoil
Silica	.31	.29	.82	.79
Alumina	15.93	19.73	18.50	14.15
Peroxide of iron	11.73	11.36	7.00	7.49
Lime	.60	.66	.75	.70
Magnesia	1.41	1.44	.45	.55
Potash	.29	.18	.10	.17
Soda	.17	.13	.14	.01
Phosphoric acid	.19	.18	.37	.35
Sulphuric acid	.11	.12	.18	...
	30.74	34.09	25.31	24.21
Insoluble residue	48.30	49.48	50.00	51.16
Humus and combined water	23.67	18.33	26.02	25.83
	102.71	101.90	101.33	101.20

The character of the surface soils in Japan is modified by the prevalence of long droughts and high winds. The finest particles of the soil are blown across the face of the country, collecting in sheltered places after the manner of snow drifts. The rice fields, being moist, do not suffer in this way; but on the contrary are fertilised by this fine dust, part of which is arrested by the moist paddy fields. This fine dust is, therefore, highly prized by the cultivators of rice.

It will be observed that the soil of the rice field is nearly twice as rich in available phosphoric acid as that of the ordinary arable field. Both soils are very rich in nitrogen.

(To be continued.)

THE AGE OF ORANGE TREES.—There has been much discussion among horticulturists during the past few years concerning the extreme age that orange trees will bear well and produce good fruit. There are many who maintain that an orange tree, no matter how much care is put upon it, will slowly wither and die after it has reached half-a-century of growth. Others have argued that about seventy-five years is the limit of usefulness of a well-cared-for orange tree. Several horticulturists who have been travelling along the Mediterranean sea have recently found trees over 120 years old, that are still producing fruit of excellent quality. On the island of Elba, where Napoleon was banished, there is an orange grove of over 700 St. Michael orange trees that was planted by an Italian in 1781, and it produced last year over 1,800 boxes of fruit, but it produced four times that quantity twenty-five years ago. There are several small orange orchards in Southern Italy that are over eighty years old, and are still productive of large quantities of fruit. On the island of Malta, James Pellman found one orange tree that, there can be no doubt, is 142 years old, and that yielded seven boxes of fruit last year. It is even alleged that in the Azores there are orange and lemon trees over 200 years old that still bear fruit, but there is no good authority for the allegation.—*Horticultural Times*, Oct. 31.

NAMES OF THE FIELD CROPS GROWN IN THE MADRAS PRESIDENCY.

A Bulletin has reached us from the Madras Agricultural Department, prefaced by the following note:—

The following list of the synonyms of the common Field Crops of the Presidency has been corrected up to date; the Botanical names having been made uniform with those adopted in the Dictionary of Economic Products, and doubtful names in previous lists have been verified. Information regarding additional or local synonyms or pointing out errors in the list is invited by the Department.

The names are given in English, with the botanical equivalents. Then follow the names in Tamil, Telugu, Malayalam, Canarese, Hindustani and Uriya. We give the three first columns, the Tamil names being those ordinarily in use:—

English.	Botanical.	Tamil.
Paddy	<i>Oryza sativa</i>	Nellu
Great Millet.	<i>Sorghum vulgare</i>	Sholam
Spiked Millet.	<i>Pennisetum typhoides</i>	Kambu
Ragi	<i>Eleusine Coracana</i>	Kazhva ragu
Italian Millet	<i>Setaria italica</i>	Tinai
Do.	<i>Setaria glauca</i>	...
Little Millet	<i>Panicum miliare</i>	Shamai
Common Millet	<i>Panicum mileaceum</i>	...
Sawya Millet	<i>Panicum frumentaceum</i>	...
Kodo Millet	<i>Paspalum scrobiculatum</i>	Varagu
Wheat.	<i>Triticum sativum</i>	Godumai
...	...	Valgodumai
Barley	<i>Hordeum vulgare</i> varieties	Ganji
Maize Indian	<i>Zea mays</i>	Makkacholam
Corn	...	Kadalai
Bengal Gram	<i>Cicer arietinum</i>	...
Candju Pea, Red	...	Tuvarai
Gram or Dhol	<i>Cajanus indicus</i>	Kollu
Horse Gram	<i>Dolichos biflorus</i>	Moccaikkottai or Avarai
Field Bean	<i>Dolichos Lablab</i>	Paocaippayaru
Green Gram.	<i>Phaseolus Mungo</i>	Ulnndu
Black Gram.	<i>Phaseolus Mungo</i> var radiatus	Vayalpayaru
Field Gram	<i>Phaseolus trilobus</i>	...
Do.	<i>Phaseolus aconitifolius</i>	...
Oow Gram	<i>Vigna Catiang</i>	Karaman
Garden Pea	<i>Pisum sativum</i>	Pattaani
Ohilly	<i>Capsicum frutescens</i>	Milagai
Onion	<i>Allium Cepa</i>	Vengayam
Garlih	<i>Allium sativum</i>	Vellappundu
Turmeric	<i>Curcuma longa</i>	Manjal
Coriander	<i>Coriandrum sativum</i>	Kott
Cumiu	<i>Cuminum Cyminum</i>	Shira
Mustard—White.	<i>Brassica alba</i>	...
Black	" nigra	Kdangu
Indian	" juncea	...
Tamrud	<i>Tamarindus indica</i>	Puli
Pepper	<i>Piper nigrum</i>	Milagu
Ginger	<i>Zingiber officinale</i>	Ingi
Fenugreek	<i>Trigonella Fœœnum-grœœnum</i>	Vandayam
Caradamom	<i>Elettaria Cardamomum</i>	Elakkai
Jack	<i>Artocarpus integrifolia</i>	Pala

English.	Botanical	Tamil.
Pomegranate	<i>Punica Granatum</i>	Madala
Lime—Sour	<i>Citrus Medica</i> var. acida.	Elumico
Sweet	do var. Limetta.	...
Gnava—White	<i>Psidium Guayava</i> vars.	...
Red	<i>pyrifera</i> and <i>pomiferum</i>	Koyya
Mango	<i>Mangifera indica</i>	Mangai
Ca-bewnt	<i>Anacardium occidentale</i>	Mundiri
Coconut Palm	<i>Cocos nucifera</i>	Tennai
Areca (Betel) nut
Palm	<i>Areca Catchu</i>	Pakku
Plantain	<i>Musa sapientum</i>	Vazhai
Brinjal	<i>Solanum Melongena</i>	Kattiri
Cluster Bean	<i>Cyamopsis psoraleoides</i>	Kottavara
Melou Pnmpkin	<i>Cucurbita maxima</i>	Pusbio-nikkai
Cucumber	<i>Cucumis sativus</i>	Vellirikkai
Sweet Melon	<i>Cucumis Melo</i>	Karbuja
Water Melon	<i>Citrullus vulgaris</i>	Piccapazham.
Ladies' Fingers	<i>Hibiscus esulentus</i>	Vendaikkai
Sweet Potato	<i>Impomosa Batatas</i>	Vallikkizhangu
Tapieca	<i>Manihot utilisima</i>	Maravallikkizhagu
Do.	<i>Amorphophallus campanulatus</i>	Karakkaranai
Egyptian Arum	<i>Colocasia antiquorum</i>	Sheppan-kizhangu
Elephant Yam	<i>Typhonium trilobatum</i>	Karanai
Arrowroot	<i>Curcuma angustifolia</i>	Araruttu
Potato	<i>Solanum tuberosum</i>	Kuikkizhangu
...	...	Urulakizhangu
Sesame, Gingelly or Til seed	<i>Sesamum indicum</i>	Ellu
Castor oil seed	<i>Ricinus communis</i>	Amanakku Shittamanakku
Groundnut	<i>Arabis hypogæa</i>	Verkkadalai
Niger seed	<i>Guizotia abyssinica</i>	Peyellu
Linseed	<i>Linum usitatissimum</i>	Alivirai
Rapeeed	<i>Brassica campestris</i>	...
Safflower	<i>Carthamus tinctorius</i>	Kusumbavirai
Mobua	<i>Bassia longifolia</i>	Iluppai
...	<i>Bassia latifolia</i>	Kattiluppai
Sugarcane	<i>Saccharum officinarum</i>	Karamou
Palmyra Palm	<i>Borassus flabelliformis</i>	Pani
Date Palm	<i>Phoenix sylvestris</i>	Icamaram
Cotton	<i>Gossypium herbaceum, arboreum, and exotic species</i>	Parutti Puliccai
Dekkan Hemp	<i>Hibiscus cannabinus</i>	Shanal
Sunn Hemp	<i>Crotalaria juncea</i>	Kattazhar
American Aloe	<i>Agave americana</i>	or Rakai samattai
Indigo	<i>Indigofera tinctoria</i>	Avuri
Indian Mliberry	<i>Morinda citrifolia</i>	...
Morinda	" tinctoria	...
...	" umbellata	Nuna
Chay-root	<i>Oldenlandia umbellata</i>	Shayavér
European Mad-der	<i>Rubia tinctorum</i>	...
Indian Madder	" cordifolia	Mandishti vér
Safflower	<i>Carthamus tinctorius</i>	Kusumba.
Betel	<i>Piper Betle</i>	Vettilai
Tobacco	<i>Nicotiana Tabacum</i>	Pagaiyilai
Indian Hemp	<i>Cannabis sativa</i>	Gauja
Opium	<i>Papaver somniferum</i>	Api
Anise	<i>Pimpinella Anisum</i>	Si.ombu
Bishop's Weed	<i>Carmm copticum</i>	Omam
Country Senna	<i>Cassia obovata</i>	Nattu Nilavirai
Tinnevely Senna	<i>Cassia angustifolia</i>	Nilavirai
Tea	<i>Camellia heifera</i>	Tévilai
Coffee	<i>Coffea arabica</i>	Kápi
Cinchon	<i>Cinchona officinalis, succirubra, &c.</i>	Shurap-pattai

TEA ESTIMATES.

One "keenly observant" planter replying to "H.A.T." reminds us that he never said a word "against" the planters using their one great organization to collect an annual estimate of tea crop, *in place of numerous inaccurate irresponsible estimates*" (italics are ours), but against any estimate official or otherwise. He adds:— "If newspapers and representatives in Council erred greatly early this year, so did hundreds of superintendents in the case of the properties under their charge. And they are liable to do so again. An estimate now, when all are smarting under a sense of disappointment, if followed by a genial season, is likely to be as far under the mark, as estimates this year were over. Then what will become of the credit of the official estimates! A low official estimate would undoubtedly encourage shipments from China. Then, given a genial season, a crop 12 to 15 per cent over estimate, more China teas than would otherwise be the case, a fall in prices, and a happy time for the official estimators! "H. A. T." admits that, for the last nine months, the telegraphed shipments probably formed the only true basis for London operations. Why not let them do so in the future?"

Mr. J. L. Shand, writing on the 24th ult., offers a word of warning in respect of the Estimate for 1893. He will probably be pleased to hear of an "official" Estimate being arranged for by the P. A. Committee. He very fairly takes credit for having made the best estimate for 1892. He writes:—

"In February after I had had a good look round I wrote home:—'I do not think so far as I have seen, 1892 will be far ahead of 1891, 70,000,000 lb. with an ordinary season 74,000,000 lb. with an exceptionally favourable one will, I believe, be the thing. Many places show signs of having been hard plucked and will not do as much as they did last year.'

"This was the text from which a good deal of childish abuse was lavished upon me, but I adhere to every word of it. Nearly all the old planters I met and I travelled between Matale and Madulsima told me they would make less tea off their fields in full bearing in 1892 than they did in 1891—their reasons being 1891 had been an exceptionally favourable season and they had all let their tea run longer and plucked harder than they intended to do in 1892. In spite of all that has been said to the contrary 1891 was a more abnormally favourable season than 1892 has been abnormally unfavourable—the normal yield for 1891 should have been 59,000,000 lb.; for 1892 71,000,000; and for 1893 78 to 82,000,000. The weather alone is not to blame for the apparent shortcoming of 1892. If tea is plucked for 16 18 or 20 months without pruning, it of course takes longer to recuperate after pruning."

Now, we must say that the opinion we have formed is rather different in respect of the weather and this year's crop. At any rate during September-November a great deal more tea would have been made and shipped, were it not for unusually unfavourable weather, and the cry at this moment is that nearly all individual estimates are short—that is, estimates framed when Mr. J. L. Shand was in the island. However, there is the fact that Mr. Shand's "70" millions is the nearest guess at the actual result—may we say more by luck than good guidance, just as our own estimate of 68 millions made in July 1891 happened to be exactly right at the end of that year? Curiously enough for 1893, Mr. Shand gives nearly the same figures as we put forth tentatively ten days ago:—78 to 82—we said 78 to 83 millions.

THE CHINA TEA SEASON.

The beginning of the end of the tea season at Foochow has come upon us unprecedentedly early this year. There is an unsold stock of Congou left of 9,000 chests and we understand 7,000 chests more are

expected to arrive. This, in the ordinary course of business, would take a week only to dispose of, but it would seem that the actual close of the season is not to be yet, as the foreign buyers do not care to buy and the teasmen are in no hurry to sell. It is a feature in this month's business that a full fortnight elapsed without so much as the chance of shipping to Europe. Since the departure of the "Oanfa" on the 4th instant no steamer arrived to take the berth until the "Priam" yesterday, and even after this long interval, she leaves today with less than $\frac{1}{2}$ of a million lb. It is true that the "Pingsuey" and "Glenfalloch" are due next week but they will take no larger quantity each, and the month's export will be complete. It is curious that shipping should be going on in this desultory way at the last, but it does not alter the fact that the season has virtually come to an end unprecedentedly early. The following figures are interesting:—

	Stock on 19th Nov.	Arrived after.
	chests.	chests.
1880...	50,000	26,000
1881...	73,000	16,000
1882...	37,000	16,000
1883...	31,000	20,000
1884...	50,000	3,000
1885...	5,000	14,000
1886...	55,000	6,000
1887...	88,100	10,000
1888...	55,000	nil.
1889...	35,000	8,000
1890...	28,000	16,000
1891...	45,000	7,000
1892...	8,000	8,000 expected

—Foochow Echo.

INDIAN AND CEYLON TEA COMPANIES.

(The Echo, London, Nov. 23.)

A correspondent, who considers that we have "rather persistently" disparaged Indian and Ceylon tea companies, and that this arises from "a desire not to recommend" what we have no special knowledge of, forwards a few particulars, which we place before readers of this column:—Of Indian companies, perhaps some of the best known are the Assam, Darjeeling, Dooars, Jorehaut, Lebong, and Upper Assam. The £20 shares of the first-named are now quoted at 29 to 30. The company has 9,341 acres under cultivation, and after the payment of 6 per cent. On the Debentures, the distribution on the Ordinary capital has been 10 per cent. for 1890 and 1891, and 6 per cent. for 1892—the yield at the present price being rather more than 4 per cent. The Darjeeling, with a cultivated area of 2,094 acres, has paid 6 per cent. in 1890 and 1891, and 5 per cent. in 1892. Its £20 shares stand at 18 to 20, and the return at this quotation is 5 per cent. The Dooars, with 5,178 acres, after the payment of 7 per cent. on the Preferred capital, has distributed 10 per cent. on the Ordinary shares for three consecutive years, and at the present price the latter yield £7 11s 6d per cent., and the Preference £5 17s. The Jorehaut, with a rather smaller cultivated acreage, has paid dividends at a similar rate for 1890, 1891 and 1892, and at 30 to 32, the price now quoted, the return would exceed 6 per cent. Two properties, the shares of which are at a considerable discount, are reported to be on the improve, viz, the British India and Eastern Assam. The former is likely to pay 5s per share shortly, and it is deemed probable that the other may also come to the front again as a dividend-earning concern. Nothing has been paid since 1877. The Ordinary capital of the British India Tea Company, which originally was £240,000, has been reduced to £60,800, its market value at present quotations being not much more than £18,000. There are, however, £11,000 of Debentures bearing 10 per cent. interest. Of the Ceylon Tea Companies, that of the Ceylon Tea Plantations (Limited) stands high in public estimation, a dividend of 15 per

cent. having been paid each year since 1887. The £10 shares stand at 15, and yield a return of 10 per cent.; while the Scottish Ceylon Tea Company distributed 15 per cent. in 1890, 18 per cent. in 1891, and has paid an interim dividend of 10 per cent. for the current year, the £10 shares being quoted 16 to 17, and giving a return at that price of £11 5s. per cent. The results given above are good enough to tempt investors in this kind of security, but it must be borne in mind that sooner or later the supply may and probably will, exceed the demand; and if the market price of tea gets down below a certain level many estates not only cannot be advantageously worked but dividends will fall off. Anyone, therefore, electing to buy shares in tea companies should be especially careful to select those which are of the highest class, and whose tea is thoroughly appreciated in the Mincing-lane market.

We have received the following letter on the subject of "Shares as Payment" which will be of interest both to our correspondent "Contract" and also to others:—"Sir,—Your financial correspondent appears to me to be hardly correct in his answer to 'Contract' in today's *Echo*. I consider that he ought to have advised that 'Contract' would be quite safe in accepting fully-paid shares as remuneration for services to be rendered to a company about to be formed, provided that such shares were the subject of an agreement between 'Contract' (or the party from whom he had to receive them) and a trustee acting on behalf of the proposed company, and that such agreement was lodged with the Registrar of Joint Stock Companies before the issue of the shares. If that were done, the shares would be held as in every way fully paid, and no liquidator would be able to justify any claim on 'Contract' in respect of them.—Yours &c., "Nov. 21st." "S."

QUININE FOR THE MILLION IN INDIA.

Good news for cinchona planters (and there are still some left among us) is contained in the following telegram in the *Madras Mail*:—

QUININE FOR THE MILLION.

Calcutta, 8th Dec.—Yesterday's *Calcutta Gazette* contains the Government scheme for promoting the use of quinine among the millions of Bengal. It has been arranged that the drug shall be supplied of the finest quality from the Government Factory in packets of 5 grs. each, to be sold at one pice each. These packets will be sold at all public offices in the interior of the Districts such as the Police Stations, Outposts, Dispensaries and Post Offices. Pending the elaboration of the scheme, the packets will at present be sold at the Post Offices only, and the Postmasters will be paid a small commission on the sale. Private employers desirous of utilising this method of distributing the quinine will be supplied with packets.

We should press on the Ceylon authorities to follow this good example for the benefit of our natives in many feverish districts; the packets would no doubt be supplied by the Government of India for such a purpose at cost price. The benefit to planters will be found in the great stimulus to consumption, when the people of India realize the full benefit of the febrifuge, and their example is followed by the Burmese, Siamese and Chinese. All the bark as yet grown in the world would not then suffice for one-tenth of the demand. The *Mail* has the following editorial remarks:—

The experience of planters has proved that it does not require many doses before the coolie becomes fully cognisant of the benefit he derives from this febrifuge. There is but little doubt that if only subordinate officials were for a year or two to exert themselves in effecting the sales of these small packets of quinine, the demand would increase with astounding rapidity. We believe it is no exaggeration to say

that India does not produce sufficient cinchona bark for the manufacture of the quinine necessary for the proper treatment of the malaria that prevails in this country. Up to the present time only a minute fraction of the people suffering from this malaria has been either aware of the existence of this febrifuge or able to purchase it. There should be an enormous demand in Bengal, where hitherto practically none has existed. We trust that success may attend this new scheme, but this will only be when District officials take a direct interest in the sale of the quinine. The small commission to postmasters may prove an incentive, but the direct interest of the officials is what is chiefly required. At first prejudice must be overcome, but when once this has been effected, we feel confident that the millions of their own free-will will hasten to purchase the febrifuge. We are glad to see that the Government of Bengal permits employers to purchase these packets of quinine from it for the purpose of distributing them amongst their employees. This will probably be found in the end one of the most effective means of popularising quinine.

A BREED OF FOWLS SPOILT BY POULTRY JUDGES.

It is deeply to be regretted that in great measure the economic merits of the true Brahma, as the fowl actually was, belong now to the past, and are not found in the same degree in the fowl of today. Probably in no case have the vagaries of judges done so much harm as in this breed. At one time the two most prominent arbitrators of the day (since deceased) gave prizes so entirely to a peculiar pencilling composed of very broad dark markings, quite foreign to the Brahma fowl, that pullets resembling in shape and size small Silver-grey Dorkings displaced the truer-bred birds. Then an excessively pure "silver" pencilling was encouraged by the same judges and with the same result. These were temporary aberrations, and were both recovered from in due time, though not till a weak constitution and weedy habit had been introduced into many yards. But a more permanent mischief has been persistent judging and consequent breeding according to the Cochin type, and including the encouragement of profuse feather and vulture-hocks. The change in these respects has been enormous since the first edition of this work; as may be seen by comparing the engraved plates representing Brahmas as shown to-day, with the coloured plates prepared for the original edition of this work in 1872. What we here desire to insist upon is the fact that these differences, which can be seen at a glance when thus represented are not matters merely of personal preference, but have injured the fowl, which is no longer what it once was. With heavy hocks have come deficient breast and loss of constitution; the Cochin type itself has fostered the same want of breast; with the looser and more fluffy plumage are associated a more or less yellow skin, coarse flesh, inferior laying powers and sluggish temperament; for it may be stated as a general truth, that no "loose-feathered" breed is ever a good table-fowl, or a first rate layer. To a great extent, what was truly characteristic and best in the breed—its hardness, its pink or white skin and good flesh, and its splendid laying powers—have vanished, and we have instead (in reality now, what was wrongly affirmed in the early days), simply Cochins of another colour. This is in no way consistent with our remarks in Chapter IX. It has been no unavoidable result of "fancy" judging, but a result long and persistently foretold by the present writer, of foolish and flagrantly wrong judging. So really is this the case, that present profit and satisfaction from the fowl will largely depend upon simply reversing the disastrous path which has been followed, and returning to the older and more tight-feathered model. In keeping the Brahma for profit, all this must be considered. It will generally be found, at present, that the light variety is most valuable, both as a

table bird and as a layer; and if the Dark be chosen, the stock should be carefully bred and chosen by the *owner himself*, with reference to the neglected points, by which means a vast improvement may be rapidly effected.—From "*Wright's Illustrated Book of Poultry*."

TEA CHESTS OF UNSEASONED WOOD.

We had hoped that what had been previously written with respect to the injury inflicted upon the Ceylon tea industry by packing teas in chests of unseasoned wood, had completely put an end to the practice and to the many complaints reaching us from London to which it had given rise. For the last two years, there has been complete silence upon the subject of such complaints; and it was natural to conclude from this fact that a great, and, it was to be hoped, permanent improvement had followed upon the agitation previously raised upon this question. There is now, unfortunately, a recrudescence of such complaints. The Secretary of the London Wholesale Tea Dealers' Association had been directed to write to our London Association bringing to its notice a resumption of the objectionable practice by some Ceylon tea planters, and pointing out the injury thereby caused to the reputation of Ceylon tea generally. It is neither necessary nor desirable for us to again traverse the same ground that we followed when we wrote last on this subject. The evil consequences of packing teas in chests of unseasoned wood are now so fully acknowledged that nothing that we could add to our previous denunciation of the practice would or could be of any useful effect. The letter of the Secretary of the Wholesale Tea Dealers' Association would seem to indicate the existence of a belief that a return to the evils complained of may be due to the establishment of private saw-mills upon certain estates. It may be worth while to consider how far such a belief may have sufficient ground. Estate proprietors, undertaking their own supply of wood, must of necessity entrust it to men who might not unnaturally be deficient in the knowledge enabling them to discriminate between wood that is thoroughly seasoned and wood that is not so. They may also very possibly be duped in the matter by unscrupulous contractors or subordinates, an imposition to which specialists would not be likely to be open. Then again, it may be far from impossible that such private and unskilled agents may be deceived as to the nature of the woods they obtain and as to the suitability or unsuitability of many descriptions to the purpose designed. We apprehend that, if there be any known cases which have guided the suspicion of the faults exhibited being traceable to estates employing their own saw-mills, then the fault may be attributable to the possible wants of knowledge to which we have referred. For it would be most unlikely, we should assert, that, knowingly, any estate superintendent would be willing to risk his reputation and that of the estate the interests of which may be entrusted to him, by packing tea in chests of wood which he was aware was of inferior description or insufficiently seasoned. It would be cutting his own throat to do this, an operation he would certainly carefully avoid. We would, therefore, recommend all estate proprietors who may be the preparers of their own chest material to ascertain how far their agents may be qualified to pronounce upon the character of the timber they may work up. It will be poor economy to take the supply of their needs into their own hands, ignoring the practised dealer, if it is done at the risk of ruining the reputation of their

produce. "A little leaven leaveneth the whole lump," and even a comparatively few consignments of Ceylon teas possessing the "chessiness" of flavour complained of, must do much towards sacrificing the reputation, not alone of individual estates, but of Ceylon tea generally.

VARIOUS NOTES

WILL TEA LAST IN CEYLON? This is the answer of "Old Colonist" (Mr. A. Sinclair) in his lecture on "Our Leading Crown Colony" delivered before the Aberdeen Philosophical Society:—

"But will this industry last?" may well be asked after the various vicissitudes the Colony has already come through. I see no reason to doubt it. In the first place, tea is not an exotic like coffee; second, no island in the world produces tender leaf so profusely; labour is cheap and abundant; and third, the crop is not exhausting like the fruit or seed crops taken from coffee or cocoa. Moreover, there are tens of thousands of acres eminently suited for tea that never would have produced coffee. The only real danger is over-production. There is a limit to the capacity of even this tea-drinking nation, but in any case the Ceylon planter deserves well of British housekeepers. The fact that the price of tea has been reduced by one half during the last decade is chiefly, if not entirely, owing to the persistent energy of our countrymen there.

FRUIT GROWING IN CEYLON.—"R. S. M." writes to the *Morning Post*:—"Quoting from 'Ferguson's Ceylon Mercantile and Planting Directory,' I learn that in Ceylon there are 9,000 acres of pineapples and about 28,000 acres of plantains, or bananas. In 1890 fine oranges were offered freely in the market in Nuwara Elyya for 50c. (half a rupee) per hundred. What a field is open here for European energy and capital. All these products (and some of them can be grown with a minimum of labour and attention) are sure to meet with a ready sale either prepared or *au naturel*. It would be possible, I think, for Ceylon to enter into competition with Florida, and the transport would not take much longer. When the railway in Ceylon is opened to Haputale a magnificent country will be opened up for ventures in fruit growing, as well as the hitherto recognised staple products. In Badulla orange trees thrive wonderfully without any care. This town is 2,200 feet above sea level. I have heard of 200 oranges being picked off a tree without much affecting the appearance of the crop."

COFFEE PROSPECTS IN NYASSALAND.—The following passage occurs in the report of the Directors of the British South Africa Company issued for the year ending 31st March 1892, and published in the London papers of Nov. 26th:—

Under Mr. Johnston's Administration, steady development has been effected. During the past year successful operations were conducted against the slave traders in the district by the Indian police force under Captain C. M. M. Gore. It is now believed that with the assistance which the Imperial Government has at length afforded by placing two gun boats on Lake Nyassa and a steam launch on the Upper Shire, the power of the slave traders will be effectually broken. Recent reports confirm the favourable anticipations previously formed as to the resources and capabilities of the regions lying to the north of the Zambesi. Rich agricultural and pastoral districts are ready for occupation and cultivation, and indications of mineral wealth invite investigation by the prospector. Already the cultivation of coffee has made large strides. One planter alone, the Directors are informed, owns 1,000,000 coffee plants. Additional areas are being brought under cultivation by planters who have recently proceeded to the country.

MR. BARRINGTON BROWN'S REPORT ON GEM MINING IN CEYLON.

We place before our readers that portion of Mr. Barrington Brown's able and interesting report to the Syndicate by which he was employed, regarding the general position of the properties secured: the descriptive geology of the gem-bearing region of the Ratnapura district and a description of the numerous properties acquired or offered. The rest of the report, including a notice of the mode of working gem and plumbago mines by the natives, follows after this. It will be seen that the rock formations are generally of a simple character; the all-pervading gneiss being varied by graphic granite, hornblende gneiss and rarely by beds of granular limestone. The latter is probably the source of the spinels which are found occasionally amongst the more precious sapphires and rubies. The gems are just crystallized clay, and they are found, in more or less abundance, in beds of gravel known to the natives as "illan." In many cases, several beds of this illan can be reached successively, divided by strata of alluvial matter in the shape of mould and clay. It seems to us that the chances of success on the part of the Company depend largely on their attacking the lower beds of pebbles, for most of those near the surface must have been repeatedly searched in the course of the many generations,—the many centuries—during which gem-digging has been pursued, not merely by Sinhalese but by natives of India sent over for the purpose. The strange part of the matter is that no gems of consequence have ever been found in the rock-matrix, although one case is mentioned where an abundance of valuable gems were found beneath a mass of huge gneiss rocks. Has it never occurred to anyone to disintegrate and search those and similar rocks. Gems are largely found in rivers and streams, but into those rivers and streams they must have found their way from bordering and overhanging rocks. Mr. Barrington Brown refers only to rubies, sapphires and catseyes, as the gems to be searched for; but surely there are scores of other varieties. Garnets of small size form considerable constituents of the gneiss rocks; tourmaline of various colours is sold at a few shillings the pound for cheap jewelry; and in the course of digging operations through illan of a bluish gray colour were found flat pieces of a curious gray feldspathic rock, containing blue felspar and green mica crystals along with coarse pink spinels. When a stream dredger is used and regular mining appliances, we expect to hear of specimens being found of the vast variety of gems for which—with the finest pearls—Ceylon is so famous. The beautiful form of adularia called moonstone with its pearly and opalesque lustre is not valued as it ought to be; but there is no question of the great value of good specimens of the starstone, amethyst, alexandrite, aquamarine, chrysolite, chrysoberyl, topaz, zircon, &c. An alexandrite catseye must be especially rare and valuable; one was shown by Mr. Streeter at the Colonial and Indian Exhibition of 1886. Regular hydraulic working ought to be rewarded with good specimens of these and other gems, and we trust that gemming systematically pursued will prove equally profitable with plumbago mining on scientific principles.

If natives with their very imperfect methods of working have been rewarded with so much success in regard both to gems and plumbago, it seems beyond question that greater success in proportions should result from the adoption of scientific methods, including steam dredgers and hydraulic washings of formations. We are surprised as well as pleased at Mr. Barrington Brown's opinion that in the case of a large portion of the properties acquired by his company only a trifling proportion of the deposits have been worked by the natives. In view of the bits of gold found at one time in diggings at Ratnapura, it is curious that the search on behalf of the Syndicate should reveal only a few trifling flakes. A very curious piece of socialism marks the public auctions of gems. The nominal commission of the auctioneer is $1\frac{1}{2}$ per cent, but half of this sum he divides amongst the Moormen and miners present at the auction! We suppose outsiders are excluded from this "benevolence."—As regards some of the Nambapana plumbago mines, it will be seen that some of the veins yield cubes of pure graphite, weighing up to $1\frac{1}{2}$ ton. To continue mining of this nature, our readers will see that expenditure on drainage and ventilation, such as the native mine owners cannot accomplish, would pay well,—if the price of plumbago is not materially reduced by the finds in Travancore. We wait for a final deliverance on this point.

REPORT ON MINING PROPERTIES IN CEYLON FOR THE CEYLON GEM AND MINING ESTATES, SYNDICATE LIMITED.

Contents.—Gem Mines:—I. General Position, page 5; II. Descriptive Geology, page 5; III. Description of the Properties, page 7; IV. Mode of Working adopted by Natives, page 21; V. Butiyatenne Gem Sales, page 26; VI. Opinion on the Value of the Properties, page 28. Plumbago Mines:—VII. Position, page 32; VIII. Description of Mines, page 34; IX. Opinion on their Value, page 41.

London, 28th April, 1890.

The Board of Directors,

CEYLON GEM AND MINING ESTATES SYNDICATE,
LIMITED.

GENTLEMEN,—I have the honour to submit herewith my report on the properties in Ceylon, which I have made as concise as possible. I have much pleasure in acknowledging the great assistance I received in carrying out my investigations in Ceylon from Mr. Harding, your Managing Director there, as well as from the Hon. F. R. Saunders and Mr. W. Saunders. To the Hon. F. R. Saunders I am indebted for the assistance he secured me in our two Superintendents, Peris and Mendis, whose services were invaluable.

In the Report I have not entered into the cost of working the mines, as it will require a little time to make an estimate, and the extent of operations will have to be known first. I have the honour to be,—Yours faithfully, C. BARRINGTON BROWN.

GEM MINES.

I.—GENERAL POSITION.

The lands acquired for gemming purposes by the Syndicate are situated in three localities in the Province of Sabaragamuwa, where precious stones, chiefly sapphires, catseyes and rubies, have been mined for by natives from time immemorial and where, undoubtedly, many valuable stones, have been procured.

These properties which are situated in the vicinity of Ratnapura, Rakwanne and Doloswella, will be subsequently described. It is admitted by all the natives who have any knowledge of the subject, and

who either own or work gem lands, that some of these are in the best localities in Ceylon for gems that have as yet been discovered.

II.—DESCRIPTIVE GEOLOGY.

Gneiss forms the chief rock over all this portion of Ceylon. It is of a bedded character, the foliation coinciding with the bedding; and contains layers of graphic granite, hornblende gneiss, and in some few instances of granular limestone. The graphic granite and hornblende gneiss are usually seen passing gradually into the gneiss at the planes of contact; but the former exist also as veins in the gneiss. Granular limestones occupies a very subordinate position as regards its extent in beds, being only seen in three or four places, and in such instance in obscured positions. In other portions of the country it is said to be more fully developed. Very few instances of contorted foliation of the gneiss are to be seen, and fibrous varieties are rare. In some places this rock occurs in a series of thin layers, but is chiefly met with in extensive massive beds.

High mountain ranges, entirely composed of these rocks, cross the country, one the main range—culminating in Adam's Peak, 7,352 feet in height. These fall away to the plains on either hand at various distances from the sea coast. Minor ridges and isolated hills lie between, amongst which are extensive valleys, in which flow numerous rivers and streams having their sources in the mountains. All the ranges trend in a south-westerly and north-westerly direction about Ratnapura and Balangoda; but westward of Dodampe they run almost north and south; while at Rakwanne they lie nearly east and west.

The streams in their courses flow through alluvial valleys where nearly all the flat land is given up to rice cultivation. In the alluvium are layers of gravel which in many places are worked for gems, either by a sort of hand-dredging process with hoes under the beds of the rivers, or by pits sunk to them near the banks of the streams.

Upon the hill sides, bordering mountain streams and torrents, there is usually a heavy coating of hill-wash, in which are layers of gem-bearing gravel, which in some places is mined for gems. This class of gem-mining is the most important one in the whole colony, and the mode of working adopted more systematic than that carried on in the flat alluvial diggings.

By the decomposition and subsequent disintegration of the rocks forming the mountain and hill masses the precious stones contained therein in crystallized form have been liberated, and after transportation to greater or lesser distances, deposited in the alluvia.

As far as can be ascertained no stones have yet been discovered in the matrix, which undoubtedly is gneiss, graphic granite and granular limestone. Garnet crystals of small size very frequently occur in the gneiss and granite, forming in many instances a large proportion of the constituents of the rock.

III.—DESCRIPTION OF THE PROPERTIES.

The following is a list of the properties leased to the Syndicate by Native Owners, or offered for selection by the Government, and also includes one which was purchased:—

IN RATNAPURA DISTRICT.

1. Millewitiya ..	790 acres.	Leased by Owner.
2. Kahangama ..	253 "	" "
3. Maraiya ..	10 "	" "
4. Maraliyawatte ..	13 "	" "
5. Hiddelena ..	14 "	" "
6. Pothgool ..	20 "	" "
7. " ..	9 "	" "
8. Haldola ..	21 "	Offered by Government.
9. Weraniyagoda ..	55 "	" "

1,185 acres.

IN DOLOSWELLA DISTRICT.

10. Doloswella ..	1,200 acres.	Leased by Owner.
11. Dela Mindagama	1,000 "	" "
12. Erabodda ..	1,800 "	" "

4,000 acres.

IN RAKWANNE DISTRICT.

13. Butiyatenne ..	357 acres.	Leased by Owner.
14. Golden Grov ..	507 "	Purchased.
15. Spring Vale ..	235 "	Leased by Owner.
16. Depedene ..	220 "	" "
17. Fernlee ..	267 "	" "
18. New Depedene ..	226 "	" "
19. Melbrake ..	185 "	" "
20. Bulatkande ..	244 "	" "
21. Tulukan ..	213 "	" "
22. Upper Tulukan ..	123 "	" "

2,577 acres.

22A. Aratchy's Lot .. 2 acres. Leased by Owner.

IN KUKU KORALE (RAKWANNE).

23. Traquair .. 163 acres. Leased by Owner.

IN BALANGODA DISTRICT.

24. Morahela .. 7,000? acres. Offered by Owner.

The positions of these properties is shown on the accompanying map of one inch to the mile.

1. Millewitiya is a large property the greater portion of which is level, or very slightly undulating land, while the remainder is hill-side. Its northern boundary is about a quarter of a mile from the western side of the Kalu Ganga River, about $3\frac{1}{2}$ miles from Ratnapura. A fine stream comes off the hill, and flows through it, emptying itself into the Kalu Ganga; while the Hincla Ganga flows in a level bottom close by its southern side.

Pits were sunk on this property to test the value of the gem bearing gravel, "illan," as it is called by the natives, and which being short, is a convenient term to use. One of these was sunk on the edge of the stream above-mentioned, at a height of some 200 feet, in the alluvium bordering it, which showed nearly 4 feet of illan, with a cover of only 2 feet 6 inches of loam. Twenty-five cubic feet of illan, when washed, produced a good prospect. (See prospect No. 1.)

In the second pit, which was sunk at the head of a small stream on the level land in the vicinity of numerous shallow pits of some 2 feet in depth—where natives gem during wet weather, when water can be obtained for washing the illan procured—a depth of 13 feet 6 inches was reached. Here the first illan commences at the surface, and descends to a depth of 2 feet 6 inches, being composed of mixed gravel and loam. From this downwards there was yellow clay and 2 feet of illan a second layer; and beneath was bluish-gray clay covering a third illan of 2 feet in thickness. The fourth illan, of 3 feet in thickness, was of a bluish-gray colour, similar to the third, but mixed with flat pieces of a crinous gray felspathic rock, containing blue feldspar and green mica crystals along with coarse pink spinels.

The first and fourth illan, when washed, showed very good results, whilst the third was good and the second poor. In all, about 125 cubic feet was operated upon with very promising results. (See prospects Nos. 2, 3, 4, 4A & 5.)

The miners say that the top part of the illan produces catseyes and rubies and the lower sapphires.

In all, we obtained 42 pale blue sapphires of fair size and 13 pale rubies, besides chrysoleryl, topazine and pink spinel. The inference is that when working a large amount of gravel good sapphires may be met with amongst the large number of good-sized though off-coloured stones known to exist in the illan.

From the way this place has been worked, it is natural to conclude that it pays those who dig the numerous holes in the immediate vicinity which extend over acres of land. There is over 100 acres of this land, the surface illan of which could be easily washed in a sluice, water being led round the hill from the stream before-mentioned; besides other portions of the flat land to the south.

A few hundred yards north of this, on a small stream, are the remains of large workings in its bed, which is known as the King's Gem Pond, and the tradition relating to it, according to the natives living near the spot, is that at one time, ages ago, a Tamil king in India sent over every year one

thousand coolies to dig gems for him there. From this, across the level to Maraliya, there are numerous old shallow gem pits where natives have sought for precious stones.

2. **KAHANGAMA** has an area of 250 acres of hilly land with two flats, one at the head of a small stream and the other lower down on the same. This stream runs south for about half a mile in the property, and then turning east forms its boundary for a short distance, running still in an easterly direction, through it.

The prospects obtained from three shallow pits to surface illan resting on decomposed bed rock in the upper flat was good and showed a large proportion of sapphires, although of a pale blue colour, and one ruby of fourth quality of about $1\frac{1}{2}$ carats. Our other pit, in the lower flat, gave poor results, and contained surface illan. Both of these flats have been worked by natives to some extent, but to what degree can not be accurately determined. (See prospects Nos. 6, 7 and 8.)

3. **MARALIYA**.—This is a small property of some 10 acres, adjoining Millewitiya on the north-east. One pit on it was put down to a depth of 6 feet 3 inches, of which, from the soil downwards for 3 feet 3 inches there was a yellowish-brown clayey loam mixed with illan, in which were blocks of an old gravel bed cemented firmly by sesqui-oxide of iron. The prospect obtained from it was a very poor one, there being only one pale blue sapphire of about 1 carat found.

Owing to the illan being at the surface it could be easily worked when carted to a sluice on Millewitiya close by. Maraliya is constituted of flat land, with one small patch of rocky rising ground not far from the river. (See prospect No. 9.)

4. **MARALIYAWATTE** adjoining Maraliya on the north, and is all flat, or of a slightly undulating nature, similar to the latter property, having surface illan.

5. **HIDDELANA**, which is a small piece of land close to the Ratsapura main road, has a very small workable area of surface illan only, and seems to have been pretty thoroughly worked out. From the pit we had sunk we obtained very poor results, and from some illan I had washed from a pit of one of the owners there was not a gem of any sort to be seen. (See prospect No. 10.)

6. **POTHGOOL** is situated in a portion of a group of hills two miles due west of Ratsapura, near Karugola, the western face of which slopes down to the Hangomawa Ganga River. A small mountain stream flows through it called Nagaha-dola, and falls into the above-mentioned river. This small tract has been leased to the syndicate by the Gem Notary, who is credited with having made quite £200,000 at stemming. He informed us that he had made £85,000 out of his famous Ukatedenya alluvial mine near Ratsapura.

Near this property comes a lot of land of six acres in extent; and between it and the Hangomawa Ganga, partly on the lower slope of the hill and partly in level ground, a small tract of 9 acres (No. 7) which has been leased to the Syndicate and being similar, may be embraced in the description of the Pothgool lot.

On the upper part of the Nagaha-dola, on the hill top, a good amount of illan has been taken out by the owner, as well as on the side of the very precipitous face of the slope, from amongst large blocks of gneiss on each side, as well as in the bed of the stream. A large open cutting with a face of 60 feet in height has been excavated there which, if properly drained, could be worked by hydraulic power to good account. No work was being executed at the time of our visit, but the Gem Notary's brother said that they had got a quantity of precious stones out of this property, and pointed out a place under some huge gneiss rocks from which he had procured £2,000 worth of sapphires.

9. **WERANIYAGODA** is a tract of hill-side, adjoining Pothgool, on the south, of 55 acres in extent, offered for prospecting to the Syndicate by the Government of Ceylon, but without promise to lease, in the event of their agent applying for it. It has not been considered worth testing by the natives.

More to the northward, on the western face of the same group of hills, is the other property, called Haidola (No. 8), which they have intimated that they may perhaps let the Syndicate have. It consists of a little over 21 acres. The hills here are from 150 to 200 feet in height, and are traversed by two small streams, which, it is said, contained surface illan but which our local guide stated had all been gemmed by natives long since, and was now considered to be exhausted ground.

It was not deemed advisable under the circumstances to have trial pits sunk on these two properties as the chances of acquiring them after having done so were very uncertain.

10. **DOLOSWELLA**.—This is a large tract of land containing in all 1,200 acres, consisting of hilly country some of the ridges rising to a height of nearly 800 feet. Along the borders of the Hangomawa Ganga, which flows through it, are extensive reaches of flat alluvial land.

A trial pit was sunk close to a large mountain stream, flowing amongst gneiss rocks, and having a considerable fall, which is a tributary of the Hangomawa, joining it at about half a mile on to the northward. Here we reached the illan at a depth of 10 feet, at a lower level than the bed of the stream. The illan obtained was a dark gray sandy material, containing water-worn pebbles of gneiss and quartz, and gave promise of the lead extending into the hill. We were unable to bottom this pit owing to a heavy fall of rain, after we had dug out a large quantity of illan, causing a landslip which covered it over completely.

Out of 150 cubic feet of the illan, washed in basket batens, we obtained excellent results, although none of the sapphires were of first quality, though of very fair size. Judging from this, the promise of valuable stones, were a large quantity of ground worked, is very encouraging. The fine stream there having a steep run, can be turned to good account by hydraulic. Close by our pit is one not long since dug by the natives, from which, they say, they procured some good rubes and sapphires. One sapphire shown me, which came from a pit on the same stream, three miles higher up was of 12 carats, partly of first water and partly off colour. (See prospects Nos. 11 and 12.)

11. **DELA MINDAGAMA** is a large property a few miles northward of Doloswella, not far from Newitigala; its eastern boundary being the Wey-ganga River. The ground is hilly, but the ridges do not attain a height of more than 300 feet. Along the margin of the Wey-ganga is a strip of level alluvium, in which a pit was sunk at a distance of 20 yds. from the river. It reached a depth of 15 ft., in which was some 6 ft. of illan. Of the portion we washed we have obtained poor results. Owing to the friable and sandy nature of the alluvium, and the quantity of water in it, drainage is there rendered next to impossible. (See prospect No. 13.)

12. **Er boda** lies along the opposite side of the Wey-ganga to Dela, and has hills of the same height, with alluvium on the river's edge here and there.

Our pit on it reached a depth of 19 feet in yellowish clay and sand, but did not reach the gravel; the dangerous nature of the clay and sand passed through, and the influx of water prevented the men from sinking further.

Both Dela and this property are considered to be good gem lands; and the natives work the illan below the bed of the river, when the water is low, with long-handled hoes, with good results. A Sinhalese at Dela, who owns a small property, a good bungalow and 50 head of cattle, made his money out of precious stones, obtained by dredging in the river bed one quarter of a mile from his place, during the last 16 years. Commencing with absolutely nothing, he is now if not rich exceedingly well-off. He told me he has sold sapphires for as much as £100 a piece.

It has occurred to me that a stream re-digger, which could take up the bottom to a depth of 10 feet, worked in those portions of the river bed where there are no large rocks, would be able to deal with a large

quantity of material, and have every chance of success.

13 to 20. THE RAKWANNE PROPERTIES.—As these are all adjoining each other in the same valley, and are similar, they are described together.

BUTIYATENNE is situated on the south side of the headwater of the Rambuke River, and consists of rough undulating and hilly land lying between it and a steep mountain range to the south. Adjoining it on the west is Golden Grove Estate, consisting of undulating valley-land between the continuation of the same mountain range and the river; while next beyond it comes Spring Vale and Depedene, the latter properties extending across the Rambuke for some little distance on its northern side. Bulat-kande and Melbrake lie, one on the South, and the other on the north of Depedene, and are chiefly mountain-side lands; while Fernlee lies north of Spring Vale. While Butiyatenne, Golden Grove, Bulat-kande and Fernlee, are not at present under cultivation, Spring Vale, Depedene, and part of Melbrake are planted with tea. The Rambuke is, in this part, a mountain torrent of considerable size, flowing amongst gneiss boulders, whilst numerous similar rocks are spread over the surface of the surrounding country. On the road, the watershed between this and the Rakwanne River is 2,600 feet above the sea, while at Depedene, the river flows at a level of 1,770 feet, showing a rapid fall of 830 feet in a distance of two and a half miles; which renders the district a most suitable one for hydraulic workings, any amount of pressure being obtainable. Both Butiyatenne and Golden Grove are watered by numerous streams, two of which—Handapan Dula and its branch—are of considerable size, and contained a good supply during the dry season. From either of these an abundant supply of water may be obtained for working purposes, which can be easily led to any portion of the four properties situated on the south-side of the Rambuke.

Gemming on these lands had long been carried on in the shallow illans in the river and stream beds, and adjoining hill-wash, when some 16 years ago a rich layer of gem-bearing gravel was discovered near the watershed of the Rambuke. In working this, it was found that it formed a lead becoming deeper and richer when traced westward down the valley. This induced one of the Sinhalese mine owners to sink a deep pit in the stream bank on Butiyatenne, in which, at some 60 feet, he came to the lead which proved of exceptional richness, chiefly in sapphires of a fine colour. Since that time numerous pits have been sunk, and a large extent of ground mined by means of shafts, with tunnels driven from their bottoms, by which more than one gutter was discovered, and the contained gem-bearing gravel extracted. The main lead runs in a southwesterly direction, and will be most probably found in the portion of Butiyatenne leased to the Syndicate. On the six acre Butiyatenne lots, worked by natives, the deepest pit at present is 90 feet; and there the illan lies at a depth of 40 feet below the level of the present bed of the Rambuke. This deep illan does not appear to be in the hill-wash (though under it), but is a true alluvial deposit, and has a layer of under-clay called "Malawa," between it and the bed-rock. In this part of Butiyatenne a shallow illan, a few feet below the surface, likewise produced valuable gems; and in various other portions of these properties are layers of gravel in the hill wash, all of which are gem-bearing a greater or lesser degree.

The following information received from persons living on the spots, I think, well worth recording, as it throws some light upon the possible capabilities of these properties. On the hillside not far from the Depedene Bungalow, a coolie picked up a catseye which he sold for 50 rupees to a Moorman, who subsequently re-sold it in Colombo for 1,000 rupees. This stone was found lying on the surface at an illan out-crop. On other parts of the same estate the coolies turn out after heavy rain, and search on the surface of the ground in the tea fields for gems, sometimes with success.

The Manager of the Estate found some men gem-

ming in Depedene, one quarter of a mile west of the Bungalow, and had them arrested. The illan they had dug out of a small pit was washed by the conductor, and a sapphire found which sold for 400 rupees.

Mendis, our Superintendent, states that the natives formerly worked the shallow illans on part of Depedene and Spring Vale, as in Butiyatenne, and he has seen many valuable sapphires sold by auction in Rakwanne which have come from these estates. He himself, from a small pit in the latter property, of some 6 feet in depth, got out £200 worth of sapphires. He also said that whilst sinking our Golden Grove Pit, No. 2, a Rakwanne man, well-known to him, in passing visited it, and told him that 7 years ago, when Spring Vale and Depedene were abandoned estates, he put down a pit within 30 feet of where we were sinking, from which he got, besides sapphires, a catseye which he sold for 5,000 rupees. I found this pit to be about 12 feet deep and as it is on the slope at a level of 10 feet below ours, the illan there is evidently the one we passed through at a depth of 25 feet from the surface.

Across the road from our pit there are numerous old shallow pits from which, it is said, some very fine sapphires were formerly obtained; and that in the bed of the small stream at the lower rice store in Spring Vale, a catseye was dug out of shallow illan which fetched 4,000 rupees.

Our head man at Fernlee pit, who has ganned for years on Depedene and Spring Vale, showed me a place at the head of a small stream in the latter property flowing down to Depedene Bungalow, where there were numerous shallow excavations under large gneiss rocks, from which a good many stones had been procured. He said he had secured sapphires there of the value of 400 rupees each. When these estates were again put in cultivation, no gemming was allowed. The Rakwanne miners, if allowed, would gladly resume mining for gems in Golden Grove and the two above-mentioned estates.

It was deemed advisable to sink a few trial pits in these properties, for the purpose of ascertaining the positions of the various illans; and if possible to try for a deep illan in places where the covering might reasonably be supposed to be not great. Owing to the rocky nature of the hill-wash, which contained numerous large boulders of gneiss, the work was difficult and slow, and a great deal of blasting with dynamite had to be performed. We put down five pits, one on Butiyatenne near the foot of the mountain; two in Golden Grove; one in Fernlee; and one in Depedene. Of these, the centre pit in Golden Grove, at a depth of 27 feet, got into running ground and had to be abandoned the one in Fernlee, at 51 feet, reached the under-clay without passing through and well defied illan; while that in Depedene reached the bed rock at 42 feet, 32 feet below the bed of the river, after passing through a layer of gravel, 3 feet 6 inches from the surface, of one foot in thickness, which gave a poor prospect. (See No. 20.)

The second pit in Golden Grove, at a depth of 21 feet, struck an illan of a grey sandy nature, containing large well water-worn pebbles of quartz, which, however, did not give good results; and eventually came to the bed rock at a depth of 50 feet, 30 feet below the bed of the river. The pit on Butiyatenne, where we expected to reach illan at 18 feet or so, was down 50 feet without reaching the deep gravel; but as it promised well when I left, it was being continued. A so six men were engaged in getting out some more illan from the second pit in Golden Grove by a tunnel driven in on the south side, which work would only occupy a few days.

Besides these pits, some shallow ones were made, and gravel from three tunnels was tested; the resulting prospects from which, though promising, did not show any gems of value. But this could hardly be expected where a few trial pits are put down over such a large area. The object of so doing was to ascertain if the gem-bearing gravel was there, and if it gave indications of containing precious stones; and this I have satisfied myself is the case. (See prospects Nos. 14 to 24.)

Nearly all the properties mentioned, with the exception of Golden Grove, are leased to the Syndicate, some on one-tenth and others on one-fifth of the profits made in working them, and for all tea destroyed during mining operations the owner is to receive compensation at the rate of £60 an acre. The only ones now under tea cultivation are Depedene and Spring Vale.

During the time I was investigating the Rakwanne properties, I was informed by your Ceylon representatives that they had an opportunity of purchasing Golden Grove estate; and as other parties were trying to negotiate for it, they would be glad of my opinion on the subject at once. As I considered your mining operations in that part would be greatly hampered, should it fall into the hands of a rival company, I replied recommending its purchase on that ground alone, for at the time my examination of the properties was incomplete. Subsequently I fully satisfied myself of its intrinsic value.

22a. **ABATHY'S LOT.**—This small property is situated on the borders of the Rakwanne River, a short distance down from the village of Rakwanne, and contains not more than four square chains of alluvial land. The prospect obtained from the pit we put down in close to the stream was poor; and as the illan is below the bed of the river it would be difficult to work. (See prospect No. 26.)

21. **TULIKAN** is situated on a steep mountain side about one mile west of Rakwanne, but does not extend down to the valley. It contains one stream, flowing from Upper Tulikan, the illan of which does not show any gems.

22. **UPPER TULIKAN** is a mountain top property above Tulikan which has two small streams, upon which are three diminutive level flats, having a layer of shallow illan, showing no gems as far as my prospecting went. (See prospect No. 27.)

23. **TRAUVAIR.**—In the young tea cultivation of this estate is a small valley through which flows a good sized stream having small branches, where some gem diggings are situated, as well as in the jungle adjoining it on the west. There is an area of 7,000 square yards of land suitable for gemming purposes a portion of which is leased to a Sinhalese miner of Rakwanne. It is said to be a novel place for catseyes as is also the Government land in the vicinity. Near the Bungalow of the estate, a few yards from the stream the illan is met with at a depth of 9 feet, and is some 2 feet in thickness. Besides chrysoberyl, catseyes and small worn pieces of plum-bago, a violet red tourmaline—a sort of rubellite—is found. The latter, which is common there, when heated becomes white, and is sold at six rupees a pound, to be cut for cheap jewellery. This property could be worked to advantage, the fall of land allowing the gravel to be drained. The conductor of the estate has a pit there from which he obtained a catseye which sold for 400 rupees. (See prospect, No. 28.)

24. **MORAHELE**—Here the Syndicate has only a promise of a large tract of land along the Wellaway ganga of seven miles in length. I went through the property, but did not see any signs of gemming having been done there, and from the information obtained from the native, I was led to conclude that it was not a place where gems had ever been found.

We visited an estate near by called Massena, which was offered for sale, and had a pit put down in one part which showed poor results. The illan there was at the surface, and apparently of no great extent, and the place is not worth buying. (See prospects, No. 29.) With exception of a small tract of land at Athede, a place some ten miles down the Wellaway ganga from the main road, where in the alluvium of the river a few people are gemming, there is little being done, as far as could be ascertained, in this district.

IV.—MODE OF WORKING ADOPTED BY NATIVES.

Surface illans occur in the upper parts of river alluvium in some places, and in the upper portion of hill-

wash on mountain sides in others. They are easily worked, the ground being first loosened by means of short chisel-end crowbars, and then dug out with hoes called "mamatees." In all kinds of mining in loose ground these are the only tools used. When working amongst large rocks on the mountain side, blasting is frequently resorted to, to enable the miners to extract the illan from beneath; while in some instances fires are built under them, and when heated, water is thrown upon them, which causes them to split up, and thus their removal is facilitated. Small tunnels are often made under the large boulders. The extracted illan is put in small baskets made of rattan cane, and carried to the nearest stream, where it is washed in large, closely-constructed baskets of split bamboo, shaped like a batea, and having a rounded thick rim inside its upper edge. The baskets are worked with a semi-rotatory motion, the clay loam and sand being thus washed out, while the lighter particles of pebbles are run over the rim, the heavier and precious stones, by their gravity, remaining behind. After a certain number of small basketsful have been put in and washed in succession, the number being regulated according to the supposed richness of the material, the washer sorts the resulting gravel carefully over by hand, picking out the gems and placing them in small bamboo tubes. This mode of procedure is continued until all the illan extracted from the pit or hole has been washed and sorted. From many of these diggings valuable stones have been procured.

PITS IN ALLUVIUM.—These are sunk in the alluvial strips along the edges of small rivers, to the layer of illan which is usually met with at a lower level than the bed of the present stream, usually from 1 to 10 feet below it. No large rocks are met with, and seldom is it necessary to timber the pit's sides, unless in sandy, running ground. Accumulated water is hoisted out, as well as the excavated material, by buckets and baskets attached to a balance pole. These pits are usually made of a considerable area so as to obtain as much illan as can be got at beneath; but when that is taken out for the full size of the pit's bottom, the shaft is abandoned, and a fresh one sunk close by. The mode of washing is the same as adopted in the case of surface, and all other illans, no matter from what depth it has been procured. But in one or two instances a large, long, wooden trough—a kind of sluice—with perforated iron gratings is used, a stream of water being conducted through it. By this method of procedure all the clayey matter is carried off in suspension; but, owing to the imperfect way in which it is used, much sand remains behind, thereby rendering it necessary to wash the resulting gravel in batea baskets. When timber corner posts are used they are braced across with round timbers, wedged horizontally, to keep the sides apart, and either upright planking, or small poles, and grass are placed behind to prevent the walls from falling. This is the chief method of working adopted by the natives, and from these sources have come most of the gems for which Ceylon is so celebrated.

DREDGING IN LARGE STREAM BEDS.—When the rivers are low, from November to April, this method of obtaining gems from below the beds of the streams is resorted to. Selecting a spot where there are no rocks, a rude dam of bamboo is constructed almost across the river, and the force of the current concentrated upon the spot to be worked. Five or six men with large hoes, having handles 20 feet in length, drag off the sands and clays of the river's bottom down stream towards them, which the current sweeps away. In this manner they excavate a large paddock to a depth of 8 or 10 feet, as the case may be, down to the surface of the illan. This they carefully haul out, and placing it in baskets, transport it to the bank, where it is placed in a heap. When they have extracted all they can obtain, it is washed in the usual way. Where possible, they cut down the banks of the river, which are some 15 feet in height, and proceed as in the case of working in the stream. In one instance I saw a party of these dredging miners who had cut down and removed, assisted by the rush of the water, a

corner of a bend 30 yards in length with a greatest width of 15 yards, and thereby procured, at a depth of 9 feet below the water, and 21 feet below the top of the alluvium, a large area of illan of 1 foot 6 inches to 2 feet in thickness, from which they said they were obtaining a good return.

In most of these dredging places the miners get fine specks of gold in the underclay, but not in paying quantity.

Near Ratnapura I saw two large batea baskets of illan washed by a small party of men engaged in dredging, which showed one large pale sapphire of about 10 carats, some small similar ones and a catseye.

DEEP PITS NEAR MOUNTAIN STREAMS.—This mode of mining is conducted on more systematic principles than any other gem mining in Ceylon, and at present, as far as I am aware, is only carried on in the Butiyatenne district, from near the watershed of the Rakwanne and Rambuke Rivers, to some distance down the Rambuke Valley.

The nature of the gem-bearing gravel is of a different character in Butiyatenne to what it is elsewhere in elevated valleys, and more nearly resembles a deep lead, in countries where gold is obtained. While the old gutters, some 40 feet below and alongside the present bed of the Rambuke stream, have had gem-bearing gravel washed into them, the superincumbent strata is old hill-wash, being a homogeneous reddish and yellowish clay, in which great boulders and blocks of gneiss are embedded, that have not been brought into their present position by the stream, but by the washing down of clay from the hill-sides. These leads are said by the miners to run more or less parallel to the beds of the river at first, and then to turn more to the south-westward, and are supposed to continue under the Golden Grove property. About 16 years ago the Government sold some reserved lands along the edge of the Rambuke, commencing about 300 yards or so westward of the watershed at Butiyatenne, in six acre lots, and these were purchased by the owners of the adjoining estates. Some of these, bought by the proprietor of Butiyatenne, are leased to Sinhalese men who have some capital to enable them to work them on one-fifth of profits. A description of the mode of working one of these pits will suffice for all. The shaft, 12 feet by 7 feet 6 inches in area, in reddish hill-wash, has no planking, as the ground is firm, but has upright corner posts held in their places by round timbers between each, at distances apart of about three feet; while across the centre of the pit are timber braces in line at every four feet or so. The depth from the surface to the bottom is 90 feet. Over it is a thatched shed for protection from the weather, and a windlass with buckets for hoisting out the stuff and water. From the bottom of the pit are levels driven in various directions, at first in search of the lead, which was found a little to the south of the shaft, and followed in a south-westerly direction for 180 feet, where from want of ventilation no further work could be done. The drift under the river also struck illan and a lead was worked both north and south. These drifts and cross cuts are small and low, except in places in the gutters, where they are three to four feet high in illan, but narrow, the bed-rock rising up on either hand. In some parts the gravel is not more than six inches thick, and almost dies out, being connected with the next by a thin layer of sand. Beneath the illan is usually a layer of stiff yellow under clay lying on the bed-rock. In the leads nearest the river are found precious stones of small size and much waterworn, while those in each succeeding lead become larger and less worn. The lights used by the miners are small, flat, open earthenware oil lamps, with pieces of wick lying in them, the ends hanging over lips in each corner. They also use the ordinary tin kerosene oil lamps near the bottom of the shaft. From the pit bank, where the gem-bearing gravel is stored when brought up, it is thrown in a long, steep, wooden shoot, which carries it down to the water's edge, where it is washed. When a pit is abandoned, the timber is all removed for future use.

Only Sinhalese men are employed in mining, and as many as 100 are engaged about one pit at a time. Six

pits were in operation at Butiyatenne in January and February last.

In order to point out the value of these mines I may here mention, that I obtained a statement from our Superintendent which I got from the owner of the pit just described, whereby it was shown that the latter had, for the year 1889, obtained from his pit gems that were sold, chiefly by auction at Butiyatenne, for 17,500 rupees; and that the cost of getting these amounted to 7,400 rupees, leaving a profit of 10,100 rupees. The principal pit owner there as per a similar statement sold gems during the same period amounting to 40,000 rupees in value, at a profit of 24,500 rupees. The wages paid to men working in the mines is from 1 to 1½ rupees per day, while surface men receive from 50 to 87 cents.

It is impossible to obtain any reliable information regarding the number of natives engaged in gemming operations, but it is supposed that the greater portion of the inhabitants of the Ratnapura and Rakwanne districts make their living out of this class of industry. Numbers of Moormen are engaged in the gem traffic, and they employ a considerable number of men cutting and polishing inferior gems for cheap jewellery, which finds a market in India.

The deep pits are worked all the year round, but the other classes of gem mining, owing to the rains can only be prosecuted, it is said, from October to May

V.—BUTIYATENNE GEM SALES.

On the 2nd of January I attended a sale by auction of precious stones obtained from three pits, the proceeds of their working from 27th of November, 1889, to 3rd of January 1890:—

FIRST PIT.				
1 Parcel	{ 2 large Catseyes	...	} Sold for	
	{ 12 Sapphires, weighing 26 carats	...		
	{ 70 do do 73 "	...	} R	
	{ 1 Parcel of mixed stones	...		2,310
			225	
SECOND PIT.				
1 Parcel	{ 13 large Sapphires, weighing	carats 31	} R	
	{ 41 small do do	32		
	{ 1 Parcel of mixed stones	...	} 910	
				165
THIRD PIT.				
1 Parcel	{ 21* Sapphires, weighing	49	} R	
	{ 60 do do	42		
	{ 1 Catseye	...		
			} 1,400	
				35
				24
			35	
			Total	
			R5,104	

On January 22nd, the principal mine owner at Butiyatenne brought me the result of one week's work in his pit to show me the pick of the stones he got—a lovely lot of sapphires of first quality, without flaws. One was a sapphire of little over five carats, valued at 300 rupees; the remainder of small sapphires, valued together at 300 rupees. Next day he sold the whole to a Moorman for 550 rupees.

I attended another sale at Butiyatenne on February 26th, the result of some seven weeks' work of the pit I have above described.

Carats.				R.	
1 Parcel,	30 Sapphires of	170	...	}	5,120
"	60 "	124	...		
"	84 "	95	...		
1 Parcel,	3 large Catseyes		280
1 Parcel of	mixed stones		620
					6,020

There were also some small parcels from other pits which realized together 153

At these sales the auctioneer receives 1½ per cent on the amount realized, of which he has to distribute half, ¾ per cent, amongst those who attend the sale, whether Moormen or others, in proportions in accordance with their standing in life—a most curious custom.

* One of these sapphires was of 25 carats.

On March 1st, the principal mine owner sold the gems he obtained from two pits, one an old abandoned one, which he re opened on the six acre lots at Butiyatenne, and the other on the Aratchy's lot, near by.

OLD PIT.

	Carats.	
1 Parcel, 3 Sapphires of 13 ...	13	} R900
" 12 " "	24	
" 9 " "	15	
" 9 " "	26	
" 31 " "	31	
" 13 " "	17	...

	Carats.	
1 Parcel, 6 Sapphires of 16 ...	16	} R650
" 19 " "	31	
" 2 Catsyes	...	
" Mixed stones	...	

He also sold at private sale as follows:—
 1 Parcel for R400
 " " " " R170
 R570

The price of good sapphire in Ceylon is £6 a carat, and there is a fair sale for all gems of inferior quality. Catsyes are at present in demand, and bringing high price.

VI.—OPINION ON THE VALUE OF THE PROPERTIES.

In order to form an opinion on the probable value of the properties you have leased, or secured in other ways, it was found necessary to obtain all the procurable information as to what had been done by natives in the gemming line in these districts and other parts of the country, so as to render the investigations as searching as possible, and to supplement this with my own personal observations. With this object in view, I visited the native mines within reach, however, were somewhat limited in extent, and procured a reliable information as I could. In this I was greatly assisted by the help I received from those who were appointed by your representatives here to carry out my instructions, in testing the lands required by you.

Gemming having hitherto been carried on by natives alone in an unobtrusive way, very little is known of what has been done, and only when sales have been held, at which anyone who pleased might attend, has any accurate idea been formed of the extent of the production of this class of mining, by the value of the gems sold. The Government has not interfered in any way in the matter, save with the exception of exacting licenses from those working on Crown Lands, and no official records have been hitherto kept. Thus it is not known for how many years the alluvial deposits have been worked, nor data at hand to guide anyone investigating the matter in coming to a conclusion on the value of these deposits. I have given above all the information that could be collected from native sources, together with my opinion of the prospects I have obtained from your properties.

From my experience of the deposits in which precious stones are discovered, and the prospecting I have done, coupled with native results and information, I have been enabled to arrive at the following conclusions, viz:—

That there are extensive gem bearing deposits in certain districts in the Colony.

That some of these are more or less rich in gems of value.

And that some of the lands leased by you, if judiciously and scientifically worked, should undoubtedly yield good results.

Some of your properties, viz.: Butiyatenne, Golden Grove, Spring Vale and Depedene, are so situated that hydraulic mining can be resorted to with good effect, so that a large extent of gem bearing deposits of a promising nature can be worked rapidly and reasonably. By this method of working the large amount of material, yielding gems in various quantities, and of various sizes,

when worked by natives in a slow laborious way thus subjected to treatment in a short space of time, should produce a large amount of precious stones at small cost.

The nature of the alluvial deposits, more especially of the hill-wash, which contains layers of illan disposed in uncertain positions and directions, which renders pit sinking in order to strike them a risky and expensive undertaking should, with hydraulic mining, be rendered easy and profitable; and all the small irregular layers of illan should be found and utilized; while the deep leads, on being thus exposed, should be discovered and easily worked where they exist. These latter are in places, such as beneath the 6 acre lot mines on Butiyatenne, proved to be very rich in sapphires of the first quality, and often of large size, besides good catsyes and other gems. They are at various depths below the present level of the bed of the stream, in old gutters as deep in places as 100 feet from the surface. By commencing operations at the lower ends of Depedene, Golden Grove and Butiyatenne, and cutting away with water about 100 feet in depth of surface deposits for some distance, a perfect drainage can be obtained, and continuous workings upwards of the properties be thus effected. One of the chief difficulties will consist in the getting rid of the huge blocks of gneiss in hill-wash, but I think this can be done. Water in abundance can be obtained, and led from streams in the higher parts of the properties along the mountain sides, or in flumes, and any degree of fall, producing any amount of pressure may be obtained. No expensive dams for storing water will be required. By this means continuous workings of 100 yards in width, in a distance of nearly three miles, may be secured.

On Millewitiya, water can be led to the shallow illans there, for washing purposes in sluices, but they will have to be dug up. In the case of the surface illan, this can easily, and I think, be profitably done; for here we had good prospects though the colour of the sapphires was light.

At Doloswella, where I prospected, the place is suitable for hydraulic mining, and should also yield good returns of sapphires, as the result of our pits there showed great promise, and the lead was running into the hill.

At Dela and Eraboda, the chief difficulty will be in getting rid of the water, as the river is large, and the illan in the alluvium is below the level of the bed; but I think, with a steam dredger provided with a shoot, at certain states of the river, in those parts where there are no rocks, the gem-bearing gravels, 10 feet to 12 feet below the bed of the river could be excavated and washed for gems with advantage.

In giving an opinion on the paying capabilities of such deposits as those described, it must be understood that the irregular nature of the gem-bearing gravels makes it a most difficult matter to give a positive and decided answer to the question—will they pay to work? The working of such is a lottery, like the manipulation of most superficial deposits. But there is little doubt of the gravels containing valuable gems, and when such are discovered, as should be the case at times, along with small stones, they will pay for dead work, or the finding of numerous light off-colour stones, and leave a considerable margin for profit. The latter are, as my prospects show, on some of the properties, very numerous. On Butiyatenne quantities of fine stones of small, and many of large size have been found, as described above in my notes on those I saw at the sales I attended; and some which were besides shown me by their finders—the lessee of the pits—who afterwards disposed of them by private sale. There can be no doubt of this, I think, that quantities of valuable sapphires and true catsyes have been dug up in these gem districts of Ceylon by natives for a long series of years; and that but a trifling portion of these deposits has been worked out.

I certainly can recommend the Syndicate to commence hydraulic mining on their Rakwanne properties, which I am of opinion will turn out to be a profitable undertaking. They might also at the same time

begin operations at Millewitiya and Doloswella, and elsewhere should these prove remunerative, as I think they will.

Limited prospecting of shallow and deep illan gives but a slight clue to the value and extent of the illan beneath the surface, and a preliminary examination like the present one in which I have been engaged, produces but a slight idea of what the probable results may turn out. It would take a long period of time, at great cost, to enable one to say positively where the best grounds are situated; and it is in these cases only by actual workings, as I have described, that a true knowledge of the value of the properties the Syndicate has procured can be accurately ascertained.

On the Rakwanne properties, apart from a portion of Butiyatenne, no gemming operations by natives are now being carried on, as the owners of these have not permitted it.

REPORT ON SOME PLUMBAGO MINES IN CEYLON.

VII.—POSITION.

NAMBAPANI DISTRICT.—The plumbago mines I visited in this district are situated on the sides of a mountain range, of about one thousand feet in height, trending nearly south from Kirillawella point; and are distributed over an area of seven miles in length by one mile in width. There are two sets of veins, the one on the western side of the range dipping with gneiss rock which encloses them in a westerly direction, and those on the eastern side in an easterly direction. The gneiss is of the usual composition and character as before described, but the bedding and foliation here strike north and south, instead of north-east and south-west at Ratnapura, and east and west at Rakwanne. In all other respects the rock is the same. Flowing in a gorge across this range is the Katuganga, a fine river, at a distance of $2\frac{1}{2}$ miles from Nambapani resthouse by the road, or $1\frac{1}{2}$ in a straight line.

Eight mines are at present being worked, the principal being designated as follows:—

1. Kirillawella Owners Pedrick and Brampy Peris
2. Tunpel-hena Owner Priest of Dumbra Temple lands
3. Palapola " " " "
4. Malipola " " " "
5. Ehetepola " " " "

Of the other mines, $4\frac{1}{2}$ and 5 miles from the river in a direct line, upon the same veins, one belongs to Pedrick and the other to the Dumbra Temple; but these were not visited.

Of the five mines mentioned in the list, one leased to the Chetty, known as the famous Dumbra plumbago pits, are second to none in the island for the production of plumbago of the first quality. Next to this in the district is Kirillawella mine, and probably the third is Tunpelehena.

They were all discovered many years ago by the natives living on the spot finding small loose pieces of plumbago on the surface of the soil, when open diggings were commenced, and continued to a depth of many feet, where the veins were small, narrow and branching; but these when followed in depth seemed to come together. When the solid undecomposed gneiss rock was reached they increased in size, but, owing to the influx of water and hardness of rock, were more difficult and expensive to work. At this stage, such mining required the aid of capital and skill, in order to free the workings from water, and in this the natives are deficient; so the works are not prosecuted as they might be by European companies in command of capital.

I will now proceed to describe each mine in the order in which I visited them.

VIII.—DESCRIPTION OF MINES.

TUNPELEHENA MINE.—This mine, some three miles south of the Kalu ganga, is reached from Nambapani by traversing the main road to Ratnapura for $3\frac{1}{2}$ miles, and then crossing the river in a ferry to the south side, and continuing the journey along a path for 3 miles to an elevation of about 600 feet.

The main vein is in a decomposed gneiss for a depth

of 50 feet, and in grey gneiss of a solid character downwards. Two large open cuttings, and one pit, 7 feet by 10 feet, of a depth of 60 feet, timbered, and provided with a strong windlass form the chief workings.

No. 1 Cutting has had 45 tons of plumbago extracted from it in decomposed rock, and some from the solid gneiss. It is 40 feet by 50 feet, with a depth of about 50 feet. On its south side are three drifts, one above the other, and on the west are three more on a sort of imperfect parallel vein, but these have been discontinued. Both this and the main vein have branches which shoot in various directions, but are small; and the main vein, where first worked, is 4 inches wide, dipping east at an angle of 10° in the decomposed rock, while the solid beds of gneiss dip at an angle of 50° in the same direction, and there the vein coincides with this. Fifteen feet from the south end of the cutting is the pit which struck the main vein at a depth of 50 feet, and the lessee says cost 5,000 rupees to sink; but this I think cannot be correct, and probably includes work done on the vein besides.

The main vein runs in a south 15° east direction, and has been proved for 100 yards in length by open cuttings. From the first cutting, one of the drifts was driven through to the pit, which in its south side has 3 drifts at various levels, the longest being 82 feet; and 8 on the north. In the deep level the width of the vein varies from 5 to 6 inches, but in places is nipped to smaller dimensions.

No. 2 Outing is 100 yards southward of the first, and is 60 feet by 70 feet, and 60 feet deep, in which is seen the main vein of 4 inches in width, together with small parallel and branching ones. The shaft was partially sunk by other lessees, and 6 months ago the present lessee continued it and struck the vein. When in full work, from 75 to 100 men are employed. At the time of my visit, only 20 men were at work on the windlasses, taking the water out by means of large iron-bound buckets, one ascending full whilst the other descended empty; and 2 men and 8 boys were cleaning the plumbago with small triangular hatchets and knives, on the dressing floor, the others being away getting in their rice harvest. Plumbago got from this vein, in the upper part of the decomposed rock, is broken up and washed free from earth and impurities in basket baskets. The lessee (Arriolis) informed me that their output averaged about three-fourths to 1 ton per working day, or about 300 tons per annum; which he sold on the river's bank to boat-owners for from £8 to £10 per ton. At the time there were three large cows awaiting loads at the ferry, from these and mines to the southward.

The plumbago is carried in baskets down to the river by both men and women, the former receiving 50 cents for a load of two baskets for every two trips, and the latter 15 cents.

Gray gneiss forms the country rock, and the veins of plumbago are in parts in a coarse felspathic rock, a sort of graphic granite, which is in layers in the gneiss.

From a rough calculation I make out that the profits to the owner on the output he named is £700 per annum.

Madapola Mine.—Madapola is leased to a Chetty, who chiefly resides in Colombo.

This Mine is on the western side of the range, at an elevation of 375 feet above the sea, and $\frac{1}{2}$ of a mile south of the river, at a distance of 2 miles by road from Nambapani.

Along the vein, for a distance of 100 yards, there are eleven pits, the most northern one being down through the decomposed gneiss into the solid rock. The northern pit, 120 feet deep, has two 7-inch pumps, worked by a horizontal steam engine, for draining the mine; but the pumps had recently split, and the crank of the forcing set was broken, so that the machinery was at a standstill, and there was 36 feet of water in the shafts; consequently, nearly all mining, except in the upper level, was suspended for the time. Altogether, there are nearly 200 men employed, of whom 32 were engaged on the windlasses, hoisting out water. When in full work, formerly, they say 800 men were employed,

The pits are 10 feet by 10 feet well timbered and planked, and have a timbered division in the centre; and drifts are driven in from their sides north and south, at different levels in the vein between which the plumbago is got out by stoping.

Besides the main vein which strikes south 15° east, and north 15° west, there are small branch veins some of which being 6 inches in thickness, are worked.

The main vein increases in size as greater depth is attained, and in the bottom of the mine is said to be from 4 feet 6 inches to 6 feet wide in places, producing pure plumbago of the first quality, which does not contain any impurities, and is sent up in blocks of almost a foot cube. The underground manager—a Singalese—told me that they had blown down with dynamite at one shot, in stoping, a mass of solid plumbago, weighing one and a half tons. One pit to the south showed the plumbago in the solid rock of one foot in width, at thirty feet from the surface.

It is said that some years ago the lessee of this mine obtained as much as £30,000 for his plumbago output in one year. Owing to the difficulty and expense of unwatering the mine in the manner in which it is now being performed, it does not do anything approaching this, though the plumbago in the mine is better and in greater quantity than ever, through being followed to a greater depth.

To illustrate the primitive way in which things are being done, I may mention that the boiler was fed from a tank supplied with water by two men, who hoisted it from a stream; and the watchmaker of Ratnapura, a Singalese native, had arrived to repair the pumps. I think it may safely be concluded that he failed in accomplishing this, for on my second visit, some time after, all work was suspended, and the water in the pits was up to within 12 feet of the surface. A large stream flowing close by could easily be turned to account to work the pumps by a water-wheel. The area of land leased to the Chetty is 10 acres in extent, and the mine has been worked or many years, but I could not obtain any lucid account of his history.

KIRILLIWELLA MINE.—This is situated on the south side of a steep gully in the same range as the last mentioned mine, but on its eastern slope, northward of the river, and six miles from Nambapali, at an elevation of about 200 feet above the valley. The mine consists of a large open cutting on the gully side, and four levels driven on the veins, which are here eight in number, apparently bedded in the gneiss, which dips east at an angle of 30°, and is mostly in a semi-decomposed condition; but in places where it has resisted the weathering action, is a dark grey rock of the usual kind. On four of the veins there are adit levels, the longest being in 46 feet.

The large paddock, or open cutting, is sunk to a depth of 18 feet, and its dimensions are 50 feet by 20 feet. It is sunk so as to show the three principal veins down to the solid rock, in which the main vein is said to have a width of 2 feet 6 inches of plumbago of the best quality.

The gneiss above is white, though decomposed, for 50 feet, and passes upwards into red loam of 30 feet in thickness. Veins of plumbago in the decomposed rock show a thickness of from 1 inch to 6 inches, impregnated with iron oxide, but have all been more or less, worked small plumbago, and freed from iron by washing in baskets.

The mine is on freehold property of four acres, originally purchased from Government. Plumbago was first discovered there 30 years ago, and was worked by the Ellawella of Ratnapura till 1873 when a huge land-slip, some 200 yards in length, occurred on the mountain side, and covered up nearly all the workings. Other parties leased it, and tried to remove the detritus for seven years, but failed; when in 1890, Pedrick took over the lease and continued the work of excavation by blasting an enormous mass of rock, which had almost filled the paddock. Besides doing some work in the veins in getting out plumbago, he is still removing rocks. Since that time, he has bought the place for £400, in partnership with Peris (our superintendent), whose shares is a little over one third. From the com-

mencement of this year, he has had 180 to 200 men at work, chiefly occupied in blasting and removing rocks, which are carted to a dump in bullock carts, while the larger pieces are hauled out by elephants. To show how this place, in spite of what is spent on dead work, pays, I may mention that Peris, who, from not finding any capital to work with, is only entitled to receive one twentieth of the profits as rent for a one-third share, has received £50 per annum from Pedrick. Thus if £50 is one-twentieth of what was made, the profits must have amounted to £1,000 per annum.

A level driven in 150 yards east of the veins would procure drainage to a depth of 150 feet on them.

No mining was being done at the time of my visit, 40 men were engaged in removing rocks and the large amount of those carted out showed what efforts were being made to re-open the place.

In the store were some 15 tons of undressed plumbago, and a few of good first quality stuff, pieces of which were of seven to eight inches across, showing that the vein from which they came was a large one.

At all these mines the wages paid to workmen were the same; a mine receiving from two rupees to 2-50 rupee per day; a surface workman receiving 50 cents, and boys 12 cents; all being supplied with rations, consisting of rice alone. It is said that plenty of Singalese labour is procurable.

Should these mines be worked by an English Company, these natives will have to be employed, for English miners could not stand the climate. They work well, and under the supervision and direction of English over men, mining could be successfully carried on.

Immediately adjoining Kirilliwella mine in the north is a property of 9 acres in extent, which is said by Pedrick to contain the northern extension of the plumbago veins he is working, which widens out in that direction but no work has been done on it. This property will be leased to the Syndicate by the owner, Kirilliwella-manaka's son.

EHELEPOLA MINE.—Ehelepolo is one mile south of the Chetty's pits on the same vein, at an elevation of about 500 feet above the sea. It has one pit 50 feet deep on a vein of plumbago 6 inches wide, and a large open cutting on the hill side. There are three adits, one 46 feet long, driven in from the face of the cutting, from which the veins tapped are small, the largest being four inches wide. Very little is being done there, and they were full of water.

Three quarters of a mile south there is another small plumbago mine, on the same vein.

MINEs NEAR PANTURA ROAD.

RATMALGODA plumbago mine is situated one mile north of the Pantura road in undulating country, not more than 100 feet above the sea level, and has been offered to the Syndicate on a share of profits; but no terms have been arranged. All that is here seen is a long cutting 20 feet deep, and two large other paddocks, all in decomposed gneiss, in which are four small veins lying south 25 degrees east at a high angle. From this small sized plumbago has been taken out, but the miners, having much water to contend with, are not now prosecuting the work with much energy. In the bottom of the mine the chief vein is from 4 to 6 inches wide.

PELPIGODA mine is also in low undulating country, about one mile from Ratmalgoda, and consists of two large open cuttings. In the one to the eastward, which is 40 feet deep, are two pits one 102 feet deep and the other 114 feet. The main vein runs in a south 60° east direction, and is said to be from 1 foot 6 inches to 3 feet in width at those depths. Besides the main vein, there are two smaller ones, and a number of small branches. The large cutting is 100 yards by 20 yards and 40 feet deep. A number of pits along a vein below it, now abandoned, are said to be 210 feet deep.

For 25 years these mines have been worked off and on and continuously for the last six years

They are celebrated mines, and the land on which they are was not long since sold for £600 an acre.

PROPERTY IN KURNEGALLE.

WOODSLEE ESTATE.—I examined a vein of plumbago in this property, but so little work has been done in it that there was hardly anything to be seen on which to base a judgment. But as the owners wanted to sell the property, and asked a large price—£1,800, I believe—I could not recommend its purchase.

IX.—OPINION ON VALUE OF PLUMBAGO MINES.

I consider that the Madapola, Kirilliwells, and Tunpelehana mines, especially the two former, if scientifically worked, would be a most profitable undertaking, owing to the purity of the plumbago, and to the width of the veins. All those who have worked in these mines affirm that the plumbago widens and improves in depth.

From what I could learn, their owners have derived considerable gains from them, though worked in a most primitive way most of the money expended being wasted in unwatering them by manual labour.

They have only been proved to a depth of 120 feet at most, but their lateral extension for over 100 yards has been confirmed.

I think it only rests with the expenditure of capital, and good management, to obtain from them a large out-put of plumbago of the best quality, for which a good market could be procured.

Here the wages to miners and surface laborers is most reasonable, and would render the getting of the stuff at the cheapest possible rate.

Pumping machinery, either by steam, or, in the case of Madapola, perhaps by water power, would be most effective.

Owing to the nature of the rock in which the veins are situated they are very irregular in width, but are shown to widen and narrow by turns when followed.

A width of 6 inches, I estimate, will give 1-13 tons to the fathom, and in the hardest ground this would not cost more than £7 13s per running fathom. Two men should get out 2 tons a month, and 50 men 600 tons a year. 600 tons at £20 will bring £12,410. The cost of production being £4,593, will leave a profit of £7,410 on the 600 tons. This does not, however, include any other expenses, except those of actually getting.

From the table of Exports and Imports from Ceylon, in "Ferguson's Ceylon Handbook and Directory," it will be seen that for the years 1880, 1885, 1886 and 1887 the export of plumbago has been as follows:—

1880—205,738 cwt.	1886—241,760 cwt.:
£205,738 value.	£241,760 value.
1885—196,400 cwt.	1887—238,599 cwt.:
£196,400 value.	£238,600 value.

Judging from these values the price of plumbago has averaged £1 per hundred weight, that is, £20 per ton for these years. In February last I was told it had risen to £24, but fell again.

The table just referred to gives an idea of the large quantity of plumbago mined solely by natives each year; but the value they receive for it from the merchants does not appear. Another good feature in these mines is their situation within easy reach of a fine river, navigable to the sea at Kalutara for good sized scows, and with a railway connecting the latter place with Colombo. There is timber on these properties to a certain extent, and plenty is to be obtained in the neighbourhood. Amongst the natives the district is considered to be a very healthy one, there being but little fever there.

I can most highly recommend the Madapola, Kirilliwells, Tunpelehana properties to the Syndicate, the first two mentioned being the most valuable. The other property of Ratmalgoda is also well worth securing, though quite unproved at present.

C. BARRINGTON BROWN, Assoc. R.M.S., F.G.S.

London, April 28th, 1890.

VARIOUS NOTES.

FRENCH TOMATO PICKLE.—First of all you must have a peck of green tomatoes. Then you will also require six large onions, half a pint of salt, one pint of brown sugar, two tablespoonfuls of curry-powder, two table spoonfuls of turmeric, two teaspoonfuls of ground cinnamon, two teaspoonfuls of ground clove, two teaspoonfuls of ground allspice, two teaspoonfuls of mustard, three quarts of vinegar and one quart of water. Slice the tomatoes and onions and put them in a large bowl or stone jar. Sprinkle with the salt, and let them stand over night. In the morning, drain off the liquid, and put the vegetables in the preserving kettle with one quart of vinegar and one quart of water. Let them boil for five minutes, and then drain off the liquid. Return the drained vegetables to the preserving kettle. Mix the spice smoothly with a part of the two quarts of vinegar. Add to this, the remainder of the vinegar and the sugar to the vegetables, and heat to the boiling point. Cook for fifteen minutes after the pickles begin to boil. Put it up in small jars and seal.—*Good Housekeeping.*

WASTE PRODUCTS.—In the current number of the *North American Review*, Lord Playfair shows how waste products are made useful. He says there are some perfumes which are really oils and ethers extracted from flowers. There are others which are made artificially, and curiously most frequently out of bad-smelling compounds. Fusel oil which has a most sickening odour, after treatment with acid and oxidizing agents, is used to make the oil of apples and the oil of pears. Oil of grapes and oil of cognac, we also learn, are little more than fusel oil largely diluted. On the other hand, oil of pineapples is best made by the action of putrid cheese, or by distilling rancid butter with alcohol and oil of vitriol. It is to be feared that his lordship's disclosures will be a distinct shock to the feminine mind. Probably they would prefer to be left in ignorance of the fact, as Lord Playfair, following Lord Palmerston, states that "dirt is only matter in a wrong place."—*Sala's Journal.*

INDIAN PATENTS.—Nov. 2nd.—No. 269 of 1892.—Beresford Lovett, a Colonel in the corps of the Royal Engineers, at present Chief Engineer in the Military Works Departments and residing at Auckland, Ootacumund, for "Cleaning grain, such as gram, kolti and rice, from grit, gravel and sand." No. 271 of 1892.—Henri Galopin, of Temple Court Place, Chancery Lane, Melbourne, in the Colony of Victoria, Scientific Engineer, for Improvements in and connected with apparatus for "Using Liquid Fuel for Lighting and Heating purposes." No. 46 of 1892.—Eva Jennie Hall, wife of Hugh Hall, residing at No. 1010, Sixth Avenue South in the City of Stillwater, County of Washington and State of Minnesota, one of the United States of America, for "Improvements in and relating to needles for use in sewing machines." (Filed 23rd September 1892) No. 56 of 1892.—Andrew Charles Guy Thompson, Engineer and Tea Planter of Sagmoctea Tea Estate, Nowgong, Assam, for "Transporting or conveying material or substances from one point or place to another and is specially adapted from its portability and ready means of applying tension and speedy discharging apparatus to such works as conveyance of earth or soil (commonly called top dressing) or making up earthworks." (Filed 17th October 1892.) No. 158 of 1892.—Samuel Cleland Davidson of Suceco Works, Belfast, Ireland, Merchant, for "Improvements in the manufacture of tea leaf into black tea." (Filed 14th October 1892)—*Indian Engineer*, Nov. 12.

THE POSITION OF THE AMERICAN CEYLON TEA COMPANY.

This, we regret to hear from intelligence reaching us by a recent London mail, is by no means so assured as previous statements sent to us seemed to indicate. It had been quite understood that the liberal grant made by our Tea Fund of ninety chests of tea would so establish the footing and prestige of the Company that no difficulty would be experienced in raising the money required to carry on its affairs. Mr. Farr, of Messrs. Watton & Farr, had, we were given to understand, felt assurance that this would be the case; but we now hear that before leaving England on his return to New York that gentleman had signified that the Company was without any capital to carry on its work, and that unless early financial aid were forthcoming it would have to proceed to almost immediate liquidation! It can only be concluded from this regrettable statement that Mr. Farr had been much too sanguine as to the effects the grant made here would have upon the minds and purses of capitalists in London and New York. The discovery of this overestimate by Mr. Farr appears to have been made before his departure from London, and he had written to make it known to be his intention to issue £10,000 of new shares in the Company, each £1 of which was to be sold for five shillings with no remaining liability to the purchasers of such shares. If these can be placed it would render available an immediate sum of £2,500 for carrying on the operations of the Company. Whether it will be possible to obtain this sum must of course be for the present in doubt. Certainly the terms offered should be alluring to those interested in the continuance of the work in America from which we hope so much. At the same time the issue of the shares at a discount of 75 per cent is a very liberal watering of the Company's new capital, but the peculiar circumstances of the case would perhaps warrant such a proceeding, one, we believe, not to be unusual in the endeavour to float schemes having a somewhat speculative character. We must say that the intelligence as to what is now proposed has come upon us with somewhat of a shock after all we had heard recently of the probable issue to the grant made by the Tea Fund Committee. Mr. Farr stated in his letter that he had cabled to Mr. Grinlinton the position of affairs; and it remains to be seen what steps can be taken by the latter gentleman to avoid the collapse of the Company in which from first to last he has shown so great, so intelligent, and so patriotic an interest. For it cannot be denied that the collapse of this Company, and its proceeding to the almost immediate liquidation with which it is threatened, must strike a severe blow to the prospects of Ceylon tea in America, just as we are hoping so much as the result of the efforts making for the due representation of our staple product at the Chicago Exhibition. We sincerely trust that such a fiasco may be avoided, but those concerned will have to bestir themselves to secure this. It does not seem to be a large sum that Messrs. Watton & Farr state to be required. Surely among our planters and merchants £2,500 might be subscribed, and the more readily because of the very liberal terms offered to secure it. If the money be not forthcoming we greatly fear the chances of Ceylon tea finding a ready market in America will be almost indefinitely postponed. It has, we know, to battle against many antagonistic conditions, and to overcome these it is necessary that all concerned in the enterprise should put their shoulders to the wheel.

This is one of those companies in favour of which, in common with the Spinning and Weaving Company, the editors of the *Tropical Agriculturist* felt bound to depart from the rule they had laid down for themselves, not to take shares in concerns which it might become their duty freely to criticize. We (the senior editor) hold five shares in the American Tea Company, fully paid up, from which we never expected and do not now expect any return beyond that we should share with other estate owners from extended demand for Ceylon tea. There was quite a rush of withdrawals by planters and others from the Company when it became an American corporation; chiefly, we believe, from the unfounded dread that liability would not be limited. Although limited liability was secured, there was no further encouragement offered, that we are aware of, by the planters taking shares, and we suppose Mr. Grinlinton, who paid for all shares thrown up, is by far the chief shareholder in Ceylon. We feel sure he will do what he can to prevent the collapse of the Company at this juncture, not for the sake of his own personal interests, but for those of the Ceylon tea enterprise in America. A deliverance from Mr. Grinlinton on the subject will be welcome.

THOMSON'S PATENT TEA PLUCKERS.

Mr. E. B. Creasy writes:—

"In your issue of September last a correspondent signing 'M.' asked for results of Thomson's Patent Tea Pluckers. Will you kindly send him a copy of enclosed and I send a second copy for your notice? I think the results so far show that a very large economy can be gained by the use of the pluckers."

The best thing we can do is to reprint the account sent us:—

Copy of a letter received from J. Ashington Thompson, the Inventor of the Patent Tea Pluckers.

Salgunga Tea Estate, P. O. Kumbir,
Cachar, 3rd August, 1892.

E. B. Creasy, Esq., Colombo, Ceylon.

Dear Sir,—I see I last wrote you on the 3rd May and since then have received yours of the 14th id. and 4th June the contents of which have my attention. I have also to thank you for copy of your pamphlet.

My pluckers have not done badly so far but a great many planters have not had the patience to try them long enough. It takes a *whole season's working* to prove their capabilities, for it is not till the latter half of the year that they prove their superiority over hand plucking, and the second year's working gives better results than the first. At the first start off they do not give as good or as much leaf as hand picking, but in the second half of the season *when the bushes are formed*, they soon make up for lost time and in the end my pluckers show a decided gain and leave much better bushes for next season than is to be got by hand picking.

I would impress on you and would wish you to impress strongly on all purchasers of my Pluckers that *less than 12 months working* is no test of their capabilities. It takes nearly 6 months to train the coolies to work them properly, and it takes nearly as long for the bushes to spread and show a large even surface which is indispensable to the successful working of my Pluckers. I would also remind you that the baskets are *very important*. The Tea Pluckers should be used as shown in the Photo I sent you.

I now forward for your information copy of a letter to Messrs. T. E. Thomson & Co. received from a planter in Sylhet. He is one of the men who has persevered with my pluckers and is now reaping his reward. His neighbours just tried them for a month and threw them aside. 16 lb. leaf an hour is about 160 lb. a day. The average plucking, in Cachar and Sylhet is about 30 lb. leaf a day.—I am, yours faithfully,

(Signed) J. ASHINGTON THOMPSON.

The letter referred to above:—SONAKHRA, Patharkandi P. O. Sylhet District, 20th June, 1892.

Dear Sir,—Your favour of 16th inst to hand. Re pluckers the pluckers are getting an honest trial here, and so far they have done as well as could be expected, but now that my bushes are in good order for plucking I expect greater results from them. At the present time I have women who can pluck 16 lb. per hour which is saying a great deal and hope still to do better when all my pluckers are in order. I shall have more to say about pluckers later on in the season, as I am keeping a record as against hand plucking. I am getting other 10 pluckers through O. S. & Co. This will increase my stock to 45 so that you see that some are getting a fair trial.—In the meantime, I am, yours faithfully,

(Signed) ALEXANDER WHITE.

N.B.—Copies of the photographs alluded to above can be had on application also sample baskets.

E. B. CREASY, Agent,
Thompson's Patent Tea Pluckers.

Copy of a letter from Mr. T. S. Dobree, Dikoya Estate, Dikoya, Ceylon.

Tea clipped from 15 acres with Thompson's Patent Clippers with cost of clipping per month and yield of tea per acre per month.

	lb. made tea per acre.	Cost of clipping per lb. tea made.	
June.....	30	6 cts.	Fair flushing month
July.....	16	8 6	} Exceptionally had flushing months
August ...	20	7 3	
Septemr...	18	6 2	

The field was first tipped after pruning in May with the clippers.

The bushes have spread and found a better flushing surface than they would have done if hand plucked but to a certain extent have rather a nibbled appearance up to now in four months clipping. I consider the clippers a decided improvement on hand plucking, but whether the bushes will run as long as they would if hand plucked I cannot say. I am inclined to think they will not. The cost of clipping up to date is much cheaper than hand plucking.

(Signed) T. S. DOBREE, Dikoya.

September 30th, 1892.

N.B.—The first pluckers were supplied to Mr. Dobree five months ago. E. B. CREASY.

BOTANY, &c., IN CENTRAL AFRICA.

MR. A. WHYTE, BOTANIST OF THE BRITISH CENTRAL AFRICAN ADMINISTRATION, TO MR. W. NOCK OF THE HAKGALA GARDENS, CEYLON.

We have been permitted to publish the following interesting communication:—

The Residency, Zomba, B. C. A., 1st August, 1892 (3,000 ft. altitude and about 50 miles north of Blantyre, the mission station).

You will scarcely expect a letter from me from this centre of savagedom, but I would have written to you sooner but for the great variety of work I have had here, collecting and laying out experimental gardens, planting of some, and in fact a hundred odd little jobs requiring immediate and close supervision in a new country. I am stationed here at present with Mr. Johnston, our Commissioner, and Consul General for Nyassaland; and both of us are very much interested in establishing botanical gardens in the grounds of the Residency—a fine large baronial-looking brick building—the finest mansion in Central Africa, and built by contract some years since by the Buchanan Brothers, the most enterprising planters in B. C. A. and who have now a large coffee acreage in bearing. We can grow almost anything in this climate, which corresponds very closely to that of Hakgala, and I have told Mr. Johnston that I am sure you and Dr. Trimen will willingly assist us in introducing new things. I have written the doctor and I enclose this letter in his, so that he may peruse it also, for I have no doubt you will be glad to hear what we are doing in these outlandish parts.

We shall be deeply grateful to you, if you can make us up a case of things that will be likely to carry such as fleshy roots and bulbs. Caladiums, arum lily, agapanthus, hegonias, formium tenax, cocoyam, lily bulbs, yuccas, marantas, dracenas, allocasias, in fact all or any of the common things. Then seeds of trees and creepers and showy plants you could send direct by post in packages of say 5 lb. weight and addressed

H. H. Johnston, Esq., c.r.,

H. B. M. Commissioner & Consul General,
British Central Africa,

Seeds express.

via Zanzibar.

Cases of roots and plants would go by steamer to Zanzibar, addressed as above, but also to the care of H. B. M. Consul General,

Plants express.

Zanzibar.

who would at once see to the forwarding one of them to Chindi our seaport at mouth of the Zambesi and we would get them up river from there in two weeks. Altogether they ought not to take more than 5 to 6 weeks in reaching us from Colombo to Zomba. Now in return for all this I promise to set about collecting seeds of many lovely things we have on our mountains and plains, and which you have not got and which will be despatched from here say end of September. I would send some now, but none of the seeds have yet matured, but are just beginning to do so. We have many beautiful things growing wild but no plants from the outside world have yet been introduced except such as, coffee, grains, Ceara rubber and a few more. As to English vegetables they do splendidly here and castor seeds out the best of seeds. I have raised magnificent potatoes from his seed (not sets) and have noted something like 500 varieties to select from. They are producing at the rate of 5 tons an acre without manure and there is no trace of disease. I lost all the large stocks of English potatoes I brought out with the expedition this time last year, but luckily I had some seed with me and now in 12 months I am reaping full-grown large potatoes from the second planting. These consequently will be regularly native reared African varieties, some of which I have no doubt will become of great value and suitable to the country.

As to collecting I have done a good deal and sent some collections of the fauna and flora of the Zonaba and Hielangi districts. This country is a perfect paradise for the sportsman and within a day's march of this we get on the plains nearly all the large antilopes, the sable and the water buck, bush and reed buck, the eland and buffalo and all these with zebra. I have got leopards (larger than yours) are common and hyenas, the elephant, rhino, and lion are farther a field. Hippos are abundant in the Shiré now, and we have got six. I had a very near shave with a big bull hippo in the Ruu, a tributary of the Shiré, who made for me with open mouth but fortunately I succeeded in stopping him with a No. 10 bullet down his throat out of one (No. 2) of Sir Samuel Baker's trusty old M. L. rifles. This interesting old weapon I got from Reilly, the maker, and I value it not only for its excellent shooting qualities but as an interesting historical piece, being one of a pair (No. 1 and No. 2) built by Reilly for Sir Samuel years ago and mentioned by Sir S. in his books. This is sure to be a great resort for sportsmen when the country is better known and the means of transport is better. In the meantime there is only one horse in the whole of this vast region—Nyassaland—the sole remaining one of 15 we brought with the expedition from Aden and Zanzibar! The Tsetse fly does for them and for cattle and donkeys also. At Zomba this pest is absent and all stock thrive well. Our first calf born last week, and we have donkeys, and fat-tailed sheep, goats, fowls, pigeons and muscovy ducks.

Remember me very kindly to Kellow and ask him to send me two or three roots of cush-cush yam (and anything else he thinks of), that delicious root I introduced from the West Indies. It and all the yams family would do splendidly here. A few lines from you will tell the Nuwara Eliya news would be most welcome. We have two old Ceylon men here. Henry,

Brown who occasionally writes to the *Observer* (which I should also be glad to do if I only could find some spare time), and Mr. T. H. Lloyd who recently joined the administration as surveyor.

Trusting you will be able to give us a helping hand and to hear from you soon, believe me, yours sincerely,
A. WHITE, Naturalist to B.C.A.A.

TRAVELS IN PERU AND THE UPPER VALLEYS OF THE AMAZON.

BY ARTHUR SINCLAIR.

PART II.

(Continued from page 176.)

From Guayaquil, Payta—our next port of call and first introduction to modern Peru—is reached in one day, and never was a more complete transformation seen. Last night we were sailing down a noble river, lined on either side by banks of the densest vegetation; today not a particle of vegetable life is to be seen, as far as the eye can reach. From Adeu to India the transition is equally remarkable; but that takes a week to accomplish. Here, in a few hours, the scene changes from moist luxuriance to an arid waste; from a damp, relaxing climate to a dry, bracing air; from dark chocolate soil to light driven sand. "And this is a fair sample of what you will see for the next 2,000 miles along this forsaken coast," says our captain.

The fact is, we have passed the dividing line which separates the rainy from the rainless locality, and let me say at once I prefer the latter. Refreshing as the rain-drops are to the thirsty soil and flagging plants, and taught, as we long have been, to look upon the gentle rains as blessings falling upon the just and unjust alike, still it is not only found possible to live and enjoy good health in an absolutely rainless country, but the soil can be rendered even more productive—as will be seen by-and-by—where the agriculturist does not directly depend upon these fitful supplies of moisture from the clouds.

It is, perhaps, not strictly correct to speak of Payta as an absolutely rainless district, as occasionally they do get the tail-end of a shower here—"About once in nine years," said the local weather clerk, and then there is a rush of vegetation marvellous to look upon; plants growing where seeds were never known to be cast; and particularly one was described to me, belonging to the Cucumber family, but containing a sponge and soap—a formidable rival to Pears—of which the inhabitants here stand much in need. But the most valuable plant of the interior of this locality—for nothing is to be seen on the coast—is, doubtless, the perennial Cotton-tree, a very superior variety, surpassing anything of the kind growing in North America, and, no doubt, with ordinary industry and judicious irrigation, the cultivation of this valuable product might be greatly extended.

The next port of call to which I would like to introduce the reader is Salaverry; about 300 miles south from Payta, and, as seen from the sea, an equally bleak and altogether unprotected coast. To land here without being drenched is next to impossible. The poor rickety place itself is chiefly notorious for the inquisitiveness of the not overworked Custom House officials, who will examine the toe of every stocking, and even peer into the tins of Swiss milk purchased, perchance, at Payta, and charge duty thereon. And while you haggle over the exorbitant demands, ten to one you lose the only train for the day, by which you hoped to reach Truxillo. It is better, perhaps, under the circumstances, to calmly submit to a little extortion than run the risk of being left in the lurch in such a place.

Truxillo lies about nine miles inland; was founded by, and named after the birth-place of Pizarro; a sort of third-rate Lima, containing about 15,000 inhabitants, many great and garish-looking churches, and a few more or less empty hotels, all slowly falling into decay. On the roughly-paved streets we now and again meet a decaying sample of the dignified

Spaniard; while the only busy man in the place—the Chinese cook, to wit—comes to his door for a breath of fresh air or to look for a fresh customer. In the Plaza—which corresponds to our public square—young Peru may be seen, leaning against the rail of the little central garden, smoking cigarettes and looking languidly at the few brilliant crotons, poinsettia and vincas which surround the fountain.

The priests, like great black beetles, creep stealthily along in twos and threes, entering or emerging from the always-open churches, from which we can hear what is intended for sweet, seductive notes of music. But we must push on. A run of twenty miles brings us to the centre of one of the most flourishing groups of sugar estates in Peru. The Casa Grauda Estate, which I specially visited, is an admirably-managed property of some thousands of acres; more luxuriant cane, or cane richer in saccharine juice, could scarcely be found, and yet this is an absolutely rainless district. Men live and die here without having once seen a shower of rain, and wonder to hear of the haphazard agriculturists of other lauds, who simply plant or sow their seeds, and wait for the fitful clouds to water them. Here the chief work and art of cultivation consist in applying water, when absolutely necessary, and withdrawing it the moment it would prove injurious, and unquestionably a richer cane is raised by this means than is possible in the rainy region of the tropics. The labour here is exclusively Chinese—experts at this particular work—and I doubt if equally good results could be obtained by any other class of labourers. The maturing of the cane is so managed that there is a daily supply, sufficient to produce 500 cwt. of the finest sugar. The machinery is one of the most modern description, and the whole works and yards are thoroughly lighted up by electricity. There are several other equally well-managed estates in the same valley, and the cultivation might well be indefinitely extended for hundreds of miles. It is nearly a question of capital and suitable labour.

But we must now resume our voyage for about 100 miles further along the coast, our next port of call being Chimbote, at the mouth of the river Santa, the largest Peruvian river on the western side of the Andes. This was the farthest point reached by Pizarro on his first memorable voyage of discovery. He was satisfied with what he had seen that the country was not only worth the conquest, but rich beyond his wildest dreams, and from here he was induced to return to tell the story of his adventures to his avaricious masters. But however prosperous the district of Santa may have been, it is now a poor, abandoned place; and yet with such an ample supply of water, it might vie with the richest spots on the coast of Peru in productiveness. As it is, it is chiefly interesting to the antiquarian. The remains of Inca roads, rivalling anything the Romans ever built in Britain, the marvellous aqueducts, and more particularly the hauchas, or mounds, scattered over the country at irregular intervals. When opened, these hauchas proved to be burial places, and besides the bones, various curious utensils are often found, chiefly water chatties, of which I secured a number of specimens. The bay of Chimbote itself is remarkable as the best sheltered bay on the coast of Peru, protected by a semi-circle of rocky islands which, though here lacking the vegetation that adorns the islands around the Bay of Panama, supply the means of vegetation to many an unfertile spot on the earth's surface. Those sea-lions which so startled us with their roar as we were coming ashore, and myriads of seals frequent these islands daily, to bask in the sun. It is their refuse, and not the refuse of birds, as generally supposed, that forms the bulk of Peruvian guano.

We make no further calls till we reach Callao, the chief commercial port of Peru, where, however, in the most uncommercial-like way, we were kept waiting two hours for the captain of the port, who was supposed to be at a cock-fight. Our own dignified old English salt is a Christian gentleman and not a swearing man; but as he nervously paced the bridge he looked so uncommonly like a man

whom an "aith" would relieve, that I would not have ventured near him had he not beckoned to me. "You are now leaving us" he brusquely said, "and will be coming in contact with Peruvian officials. My advice is, never believe one word they say, even supposing they should swear to it upon a cartload of Bibles." A warning, I regret to say, which proved not altogether unnecessary. Callao has no special interest for us. With its quays and wharfs, ugly warehouses, and polyglot population, it is like any other seaport town; and as Lima is only seven miles distant, we prefer to pass on at once.

And now, when in the capital, I am afraid I shall disappoint you, for I am not fond of cities: my heart lies always in the quiet country beyond. A simple man, my tastes lie among the simple people on the mountains, or culling the common weeds by the wayside. I cannot, therefore, enter into any detailed description of Lima, which at one time, we are told, was considered the gem of South America, and though now somewhat sullied, is still beautiful; picturesquely situated, and with a climate almost perfect; where the sun rarely scorches, and the rains never bedraggle the inhabitants.

The two chief characteristics of the city are, perhaps, its magnificent churches—more than seventy in number—and its great bull ring, "Plaza de Acho," where over ten thousand, chiefly women, weekly witness and applaud the cowardly slaughter of poor helpless animals. From the churches we might, perhaps, with advantage take one little lesson—they are always open from 4 a.m. till 10 or 11 p.m., while here, in Scotland, we build, by a supreme effort, substantial kirks and then lock them up, looking only at the outside, for 312 days in the year. Foreigners laugh at this, and perhaps there are few greater absurdities to be seen on the face of the earth.

The population of Lima may be about 130,000, but no one knows exactly, as they have not succeeded in taking a census for many years. The last attempt showed something like eight ladies to every man, and the ladies are as famous for their beauty and energy as the men are for their feebleness. The marriages seem only to number about 83 per annum, or less than 1 per 1,000, not a very prosperous sign.

Now for the hills. By rail to Chicla—87 miles—thence on mule back. This railway, it will be remembered, is, without any exception, the highest in the world: the engineering, the most audacious. "We know of no difficulties," the consulting engineer said to me. "We would hang the rails from balloons if necessary!"

When rather more than halfway to Chicla we reach Matucana station, at an altitude of 7,788 feet above sea level, and here we resolved to stop for two days, in order to get accustomed to the rarefied air, but were not idle. Procuring mules, we proceeded to ascend the surrounding mountains. Matucana may be described as a village of 250 inhabitants, situated at the bottom of a basin only a few hundred yards wide, but widening out to 50 miles at the upper rim, which is covered with snow. The hills rise at an angle of from 45 degrees to 75 degrees, and the so-called roads are really a terror to think of. In the distance the mountains of Peru, or the Andes, look as bleak and barren as Aden, and most globe-trotters who take a passing glimpse say so; but such is not the case. I have not yet seen an acre upon which the botanist might not revel, and but for the fact that I had to watch with constant dread the feet of my mule, I have never spent a more intensely interesting afternoon than I did during this memorable ride. Up, up, we went, zig-zagging on paths often not more than 18 inches wide, and sloping over chasms that made one blind to look down. Speak o' "loupin' o'er a linn!" here is a chance for any love-sick Duncan.

But, oh! the flowers! the sweet flowers! who could pass these unheeded? So many old friends, too, in all the glory of their own native home, to welcome us, and indicate the altitude more correctly than any of our aneroids. First comes the heliotrope, scenting the air with its massive blue clusters. So different from the

straggling exotic in Britain, or the leafy, lanky plant in India. This grows in the greatest perfection and profusion to about 8,000 feet above sea level. Then come miles of bright yellow calceolarias, intermixed so prettily with brilliant red and blue salvias, every vacancy apparently filled up with lovely little lobelias, curious cupheas, and creeping solanums, while our old enemy in India, the ageratum, everywhere intruded its white, thrummy head. Suddenly all was changed, and hundreds of acres of the most beautiful blue lupine cover the ground; this grows up to 14,000 feet, and then gives way for the anemone, sedum and dandelion, which dispute with the snow the limit of 16,000. We were contented, however, on this occasion to reach about 13,000 feet, and "sair forfochen" as we were, eagerly accepted the invitation of a Chola Indian to enter his hut. And here let me say that my ignorant prejudices against the Indian changed at once as I looked upon this evidently happy and most hospitable family. The best they had was placed before us, and one sweet lassie, seeing we were fond of flowers, disappeared into a tidy little garden and brought us such bouquets as I had rarely seen. Imagine real red roses, stock, fuschias, sweet peas, gladiola, &c., mixed with springs, of fennel; I could not help contrasting this delightful reception with what I had sometimes seen amongst more pretentious people.

The present terminus of Oroya railway is Chicla at an altitude of 12,215 feet above sea level; y dreary enough spot, where passengers not infrequently get their first experience of *Sorocho*, or mountain sickness, caused by the rarefied air, the disagreeable symptoms being headache, vomiting and bleeding at the ears and nose—the only cure, a greater atmospheric pressure. Horses and mules from the low country frequently drop down dead here from failure of the heart's action.

Leaving Chicla the real tug of war begins: the Cordilleras have to be encountered and crossed. A wretched road is made worse by the *debris* from the railway, which, for the first fifteen miles, we see being constructed still far above us. The navvies hang over the cliffs by ropes, looking like venturesome apes. Higher and still higher goes this extraordinary zig-zagging railway, boring into the bowels of the mountains and emerging again, at least a dozen times, before it takes its final plunge for the eastern side of the Andes. Meanwhile, we continue our scramble to the top of the ridge, 17,000 feet above sea level. I have no desire to magnify the difficulties and dangers of this tedious ride. The great question is, what do we see when we get there? This I cannot well magnify. It is not a case of merely going up one side of a range, like the Grampians, and down the other, but there is now before us a table land as far as the best eyes can reach, and ten times father, with its hills and dales, lochs and rivers, more than equal in extent to Great Britain itself, at an average height of about 13,000 feet above sea level.

Viewing this plateau from here, we have spread out before us a region unlike anything we have ever before seen, far above the rest of the world, upon the cares and troubles of which it looks down with calm, if cold, indifference, sharing none of its alarms, and seldom, indeed, disturbed by the insane political broils of the lower regions. The clear sky above, the occasional clouds chasing each other up from the valley of the Amazon, only to be dissipated on the snowy peaks which they cannot possibly pass; above all, the glorious sun, so welcome a benefactor here, that we can no longer marvel that it was the great object of worship by the Inca. And all this bleak but most interesting region has to be traversed before beginning our descent into the promised land beyond, the real basin of the great Amazon for which we are now bound, a region which even the Inca, in the plenitude of his power, never subdued; and, we are assured, no living Peruvian has penetrated. It would be tedious for you were I to describe too minutely the ride of the next few days over the great grassy puna. Here is the home of the gentle llama a sort of link between the camel and the sheep, the wool of which is so much appreciated; the paco

also, which supplies the world with alpaca; and their more timid relative, the vicuna, with wool still more valuable. Here and there, we came upon the remains of roads and crumbling ruins, indicating a civilisation which may date back thousands of years, even before the advent of the Inca.

Of human inhabitants there are now comparatively few but such as there are, are interesting specimens of sturdy little Highlanders. The women, particularly, are admirable examples of a hardy, industrious race. No finer female peasantry in the world, I should say.

One of the chief towns of this region is Tarma, about 200 miles inland, altitude 9,800 feet, population about 8,000. We stayed for some days here, greatly enjoying its splendid climate; a paradise, I should think, for consumptive patients. Excellent wheat and barley are grown here. This, also, is the home of the potato, having been cultivated here as carefully as we now do in Europe, perhaps hundreds of years before America was discovered by Europeans. "Papa" they are still called, being the old Inca name of the tuber, and the quality is fully equal to the best we have ever produced. Moreover they have some better varieties than any of ours, one of which I hope to introduce to Scotland.

It was in the latter end of July, 1891, that one fine morning (every morning is fine here), we managed to muster our retinue and make a fair start for the famous low country. The peculiar vegetation on the steep mountain slopes, more grotesque than beautiful, betokens a comparatively dry climate all the year round. Such expanses of gigantic cacti and broad-leaved agave we had not before seen, and prior to the age of mineral dyes, fortunes might have been made here in cochineal, as they still might be, by any enterprising agriculturalist who would devote his attention to fibres.

The resplendent flowers of the cacti were just closing as the morning sunbeams fell across their brilliant petals, and we, too, were soon reminded that we were in the tropics, being glad to hug closely the little belt of trees which shaded the lower side of the winding path.

Here a watercourse carries grateful moisture to the Alfalfa (Lucerne) fields below. The banks of this little water course are a delightful study. I can scarcely express to you the pleasure I had in recognizing so many old familiar friends: the trees themselves were chiefly alder and buddleia. The former, our "ain arm," the latter, with its silvery leaf, a well-known native of Peru. Here are veritable bourtrees bushes; there a line of the beautiful Peruvian willow, named after the illustrious Humboldt. Nor can we pass unnoticed the sweet little flowers that line the margin of the rippling stream. The yellow calceolaria, ever ready to assert its nativity, blended with the blue salvia and ageratum, various vincas, passion flowers, solanum and thumbergias, all so familiar, and all so much at home here, gave a peculiar charm to this morning's ride. We halted for breakfast at Acobamba, only six miles from Tarma, from which we had been rather late in starting. Acobamba is a beautifully situated but decaying hamlet, with about 1,500 rather seedy looking inhabitants, where not long ago there had been more than double that number; evidently destined before long to become another deserted Sweet Auburn, of which this grand Spanish colony furnishes so many sad examples. Here already

"'Ha'f the business of destruction's done."

Every second house is in ruins, and what had doubtless, once been trimly kept gardens—

"And still, where many a garden flower grows wild," is now a scene of desolation. Not without its interest, however, and as one curious in such matters, I accomplished the feat of scrambling through the straggling fence, "unprofitably gay," and I dare confess, explored the wild spot with more real pleasure than I would look upon well-clipped bushes. Beneath a jungle of tea roses were violets scenting the morning air, and many other exotics as far from home as myself, including the gaudy geranium, Southernwood, and Costmary—bachelor's buttons—

"The golden rod, and tansy running high,
That o'er the fence top smiles on passer-by."

How they came there is a question we leave to others. Buxom women squat under the trees industriously weaving on the most primitive of looms, the cloth of which their husband's ponjo and trousers are made, while their lords, such as they are, may be seen loafing in crowds round the drinking bars on the Plaza. The tippie here is appropriately called "chichi," made from fermented maize and similar to the ale from which rawl grain whisky is distilled. By no means a very deadly poison, "for," says our host, "these people live to a great age, 110 to 120 years being not unusual"; but then, I daresay, there is no Dr. Crammond in Acobamba.

The padre, we are told, not unfrequently joins his flock in their drunken orgies, indeed, the so-called Church festivals seem to have degenerated into blasphemous ribaldry, enough to make one shudder. It is the boast of the proud Spaniard that he has at least given the Peruvians a *language* and a *religion*. The language may be all right, but we cannot congratulate them upon their religion, and who will dare to say that it would not have been better for them had they still been speaking their native quichua, and reverently saluting the glorious rising sun, as they wended their way to work in their well-tilled fields as in the olden time, when industry formed part of their religion?

I have perhaps lingered rather longer over Acobamba than the reader could have wished, but it is the last remnant of a decaying village I shall at present have to notice, for, with the exception of a half-deserted hamlet, called Palca, a few miles further on, we see little more of the homes of the mountain cholas during our present journey. The gorge along which our road threads its way now gradually narrows, a gurgling little torrent runs at the bottom, and the presence of half-hardy little shrubs, growing without irrigation, shows that the tail end of many a tropical shower must now reach this limit. Amongst the native plants here may be noted the beautiful trailing Rubus and the Monnina; the bark of the root of this plant is used for soap, and the Peruvian ladies ascribe the beauty of their hair to the use of it. Amongst other plants there are many brilliant billbergias, nightshades, &c. We are now thirty miles from Tarma; the ravine gets narrower and more dismal-looking, and as the sun has already sunk behind the mountains, we decide to halt for the night at a place called Huacapistana, where there is a very miserable hovel in which benighted travellers are invited to rest; but such were the surroundings, and so strange were the bed-fellows, that of that weary night, I have still rather more than a hazy recollection of lying watching my companion trying to sleep with a loaded revolver in his hand. But nothing happened, and next morning we were off betimes. Steeper and steeper became the descent. We preferred "shank's mare" to the already tired mules. Narrower and narrower became the gorge, until it culminated in two "tall cliffs which lift their awful forms" many hundred feet high, leaving only room for the now raging river and a very narrow path between. Once through this, the valley opens out, and the vegetation assumes a more luxuriant aspect. Our aneroids indicate an altitude of 3,650 feet, and the moist steamy heat tells us that we are truly in the tropics. The district is called Chanchamayo, where for twenty years a number of Frenchmen and Italians have been trying their hand at coffee, indigo, and sugarcane growing, it must be confessed, with very indifferent success, though certes, "if vain their toil they ought to blame the culture, not the soil." But these men had evidently been sent out without sufficient training. "That is a splendid specimen of Cinchona," we said to a planter, pointing to a tree near his lungalow. "Cinchona!" he exclaimed, in real amazement, "I have been fifteen years here and never knew I had been cutting down and burning Cinchona trees." In Chanchamayo we learned that the Convent of St. Louis, on the borders of the Chuncho country, was about twenty-five miles distant; we had letters of introduction to the chief priest

there, and after resting a day in the house of a hospitable Frenchman, eagerly pushed onwards. The trip was now getting decidedly interesting, for although I have no great leaning towards the Spanish priesthood, still I honestly tried to go forward unprejudiced, thinking only of the monks of old and the good work they did in their day. But this convent was a revelation to me: we had never seen anything quite so filthy and suspicious looking before, and would have gladly escaped within an hour, indeed, did so, and began erecting our tent at a safe distance, but were implored not to insult the reverend fathers by refusing to accept their hospitality, an infliction which we now bore patiently for several days. We were introduced to a number of Chunchos—miserable specimens they were, and more familiar than pleasant. Those had left their country for their country's good. Just as a herd of elephants in Ceylon occasionally expels the incorrigible rogues, so the Chunchos, it seems, have their outcasts, male and female, who make a parley-ground of this Convent, fit converts to this fearful mockery. After sundry rather meaningless postponements, we at length got a start. In Peru every good work is to be done tomorrow; "manaña" is in everybody's mouth on all occasions. I often wonder what the degenerate Spaniard will do when there is no longer a "manaña." Two priests, who professed to know the country, volunteered to accompany us. The start was made on a Saturday morning, and as the padres pretended that they were prepared to hold service in a village next day, we flattered ourselves that we would still have another Sunday in something like civilisation, but we have not yet seen the village, much less the service.

(To be continued.)

SOUTH WYNAAD NOTES.

It looks more like settled fine weather now than it has done for some time past, and we needed the change very badly. The continual rain was doing a great deal of harm, encouraging weeds and leaf disease, and checking the ripening of crop, and driving distracted those who were anxious to get their bark dry. By the way, talking of leaf disease, it strikes me that our planting brethren must "do these things differently" on the hills, for I noticed in "Croppy's" notes, that some one from the Nilgiris had written to him that "they were longing for rain, as they feared that the continued drought would increase leaf disease. Now with us, we regard a long spell of dry weather as about the only real check to this abominable affliction. Our trees gained immensely by the long drought before unseason, and we hoped that all our crop was therefore tolerably safe. Then came this continual rainfall, followed by a sweeping attack of leaf. The consequences of this are now painfully visible, for naturally, where the branches became denuded of leaves, the crop died back, and a great deal, which we had hopefully included in our estimates, has dropped off shrivelled and useless. The trees are now recovering themselves, and there is a very good show of young wood for next year. But every severe attack is bound to tell upon old coffee, and a great deal must die out shortly, fortunately, even the most sceptical are awakening to this fact now, and everywhere you see the old patches being replanted with vigorous young Liberians. The grow in these during the past year has been simply extraordinary and most encouraging. It is quite evident that bumpers are not to be the order of the day. This season, though, I hear of one young place which is doing very bravely, and the "Happy Valley" wafts us promises of wonders!

The pepper crop seems likely to be very heavy, the vines have a most lovely show of racemes upon them, and the plant themselves have made an exceedingly fine growth this year. But our old friend, the "seperda," is busy again, and is now hard at work cutting down the Moorica standards which have been planted for the support of the pepper vines. It is not at all unusual to see fine stems, nearly as thick as one's wrist, sawn clean through during the night. If you

remember, it was just about this time last year that they persecuted us in a similar manner.

Three was an idea that very large quantities of cinchona would be coppiced in Wynaad this season; by very large, I mean, of course, as relative to our districts. But from what I can gather, the probable rise in the price of quinine, will check the wholesale harvesting, and besides the ordinary shaving, only the trees showing canker or those which need thinning for the sake of the coffee growing under them will be coppiced. It is distressing to see how in some fields the canker has got hold of fine ledgers; and, of course, most of the succirubras have been so martyred already.

I think the general spirit in Wynaad is more hopeful owing to the push we have had in the opening and planting up of so much Tea and Liberian. But still, we have the years to fight through until these come into bearing, and during that time our outlook cannot be very brilliant, as it will be a case naturally of much out-go and little in-come. Yet there is a rift in the clouds, and it is comforting to believe that dear old Wynaad will weather her storms yet and find a safe haven, independent of Arabica. Rumour whispers of things likely to happen and changes to occur in the near future, but as yet the shadow of coming events is so shadowy, that I cannot venture to speak of them as solid facts.

Crop will certainly be very late this year. So far little but "fly-picking" has been possible, and by far the greater part of the berries are still quite green. This is particularly aggravating when one realises the importance of shipping one's coffee as early as possible. I remember long ago, when we used to be afraid that we should not be able to attend the "Oat-turbury Week" in Calicut in September, because coffee was getting ripe, and chickdorais must not be off the Estates! and now, we are half over November, and can only here and there perceive a few red berries. It is sincerely to be hoped there may not be very many empty ones amongst them. But last year's experience make us somewhat tremble.—*Madras Times*, Nov. 25.

VARIOUS NOTES.

WOODEN TEA BOXES IN ASSAM.—Among the various branches of Assam Forest Revenue, the royalty paid on wood used in the manufacture of tea boxes is not the least important. The output of boxes from saw mills has nearly trebled itself during the past four years. The produce chiefly required for this purpose consists for the most part of inferior timber, such as simal, kadam and kokan, all of which are trees of rapid growth. It is proposed, in view of the expansion of this offshoot of the tea industry, that certain well-situated areas shall be reserved for supplying the demand for these woods.—*Indian Engineer*, Nov. 12.

THE SILKWORM IN ITALY.—It appears that the quantity of silkworm grain cultivated in Italy is decreasing. According to a recent report from Sir Deminio Colnaghi, 1,200,000 ounces of the grain was cultivated last year—chiefly crossed yellow breeds prepared in Italy, pure European yellow and white breeds, and Japanese and Chinese breeds—whereas, ten years ago the amount was 1,525,000 ounces. But the greater care shown in the selection of the grain and its healthy condition, as well as the diffusion of more rational methods of culture, have, to a great extent, made up for the dismissed quantity of grain distributed for incubation. Last year the scarcity of mulberry leaves, which had to be bought at very high rates, was unfavourable to the interests of the breeders; but the results of the breeding were, on the whole, satisfactory. The total yield of the cocoons was 82 million pounds avoirdupois in round figures, about a third of which belonged to Lombardy. The total value of the silk produced from the cocoons was over five million sterling.—*Times Weekly Edition*, Nov. 11.

THE GREAT TEA-PLANTING INDUSTRY:
THE CHANGE IN TEN YEARS!

THE NEED OF PLANTING TIMBER AND FUEL TREES
FOR SHELTER, &c.

ABOUT the middle of 1881, the area under the several principal products, which went to make up "the Ceylon planting enterprise" (apart from palms), was represented as follows:—

COFFEE—Arabica	..	252,000	acres
" Liberica	..	4,000	"
CINCHONA	..	34,000	"
TEA	..	9,500	"
CACAO	..	5,400	"
CARDAMOMS	..	1,000	"

Ten years later, the return for the same enterprise, ran as follows:—

TEA	..	250,000	acres
COFFEE—Arabica	..	38,750	"
" Liberica	..	1,650	"
CACAO	..	12,900	"
CINCHONA	..	9,500	"
CARDAMOMS	..	5,000	"

And the returns, which we are about to ask for, in reference to the compilation of a new edition of the "Ceylon Handbook and Directory," will probably show that, while the area of coffee has still further shrunk, that under tea cultivation has gone on until the total is perhaps at the end of 1892 in excess of 260,000, perhaps 265,000 acres. With such figures before us, we can have little hesitation in answering the question so pointedly addressed to us personally, by an old journalist and colonist who asks if we are prepared to give the same advice to tea planters in Ceylon as we have offered to the future planters of Uganda? Certainly: our advice is not to open new plantations of tea in Ceylon any more than in Uganda, or anywhere else—at least until the hold of Indian and Ceylon teas on the American and Australian markets as well as on those of the Continent of Europe is more firmly established. But, it is a very different matter opening new tea plantations and still more new tea districts, to such extension of an established planting enterprise as is involved in new clearings or new fields added to existing plantations. This process will inevitably go on both in Indian and Ceylon districts, unless a decided check is given by another fall of price or the enhancement of the rupee. All on-lookers—and perhaps the large majority of planters—are fully agreed that Ceylon has for the present enough of tea planted. We are even told that no inconsiderable proportion of gardens cropped (especially, we suppose, where formed on old coffee land) exist through the influence of the *debased rupee* rather than from *bona fide* profits due to the returns of leaf in proportion to value and expenditure. Leaving aside, for the present, the question as to whether or not the price of tea in the London market would rise, to some extent at least, in proportion to any possible enhancement of the rupee, we would simply ask, who is to lay down, much less enforce, a rigid rule to the individual planter:—"Don't plant another acre of tea—say during next year." It is all very well for the proprietor who has been early in the work and who may have got his fields fully opened in proportion to his reserve, or, alas! as we fear in too many cases, in excess of the due and safe proportion,—to say "Don't plant any more" to less fortunate neighbours who are busy making up a decent working acreage, or rounding off a few fields by new clearings. Men who can point to a considerable margin of profits from their 100 or 150 acres are not to be deterred from adding 100 or 50 acres more, in order to make a plantation worthy of the attention of a European Manager;

nor are proprietors with well-furnished Factories to be kept back from extending even a larger acreage. In such cases, it must be left to individual proprietors or the directors of each Company, to settle the point of adding to the planted area, for themselves. Still, it may be safely said that no considerable addition to the cultivated extent under tea is, for the present, to be anticipated. And one good reason for this is found in the fact that nearly the whole of the available area is practically planted up. Taking into consideration the necessities of plantations in timber and fuel, it is certain indeed that the total unplanted reserves in private hands are less than the requirements of the case. And these reserves are most valuable. Only the other day, we had such a reserve in forest pointed out to us, some 20 to 30 acres, which the proprietor, in a high district, was said to rate as highly per acre as he did his planted tea!

To judge by what we have just seen in Dimbula—and the same is, we suppose, true in Dikoya and Maskeliya—the transformation from coffee to tea is practically complete. No doubt there are certain fields of coffee still carefully watched over: it was cheering to learn from the laird of Tillicoultry that he was satisfied with his crop, and from the cheery managing proprietor of Middleton that he had his 2½ cwt. picking per acre of the old berry; and, no doubt, this could be paralleled in Agrapatanas and Bogawantalawa, as well as in Udapussellawa and Haputale. But, for all practical purposes Dimbula, Dikoya and Maskeliya—the hundred square miles of plantations formed out of the "wilderness of the Peak"—are now tea districts. It is exceedingly pleasant in this connection to hear that experiments in planting the old staple, coffee, are being made in selected, sheltered parts of Uva, and we wish all success to the young clearings, while we think a great deal more might be done in the lowcountry with Liberian Coffee. But, for the present, such cases do not affect our arguments that in the established districts—leaving out of view those favoured with cacao or cardamoms to any extent—the planters have only tea fields to attend to. The change visible to the traveller through Dimbula, for instance, is simply marvellous. Travelling by the road from Nanuoya to Talawakele, with its almost unbroken expanse of vigorous leaf-abounding tea, who could imagine that only a few years ago this was all under an entirely different plant? Looking along the verdant fields of Wangie-oya, Galkandewattie, and Great Western, or again at the young and old clearings of tea in splendid jât which cover the easy slopes of Palmerston, not to speak of the valuable younger properties, higher up the valley, it is difficult to believe that anything but their present staple ever supplanted the original forest. And yet we remember Scalpa and Great Western when they were being revived and re-planted, under the indefatigable superintendence of Mr. R. Porter, as a coffee plantation after a long period of neglect if not abandonment. Now, under the special care of one of the leading managers in the country, Great Western may be taken as a model of a well-ordered Ceylon Tea Plantation. No less startling is it to note the series of extensive, well-finished and well-furnished factories, which the tea era has called into existence in Dimbula. There was surely cause for reflection in seeing the old coffee store by the riverside near the ferry on Great Western—where, among others, Mr. G. A. Talbot had his first lessons in preparing and despatching coffee—in ruins, levelled to the ground; while on the

eminence above, we passed through Mr. Mackie's modern Tea Factory with its series of Jackson's and Brown's Rollers, a grand Britannia Dryer, Siroccos, and (still more interesting) the separate building with Jackson's Patent Witherer, the success of which we can well believe from what we saw—all being readily driven by steam engine or supplementary waterwheel. Verily, we are in the era of Buildings and Machinery as well as of Tea.

But there is one special feature of the change in Dimbula and adjacent districts, to which we must give prominence for the benefit of home critics and for the advantage of planters in other districts who have yet to go and do likewise. "If Dimbula, Dikoya and Maskeliya are "all in tea—under one unbroken product, contrary "to nature's plan, what more likely than another "visitation of widespread disease"—will no doubt, be,—

the common if the hidden thought of all,— already alluded to by us, after noting the change. We shall say nothing now of our ability to fight such a visitation in fungus or insect blight in tea, with advantages that were never possessed in dealing with coffee leaf disease. Prevention is better than cure; and though the best means of prevention—a diversity of cultivated products—is beyond our command, the next best means, the growth of trees as shelter belts, on boundaries, on path-sides, in isolated clearings as timber or fuel reserves, or in some cases all over the plantation, has taken a wonderful hold on Dimbula in this tea era. The district is no longer a bare expanse of one lowly product. It is diversified and beautified by the great show of ornamental and useful trees, not simply growing round each bungalow or along the main avenue, but along each boundary and at vantage points all over the estates in many cases. Now apart altogether from the important question of adequate timber and fuel reserves—a most vital matter to upcountry planters in old districts,—herein lies the future salvation of our tea. Shelter and boundary belts and ravine plantings of trees must become an indispensable adjunct of every tea plantation in Ceylon. No local tea planter can be regarded as fulfilling his duty either towards himself, or the community, unless he attends to this matter, except indeed he can point to such natural forest reserves around his tea as precludes the necessity for special cultivation. Tree-planting is therefore, more than ever, the immediate duty before planters who, having finished their tea clearings, want some work to do. We feel so strongly on the matter that our next Manual compilation for the benefit of the planters will be "*All about the Trees suitable to plant on Tea Plantations.*" The subject has been already most adequately dealt with in the columns of the *Observer* and *Tropical Agriculturist* by our veteran senior, and all we have to do is to go over such writings and collate the practical portions. And may we not say that no one has set a better example in tree-planting than the proprietors of Abbotsford, while their present manager, Mr. John Fraser, has unequalled knowledge and experience in the growth of timber and ornamental trees in plantations. No doubt there is much to be learned from the Forest Department; but no one is better qualified than Mr. Fraser to draw up a series of practical hints and instructions for the benefit of his brother planters, in this branch. In one clearing of some acres—now grown up into a grand forest plantation—Mr. Fraser has no fewer than twenty different varieties of introduced trees flourishing on Abbotsford. He has several splendid specimens of the true Jarrah (*Eucalyptus marginata*)

so often confounded with *E. robusta*, the latter tree above all others suitable to grow around swamps or in ravines. What a delightfully ornamental as well as useful tree, the *Grevillea* can become in a short period, can be seen alongside the Dessford and Lorne properties with their fine tea; while equally noteworthy are the splendid Cinchonas on the Inverness and Edinburgh roadsides, only beaten in circumference perhaps by some on Abbotsford. What again can be more attractive, than the rows of light green sapu trees which break the monotony along the slopes of Galkandawatta and Scalpa? Surely then we are right in urging proprietors in the old planting districts, to see to it that they do their duty in planting useful trees—useful for fuel or timber as well as ornament. Only today in casually questioning a planter from an old coffee district of medium altitude, he gave shelter as in his opinion a special condition for the successful permanent growth of tea. We trust therefore that the next few years in the older districts particularly, will be distinguished by even greater attention than hitherto, being given to the planting and cultivation of useful timber and fuel trees on the tea plantations.

It may be asked how far it can be the duty of Government to restrict sales of forest land in order to discourage the further extension of tea-planting. Until the markets already referred to, are secured for Ceylon teas, it would certainly not be wise of Government to arrange for the opening of any new district—say on the Western slopes of Adam's Peak—but the sale of blocks of land in existing districts and more especially when such are required mainly for timber and fuel purposes stands on a different footing. It may be argued, too, that the rule about no sale whatever of Crown land above 5,000 feet should be relaxed. Is all the country between Dimbula and Haputale, with a railway running through it, to be left unutilized—is it to yield not a ton of freight to this expensive locomotive line? Surely not: a system of leases, under which all valuable trees in the jungle should be conserved, can at least be arranged for, while small blocks of patana, scrub or poor jungle might well be sold to purchasers who would bind themselves to plant, a proportion of the area, with useful trees.

NEWS FROM THE CENTRAL PROVINCE : PLANTING AND OTHERWISE.

THE WATTEGAMA CORRESPONDENT in the *Observer's* issue of Nov. 26th, has hit on a very ingenious way of improving Ceylon tea, which he should patent "as a method of improving the manufacture and flavour of Ceylon tea." This method appears to be the utilization of the brains of newly imported Englishmen. There now appears to be some likelihood of a use being found for the many creepers now finding their way to Ceylon.

INDIAN TEA COMPANIES are certainly not doing so well by their shareholders as the Ceylon. An average dividend of $4\frac{1}{2}$ per cent over the whole of them is not startling, and you feel still less inclined to venture money in them, when you are told that 40 Companies are paying no dividends at all. The Castlereagh directors groan that they are only able to pay 8 per cent.

PRICE OF CEYLON TEA.—The quotations for forward delivery on the London Clearing-house point to fair average prices for some time to come. So late back as 8th September forward delivery for the next twelve months was quoted 6½d for whole Indian leaf. On November 10th, the quotation for same leaf is for next twelve months

8¹/₂d—a rise of 1¹/₂d. China black leaf congou has also risen within the last five weeks 1¹/₂d. The only danger is, China exporters in spring making contracts for heavy exports of China cheap tea to London. However, we may choke that movement off by shipping largely in the first three months of the year.

PRICE OF SILVER.—Mr. Alfred de Rothschild seems to think he is quite solving the silver difficulty by calling on the several European powers to make silver a legal tender up to £5. He also wishes the European Powers to combine to buy 5 millions of silver annually for a period of five years at no higher a figure than 43 pence per lb. What a pity it is that our late planting member of Council is not available for this Conference. Why does not the Chairman of the Planters' Association write a circular letter to the Great Powers suggesting this idea?

CHICAGO EXHIBITION.—Has Mr. Grinlinton received a sufficient quantity of tea exhibits from estates yet?

WEATHER just what was wanted. Fine, hot, dry weather. Cocoa will ripen and tea will flush on the hills in good style if this weather continues.

THE ELECTION OF MR. CLEVELAND to the office of President of the United States must be gratifying to Fair Traders. No doubt the McKinley Bill will now be much modified, with the result of trade between America and England resuming its old proportions to the increase of goodwill between the two greatest nations in the world. I am sure Ceylon planters will not grudge plenty of our money being spent at Chicago now that they know the mother country is no longer to be harassed by one-sided taxation on its exports to America.

THE AMERICAN TEA COMPANY seems to have fallen on evil times, and this sudden throwing up the sponge by Messrs. Watson & Farr must be disappointing to Messrs. Grinlinton and Mitchell, who so strongly advised the Ceylon Planters' Tea Company to intrust their funds with their American correspondents.

PLANTING IN BRITISH CENTRAL AFRICA.

THE PLANTERS' ASSOCIATION OF BRITISH CENTRAL AFRICA—MAJOR WISSMAN'S EXPEDITION—THE PACIFICATION OF ARAB CHIEFS—MESSRS. A. WHYTE AND LLOYD—SETTLEMENT OF LAND CLAIMS—WANT OF COMMUNICATION: A RAILWAY WANTED—SCARCITY OF FRUIT: A CHANCE FOR A PHILANTHROPIC CEYLON PLANTER—BUSHGRASS—FLIES AND WILD BEASTS—COFFEE AND COFFEE-BORER—THE SANITARIUM OF B. C. A.—LOVELY SCENERY.

Milangi, British Central Africa, 1st Oct. 1892.

A monster meeting was held at Blantyre lately for the purpose of forming a Planters' Association to keep our Government in check, and represent in a body our grievances to the British Central African Administration, and if no redress is obtained to petition the home Government.

We have twenty-four planters here, at least that number are interested in planting, and it is expected all will be enrolled as members at a meeting to be held on the 5th inst.

The entrance fee is to be £1 1s, and quarterly subscription 5s. I will send you a copy of the proceedings at the meeting on the 5th inst.

Major Wissman's anti-slavery expedition is at Misongwi on the Zambesi consisting of some 40 Europeans and about 200 natives. They had two steamers with them in sections, one for Lake Nyassa and the other for Tanganyika. Smallpox has broken out amongst them, but every precaution is been taken to prevent the spread of the disease by segregation. It is expected that this expedition will take 2 years to meet the expedition on its way inland from Bagomayo. They are determined to punish all native

chiefs between Tanganyika and the coast who are concerned in the massacre of some 39 Germans lately.

Mr. Sharp, Vice-Consul (whose usual residence is at Blantyre), has been sent up to Lake Nyassa to try and use his influence with the Arab chiefs in maintaining peace, as they are again assuming a hostile attitude, so much so that the manager of the African Lakes Company has telegraphed home that it is impossible to carry on trade.

Mr. A. Whyte has been laid up at Zomba with congestion of the lungs,—the first illness he has had since he came here, he seems fever-proof. I am glad he is now better for a more useful man the Administration does not possess.

A Mr. Lloyd, who was once surveying in Ceylon, has turned up here and is employed by the B. C. A. Administration. I've not seen him, but expect he will be round our way soon on duty and hope to have the pleasure of a chat about dear old Ceylon, although, I am told, he left the island before my time.

The Commissioner is on a tour trying to settle land claims. One gentleman who had 10,000 acres has had to accept a title for 2,000 or stop work, as Mr. H. H. Johnstone told him, should he not agree to his proposal he would put his veto on him and prevent him clearing another acre! at the same time saying an appeal to the Foreign Secretary was useless, and if he wished to take it before the Privy Council he would make the delay vexatious and expensive probably costing £500 before a final settlement is arrived at. So what can do? We have Mr. Rhodes's little brother here, against whom it is useless to appeal. So you see how the law is meted out to us here. We can only grin and bear it and hope the Liberal Government will give us a change, for it is sadly needed.

The Shiré river has almost run dry: only small canoes can come up to Chilomo and nearly everybody is out of the current coin of the country calico. The same thing happened last year, and nothing will satisfy us but a railway, which might be cheaply made as the country is easy and slightly undulating to the coast,—in fact so much so that I was seriously thinking of spouting coffee down to the Zambezi or Shiré. I suppose lots of old coffee spouting could be bought for a trifle in Ceylon now, as well as coffee pulpers for that matter. Postage to as well as from here seems not to be depended upon, for I have not received "All About Tobacco" and the "Planters' Manual" you advise me as having posted now nearly a year ago. I wrote to the Vice-Consul at Quilimane to find out if they were at the post office, but it seems not.

There is a great want of fruit in this country. There is nothing here except the plantain. By way of fruit it would be a boon and a blessing to man in Africa if some philanthropic Ceylon planter were to send a parcel of seed of mandarin oranges, bread-fruit, jak, soursop, custardapple, jambu, rose-apple, bullock's heart, mangosteen and any other fruits common to Ceylon and the East. They are plentiful enough in the Colombo market all the year round. I would send in return Landolphia Florida and Bogota rubber, and bush grass seed. The whole country is overrun by a large variety of bush grass. It grows up every year to about 6 to 8 feet, dries during the dry season and is burned off; it thrives even under a dense cover of forest, some of them cattle and goats fatten on but some are poisonous and they don't touch. For some cattle got down a year ago from the Lake Nyassa are doing well I mean to train them as tavalams to send away coffee. By the way this can only be done for about 20 miles of the way to the river as tsetse fly abounds beyond that limit, in proof of which Mr. Johnstone lost all his horses brought from the Cape, except one which is now at Blantyre. Our usual mode of travelling here is on foot or in a machela or dandy, a hammock slung on a bamboo. One gets about 8 to 10 men to a long journey and they take it in turns two at a time and get along at a fairly good pace about 4 miles per hour. By the bye I had a donkey here but he was killed by a leopard in broad daylight within 60 yards of a house. I set a trap gun and shot him, also another one the following night who came and had a look at his brother's hand.

work; also two hyenas, the latter are awful brutes weighing more than a full-grown leopard; they devour each other, hunt down game in packs, but strange to say the noble lion will not touch his scavenger attendant when a corpse. I saw an instance of this the other day; having shot a hyena some lions came roaring to the scent about dawn but not one of them touched the carcase. I got out of my tent and tried to get a shot, but they cleared off before I got within range.

For the past month hush fires have been running along the mountain slopes on both sides of me and have driven the leopards into a corner behind my bungalow. I can hear them night and day barking to each other. I've got a trap set in the old Ceylon fashion with a goat as a bait, but they walk past. About 7-30 one evening when my servant had gone a rather cheeky fellow walked into my kitchen, seized one of my dogs (an African pariah), who made the rocks echo with his yells. I ran out gun in hand, but Master Spot had got too far off for me to get a good shot, it being dark too. I, however, made him drop the dog with two bullets from my express, one of which I found hit him somewhere about the loins, for he got away dragging his hind quarter leaving lots of blood on his trace. The dog died next day, although I heated his neck wounds immediately with warm water and put cotton steeped with carbolic lotion into them.

I have a blossom in spike on the coffee, about 8 acres, planted with stumps brought from Mandalay 18 months ago. It looks well and healthy. About 5 cwt. per acre blossom I should say. We have no signs of leaf disease or bug here, the only enemy coffee has is borer and grub. The former attacks the tree when 12 to 18 months old going up and down the pith the same fellow as I've seen in Travancore and Ceylon, but spare me from grub, the larva of the cockchafer evidently the same as the Ceylon. Our own land is full of them. I have lost about 25 per cent of plants in my new clearing. I managed after all during last planting season to put out 28,000 plants—not had in one year for wild Africa.

If I can get the labour I am going to make a hridle path up to the Milanji upper plateau 6,400 feet above sea level. This to be our sanitarium. For about 2 months in the year there is hoar frost on the grass and during the hottest months the thermometer is only reached to 68° at noon, and 50° at 6 a.m. The scenery is lovely with its cedar forest, spruce, firs, heather, heath, mosses, &c. It is really a wonder in Central Africa Mr. Johnston says there is no place like it from Kila-manjaro to Basutoland.

I shall send you some hunting yarns in my next if you care for them. H. B.

UNITED STATES CONSULAR REPORTS.

FOOCHOW TEA TRADE.

REPORT BY CONSUL GRACEY.

The chief export from Foochow to the United States is tea, the retrograde in which trade, beginning eleven years ago, still continues. In the year 1880 the shipments of Congou tea from this port were about 850,000 chests, or 654,000 piculs, and of all kinds 738,000 piculs; in 1891 only 345,000 chests of Congou and 361,966 piculs of all kinds were shipped. The production and sale of Oolong tea has been about the same as in the more prosperous years, but the entire product of this kind of tea has only been about 19,000 piculs or 2,533,666 pounds. A large portion of this has gone to American markets.

The entire shipment of all kinds of tea to the United States in 1880 was 2,753,600 pounds according to the customs report, during the year 1891 it was 3,653,133 pounds, which is a gain of 1,148,000 pounds over the year 1890. Turning our attention to the shipments to Great Britain, in 1880 the figures were 71,500,000 pounds, which have fallen to 17,500,000 pounds in 1891. While the trade in tea from this port to Great Britain has fallen off nearly three-fourths in ten years, it has increased to the United States, as shown above.

As compared with England, Australia and Russia we are not a tea-drinking people. Three years ago statistics showed that the consumption of tea per capita by Americans was about half a pound; by Englishmen at home, 7 pounds for each inhabitant; by Australasians, 13 pounds.

The decrease in the export of China teas to Great Britain is due to the fact that India and Ceylon teas, raised under British protection by English growers, have been put upon the home markets at much lower rates than China could furnish them, and every encouragement has been given to the production and sale of the tea raised in those countries.

The trade in tea for London markets has not proved remunerative for foreign dealers at this port as compared with former years, while those shippers who have been supplying the American market report better profits. This is due almost entirely to the fact that China tea is not brought into competition with the India and Ceylon product in the United States.—*L. and C. Express.*

THE PLANTING INDUSTRY OF SOUTH INDIA.

During the time that H. E. the Viceroy remains with H. E. the Governor of Madras, certain subjects of policy and statesmanship connected with the administration of this Presidency will no doubt be discussed by the distinguished host and his more distinguished guest, and remembering that quite recently addresses were presented by the Planters of Coorg and Mysore to Lord Lansdowne and an address was handed to Lord Wenlock by the Chairman of the Travancore Planters' Association, it is not unreasonable to presume that the present status of the planting industry in South India will come up for serious consideration. There is a petition being prepared for presentation to the Governor-in-Council by the Planters' Associations in this Presidency, praying that one of their number may be appointed to a seat in the Legislative Council. With the Viceroy's notable Poona speech on the subject of Reformed Legislative Council still fresh in our minds, we should not be surprised to learn that Planters' Associations were one of the rural boards to whom the right of electing one of their members to a seat in Council was conceded. The Collector of the Nilgiris has asked the Honorary Secretary of that Association to endeavour to furnish him with accurate statistics showing the amount of money invested in plantations on those Hills. This may be feasible on the Nilgiris, where the various products cultivated by the planter have always thriven well, but there are many districts where it would be impossible to ascertain the amount of money that has been sunk by Europeans in land from the time that the first planter laid axe to tree. To exemplify the foregoing, let us turn to Travancore, now a young and flourishing tea-district, which compares favourably on a small scale with Ceylon. The Chairman of the Travancore Planters' Association could with but little difficulty show the amount of the money at present invested in the tea-industry; but could he make even a remote guess at the lakhs of rupees swallowed up by coffee? We doubt it. Further, there may be cases in this district—we know there are in others—where a few acres under cultivation represent hundreds of pounds sterling sunk by one planter in land now reverting to jungle or in the occupation of others who bought it for a song; but the sum sunk by such a man could hardly be returned as money invested in the small acreage under cultivation.

HOW THE COUNTRY AND PEOPLE HAVE BENEFITED BY PLANTING CAPITAL.

We have thus shown how impossible it is to obtain any accurate information concerning the volume and extent of that Pactolian stream of British capital which for the last half century and more has been flowing steadily and perennially through the jungles and forest glades of South India, enriching directly the peasantry of the surrounding districts and indirectly the coffers of the Governments of India, of

Madras, of Mysore, Cochin and Travancore. But while accurate figures cannot be obtained, showing the full benefit the country has reaped from the Planting industry in the past, we may shadow forth slightly the sum of money that is being spent annually by the planting community. Taking Travancore, for instance, we find that the number of pounds of teas sold in the Mincing Lane Sales' room last year—a figure not altogether identical with the number of pounds exported or produced—was 1,331,280. The actual cost of a pound of tea f. o. b. in Travancore is 4as. 6p., so that the total cost of production was R3,76,500; that is to say, the actual sum of money that had to be spent in this country before this amount of tea, could be exported was over 3½ lakhs. It may be taken, roughly speaking, that a further 3½ lakhs were realised by the sales of the tea and of this sum we do not suppose that a pie was spent out of the country, but was sunk in new clearings, improved machinery, &c. 7½ lakhs may thus be set down as the minimum that the tea industry of Travancore, still in its infancy, expended last year in that province, and we should not be surprised to learn, should a statistical table be prepared, that the sum was even larger. Tea, it should be mentioned, is only one of the products of the Travancore planting industry, both coffee and cinchona being cultivated, the latter largely. Turning to the coffee industry, we find from Messrs. Alston Low & Co.'s figures that in 1890-91, 78,464 cwt. of plantation coffee were shipped from the West Coast. We choose this season as it was so abnormally bad that it was a moral impossibility for the coffee planter to spend a penny outside his estate, and on many large properties the sum realised by the sale of crop had to be largely supplemented from other sources. Taking R65 as the average value per cwt. of plantation coffee f. o. b. that year, the total sum realised by the plantation coffee exported from the West Coast that season was just over 58 lakhs, and, as we have pointed out, all of this money must be spent in the country. This is only a moiety of the cost of the production of the coffee crop that season. No little plantation coffee from Mysore and Coorg is shipped from Madras, and also no inconsiderable sum of money is realised by the sales of small crops and the stripped cherry coffee to local native dealers, which is either consumed in this country or exported as native coffee. During the season 1890-91 the plantation coffee exported from the West Coast totalled 156,827 cwt. or a value f. o. b. of R1,09,77,890, taking R70 as the average value per cwt. Of this sum if we bulk the districts, not much, we are convinced, found its way out the country. The number of acres under coffee cultivation in this Presidency are returned at 64,511, but as these figures apparently include native gardens and *parumba* cultivation, it is impossible to draw from them any conclusion concerning the annual expenditure for cultivation. The Dewan of Mysore has kindly sent us statement showing the acreage under cultivation in that province, from which we learn that the total number of acres at present under coffee cultivation in Mysore is 125,773; this also includes the small coffee gardens of native cultivators. The last figures available showing the acreage of European plantations were compiled in 1881, in which year it was set down at 40,262 acres. Since then the total area under coffee has increased in that Province by 21,200 acres, of which a certain proportion at any rate was due to European capital. In Coorg 32,500 acres are the extent of European plantations, and the cost of cultivation is returned at R100 an acre, which proves that in that Province alone 32½ lakhs are spent annually by European planters. These figures are necessarily incomplete, but they give some idea of the great importance of the planting industry in South India. Now we take it that the value of an industry in the eyes of Government depends not on the sum taken out of the country but the sum of money annually spent within its borders. It would be very easy for planters to put this on record and to establish once for all, beyond all cavil and beyond all doubt, what the community does expend annually in this country, if each man were to consent

to furnish the Honorary Secretary of his Association with the average amount that he has spent on this estate during, say, the past three years. These figures could be submitted privately to the Honorary Secretary of each Association, and no one beyond this gentleman need be aware of his neighbours' annual expenditure. Such a statement from each district would finally establish the great benefit this country derives annually from the Planting Industry, and would, we trust, lead Government to do more to assist in the development of this industry.

A PLANTING MEMBER OF THE MADRAS COUNCIL.

We need not refer here to the advantage which a Planting Member of Council will be to the community, or to the grievances about which the community have just cause of complaint. We will confine our remarks to that question of most vital importance to this industry, the establishment of good communications. It is no exaggeration to say that in the majority of districts, highways that pass under the name of roads are little better than the tracks along which at the beginning of the century the grower of jungle produce conveyed his scanty store to market in a vehicle drawn by buffaloes and mounted on wheels of solid blocks of wood, once almost round. Bridges are constructions that are conspicuous only by their absence in many districts, and in the monsoon estates are isolated from the rest of the world for weeks at a time. It is ridiculous to suppose that any agricultural industry can be properly developed without good means of communication and transport. An argument, at times adduced and one not unknown to the lips of Government officials, is that the planter came to this country of his own free will and with the intent to make money, and he should therefore put up with the existing surroundings and not grumble. Now, we consider it may be laid down as an axiom that all Europeans come to this country with the purpose of making money. How many succeed does not at present signify. He would remind those who bring forward this argument that until the planter came, the tracts of country in which he sunk his money were practically unproductive, and that the planting industry is—private enterprise. Lord Lansdowne at Mysore told the Planters' Deputations that if a railway to the West Coast were to be constructed in the near future it would have to be by private enterprise. If His Excellency had been cognisant of what his Government had done to encourage private enterprise in Coorg as represented by the large planting community in that province—and what it is still doing to encourage it he could hardly have supposed that any Coorg planter blest with an ordinary degree of sanity, or any Associations which had the least regard for its probity, could advocate private enterprise expending money on a railway. There is at the present time a more than usual amount of vitality about the planting industry, and we hope that the combined deliberations of Lord Lansdowne and Lord Wenlock may result in some greater degree of official recognition being extended to this enterprise; that in the near future those just grievances from which the community suffers may be removed, and that some endeavours may be made to assist in a greater degree than in the past the development of this important industry. If Government be honestly and truly desirous of encouraging private enterprise, it can prove it to the world at large with but little trouble by its actions in the future towards the Planting Industry of South India. Until it does do so, it need not expect that private capital will be forthcoming for other enterprises when a private enterprise that expends annually in South India a crore of rupees or more has been up to now, to all intents and purposes ignored.—*Madras Mail*, Nov. 24.

PLANTING IN TRAVANCORE.

SIR,—My attention has been drawn to articles that have appeared in your paper signed "Totum" As it is a pity that incorrect information should be

handed down to posterity, I hope you will allow me to correct one or two of the errors that have crept into what otherwise may be considered interesting articles. In the Peermaad District coffee was first opened by Mr. J. W. Munro and General Stevenson in 1861.—Stag Brook was opened in 1862 by Mr. Robert Baker, and Twyford in 1863 by Mr. F. G. Richardson. Fairfield was only opened in 1865, and the other estates some years afterwards. Your correspondent, in alluding to the failure of his own coffee as well as that of others, but let us hope, unwittingly omitted to mention the fact that the Twyford Estate, some 400 acres in extent, is *entirely* coffee still, and, when I saw it a few weeks ago, was in a most prosperous condition. To the owner of Peshurst, doubtless, belongs the credit of having started the first Tea Estates on Peermaad. The seed was procured for him from the Catisfield Estate, Kotagiri, then the property of Mr. E. J. O. Brace, who is still well remembered as having done a great deal towards improving the cultivation and manufacture of tea on the Nilgiris. The seed from Peshurst was very much in demand for many years, as also seed from The Mount, which was planted from seed also grown on Catisfield. The owners of both Peshurst and The Mount have great cause for thankfulness that they were induced to procure tea seed from Catisfield, and your correspondent is proud to think that he had a little to do with the introduction of a good *jat* of tea into Travancore. The Mahendragery tea was grown from seed procured from General Oullen's garden, and I am making enquiries at Trevandrum with a view to ascertaining, if possible, where the General procured the seed that has of late years attracted so much attention.

Nov. 23rd.

"LABUNTER ANNE."

—*M. Mail*, Nov. 26.

ANNUAL ADMINISTRATION REPORT OF THE GOVERNMENT BOTANICAL GARDENS AND PARKS, NILGIRIS, FOR THE YEAR 1891-92.

From Mr. Lawson's report we quote as follows:—
SEASON AND RAINFALL.—The rainfall for the year, as registered at the Government Gardens, Octacumund, was 51.29 inches, or 2.68 inches more than that gauged the year before. The average for the last seven years has been 53.61 inches, so that the amount registered for the year, viz., 51.29, was about the average. October was a very wet month, in which there fell the unusually large quantity of 17.07 inches. This was in fact one-third of the rain for the whole year. The weather in January, February and March was very dry and the drought was trying to the smaller and younger plants.

COONOR.—SIM'S PARK.—The park itself was, during the year, maintained in good order, and the coppice mentioned in last year's report has grown rapidly and has made considerable progress during the past season, notwithstanding the drought which occurred during several of the months. The frost on several occasions was again very severe, and damaged many of the less hardy plants, especially the *Acrocarpus fraxinifolia*, all of which were much injured.

BARLIAR.—EXPERIMENTAL GARDEN.—The storms of October last created havoc in these gardens. The upper portion was almost completely swept away. Boulders, 3 feet in diameter and more, crashed through the garden and destroyed in their downward course nearly all the fruit-trees which had been imported from the Straits Settlements ten years ago. The Durian, which was over 40 feet in height, and was an exquisitely proportioned tree, was grazed by one of these boulders, and the bark for 6 feet from the ground was removed entirely from the stem, with the exception of about 4 inches on one side, and it was expected that the tree must speedily die. It was, however, promptly covered with moss, and watered daily all through the dry season. The tree at the present date is not only still alive, but it produced for the first time this spring both flower and fruit.

The two fruits, which were quite spherical, were 5 inches in diameter, and possessed the grateful taste and nauseous odour of those grown in Burma. During the same storm the lower part of the gardens suffered very greatly from wash, many of the trees having their roots completely denuded of soil. Such a storm as that which occurred in October last has probably never happened before on the Coonoor ghât since it was first opened out for European traffic.

The wooden bridge with its stone pillars was completely swept away, apparently by the agency of a single rock which was dislodged from the upper part of the Barliar Garden and carried by the force of the stream about a furlong and a half, where it was at last pulled up by a bend in the river. Many persons attributed the excessive amount of rain to the constant blasting of rock on the new railway, which was then and is now in progress, and this blasting may perhaps have aggravated the local atmospheric conditions; but as the rainfall was unusually excessive, at the same time, all over the plateau, the blasting ought hardly to be regarded as the primary cause of the storm.

ECONOMIC PLANTS.—(1) *Bluegum boiler fluid extract.*—A reference to this, as a scale preventative for boilers, was made in the report for 1889-90. It is a bye-product, obtained in distilling the essential oil from the bluegum leaves, and in order to make its properties more widely known, in January last some was made, concentrated in bulk to one-sixth of that which is ordinarily used, and a sample was sent to the Muir Mills, Cawnpore, Messrs. Borham & Co., Madras, the Bombay, Baroda and Central India Railway, Bombay, the Commissariat Storekeeper-General, Madras, and also latterly through him to the Commissariat Department, Mandalay, Upper Burma. The Manager, Muir Mills, wrote to say that they have been able to obtain the leaves of the Eucalyptus in the North-West Provinces, and now make the extract for themselves. Messrs. Borham & Co. wrote that they could not report favorably on the extract, as it was found to cause an accumulation of sediment about the cocks and valves, which out the latter up to such an extent that they had to be ground down three times during the time that the fluid was being experimented with. The Manager of the Bombay, Baroda and Central India Railway Company wrote to say that they had sent the extract to the Locomotive Superintendent, Ajmere, but did not want any more to be sent till he wrote again, and this he never did. The Commissariat Storekeeper-General, Madras, reported that it was tried in the Government Bakery, with the result that it was found superior to any previously used, and asked for a further supply of 2 gallons to be sent to Mandalay, Upper Burma. This was sent, and he was informed that after making careful experiments as to what the cost of manufacture of the extract would be, it was found that it could be turned out at 6 annas 10 pies per gallon, and that this represented the cost of the fluid, without bottling, package, or profit. Also that the fluid could not be sent out in any large quantities from the gardens and as he had an offer from Mr. Wallace to supply him with the fluid, he was recommended to make arrangements with him, as his charges were not considered exorbitant.

Broomstick grass (Aristida setacea).—In a letter dated 18th May 1891, No. 947, the Government of India asked that they might be supplied with specimens of this grass, which is said to be used largely in the brush-making trade. Specimens were obtained from the Acting Collector of Nellore and identified as *Aristida setacea*, and a report thereon, with properly prepared specimens, was sent to the Board of Revenue for despatch to the Government of India in January last.

[After discouraging reports of ipecacuanha.]

Jalap.—Some years ago, Nilgiri grown jalap excited considerable interest in the London market on account of the high percentage (18 per cent) of activeresin which it yield. Mr. Hooper in January 1891 examined some samples of well-powdered and mixed jalap and found 16 per cent of the resin, while Dr. Warde, on

analysis of various tubers from Mussoorie, only obtained from 6.4 to 10.7 per cent. This shows that the Nigiri jalap is in no way deteriorating. The price of jalap during the past year ranged from 1s to 1s 9d, while the cost of production is something under 3 annas per pound.

Eucalyptus ficifolia (Scarlet flowered gum).—Seed of this elegant Australian tree was presented by the Hon. J. F. Price. The seed germinated freely and the young plants are growing vigorously.

[This must be due to the drier climate; as the rain at between 5,000 and 6,000 feet in Dimpbala seems to be adverse to this fine tree.—Ed. T.A.]

Blugum oil.—During the last two years the demand for this oil has greatly increased. It is satisfactory to be able to state that the manufacture of this very useful drug has been taken up at last by Mr. S. G. Wallace, who not only makes it on a large scale, but also, according to analysis of several samples by Mr. Hooper, of very excellent quality; and it is to be hoped that he will receive sufficient encouragement to continue its manufacture. Mr. Wallace makes also many other preparations from the indigenous plants of the hills, and notably, amongst other things, oil of Winter Green, from the leaves of *Gaultheria fragrantissima*.

Consignment of seed from New Zealand.—In May 1890 the Commissary-General, Madras, brought to the notice of Government that some vegetables raised in the Commissariat gardens at Fort White Chin Hills, Upper Burma, from seed obtained by Conductor Mills from New Zealand far surpassed anything raised from English, or Indian seed, and he, the Commissary-General, suggested that a consignment should be obtained for experiment in these gardens. In G.O., No. 2863 of 10th May 1890, Revenue, Government desired that an indent for this seed should be sent in, and on this being done, Government in G. O. No. 485 of 21st June 1890, Revenue, ordered that the seed should be obtained direct by this office. Messrs. Hesketh and Aitkin, Florists and Seedsmen, Auckland, New Zealand, was accordingly written to on the 30th June 1890, and they despatched the seed, so ordered, on the 23rd September 1890. Nearly a year passed away, however, before the seeds were received, and though the Agent for Government Consignments and Messrs. Arbuthnot and Co., Madras, Agents for the Peninsular and Oriental Line of steamers, were addressed on the subject, no trace of the package could be obtained, and it was assumed that it had either miscarried, or was altogether lost. Government in G.O., No. 4521 of 17th August 1891, Revenue, desired that Messrs. Hesketh and Aitkin should be written to again. Meanwhile, on the 31st July 1891, the Sydney Transfer Company wrote to say that the seeds were on their way here, and that the delay was due to the Peninsular and Oriental Company having at first refused to carry them, but afterwards agreed to do so, and the Agent for Government Consignments wrote and advised that he had cleared the case. The seeds arrived here on the 21st September 1891, exactly a year after despatch from New Zealand, and when sown in these gardens, it was found that they germinated freely, and that the plants raised produced vegetables of an excellent quality, proving that the seed had been carefully harvested, and well packed.

[A very unexpected result, surely.—Ed. T.A.]

Scrub Exterminator.—In the last year's report it was remarked that the material which went under this name was very poisonous, and might be the source of much danger to people possessing it, and also to cattle grazing where it had been used for the destruction of noxious plants. This opinion was founded on Mr. Hooper's analysis of the compound, and the view of the dangerous nature of the compound then taken has since been justified by several cases of poisoning which have taken place in England.

In the Government order on the report it is stated:—

In last year's review the Director was requested to expedite the submission of his proposals for a

Botanical Survey of the Presidency called for in G.O., No. 1988, dated 21st April 1891. In May 1891 he reported that he was in communication with Drs. King and Trimen on the subject and expected to be able to submit a reply shortly, but in his statement of unanswered references for the quarter ending 31st March 1892 he has informed Government that he will not be able to organize a survey during the current year. The reasons for this inability have not been stated and the matter should be more fully explained, as the survey has been ordered under instructions from the Government of India and should not be unnecessarily delayed.

[It seems probable that Dr. Trimen's absence in Britain may, to some extent account for the delay.—Ed. T.A.]

MAURITIUS TEA.

The fact is recorded that tea of very good quality has been grown in Mauritius, and a total weight of 865 pounds has been manufactured since January last. This, it is true, is only a small beginning, but if the island produced only sufficient tea for its own consumption it could very well support one or two small estates on hilly land in the interior, not required for other cultivation. A recent letter from the Administrator of Mauritius to the Colonial Office forwards copy of a letter which I have received from Mr. Regnard, chairman of the Experimental Plantations Committee, enclosing a report from Mr. Corson relative to the experiment which is being made in tea planting in the colony. A report and valuations made in Ceylon by Messrs. Somerville & Co. on the samples of Mauritius grown teas is also included. The experiments in this direction, so far they have gone, augur well for the future development of tea planting in this colony, and I will not fail to keep your Lordship informed of the progress made in extending this new industry. It may interest your Lordship to know that during the recent hurricane these plantations did not suffer in the least.

Messrs. Somerville and Co. report as follows.			
Orange Pekoe...	Loudon	value 2s.	Blackish, well made very tippy broken orange pekoe leaf. Liquor, strong, dark, fine quality.
Broken Pekoe...	Do	1s 7d.	Blackish, well made and twisted orange pekoe leaf. Liquor, strong, dark, fine quality.
No. 1			
Broken Pekoc...	Do	1s 8d.	Blackish, well made, very tippy leafy, broken pek
No. 2	Do	1s 9d.	Liquor, strong dark, some flavour (quality fine).
Pekoe Souchong	Do	9s	Blackish greyish, small ohoppy leaf, little flakey. Liquor, strong, dark, good quality.

P.S.—The orange pekoe and broken pekoes are very fine in appearance.

—L. and C. Express, Nov. 11.

ALLYNUGGER TEA COMPANY, LIMITED.

Registered by Sanderson, Holland and Adkin, 46, Queen Victoria-street, E.C., with a capital of £120,000, in £10 shares (5,000 £8 preference and 7,000 ordinary). Objects: To enter into and carry into, effect an agreement with Thomas McMeekin to purchase or otherwise obtain grants or leases from Government, and to purchase, take on lease, or in exchange hire or otherwise acquire from any company or companies, person or persons, any tea or other estates or lands, real or personal property of any description situate in British India or elsewhere; and to cultivate tea and other produce, and to carry on the business of cultivators and buyers of every kind of vegetable, mineral or other produce. The first signatures are:—

Remuneration, £100 per annum each. Thomas McMeekin managing-director till December, 1896, with a salary as fixed by the directors.—*Financial Times*.

THE PRODUCTS TO CULTIVATE IN

EAST AFRICA.

COFFEE *versus* TEA.

The following letter appears prominently in the *London Times* of Nov. 10th:—

THE RESOURCES AND DEVELOPMENT OF UGANDA.

To the Editor of the *Times*.

Sir,—At a time when the commercial importance of Uganda is attracting attention it may be well to mention one important tropical product which can be cultivated successfully in, and abundantly supplied from, this division of East Africa. One authority, indeed, has already mentioned in your columns that coffee is indigenous to the forests of Uganda. This I can well believe; for Abyssinia—the recognized *habitat of Coffea Arabica*—is not far distant, and already flourishing coffee plantations have been formed by Ceylon planters further south at Blantyre. I wish specially to emphasize the fact I tried to make clear in a paper read before the London Chamber of Commerce a few months ago—namely, that the present supply of coffee—unlike that of most tropical and other products—is scarcely equal to the demand; the price of good coffee is abnormally high, and, since the appearance of the fungus disease in Ceylon and India, British dependencies especially have been able to supply very little coffee. Brazil and Central America are now the great coffee-growing countries, and it is a matter of some importance to British merchants and planters (the latter available from Ceylon) to revive a great coffee industry in a British State.

On the other hand, I would venture to repeat what I stated in the Chamber of Commerce, that there is no such encouragement to introduce and extend tea cultivation in East Africa. India and Ceylon (leaving China, Japan, and Java out of view) have of late years so increased their output of tea that the price has fallen perilously near the average remunerative limit, at any rate for a new country.

Cacao (the "chocolate" shrub) is a product that can be recommended for Uganda; while the collection of rubber from its forests ought to be specially profitable, considering the increasing demand both in Europe and North America.—I am, &c., J. FERGUSON, of the *Ceylon Observer and Tropical Agriculturist*.

GENOA, Nov. 5.

P.S.—I would just add that, while coffee, cacao, and rubber are recommended to the notice of British capitalists and planters for East Africa, the products which are in danger of being over-supplied include, besides tea, pepper, cardamoms, cinnamon, and the oil, fibre, and nuts of the coconut palm, though for local consumption the latter should be valuable in East Africa as everywhere else.—J. F.

VARIOUS NOTES.

MAURITIUS TEA.—Mauritius is now among the tea-growing colonies. Samples of leaf cultivated and prepared in the hilly parts of the island are pronounced of good quality, so that even if none is exported, it may before long supply not only its own population, but much of the neighbouring parts of Africa.—*British Trade Journal*, Nov. 1.

THE COFFEE ENTERPRISE IN BRAZIL.—The coffee fields of Brazil cover an area of two million acres, and contain upwards of eight hundred million trees—that is, four hundred per acre, each tree producing on an average one pound of berries per annum. The industry finds employment for over eight hundred thousand men.—*Horticultural Times*.

COFFEE IN THE UNITED STATES.—The imports and exports of coffee for the fiscal year were as follows:—

	1891-92.	1890-91.
Imports, free of duty..Pounds	632,942,912	519,528,432
„ dutiable ..	7,268,876	...
Total .. „	640,211,788	519,528,432
Exports .. „	10,539,040	8,486,973
Net imports .. „	629,672,748	511,041,459
Average import value ..	20.07c.	18.50c.

The increase in the average import value of coffee, nearly 1½c per lb., was no doubt due to the imposition of the duty of three cents per lb. on certain mild grades, under the reciprocity provisions of the tariff. The announcement of the intention of the President to levy the duty caused heavy importations of the said grades and the relative increase of the average value of the total imports of the bean for the year.—*New-York Merchant's Review*, Aug. 2.

THE INTRODUCTION OF COFFEE.—Paris is celebrated above all the capitals of Europe for its cafés; and the beverage which gives its name to these establishments seems to have been known earlier in France than in any other European country. Coffee was introduced into central Europe in 1863, the year of the battle of Vienna; and from the Austrian capital the use of coffee spread rapidly to all parts of Germany. The circumstances under which the Austrians first became acquainted with it were somewhat curious. The Turks had brought with them to Vienna an imposing siege train. No European power possessed such formidable artillery; and their stone balls of sixty pounds each were not only the largest projectiles ever fired, but were regarded as the largest which by any possible means could be fired. According to the ingenious, but incorrect, view of one of Sobieski's biographers (the Abbé Coyer), the amount of powder requisite for the discharge of a missile of greater weight would be so enormous as not to give time for the whole of it to become ignited before the ball left the cannon. Kara Mustapha, the Turkish general, had also brought with him a number of archers; and when a letter from Sobieski to the Duke of Lorraine was intercepted by a Turkish patrol, the document was attached to an arrow and shot into the town, accompanied by a note in the Latin language to the effect that all further resistance was out of the question, and that the Vienna garrison had now nothing to do but accept its fate. The Turks, moreover, brought Vienna an immense number of women, whose throats, when the Turkish army was forced to retire in headlong flight, they unscrupulously cut. The stone cannon balls of prodigious weight, the arrows, and the women could all be accounted for. But the Turkish left behind them a large number of hags containing white berries, of which nothing could be made. Of these berries, however, after duly roasting and pounding them, an Austrian soldier, who had been a prisoner in Turkey, made coffee; and as he had distinguished himself during the battle, the Emperor granted him permission to open a shop in Vienna for the sale of the Turkish beverage which he had learned under such interesting circumstances to prepare.—*From "Old and New Paris"* for November.

CEYLON TEA CROPS :

ESTIMATE AND RESULTS.

WHAT IS THOUGHT OF AN "OFFICIAL" ESTIMATE, AND OF THE PATENT "TEA-PLUCKER."

What is the correct explanation about the great discrepancy between the estimates of our Tea Crop or Exports this year and the actual results? Local estimates varied from 78 to 85 million lb. we believe. In London, we think Mr. J. L. Shand, after his visit to the island, as well as Mr. Rutherford were credited with going a good deal lower; but we scarcely think anyone put the total outturn at so low a figure as 66 million lb. of tea to the United Kingdom apart from 6 millions to Australia and other countries, or only 72 million lb. in all. After shipping over 68 million lb. in 1891 and considering that according to the Directory returns, no less than 22,000 acres of tea were planted between 1888 and 1889, there can be no doubt, of the disappointment attaching to such figures. Early in 1890, we offered estimates of the years' crops, which ran as follows:—

1890 equal to	46,500,000 lb.
1891 "	54,000,000 "
1892 "	61,000,000 "

But about the middle of 1891, we saw reason to alter our estimates as follows:—

1891 equal to	68,000,000 lb.
1892 "	80,000,000 "

In respect of actual results, we now stand as follows:—

	ESTIMATE.	RESULT.
1890 ..	46,500,000 lb.	46,900,554 lb.
1891 ..	68,000,000 "	68,274,420 "
1892 ..	80,000,000 "	72,000,000 "

It may be interesting to repeat here the detailed estimate for 1892 compiled in January 1890:—

1892.	Acres.	lb.	Yield lb.
6 years old and upwards	.. 99,000 at 340	=	33,660,000
5 to 6 years	.. 33,000 "	300 =	9,900,000
4 to 5 "	.. 51,000 "	250 =	12,750,000
3 to 4 "	.. 20,000 "	200 =	4,400,000
2 to 3 "	.. 12,000 "	100 =	1,200,000
Not in bearing			
planted in 1890-91 (say) ..	20,000 "		—
At beginning of (1892 acres)	.. 235,000*	lb.	61,910,000
Local consumption (say) ..			660,000
		For export lb.	61,250,000

In July 1891, we added the following note:—

[This estimate is still interesting, for comparison, although the yield in each case, must be increased one-third.]

The total acreage at the beginning of 1892 was, we need scarcely say, 250,000 rather than 235,000 acres. Now, while our forecast was almost exactly right for 1890 and also (as revised in July 1891) for 1891, it seems that, eighteen months ago, and again in London early this year, we were 8 millions above the mark in our estimate of 80 million lb. for 1892. Had we added one-sixth instead of one-third to our detailed estimate of January 1890, we should have been nearer the actual result. But then we worked on precisely the same basis in our final estimate for 1891 as in that for 1892. How then did the one come right, while the other proves so far out? So far as we can learn there are two diametrically opposite opinions generally held among the

* Leaving out native gardens.

planting community on this point. On the one side we are told, that the year 1891 was an entirely abnormal one—in a favourable sense—and that moreover there was decided encouragement in London prices, to pluck "coarsely"; while it is stated, in the case of the year just closing, we have simply got back to our normal condition and to an outturn which corresponds very fairly with the estimates of earlier years. On the other hand, it is pressed upon us by many planters whose estimates have not been realized, that the year 1892 was a very abnormal one in the number of months with exceptionally bad weather and that herein lies the true explanation of such poor returns this year from August till November inclusive. They admit that "coarse" plucking, no doubt, influenced the exports of 1891; just as they feel sure that a spell of "fine" plucking has this year reduced the outturn. Broadly speaking, however, they maintain that while 1891 was a favourable year all through for tea-plucking, the year 1892 was an exceptionally bad one. Very many careful planters, whose individual estimates are out from 7 to 15 per cent, insist that not they are at fault, but that the weather is to blame. At the same time, it is quite evident that, as a whole, our tea planters will profit by their experience during both 1891 and 1892. Considering how much depends on the weather all through the twelve months, and how impossible it is to forecast it from the beginning, the safe way in future would be to render Estimates after a minimum and maximum fashion, as from ——— to ——— according to the season being favourable or unfavourable. We shall await with interest the result of the "official" Estimate now under collection in the different districts, and this we may be able to check by means of our own Directory returns. In the meantime we suppose the safe course would be to say that the figures representing the total exports for 1893 will probably be found between 78 and 83 million lb.?

Having thus expressed our view of the "situation" so far as we have been enabled to form an opinion since our return, we have pleasure in giving prominent insertion to the rather different ideas of a thoughtful and keenly observant tea planter. He is good enough to write as follows:—

"I don't note much that is significant of change for better or worse with regard to tea, so far as its health or cost is concerned. It grows everywhere, and this year's total exports will slightly exceed last year's, although most estates are short on the same acreage. The increased age and area make up for falling off in older portions. We were all depressed until prices recovered two months ago, but you know what a mercurial creature the Ceylon planter is, and now a Company would float were the chances of getting paying crops as meagre as those of a dairy farm on the Aden sands. The 'pest' we heard of on some of the Kelani Valley places last year is never mentioned now, and I hope never seen also. What did us most injury this year was the excessive expectations we formed early in the year. The London buyers took us at our word!

"The truth is, we now find it is more difficult to estimate a year's tea crop than it was to forecast a coffee crop. The weather and appearance of the trees during the first four months of the year, were a fair criterion to one who looked at facts with his eyes, instead of through the lamps of Faith and Hope, in the days of coffee. Now we have the weather of the whole year to take into account, and this year S.-W. from July to October has taught us a lesson. Four estates I know uncountried are to be 20,000, 30,000, 40,000 and 140,000 lb. short of estimates! And mind you, finer plucking has nothing to do with this. It is due to the undoubted fact that the trees would not flush.

"I see a movement is on foot for an official estimate. I am sorry for it. Our monthly shipments are wired to London, and these form the only true basis for London operations. They are known a month before the teas are sold. An official estimate now may be quite upset by a favorable season (unless we all agreed to pluck fine down to our estimates) and then our estimates would be discredited in future. Then nothing is gained by such an estimate, nor any purpose or want supplied.

"The 'clipping' machine now being used or tried on many estates may and probably will enable us to dispense with 2-5ths of our labor force, and pluck our tea at 6c. per lb. dry weight. But then it will enable half the world to compete with us in tea growing. The less said of it the better! The Planters' Association should buy the patent, and suppress it. The export to the Colonies is now a great factor, and Ceylon teas are being exported in fast increasing quantities from London. Then much is hoped from the Grand Show 'J. J. G.' is to make in Chicago, his energy, courage, faith in his brother planters and theirs in him, and his readiness, and fearlessness in undertaking responsibility are unbounded, and he is admirably backed up by his assistants. The seed he will sow may yet blossom into 10,000,000 lb. and this will take off our surplus for some years.

"Your advice to Government should be sell no more tea land; to planters, plant no more; cultivate what they have; lay up their profits in something more stable than banks, and in every way make provision against the next reverse even although the horizon seem cloudless for years ahead."

As regards the alleged "injury" done by the over-estimates, what does our correspondent say to the fact that we were assured in the City, again and again, that London tea-buyers and country dealers pay no attention to estimates,—what they look to are the statistics of stocks in bond and of actual shipments from Colombo and Calcutta, and of deliveries. But on the other hand, we learned that *the importers of China teas into Europe do pay special attention to the Estimates of Indian, Ceylon and Java crops and upon them base to a great extent, the orders they give in the Foochow and other China tea ports.* There is therefore another side to the question of over-estimates affecting London prices. Of course it must be the desire, as it is indeed the duty as well as good policy of all concerned, in every way to be as accurate as possible in their estimates; and we, at least, have shown in the past, a uniform tendency to be below rather than over the mark; although like so many others this year, we were entirely out in our reckoning—very much due to the fact of our being out of touch with the planting districts.

Our correspondent's opinion respecting an "official estimate" deserves to be carefully considered by his brother planters.

THE INDIAN TEA CROP.

In all probability the Indian tea crop of 1892-93 will not exceed that of the previous season, and even the most sanguine can only look for an infinitesimal increase. With the prices that were ruling at the opening of the season such a falling off in the anticipated increment for the season as ten millions of pounds would have meant ruin to many planters, but fortunately the Home market during the past three months has awakened to the fact that the supply from India will be far short of that anticipated, and the Ceylon equally deficient and China showing its annual decline in export, prices have risen. The averages realised at the last few public auctions in Calcutta must have gratified Managers as well as Shareholders. It may be said that the rise in price has more than compensated for the falling off in output, and that prospects for the coming season are brighter than they have been for several years past.

The supply of tea is certainly not equal to the demand, and stocks at home will be depleted before the next crop can be placed on the London market. In former years, when Ceylon had not entered the arena as a serious competitor, the prospects would have been more than bright, but with this vigorous competition the spring season at home is no longer what it was for Indian planters. The new Ceylons now reach the London market at the very time when India is barely beginning manufacture for the new season, and of necessity it will benefit first from the depleted state of the Home market. But India must also gain with every maund of tea sent forward early in the season. Under the circumstances the question of pruning will occupy the serious attention of the planter during the next two months, for he must know that as he prunes so he will reap, either early or late. This is specially true of those parts where the China plant predominates. The fact to bear in mind is that in the coming season the race will be to the swift, and the advantage will rest with those who get their teas first to market. Darjiling and the Dnars are to a certain extent favourably situated in this respect.

Although, as we have said, the heavy prices that are now being realised will more than compensate for the shorter outturn, the remark must be taken in a general sense. There are districts such as the Darjiling Terai, where owing to the ravages of mosquito blight no rise in price can cover the disastrous yield of the present season. So serious, indeed, is the situation in some parts that there is nothing for it but abandonment, and that means instant sacrifice of invested capital. In many instances not a third of the estimated crop has been gathered. Mosquito blight set in unusually early, and with its appearance many gardens ceased to yield. It is no exaggeration to say that the many lakhs of rupees that have been spent in opening out the Darjiling Terai have been practically thrown away. All endeavours to deal with the blight, have been unavailing, and in many instances it has been decided to allow the garden to run into jungle for a period of, say, two years. So far, the low China plants has succumbed to the attack of the pest, but in some cases even the best plant has begun to feel its effects, and the neighbouring District of the Dnars has this year found it spreading. Mosquito is as deadly as the leaf-disease in Ceylon, and it is but poor consolation to learn that other Districts have so far escaped the blight. It would surely be worth while if the Tea Association were to secure one of the abandoned gardens in the Terai, and institute at the general cost a series of experiments with the object of discovering a cure for the disease. This very blight at one time threatened Northern Assam with ruin, and is said to have disappeared after a few years, but nothing certain is yet known as to the causes which lead to the sudden migration of this terrible pest. It is, indeed, lamentable to see a model tea-garden, otherwise healthy and well-cultivated, and to know that every shoot that appears is doomed by this plague. An expert is now in the country from the Tea Association analysing the various soils, and this may lead to some good. But so far his services have not been directed to the Districts where blight is so prevalent, and which is now on the point of being abandoned wholesale. Obviously that is the point to which the investigations of the expert should be directed, for it is the latest battle-field upon which this pernicious insect has inflicted a serious reverse upon human industry and enterprise.—

Englishman.

THE PROJECTED QUININE FACTORY IN JAVA.

We are indebted to one of our friends among the cinchona planters in Java for a copy of a small pamphlet which is being circulated to the bark-growers in that island by one of their number, and in which definite proposals are sketched for the establishment of a quinine factory in the Preanger district (Western Java). The pamphlet seems to us to contain many

sound arguments, although the writer does not seem to give the difficulties in the way of the undertaking the same prominence as its advantages. Our correspondent tells us that the proposals are being discussed with much interest in the island. The chief features may be summarized as follows:—The total share capital is to be 800,000*l.*, of which 200,000*l.* (to be represented by preference shares) are estimated to be required for the erection of the factory, with plant to manufacture quinine and other cinchona alkaloids, cocaine, caffeine (from tea refuse), theobromine, arrack, ether, hydrochloric acid and sulphuric acids, and sulphate of ammonia. The raw materials for the acids are obtainable in the island at very little cost, and arrack is, of course, obtainable very cheaply in a sugar-growing country. Petroleum is also obtainable cheaply, as it has recently been found in many parts of the Dutch colonies. All other chemicals that may be required must be brought from Europe. Another 400,000*l.* of the capital is to be subscribed among the planters, who must either pay their shares in cash or furnish their equivalent in cinchona for manufacturing purposes. The output of each separate bark plantation is to be ascertained by a commission, and no planter will be allowed to supply more bark than his proportionate share. The planters are to be repaid for their bark as soon as the quinine is sold. For every kilo of quinine sold a sum of 20 cents is to be placed to the credit of a fund for the payment of interest to the holders of the 200,000*l.* in preference shares. The factory is to be managed by a Board of seven members; elected from among the shareholders. The quinine is to be consigned for sale to two chief agents, one in London and one in Hamburg. The profits of the factory are put down (on paper) at 17½ per cent per annum, on an average price of 18*l.* per kilo (about 10*l.* per oz.) of sulphate of quinine, rising to 70 per cent per annum with a quinine price of 24*l.* per kilo (or about 1*s* 2*d* per oz.).—*Chemist and Druggist*, Nov. 12.

TEA-GROWING AT BATOUM.

A representative of the firm of K. S. Popoff, well known in the trade in China teas in Russia, has conceived the idea of introducing the cultivation of the tea plant in Russia. With this object, says the *Russie Commerciale*, he has visited the Chinese provinces producing the better kinds of tea, and has closely studied the cultivation of the shrub and the processes connected with the drying and the preparation of the leaves. After an attentive examination of the Russian provinces presenting some prospects of success for the proposed cultivation, M. Popoff came to the conclusion that the district of Batoum was the most suitable spot by reason of the salubrity of the climate, and of the warmth and other conditions suitable for the regular growth of this plant. It is said that the plantations will shortly be commenced, and the workmen and Chinese foremen who are thoroughly conversant with the processes to be adopted with the plant and the manner of preparing the leaves, will at first be engaged.—*L. & C. Express*, Nov. 18th.

NOTES ON PRODUCE AND FINANCE

INDIAN AND CEYLON TEA AT THE CHICAGO EXHIBITION. —At the ordinary general meeting of the Society of Arts, on Wednesday, Sir Richard Webster referred to the British exhibits at the forthcoming Chicago Exhibition. Ceylon, he said, would have one or more tea houses in the grounds of the exhibition for the sale of Ceylon tea. As regards India, while he deeply regretted that the Government of India did not see their way to assist actively the exhibition, the tea planters would be well represented, and there would also be a collection of Indian art.

THE CEYLON PLANTERS' TEA COMPANY OF NEW YORK.—From copies of extracts from American papers just to hand, it is clear that Mr. Elwood May is going the right way to work in order to popularise

Ceylon tea in America. He has been interviewed by some Press representatives, and he told them a few truths about tea. He has persuaded them at last, to use the language of one of the interviewers, that "the worst teas in the world are sold to Americans. English breakfast tea is a name invented to humbug with; there is no such tea. American teas are weighted and coloured; some of them steeped, and the leaves 'manufactured' over again." The company publishes a list of its agents throughout the United States, and its advertisements are very much to the point.

THE TEA TRADE OF DANTZIC.—The trade of Dantzic during 1891 was anything but flourishing. The reason for the diminution of the import of tea to nearly half of the quantity was the small demand, owing to the large stocks of the preceding year; further, the low exchange of roubles and the bad harvest and its consequences in Russia. Besides, China tea, which was formerly largely imported *via* Königsberg, was last year mostly forwarded *via* Odessa or there consigned. The bad experience of the last year, however, which Russian tea merchants had to suffer induces the hope that, as formerly, this article will find its way *via* Königsberg, and so enable Russian merchants to cover their requirements of those qualities which they want in course of the year at the London and Königsberg markets.

A NEW VARIETY OF SUGAR CANE.—According to the *Kew Bulletin* a new variety of sugar-cane is stated to have been discovered in the Upper Niger region of Central Africa. It is described as "a giant variety possessing great saccharine richness, and capable of being readily reproduced from seed, which in this variety is well developed." Several enquiries have already been addressed to Kew in regard to this cane, and it may be well to state at once that there are grounds for believing that the plant mentioned is not a sugar-cane at all, but the ordinary Guinea corn or sorghum (*Sorghum vulgare*), which is widely distributed over Africa. This plant, it is well known, yields a useful syrup, and strenuous efforts are being made in the United States at the present time to extract a granulated sugar from it. Should the Niger plant prove to possess any special merits as a sorghum, we shall, no doubt, hear more about it. It can have, however, little or no interest to the tropical sugar planter.—*H. and C. Mail*, Nov. 18.

THE CEYLON PLANTING ENTERPRISE:

OPINION OF EXPERIENCED PLANTERS ON THE SITUATION AND PROSPECTS.

We are much indebted to a number of gentlemen who have been kind enough to write to us from different districts, and who, besides conveying their good wishes on our resumption of the editorial chair, convey valuable information in reference to the all-important Tea Industry. We quote as follows: and first from Uva, we have the following interesting though pungent report:—

I am very glad you have returned to Ceylon and hope you have benefited by the change, I suppose I may say holiday, although you seem to have been very busy in our interests.

The *Coffee* crop in Haputale will be short this year, due chiefly to showery weather at the time we should have had dry. Coffee still goes on; but if things go bad as at present, it is only a matter of a very few years. I do not think bug does such extreme damage as it did (I have known one attack kill out strong coffee); still it helps to weakening the tree, thus preventing blossom from setting, and it also causes crop in all stages to fall off prematurely. Leaf-disease is as bad as ever. It may be that the attack is lighter one season, but it makes up for it the next. Leaf-disease (unaided by bug) can be fought to a certain extent by cultivation. Bug cannot, to my knowledge, be checked by any paying means in our power.

Tea will require help like everything else? I do not think that manure will pay on a very large acreage.

that has been planted up with tea, the soil being exhausted. On good land and where transport is cheap manure will pay with tea at anything over 8d to 9d. I do not see how we can avoid attracting some known, or giving rise to some at present unknown pest. Thousands and thousands of acres have been very badly planted, the result of want of funds. The unfortunate bush gets no rest. Plucking was commenced at far too early a stage of its existence. And certainly one-third the area planted is on land that cannot continue to give a paying yield.

What more do you want to start a pest? With regard to the remark I have made on the impossibility of our old and poor land continuing to produce tea, I am simply going by the experience gained in Assam, where with far richer soil than ours ever was, and with a winter rest for the bushes, it is found that tea after a time ceases to yield in paying quantities. We may talk of climate and subsoil, but this will not last us long; and the yield must fall to such an extent and make it worthless to continue, or the leaf will be so poor that it will not be worth manufacturing. Tea is hardy, extremely so, and treated as it is in China would last, I should think, an indefinite time; but treated as ours is, it cannot hope for a long paying existence.

I am sure it would pay us to allow our bushes to run and rest for a time before pruning. The best thing that could happen to us would be, I think, for a lot of the tea planted on the poorer land to go; it would lessen the chances of a pest, and it would do something to keep up the good name Ceylon tea made. Tea in its earlier stages in Uva generally grows slowly, as did coffee, but the latter was none the worse for that, and if people would only have patience tea would benefit immensely.

Try any bush or shrub in your garden and nip off all the shoots steadily; the earlier you begin the treatment the sooner will you stunt the plant; no plant will stand it permanently and tea is no exception.

On the contrary, practical horticulturists point to hedgerows, the more you clip them the better they be! And our correspondent forgets we have tea plucked for 24 years in Hewahetta and as good today as at the outset.—From a friend in one of the higher districts we have:—

Welcome, thrice welcome, back to you. You'd be glad to find everything so wonderfully prosperous on your return, and so far as we can see, there is every likelihood of a continuance for some time to come. May it be so. That was an admirable article "Ceylon and its Cycles" in Saturday's *Observer*, and I hope many will take the good advice to heart. From a low district we learn:—

We are doing finely. Crop will be short of estimate but that is a general thing. The estates in the valley as far as I have seen, seem to me to be good for years and years to come.

From a northern district, one report is:—

TEA, both in Kelebobka valley and Laggala, is doing as well, I imagine as in any of the Kandyan districts. I may say that nearly all are behind last year's output; and as you quoted one top estate here as the rainiest station in Ceylon for number of wet days there is surely some reason for this deficiency! Mr. Gordon Reeves has sold out of Laggala, and the new proprietors of the Brae group, now including Hattanwella, are opening very largely and will, I believe, ere long have some 600 to 700 acres under tea; and this practically all new forest land and sure to do well.

Again from a resident in a north-eastern district we have the following —

I was very glad to hear of your safe return to the little island once more, and with renewed health and vigor to do battle for us in the old *Observer*. I am glad to say tea is doing very well both in old and fresh lands in these districts—always provided we do not get below 3,000 feet; anything under that altitude seems to suffer, I fancy, mostly from insufficient rainfall.

We have been so busy in the past planting up,

that very little has as yet been done in the way of manuring; but we have commenced experiments, and I will be glad to keep you posted in results later on. For my own part, I am rather dubious about manuring tea—considering there are 4,000 and more bushes to the acre against 1,600 of coffee: its rather a serious undertaking.

And another:—

Tea on this side has been rather backward in flushing during most of the present year, mostly owing to excessive wet and cold weather, most of places are behind with estimates, but there are some who will get the quantity estimated. Tea planted in old coffee land continues to *improve*: in the high fields where coffee did little in the way of crops, except in a very dry season, the tea is good and where it has got to 10 years old it does well; the tea planted in the lower fields where we had heavy bearing coffee is rather poor and gives very little leaf, but I think will improve as the roots get farther down. I have not heard of anyone abandoning any fields or even patches. I am not aware of any one manuring or experimenting with manure; and I do not think it would pay where transport is heavy, at least I would not care to try the experiment. The weather throughout the year has been most unusual: we have about 50 per cent more rain up to date than we usually get, and have had no lull between the S.-W. and N.-E. monsoons. A certain percentage of the shortness of crops for the year, I think, might be found to be due to people plucking rather finer when the prices were low.

Cardamom crops, I believe, will be a good deal under the quantity estimated owing to the continual wet misty weather.

PLANTING NOTES FROM PEERMAAD.

TEA AND COFFEE; CARDAMOMS; TIMBER TREES; BEES, CINCHONA; TEA "POOCHIE."

The weather since I wrote last has been steadily improving; but mornings and plumps of rain towards dark are now the rule, and whilst the latter keeps the ground damp, it is not enough to cause waste on the hill sides, and the hot sun in the mornings produces a steamy atmosphere most beneficial to the tea plants, and also for ripening up the coffee. The thing we now all dread is the approach of the land wind, which dries up ground and vegetation, and is neither good for man, beast nor plant! This month, after the many rains of October, will probably give far the biggest yield of tea of any month during the year. I heard this week of one estate giving a picking of 4,000 lb. in a day, and oolies generally all over the district are picking 20 to 25 lb. of leaf a head. On some estates every work has had to give way to the rush of leaf men, all being employed in keeping down the flush. Luckily up here, the labour supply is fairly good, but I question if any single planter would not hail an increase to his force with delight? Prices are going up steadily. I see that little if any tea sold under 7d. during the week ending October 26th, and 3 months ago few places could rise much above 8d. Supplies seem short everywhere, so there is every prospect of prices keeping up, at any rate till April next. And as tea can be sold for about 6½d. a lb., in London, without a loss, an average of 9d. or 10d., which no doubt will be obtained shortly, should show a good balance on the right side. Coffee crop is coming in but slowly; still it seems now-a-days that it never does much else.

Coffee now is so difficult to get by fair means or foul, that natives are taking to use tea to some extent. And I have already noticed signs of a new industry being started for getting this article at not too expensive a rate! I fancy an Act will before long have to be granted for this product.

The cardamom crop, which of course is a Government monopoly, is now getting into swing. These old monopolies are very curious things. In Travancore you are bound to give up all the cardamoms that

grow on your land to Government, who sell it and give you one-third of the price. They, however, give a small advance first. Upon the cardamom hills the ground is worked by ryots from the low country; these men cultivate and give it up to the Sircar, getting payment in the same way; they weed it once a year and then pick the crop, if they want seed they buy it from the Sircar. I believe the Sircar has no idea as to the acreage in cultivation; the gardens extend parallel with the British boundary for about 80 miles, and there is a Sircar official (European) in charge. Peons are left at various watch stations at the heads of passes to prevent theft, and a certain number of the Maharajah's army are sent off every year to protect the crop when it is handed into the store, and to assist in the protection, generally, of the Sircar interests. But what an extraordinary idea these monopolies are. Go into a cardamom garden here, and you will see the plants growing luxuriantly, it is true, but irregularly, and uncared for, to the last degree; especially does this strike you before the annual weeding! No one goes near them for months, and elephants live in them for weeks together. I suppose it is no exaggeration to say that 10 acres of cardamom in Ceylon cultivated, give the equivalent of 50 under this system; and what an inducement to theft! when a man knows that all he can take away, or have taken away, realises thrice as much as what he gives up.

I wonder how many people there are in India who have any idea of the wealth of Travancore in the matter of timber? Sawyers are conservative, and if you put them to saw timber in any 100 acres of untouched forest, will in a brief space declare it is all finished, that is because they know about 10 trees their ancestors have always seen, and of which about one-third are rather inferior timber. And as a matter of fact, there are probably about 50 kinds in any fair forest that make excellent timber, some for one work, some for another.

I believe there is nothing they will not do within their limited art, to prove that any new wood is ever tolerable. I believe there are in Travancore some 400 odd different trees, and I do not suppose that anyone not in the forest department knows more than 20 of them. The hillmen are just as ignorant; in fact, their knowledge extends only to what they call, good honey trees, *i. e.*, trees the bees select for their hives, and these, except those favoured by the big bee, which bites most disagreeably, of course are only hollow ones. The big bee called in Ceylon the Bambara bee, has, I believe, there been captured and taken to Europe. But I never heard if anything came of the experiment.

By the way, we have been inflicted with an extraordinary little caterpillar who coils himself round the young shoots of the tea leaf and twists two or three of the tenderest shoots into a little nest; he is never over quarter of an inch long. When small he is the colour of a maggot, but when full grown develops into a black sort of beast. I do not know what he hatches out into, but probably it is a sort of fly; that is a question I have not seen solved yet; and the idea is he is a product of the wet weather and will die off in the dry; this may be the case, but last year I only noticed a small number, and this year I have seen thousands; in fact, during September, one or two flushes have been reduced 15 per cent. by it. So this looks as though it at any rate does not die out in the dry weather, and as I have seen on a single bush as many as a dozen of these little *poochies*, it may be very serious certainly if only a small percentage hatched out and laid a few hundred eggs, in another year we shall run the chance of having something very like a plague. I wonder if any of your readers interested in planting have come across them in other parts? Except for this animal we are very free of tea ills. I wonder how long it will last?

There is a good deal of harking Cinchona going on in the district, and as this product if by itself does no harm and does not cost 1 anna a lb. to harvest and put on the coast, it will be a nice little addition to places which have it. But though exports

have gone down, the price is absurdly low, and is, I suppose, likely to keep so. It is wonderful what an enormous sum, freight and selling charges amount to in this product. Ordinary bark fetching 3d a lb. has a deduction of over 1d. always to be made for these charges, whilst quill bark, which of course has to be packed in cases, will cost quite 50 per cent., that is if it does not fetch over 6d a lb.; this takes away a good deal of the margin, and in fact it is only the ridiculously small amount it takes to harvest and get it down that makes barking pay at all. Ceylon reports are very good, I see the average for tea is higher now, than it has been for 18 months.—*M. Times*, Nov. 3.

THE FUTURE OF TEA IN CEYLON.

A successful tea planter, who has closely watched our industry from the beginning, writes:—

"I never felt more satisfied or convinced about the permanency of tea than I do at the present time. If tea not only grows but yields 300 lb. to 400 lb. per acre in land that was in coffee for 30 years or more what is likely to be the length of life of the plan in new land carefully drained and cultivated from the first. In Darjiling two years ago, I asked poor Curtis, the manager of Tukvar (since dead), to show me his oldest tea. We went to a certain field, and I said 'What is the age of this?' 'Well' he replied, 'I have been here 18 years; my predecessor 15, and when he came it was old tea!'—and this planted on land as steep as Ramboda Pass, but a peculiar soft mica-looking sort of soil being free from stone and grit and no wash visible; wash in steep stony lands is the thing to be dreaded."

A well-known Dimbula planter writes:—

"We are getting a good cover of tea in Dimbula; and as you will see by the tea sale lists good average prices. The yield varies considerably from 400 lb. made an acre up to 600 lb. to 700 lb.; but 400 to 500 lb. may now be put down as the average yield of the whole district in bearing. I am assisting in collecting figures for the estimate from the island for the coming year."

A planter in a high district beyond Nuwara Eliya writes:—

"As to tea, some of the best paying estates don't give more than 300 lb. per acre, but they get price, but all the low-priced places can't go on, I should think on less than 300 lb., and I don't think it will pay to manure. There is no doubt, that a great deal of unsuitable land is planted and it won't pay to work it. Tea is a wonderful weed, but even tea can't do well everywhere."

TEA IN EASTERN HAPUTALE.

An old planter writes:—

"Tea is doing very well in Haputale, and as far as anyone can see at present, will be permanent, barring visitations of pests as yet unknown, such as bug which extinguished coffee. Last year hopes were high that there was to be a revival of coffee, prices being so good, the little that was left was cultivated with great care, pruned, and in some cases manured, and all for what; the worst attack of bug I have seen for many years, and crops woefully short. There are exceptional fields in the district where bug is not so bad, and crops are fair; these are few and far between. The appearance of coffee in this district at least is not very encouraging; some of the best fields may give a crop or two; the results of the season will convince most men that all coffee must give way to the new Queen Tea at no distant date. Uva-grown tea will hold its own so far as quality is concerned, and with the railway to Haputale approaching completion, it will not be so heavily handicapped in the way of transport, although it can never compete with the Kelani Valley for instance, in cost of transport. Still there are not a few estates in Uva that will run them very close in yield per acre,

BARK AND DRUG REPORT.

(From the *Chemist and Druggist*.)

London, Nov. 17.

	1,620	1,427
CINCHONA.—Tuesday's periodical auctions were of very small extent, the seven catalogues including only:—		
	Packages.	Packages.
Ceylon cinchona...	819 of which	819 were sold
East Indian cinchona	230 "	230 "
Java cinchona	60 "	60 "
South American cinchona	511 "	318 "

The assortment was rather above the average, and comprised a fair proportion of grey and yellow barks from Ceylon, but Indian kinds were very poorly represented. Competition was dull at first, but gradually a slight improvement set in, and ultimately almost the entire supply offered was disposed of at unaltered rates, the unit averaging from 1½d to 1¾d for common red to good yellow barks, which is slightly above that of the recent Amsterdam auctions, and not quotably below the last London sales.

The approximate quantities purchased by the principal buyers were:—

Agents for the Mannheim and Amsterdam works	Lb.	99,005
Agents for the Brunswick quinine works ...		61,250
Agents for the Frankfurt-o/Main and Stuttgart works		44,093
Agents for the Auerbach factory		37,150
Messrs. Howard & Sons		30,732
Agents for Paris factory		13,930
Sundry druggists		24,120
Total quantity of bark sold ...		310,330
Bought in or withdrawn ...		31,670

Total quantity offered ... 342,000

It is worthy of observation that the agents for the American factory, for the first time for some years, did not make a single bid.

VARIOUS NOTES.

COFFEE IN SELANGOR.—The district officer of Kuala Langat (Selangor) in his report for October, tells how, early that month, he visited a small coffee plantation owned by a Tamil named Sangilie. It is a 12-acre patch on a steep spur of the Jugra Hill, of which he has 10 acres planted up with about 8,000 plants; of this, 6,000 plants have been in bearing for 18 months, yielding 10 piculs of beans, and the balance of the trees are in blossom. The beans he sells there to a trader, who furnishes him with supplies, at 23½ per picul, or at a loss of about at least \$10 per picul market rates. He works himself with six Tamil coolies, whom he pays at the rate of \$7.50 per mensem, and is quite satisfied with his prospects. The plants look healthy and robust and are heavily laden, a matter which surprised that officer, as the patch he selected has been covered with lalang for years. The soil is a composition of yellow earth with a large proportion of decayed granite in it.—*Straits Times*.

TEA DRYING BY ELECTRICITY.—The practice of electrical engineering is very different from other branches of engineering—for instance hydraulics and mechanics, inasmuch as, while the latter are fairly well defined in their scope, no one really knows what branch of business electricity will not invade. And in this lies the great charm, and the great chance for young electrical engineers. At any time an entirely new field may open out lying quite outside ordinary practice. Of this we have a very good example in the business of tea-drying in Ceylon, now proposed, we see, to be carried out by means of electricity with a simple, clean, and economical process. Some gentlemen resident in Ceylon have brought the idea before certain influential electrical and mechanical engineers, we are told, in England, and the idea being favourably reported upon may result in transforming the process.—*Electric Engineer*.

CELERY COFFEE.—A company has been organized in Glasgow, Scotland, as we learn from the London *Vegetarian*, to manufacture celery coffee. The celery is dried, roasted and ground, being sold in the form of a brown powder from which a beverage is made which is considered exceedingly wholesome and valuable for dyspeptics, rheumatics and sufferers from nervous prostration. It is described as "free from those strong stimulative elements which render tea and coffee so dangerous." The celery growers should take the hint and use their trimmings for this purpose.—*American Grocer*.

VALUE OF CHEMICAL MANURES.—The experiments which continue to be carried on at the Cawnpore Experimental Farm, judging by the last report of the Director of Agriculture, appear to have but little practical value, and absolutely no effect in improving the indigenous methods of agriculture. It has been found that chemical manures, and the more expensive manures generally, have a less marked effect in increasing the outturn than the ordinary farm-yard manures which are within the reach of the native agriculturist, but it has been satisfactorily proved that the reduction of farm-yard manure to ashes seriously reduces its fertilising value. Anything, therefore, that can be done towards enabling the ryot to conserve his one valuable fertilising agent, by providing him with cheap fuel in another form deserves encouragement. The Assistant Director advocates the use of saltpetre, but has to confess that the value of saltpetre earths for manurial purposes is already well-known to the native agriculturist.—*Indian Engineer*.

INDIAN TEA AND THIBET.—The *Statesman* says:—The question of introducing Indian tea into Thibet is now exercising the minds of the plenipotentiaries engaged in conducting the interminable negotiations between the Indian and Chinese Governments. It is demanded on the Indian side that the produce of Darjeeling gardens should be admitted. The Chinese, on the other hand, decline to admit the possibility of Indian tea competing with that of Szechuen, which now holds a monopoly of the Thibetan market. The "cup that cheers" is unknown on the northern slope of the Himalayas. Coarse China tea is imported in compressed cakes. These are broken up and boiled with water and mutton-fat, and the resulting soup—for such it is—is greatly appreciated in the valleys of Thibet. Indian tea is not suitable as a basis for this decoction; and a planter who, some years ago, was at the expense of importing machinery for compressing his leaf into bricks, reaped nothing but disappointment and loss from the venture. The inhabitants of Bhootan, Sikkim, and Thibet will have nothing to do with Indian tea in any shape, averring that it deranges their digestions. It is, in fact, too strong, too rich in tannin and theine, to be consumed in their fashion. China tea is actually sold in the Darjeeling bazaars at a price considerably above that of good, honest Indian leaf from the neighbouring gardens. A sample was sent home two years ago and an eminent firm of London brokers, after subjecting it to a minute examination, informed the exporter that it was a species which they had never previously met with. It strongly resembled the leaf which was produced by Ceylon in the earlier stages of the manufacture there. With care and scientific treatment, they wrote, considerable improvement might be expected, but they deprecated the addition of another field of supply, as likely to be detrimental to the interests of an industry which was already suffering from over-production.

ACOME TEA CHESTS.—We hear of a small consignment being on the way to the island of 150 half-chests from the Acome Company Ltd. As the Acome chest is said to have many special qualities it will no doubt attract attention. The consignee is to send a sample chest to the Office of the *Tropical Agriculturist* for the inspection of all interested in the careful packing of our staple product.

TREE-PLANTING UPCOUNTRY.—Mr. Mackie of Great Western assures us that great as is the change which we have seen come over Dimbula within the past few years, it is nothing to that which will be seen in the next half dozen years; for half the tree seed or young tree plants put in are not visible yet. In his own case, he has put grevilleas not only on his roadsides, but all along the sides of drains, ravines, the riversides and the boundaries, and most of them are still very young.

COFFEE IN JAMAICA.—While we read that on the whole coffee cultivation is extending in Jamaica, we regret to learn from our old friend, Mr. Wm. Sabonadière, that his plantation of Arntully is not turning out a success, bearing very poor crops, much of the land being too steep and light to pay well. Mr. Sabonadière now feels that he would have done better had he returned to Ceylon and gone into "tea" at the time he went to Jamaica. Mr. Sabonadière is 63 years of age. We hope yet to hear of greater success for him on the Blue Mountains, and of his being able to revisit Ceylon and take a trip by-and-bye on the Railway to Uva.

INDO-CYLON TEA IN CANADA.—To Messrs. Kearney Bros., of 27 St. John street, is due the credit of introducing pure Indigo-Ceylon Thistle brand tea, which is now consumed all over the Dominion, and is daily growing in popularity. The sales of this enticing article at first were small, but when its good qualities became better known they rose very rapidly, putting Messrs. Kearney under the necessity of largely increasing their staff in order to supply the demand. Judging from the past, there is very little doubt it will become the recognized article for every home. Visitors to the Exhibition should not fail to call at Messrs. Kearney's handsomely arranged exhibit in the main building, where Mr. Kearney will personally present them with a sample of the Thistle Brand Tea in order to give them an opportunity to test for themselves its quality.—*Montreal Daily Herald*.

COFFEE IN SELANGOR.—Mr. C. H. A. Turney, in his report for the month of October, states that on 5th, he visited a small coffee plantation owned by a Tamil, named Sanglie on a steep spur of the Jugra Hill. It is a 12-acre patch of which he has 10 acres planted up with about 8,000 plants; of this 6,000 plants have been in bearing for 18 months, yielding 10 pikuls of beans, and the balance of the trees are in blossom. The beans he sells to a trader, who furnishes him with supplies, at \$23 per pikul, being at least \$10 per pikul under market rates. He works himself with six Tamil coolies, whom he pays at the rate of \$7-50 per mensem, and is quite satisfied with his prospects. The plants look healthy and robust and are heavily laden, although the patch he selected has been covered with lalang for years. The soil is a composition of yellow earth with a large proportion of decayed granite in it.—*Penang Gazette*.

"SECRETS ABOUT TEA".—This is the title of an interview which representative of the *Mail and Express*, New York, had with Mr. S. Elwood May. After some general remarks the president of the Ceylon Planters' Tea Company thus referred to the famous Ceylon tea:—

"The tea of Ceylon has two strengths: that of tea, which is delicate, fine, inspiring and that of tannin, puckery, harsh, unpleasant, bitter. One is a beautiful amber; the other is dark and forbidding. All tea has these two strength. A proper

steeping extracts the better and leaves the worse. Japan and China teas at their best, are, coarse compared with that of Ceylon, which is new to your taste. This newness is 'herby.' Why not? Is not tea an herb? Would you have it metallic? Excuse the herby taste for a week; you will find it outgrowing excuse. Your taste is righting itself." Mr. May also related how a lady had called at his office and desired to be supplied with golden tip Ceylon tea:—

"I was not long in presenting myself, and informed her that the last sale of Golden Tip Ceylon tea brought at public auction \$183 in London and was bought by an English lord, that it would be impossible to say when the next parcel would be offered, and that only five to eight pounds came to the London market at a time, and that only occasionally. There must have been some of the curiosity I felt as to what she could want with such costly tea depicted on my countenance, for after a short pause she said: 'I would gladly purchase five pounds at \$200 a pound, as I am going to give a tea. I am constantly going abroad, and always proclaim, when provoked to do so, that we Americans have the best of everything. I should like to feel that we had entertained our friends in America with tea at \$200 a pound, for I recently read of the sale of tea you speak of in London at \$183.' I was so carried away with her national pride, that I forthwith offered, if she would permit me to send her some of our best Bhud tea, with my compliments. After her departure my mind turned to other whims that rich Americans had indulged in, and I concluded that nowhere are there so many people willing to spend fabulous sums for the gratification of their pride and fancies."

CYLON TEA IN AMERICA.—The inconsistency of some people is wonderful! Here is a journalist and certain other members of the community who have taken care, we suppose, that their own pockets have not suffered, sneering away at the advertising of Ceylon tea effected in the United States by the Planters' Tea Company, during the last three years and yet they are as urgent as any of us in the desire to spend £20,000 of Ceylon money at Chicago, in what is nothing if not a big advertisement, and mainly with the view to advertise Ceylon tea! What is the Columbian Exposition to this Colony save as a big advertisement for Ceylon tea? Were it not for the need of making known our staple at the Show, we question if an expenditure of even 20,000 rupees would be sanctioned at Chicago. Some people indeed doubt if we are doing altogether the right thing in order to get the greatest return for our money. Here is what a City man (not a merchant or broker and yet interested as an outsider in Ceylon tea) writes to us:—

"In America the £20,000 that is to be spent seems a large sum for Ceylon to spend in helping private firms to start a new business."

As regards the increased demand for Ceylon tea in America since the Company began its work, it is simply silly of our contemporary to take advantage of a slip made in our absence, and for him to repeat the figures of local export, as if they represented all the Ceylon tea sent to America (see next page). In the case of Australia all the Ceylon tea taken has been shipped direct from our shores. In the case of America, we should have to get the London figures for 1889, 1890 as well as 1891 and 1892 to add to the local returns before we realized the very considerable increase which has taken place. We surely need not point out that Australia has always been essentially a tea-consuming country, whereas in America coffee has been, and still is, the drink *par excellence* of the people. The distance, too, of America from Ceylon (as compared with the Southern Colonies,) tells against our efforts to convert our American cousins to the use of Ceylon tea.

COTTON CULTURE in South Russia, which was initiated some time ago by the Minister of Imperial Domains is now giving promising results. The earlier attempts failed through the ignorance of the cultivators, but since the Kerson School of Agriculture took the matter up the propagation of American cotton seed has proved entirely successful. Specimen parcels of South Russia cotton have been sent to Mr. Howard manager of the St. Petersburg Cotton Spinning Mill, who declares that the Russian product is quite equal in quality to the American.—*Pioneer*.

QUININE MANUFACTURE IN JAVA.—Mr. David Howard, to whom we showed a copy of the pamphlet, recently printed in Java, advocating the establishment of a quinine factory in the island, writes us:—"I have examined, with much interest, the Dutch pamphlet which your representative kindly gave me yesterday to read. It is evident that the writer has no practical experience of manufacturing quinine, but derives his information from laboratory experience, and from incorrect information which he has picked up. The inaccuracies would be too many to point out, but we can only say that if quinine is to be made at a profit in Java, it will require a knowledge of the real difficulties of which the writer of the pamphlet has no idea."—*Chemist and Druggist*, Nov. 19.

PLANTING IN TRAVANCORE: COFFEE THERE AND IN DUMBARA.—Mr. Valentine of Central Travancore is at present on a visit to Ceylon, and speaks so well of tea there that he doubts if we have any fields finer than he can show in Travancore at from 700 to 1,500 feet above sea-level.—In coffee, Mr. Valentine a short time ago made a careful experiment in a clearing surrounded by forest, quite away from any other coffee, while the seed (Nalkanaad) was most carefully selected and every justice done; and yet when the young plants came over, they were just as much covered with leaf disease as in ordinary fields in the days of old. We were sorry to hear, too, the other day from Mr. Vollar that the experience of the past three years in the Dumbara Valley has not been very favourable in respect of coffee cultivation, though we believe there are still young fields in Kondesalle.

THE AMERICAN TEA COMPANY.—Nothing is easier than to cast ridicule, and to shout "Did I not tell you so?" after the fashion adopted by our contemporary of the "Times" in reference to this Company. But never were critics less entitled to exult over failure—if failure it be—than in this case. For if the planters and others who chose to support Mr. Elwood May and Messrs. Watson & Farr in their campaign some years ago, had chosen rather to follow our contemporary's advice, there can be no doubt, that the demand for Ceylon tea in America today—the day of small things though it be—would be very different from what it even now is. Look at the export figures:—

Ceylon Tea shipped to	lb.
America from Colombo in 1889 ...	42,252
in 1890 ...	204,223
in 1891 ...	163,137
Up to Nov. ... in 1892 ...	100,868

We have no hesitation in affirming that the continued demand is very largely, if not almost entirely due to the stir made by the American Tea Company as represented by Mr. May and Messrs. Watson & Farr, and that therefore, they deserve the best thanks, rather than the ridicule (and abuse) of the tea planters and press of Ceylon.

TEA IN AMERICA.—We had no idea in penning the paragraph on the Tea Company that the figures for our export in 1892 so far, would show a comparative decrease in place of increase. This is unfortunate: that the demand for Ceylon tea should be less, according to the Chamber of Commerce returns in 1892 than in 1891 and specially in 1890; but it must be remembered that these figures represent only the direct shipments. From England the shipments across the Atlantic of our staple, more than make up, we feel sure, for the deficiency in the direct exports; and this is due to the exertions of the American-Ceylon Tea Company, Mr. May and Messrs. Watson & Farr. Can there be baser ingratitude, at this juncture in the history of Ceylon tea, than to flout and jibe and sneer at the men who have managed to place our teas in the stores of so many New York grocers and outside State Agencies as detailed in a paragraph elsewhere today? Whatever be the fate of the Company, no one can deny that Ceylon tea has a position in America today, very different to what it occupied a few years ago, through the exertions of the gentlemen referred to, and that the work for tea, which we all hope to see achieved through the Chicago Exhibition, must be rendered all the easier through the splendid advertising of our staple by this Tea Company. Messrs. Gow, Wilson & Co. reported in May last, that in 1891, the United States had taken 741,000 lb. of Ceylon tea against 600,000 lb. in 1890. For 1892, the figures, we feel certain, will show a further considerable increase.

PLANTING IN EAST AND CENTRAL AFRICA.—Special attention should have been called in our last issue to the extremely interesting letter from our correspondent "H. B."—an old Malate planter—dated from the Blantyre district, 1st Oct. It will be found on page 467, and is well worth the perusal of every planter in Ceylon—at any rate of all who are interested in the rapid development of what will soon be the great planting districts of East-Central Africa. It will be observed that in our own letter to the *London Times*, written at Genoa (see page 472) we deprecated the suggestion of Capt. Lugard and other authorities that attention should be given in Africa to tea, any more than to spices or cinchona; but we showed once again that in coffee there was a product ready to the hands of Uganda, as of other East-African, planters which offered the greatest possible encouragement, in present high prices and limited supply more especially from British dependencies. It is evident that coffee planting in Blantyre is to be a great success: "H. B." speaks of a "5-cwt. blossom" and no appearance of leaf-disease or bug, although grub (as often in new clearings) is troublesome. Our correspondent's offer to exchange seeds of rubber, fruits, trees, flowers, &c., will no doubt be readily responded to. We hope we were not wrong in stating (in the *London Times*) that if the British Government decided to retain Uganda, and to encourage its development as a planting colony, Ceylon could provide the planters to pioneer with coffee, cacao and other suitable products, and to collect rubber from the primeval forests. Seeing that only very lately enterprising Ceylon planters have been taking up land for coffee in Java, under the Dutch Government, we feel sure that no less readily will men of experience, and perhaps some capital, be ready to try their fortunes, and establish a "new Ceylon" in Uganda, so soon as the news comes that the British flag is to be permanently established there, and the country to be opened up by roads and railway, or lake and river steamers,

TEA AND ITS ENEMIES.

THE NEED FOR YOUNG PLANTERS STUDYING THE T. A. The following is a disquieting paragraph from the *Pioneer* of D. c. 3rd.—

A bitter cry comes from the Darjeeling Terai tea-gardens, where mosquito blight is said to have been doing so much injury that the abandonment of gardens, in which large sums of money have been sunk, begins to be talked about as by no means a far-away contingency. None of the insecticide washes that have hitherto been tried seem to have been for any practical use, and the general opinion at present appears to be that there is nothing for it but to hold on and wait for better times. Very little is yet known of the habits of the insect, beyond the fact that it multiplies very quickly and passes the whole of its existence, from egg to winged imago, upon the tea shoots. In view of the failure of other measures, it may be worth while to call attention to the gas treatment, which does not seem to have yet been tried on any considerable scale in Indian tea-gardens, though, according to the account published in a recent number of *Indian Museum Notes*, it has been widely adopted against insects which attack orange trees in America.

What about *helopeltis* on Ceylon tea? That it is present to some extent in certain districts is undoubted. Mr. J. M. Boustead mentioned to us only the other day how, on one of his rounds, he saw the obnoxious insect freely at work on a plantation he passed through, though the superintendent in charge seemed not to be aware of its identity. Now this brings us to another question as to how many of the present generation of planters take an intelligent eager interest in their work and really read about tea, its proper cultivation and preparation and especially about its enemies? We have not a word to say against cricket, tennis, and sport generally—holidays and athletic exercises are most important in their own place; but we trust it is not the case that young tea planters, in some cases, are beginning to trust to conductors in the field and to teamakers in the factory? Ceylon planters will soon lose their reputation as leading the world, if the habits of observation, study and reflection, which have hitherto distinguished them, are given up. We were shocked the other day to hear a proprietor, who has graduated as Sinna Durai and Manager, say, that he did not think one planter in ten of the present day ever read articles on Manuring, Cultivation or Enemies of Tea, and that the *Tropical Agriculturist* is by no means studied as it used to be. Well, all we can say is that on the Proprietors and Companies, or their Agents, who give plantations in charge of planters of this modern type (who care more for sport than for a proper mastery of their work), will rest the responsibility of consequences, should troubles appear through ignorance or neglect. If a man is not up in the Manuals bearing on his profession, or in the best recent information respecting his every-day work, well, he can only deserve to remain a Sinna Durai all his life!

We have been collecting some valuable information in respect of manuring tea, which will shortly be published; and in a letter just received from Mr. John Loudon Shand, he says:—"I wish you could stir up the planting community to the importance of studying '*The Chemistry of Tea*.' I believe £5,000 spent upon securing the services for five years of a first-class chemist would do more permanent good than Chicago Exhibition." We recommend the employment of an Analytical Chemist to study our teas on the spot, as the next big operation for the Committee of the Ceylon Tea Fund; and feel sure, if the right man were got, a good deal of advantage would be derived as the result of his labours,

DRUGS FROM CAPE COLONY.

The enormous changes which have been wrought in international commerce during the present generation by improved means of communication and the rapid spread of commercial news, have tended to diminish the importance of those ports which depended mainly on their favourable position as distributing centres. They have also resulted in cheapening nearly all staple crops. That cheapening, in its turn, has had the effect of rendering the haphazard collection of natural products of the soil absolutely unremunerative and unskilled or careless cultivation nearly so. Hence, general despair among jog-trot agriculturists all over the world, followed by the appointment, in every direction, of Government commissions to find out how to help them.

The people of Cape Colony have not hitherto had the reputation either of paying much attention to the propagation of new products upon their soil, or even of making the most of what it brings forth at present. Want of suitable communications accounts to some extent for their backwardness, but, never an all-sufficient excuse, its force is lessened from year to year; and now, the Cape Government, following in the wake of other authorities, has appointed a "Commission on Colonial Industries," which is gathering expert evidence for the purpose of finding out to what new profitable ends the soil of Cape Colony may be turned.

At the last sitting of this Commission Professor MacOwan, Director of the Cape Town Botanical Gardens, gave evidence on Cape vegetable products. His testimony, as reproduced in a lengthy report in the *Cape Argus*, has not by any means a cheerful or confident ring about it. Possibly the stingy treatment by the Cape Legislature of its botanical gardens and museum affected Professor MacOwan's spirits. If the Cape people are really in earnest about the growth of new products, they should prove their sincerity by providing the funds required to make their botanical gardens as useful to South Africa as those of Kew are to this country, of Buitenzorg to the Dutch East Indies, and of Peradeniya to Ceylon.

There appears to be a feeling among the Cape Colony agriculturists that olive-growing would prove a paying investment. There are plenty of wild olive-trees at the Cape, and the idea seems to be that the best varieties of French and Italian plants might be grafted upon these. Professor MacOwan appears inclined to throw cold water upon this scheme, and not without reason. We doubt if olive-farming is a paying industry anywhere at present. Cotton-seed and other oils have replaced olive oil to a large extent, not only for manufacturing but also for eating purposes. In common or technical oils, the Cape farmer could scarcely expect to compete successfully with his fellow-agriculturists in Morocco, Tunis, and the Levant generally, and to attempt to drive out the fine French and Italian table-oils would be an altogether hopeless task. A suitable soil, a good climate, and cheap unskilled labour are excellent things in their way, but they are, fortunately, not everything. Dexterous workmanship and plodding watchfulness also count for much, and nowhere more than in industries in which the French excel. Just as the Americans find that they cannot make tin-plates or fine cutlery unless they import British workmen to teach them the way, so the Cape people would discover that any natural advantages they might possess would avail nothing without the aid of French workmen excelling in gifts acquired by training as much as in those inherited from generations of predecessors in the same industries. The same obstacles to success apply to the distillation of essential oils. Professor MacOwan mentions that some twenty years ago a London firm of perfumers sent out a small distilling and enfleurage plant for experimental purposes to a Mr. Kennedy, of Humansdorp, in Cape Colony. Unfortunately, the consignee died before the plant could be put to work, and since then no other efforts at essential-oil distillation have been heard of. We doubt whether, if initiated, they could be successful now. To say that there are

not at this moment half-a-dozen kinds of essential oils produced outside Europe which leave a fair profit to their growers is but to record a fact notorious in the trade. Whether it be eucalyptus, patchouly, lemongrass, citronella, or what not, a new grower need but attempt to find a sale for his goods in Europe or America to receive proof of the hopelessness of his task. Saffron is next suggested as a possible Cape growth, the reason given for advocating it being that the western parts of Cape Colony are pre-eminently the country for bulbous plants. We are afraid that here, again, cultivators would fail to find a profitable market. Spain and France produce saffron enough for the world's requirements; in fact, if rumour speaks truly, the Spaniards are likely to restrict their cultivation greatly next year. Some years ago samples of saffron of very good quality from Ceylon were shown in London, but the would-be shipper, upon closer investigation of the market prospects, refrained from sending any further consignments. Scammony and castor oil, which are also suggested, are similarly likely to cause disappointment, though it is but fair to say that of the latter drug South Africa now imports large quantities from India, in spite of the abundance of the ricinus plant on her own soil. But is there, then, no consolation anywhere for the intelligent and industrious cultivator, anxious to lead the way in new methods of cultivation? There is; and such a one need not go far a-field. The choicest gifts, as the poet has said, lie neglected around him—lie close about his feet. How is it that we get little beeswax and practically no honey from the Cape? To Professor MacOwan the same question has evidently occurred and he can only answer that the almost entire absence of both products from among the list of Cape exports is inexplicable to him. So it is to us. We import thousands upon thousands of packages of honey from Chili, California, Jamaica, Cuba, Australia, and other countries every year, and hundreds of tons of beeswax from almost every part of the world. Both honey and beeswax are products of which the consumption is increasing materially. Neither in California nor in Chili is bee-farming as yet a generation old. Fine pressed honey in tins is worth about 45s. per cwt. now upon our markets; good yellow Jamaica beeswax from 7l. 5s. to 7l. 15s. per cwt. But if the Cape people must needs introduce some new economical plants, we should think that the cultivation of insect-flowers offers about as good a prospect of success as that of any other drug. By providing a cheap and plentiful supply of insect-powder the cultivator would not only benefit himself financially, but he would have the satisfaction of contributing largely to the comfort of his fellow-citizens all over South Africa. The commercial cultivation of the plant, we believe, is about to be undertaken now in Natal, and the growers there commence with the prospect of a practically unlimited market at their own doors.

Professor MacOwan, in his evidence before the Commission, comments severely upon the slovenly manner in which aloes-juice is prepared in South Africa. With a proper mode of cultivation, he thinks, Cape aloes might be made as valuable as the best Socotrine kind, which now, we may observe by the way, fetches about six times as much money. The Professor mentions the interesting fact that in 1860 an English farmer in Natal showed him a calabash of treacly aloes-juice, which he had prepared experimentally for the English market, and which contained as large a proportion of crystallisable aloin as the best Socotrine aloes. Unfortunately, the experiment was not repeated. The reason that the Cape aloes of commerce contains no aloin must be sought, Professor MacOwan thinks, solely in the unworkmanlike manner of its preparation. If this view be correct, we shall have to revise our authorities. Natal aloes is, indeed, known to yield an aloin ("Nataloin"), but all pharmacognosists have hitherto held that in Cape aloes, which is the produce of a different plant, aloin is constitutionally absent.

Of the other drugs, the cultivation of which Professor MacOwan discusses, jalap would seem to us

to offer a fair chance of remunerative cultivation; and if the South African farmers could be induced to see the wisdom of investments for the future, it might be advisable to try the cultivation of camphor, which has been successfully accomplished in Florida and in certain parts of Natal. In fact, the planting of forest-trees is usually a profitable investment; "but," says our witness, "I doubt if patience is a common virtue here. In this colony we plant trees, truly, but they must be quick-growing ones or we will have nothing to do with them. Then we cut them down for timber while they are still babes, and cry out on them for not having heart-wood."

After all, perhaps, nothing among new cultures will pay the South African soil-tiller better than the intelligent cultivation and treatment of edible fruits of all kinds, and, in some parts of his country, of fibre-plants. For these he has the materials ready at hand. He might raise bad exotic drugs which would compel us to throw his physic to the dogs, much as, in the Transvaal, he throws his own peaches to the pigs.—*Chemist and Druggist.*

INSECTICIDES.

BY HOWARD EVARTS WEED.

The term fungicides is used to designate those substances which kill low vegetable organisms known as fungi, and in like manner, substances which are used to kill insects are known as insecticides. Fungicides, as a rule, consist of compounds of poisonous chemical substances, while insecticides may consist of similar combinations, as in Paris green, or simply powdered plants, as in pyrethrum. Some substances may act both as fungicides and insecticides, and in some cases we may combine an insecticide with a fungicide, so as to be able to kill plant diseases at the same time we kill injurious insects—thus killing two birds with but a single stone.

Insecticides may be divided into two general classes: (1) those which kill by external contact, and (2) those which kill by internal contact. The external contact class are applied directly to the insects, killing them either by closing the breathing pores, as is the case with pyrethrum, or by producing an irritation of the skin, as is the case with kerosene. The internal contact class kill by being eaten, and are applied upon the plants being destroyed by leaf-eating insects.

Insects destroy plants in two ways: (1) by sucking the juices, and (2) by eating the leaves, according as to whether their mouth parts are formed for sucking or for biting. Insects which suck the juices from plants have the various parts which form the mouth prolonged into a beak, and are known as *Haustelate Insects*. Those insects which eat the leaves of plants are provided with more or less well-developed mandibles or jaws by which small particles of the leaves are eaten off and taken into the stomach. These are known as *Mandibulate Insects*.

The external contact class of insecticides are applied to the haustelate insects, and the internal contact class to the mandibulate insects. Sometimes, however, it may be convenient to apply the external contact class to the mandibulate insects; but the internal contact class are never used for the haustelate insects. Thus we may apply Paris green to any true bug and it will have no effect.

Pyrethrum is a substance made by powdering the leaves and flowers of the pyrethrum plant. This plant grows in tropical and semi-tropical climates, and is especially cultivated in California and Persia. The pyrethrum grown in California is known as "Bubach," while that grown in Persia is sold under the name of "Persian Insect Powder," or "Delmation Insect Powder." Although made from the same plant, the Califorin product, "Bubach," is much stronger in its action, owing, no doubt, to the fact that the Persian product is probably diluted to make it

cheaper. Bubach sells in the drug stores for about seventy-five cents per pound, while the Persian Insect Powder sells at thirty-five cents.

Pyrethrum belongs to the external contact class of insecticides, and kills by closing the breathing pores of the insects. It is a perfectly harmless substance, not being poisonous in any way, and for this reason is most used to kill insects upon plants where we would not wish to apply poisons. Hence it makes an excellent remedy to kill the green worms upon cabbage plants, and is largely used for this purpose. It can be applied dry by means of a hand bellows, or mixed with water, a tablespoonful to the pail, and applied with a common sprinkler or a force pump. When applied dry it can be advantageously mixed with three times its bulk of flour. It is a good application for plant lice when applied as a liquid.

Tobacco belongs to the external contact class of insecticides, and is used to destroy plant lice, various caterpillars, and lice upon domestic animals. It consists of the powdered leaves and stems of the tobacco plant, and may be applied in the same manner as pyrethrum. Refuse tobacco can be obtained through a drug store at a cost of little more than the freight, and this if ground or cut into small pieces will make an excellent insecticide for many purposes. When the tobacco is used to destroy lice upon domestic animals it is applied by washing the skin with a decoction made by soaking or boiling the tobacco in water. Tobacco is also useful as a repellent whereby insects are kept away from plants; e.g., by putting it upon cucumber hills the striped cucumber beetle may be kept away.

Hellebore kills by both external and internal contact, and, hence, in some cases is a very useful insecticide. It is a vegetable poison, consisting of the powdered roots of the white hellebore plant. It is applied in the same manner as pyrethrum, and sells at about twenty-five cents a pound. Hellebore is especially used for the well-known imported currant worm.

Paris green is an arsenite of copper, and contains about fifty-five per cent. of arsenic, the proportion being somewhat variable. It belongs to the internal contact class of insecticides, and sells at about thirty-five cents per pound.

London purple is a by-product in the manufacture of aniline dyes, placed upon the market by the Hemingway London Purple Co. of London, England. Its action is nearly the same as Paris green, and it contains nearly the same amount of arsenic.

London purple and Paris green are known as the arsenites. They are used in a dry form or they can be mixed with flour to advantage in many cases. The arsenites are practically insoluble in water, the particles remaining suspended. The proportion generally used is one pound arsenite to 200 gallons of water. If too strong a proportion is used, the foliage to which the arsenites are applied will be scorched; hence, for tender foliage, such as the peach, a weaker mixture, say one pound to 300 gallons, should be used.

Damage to foliage, however, can be almost entirely prevented by mixing a little lime water with the arsenical mixture. We owe this discovery to Prof. C. P. Gillette, of Colorado, formerly of the Iowa Experiment Station. If lime water be added to the mixture the arsenites can be safely applied to the most tender foliage, when used in the ordinary proportion of one pound arsenite to 200 gallons of water.

The arsenites are used to destroy any of the mandibulate insects, and kill by being taken into the alimentary system. Eleven years ago they were first brought forward as a remedy for the well-known codling moth. Spraying with the arsenites for this pest is now practiced by all the more progressive farmers of the Middle and Eastern States, and any fruit growers who do not practice it are annually losing a large per cent. of their crop through a neglect of this simple operation.

Kerosene emulsion is the best insecticide of the external class. Kerosene itself cannot be used upon plants infested with insects as it would kill the foli-

age, hence it must be diluted if it is to be used as an insecticide. The idea of diluting the kerosene with soap suds probably originated with Mr. Henry Bird, of Newark, N. J., in 1875, and two or three years later an emulsion was made by Prof. A. J. Cook, of the Michigan Agricultural College, and Dr. C. V. Riley, Entomologist of the United States Department of Agriculture. It was first practically used and recognized as a valuable insecticide by Mr. H. G. Hubbard while conducting some experiments upon scale insects in Florida under the auspices of the Department of Agriculture. During the last three years the kerosene emulsion has come into general use.

There are two formulæ for making the kerosene emulsion now in use. The one is known as the Hubbard-Riley formula and the other as the Cook formula, the difference between them being that the former contains eight times more kerosene to the same amount of soap and water than does the latter formula.

The Hubbard-Riley formula is made as follows: kerosene, two gallons; hard soap, one-half pound; hot water, one gallon. The soap is dissolved in the hot water; and, while still hot, should be poured into the kerosene and thoroughly mixed by pumping through a force pump, when the soap suds will unite with the kerosene, forming a thick, creamy emulsion. The emulsion thus formed can be put away in bottles for use at a future time, or can be used at once. When used it should be diluted with about nine times its bulk of water.

The Cook emulsion is made in a similar way according to the following formula: kerosene, one quart; hard soap, one-half pound; hot water, one gallon. The soap is dissolved in the hot water, and the kerosene mixed with it as before. When ready for use it is diluted with two or three times its bulk of water.

A good emulsion is one in which the kerosene will not separate; and either of the above, if made properly, will be found excellent for use against any insect, where we wish to kill by external contact.

Bisulphide of carbon is an excellent insecticide for some purposes. By means of volatile fumes of this substance we can reach many insects, which cannot be well destroyed in any other way. It is especially useful in destroying ants and grain insects. To destroy an ant-hill, by means of a crowbar or stick, a hole is made in the center of the hill, into which a small amount of the bisulphide is poured. The hill is now covered with a wet blanket, to allow the fumes to penetrate all parts for a few minutes, when the blanket is removed and a match applied. The fumes are explosive, and the odor will effectually destroy all ants within the hill.

For grain insects the bisulphide is used to destroy various weevils and moths found within stored grain. This is done by putting the grain into a bin as tight as possible, in order that the fumes may not escape. In such a bin the bisulphide is put into an open dish on top of the grain, and allowed to evaporate. As the fumes are heavier than air they will penetrate to the bottom of the bin.

There are many other insecticides of greater or less importance, among which should be mentioned whale-oil soap and carbolic acid, both of which make an excellent wash for trunks of apple trees, to prevent borers.—*Cor. N. Y. Independent.*

Agricultural College, Miss.

NOTES ON PRODUCE AND FINANCE.

THE WOOD USED FOR TEA PACKAGES.—The following letter has been addressed by the hon. secretary of the London Wholesale Tea Dealers' Association to Mr. Ernest Tye, secretary of the Indian Tea Districts Association:—The attention of my committee has been drawn to the objectionable flavour in some cases imparted to Indian teas by the wood used for the packages, and I am informed that in particular gardens saw mills are frequently part of the plant, and when the wood used is too green, the juices produce in'

contact with the lead, an acid, which perforates through minute punctures into the tea itself, and creates what is commonly known as a 'cheesiness' in the flavour. May I ask you to be good enough to bring this subject under the notice of tea growers, with the view of their recognising the necessity of only using wood which is properly seasoned, and this request I venture to make both in the interest of the importer as well as the buyer."

THE TEA DUTY.—There are many who hold the opinion that the entire abolition of the tea duty would be the best thing possible for Indian and Ceylon. This opinion is not shared by all those interested in tea, but it is advocated by Mr. C. J. Rowe, who writes as follows:—"Pessimists who objected to the reduction of the tea duty in 1890 on the ground that the remission of 2d per lb would infallibly result in a largely increased home consumption of cheap China teas, at the expense of British-grown teas from India and Ceylon, must now be anxious to explain away their prophecies. So far from the ruin of the tea industries of Ceylon and India having been achieved by John Chinaman, the exact opposite has been the result. The reduction became operative in May, 1890. For the year ending June, 1890, the home consumption of China teas was, approximately, 60,000,000 lb. For the year ending June, 1892, it was 40,000,000 lb., thus showing a reduction in the two completed seasons following the remission of 33 per cent. From Jan. 1st to the end of October in the present year rather over 28,000,000 lb. of China tea has been consumed at home. At the same rate for the remaining two months of the year the home consumption will be about 33,000,000 lb. a falling off, as compared with 1890, of 45 per cent. On the other hand, the growth of British-grown teas in public favour has undoubtedly been the factor that has procured the displacement. Their quality, as evidenced by market price—the reflex of quality—has enabled them, since reduction of duty, to come into enormously increased use in the United Kingdom and practically, to drive China teas out of the field. The increase in Indian teas consumed at home for the season 1891-2, as compared with the season of 1889-90, was 5½ per cent. But in Ceylon teas—articles of superior quality to Indian teas—the increase over the corresponding period was no less than 88 per cent and, if the rate of home consumption of Ceylons for the present year be maintained for the remaining two months, the rate of increase for 1892 over the 1889-90 season works out 105 per cent—i. e., 63,500,000 lb., against 31,000,000 lb. If there is one thing perfectly clear about these figures it is that the remission of duty was favourable to the consumption of the best and unfavourable to the consumption of the worst teas. I am therefore fully justified in assuming that the entire abolition of the remaining duty of 4d per lb. would operate as a very great stimulus to the further consumption of high-quality teas; to the disuse, by consequence, of inferior teas. As long as any duty is maintained it will act as a handicap, *pro tanto*, in favour of the worst and against the best articles—a premium on rubbish, in fact. Is not that an all-sufficient reason for effecting the entire abolition of the duty in the 1893 Budget?"

TEA STATISTICS.—The imports of tea from the British East Indies into the United Kingdom during the first ten months of the year were little above those in 1891, viz., 80,651,250 lb., against 79,241,100 lb., though, as compared with 79,011,200 lb. in the same period of 1890, there was an increase of 7,640,050 lb. On the other hand, the deliveries of Indian tea for home consumption in the past ten months were considerably augmented, and the total amounted to 90,131,250 lb. in contrast with 80,621,200 lb. last year, which exhibits an increase at the rate of 1,000,000 lb. per month; and with a heavier quantity exported, say, 3,127,900 lb., against 2,394,200 lb. in 1891, it is not surprising that the surplus stock in bond is much reduced. No separate account, says the *Grocer* in an article on Indian tea, is officially kept of each description of tea lying in the bonded warehouses, so as to show how

one sort stands in respect to another at the same time, as all kinds are included in a single total, which on the 31st ultimo was 86,610,300 lb., in comparison with 95,067,700 lb. in the previous year, and the nearest approximation to the stock of Indian tea by itself is that returned in London, as contained in our usual monthly statement, which at the latest date referred to comprised 33,393,200 lb. against 31,534,000 lb. in 1891, and 26,057,200 lb. at the end of October 1890. At the end of last year and the beginning of the present one, the excess in the London stock of Assam and such-like teas was large, consisting of about 10,000,000 lb.; but now, from the particulars just given, the overplus does not appear to be more than 1,859,200 lb. From these few facts it is easy to infer that the statistical position of Indian tea is greatly improved in the interests of holders, whether they be importers or wholesale dealers, and further evidence on this point may not be uninteresting to those who are anxious to know if the market is likely to maintain an upward tendency during the remainder of 1892.

WRONG ESTIMATES.—It is well known, says the authority we have quoted, that early in the present year very extravagant estimates were put forth of the probable yield of the tea crops in different parts of India, some authorities placing the aggregate production at 129,000,000 lb. or 10,900,000 lb. above that in 1891-92; and although the news for fear it should create a panic among the home trade at the idea of such an overwhelming supply looming in the future, was partly suppressed, and was only allowed to leak out gradually, yet, when it became more widely spread, it did not fail to have a depressing effect on the article generally, and for months afterwards prices were drooping, until in August they descended to an unprecedentedly low level. After that a material reduction was made from the original estimates of this season's crops, when the output was finally fixed at about 118,206,000 lb. Almost simultaneously with the above cutting down of the estimates came reports of a considerable falling off in the crop of Ceylon tea followed by the loss of the "Anglia" with 617,000 lb. in the river Hooghly, when it was reckoned that the actual shipments from India to Great Britain for this season would not exceed 103,000,000 lb., and a conviction began to settle in men's minds that prices had touched their lowest point, being, as they were, several pence per pound lower than in 1891. In the meantime the unheard-of cheapness of tea of every kind had acted as a powerful stimulus to the daily consumption throughout the country, and an extensive demand having been built up everywhere there was nothing to oppose a strong reaction in favour of higher rates. Week by week and month by month, as the proportion of common to fine and finest qualities in the regular supply by auction appeared smaller than hitherto, the competition for the former grades perceptibly increased, and the value unmistakably advanced until it ranged fully 3s. per lb. above that in August last—sound common quality of tea, which then went at about 5d., subsequently bringing 8s. to 8½d.

PRICES WILL BE STEADY.—The question has therefore come to this: Whether quotations will recede, remain where they are, or go higher still? For prices to decline one of two things must happen, viz., either excessive supplies and forced sales, or a diminution in the deliveries of tea for home use. In the latter case it would, says our contemporary, no doubt, be the result of the late sharp rise in the current rates, and for that reason we do not think that the distributing section of the trade would bear an additional advance without setting up some resistance, as it would assuredly tend to whittle away their profits next to nothing. Further, if holders are not too eager to sell at the top of the market, as it were, but wish to inspire confidence all round, they must adhere to the agreement entered into weeks ago to restrict the weekly public sales to an average of 35,000 packages and not stretch the offerings to 10,000 packages beyond that limit otherwise buyers may suddenly take fright especially if the very latest estimates of the crop

just wired from Calcutta, bringing it up to a par with that in 1891-92, should be confirmed, and then the whole movement will collapse. As to prices again advancing, there is little likelihood of that after the smart rebound that has already taken place; and the most reasonable deduction to make, in view of all the circumstances connected with the article, is that it will pursue a tolerable even course, being neither unduly buoyed up nor severely depressed, but preserving a steady equilibrium between one extreme and the other, so that few or no risks will be involved in keeping a fairly workable stock in reserve.

TEA AND ADVERTISING.—Tea bids fair to eclipse scap in the advertisement market. The rivalry amongst the large retailers must prove profitable to the newspapers. Large advertisements setting forth the merits of tea sold by certain firms are conspicuous just now. The profits on the advertised teas must be considerable, or the expense could not be borne. The consumer has much to learn about tea. There appears to be no standard of excellence other than that established by the various retailers, many of whom persuade the public into the opinion most in harmony with their own ideas of profit.

LEBONG TEA.—A half-yearly interim dividend of 6s per share is announced by the directors.

THE ADULTERATION OF COFFEE.—A deputation from the Federation of Grocers' Association waited on Sir W. Foster, Secretary to the Local Government Board at the Treasury Buildings, yesterday, for the purpose of urging the desirability of amending the Food and Drugs Act. Sir W. Foster, in replying, promised that the representations of the deputation should be placed before the Government and receive careful consideration, though many of the points were dealt with in the Bill of Dr. Cameron, who had been very successful in obtaining private legislation. As to the sale of coffee and chicory, he thought, however, that the provision of Dr. Cameron's Bill would be rather confusing to the public, and he suggested that, instead of one mixture, being labelled "coffee and chicory" and another "chicory and coffee" to denote the degree of admixture, the label should state the proportions, whether half-and-half or three-parts chicory and one part coffee, and so on. That would be intelligible to every one, and would be a thing that he was sure every honest trader would be desirous of complying with.—*H. and C. Mail*, Nov. 25.

TRAVELS IN PERU AND THE UPPER VALLEYS OF THE AMAZON.

BY ARTHUR SINCLAIR,

PART III.

Peruvians are not famous as travellers; as a rule they know very little of their country. They have their geographical society, forsooth, and possess maps more or less inaccurate, compiled by industrious foreigners, but the richest portion of the interior is practically a *terra incognita* to them. "Have you ever been to the interior?" I asked a leading authority in Lima. "No, my dear sir," was the naive reply; "I never but once rode twenty miles, and that only because the Chilians were at my back."

But the worst weakness of the Hispano-Peruvian race is their utter inability to tell truthfully the little they do know. David said in his haste that all men were liars, but had he lived at present in Peru, he might—as the Scotch minister put it—say the same very deliberately. The common people are born and bred to it, but their lies are clumsy, palpable and comparatively harmless; with the priests and privileged classes, however, it becomes a studied art. "We must dissimulate," said the chief priest of the convent, and I will give him the credit for consistency in this, for during the three weeks I had the opportunity of studying this great economist of truth, I never once knew him utter a word that could be relied upon, and yet we must own to the weakness of being over and over again misled by the arch-deceivers; forgetful of all warnings, we went

on trusting that by some accident they might prove truthful to us. Such were the guides with which we entered the great Trans-Andean forest after crossing the Pucartambo river. We were a goodly company to start with, consisting of seven Europeans, as many cholas and a score of mules. The shade of the gigantic trees seemed grateful at first; it was like passing from the hot blazing noonday to the cool dim gloaming. But the road was a villainous rut, at a gradient of about one in three, a width about eighteen inches, and knee deep in something like liquid glue. Before we had gone five miles, one-half the cavalcade had come to grief, and it was some weeks ere we saw our pack mules again, indeed, I believe some of them lie there still. We soon found out that the padres knew as little about the path as we did ourselves, and the upshot was we were benighted. Shortly after six o'clock we were overtaken in inky darkness, yet we plodded on, bespattered with mud, tried, bitten and blistered by various little insects. Whole boxes of matches were burned in enabling us to scramble over logs or avoid the deepest swamps. At last, there was a slight opening in the forest, and the ruins of an old thatched shed was discovered, with one end of a broken beam still resting upon an upright post, sufficient to shelter us from the heavy dews. It turned out to be the tomb of some old Inca chief, whose bones have lain there for over 350 years, and there, on the damp earth we lay down beside them, just as we were, our dinner consisting of a few sardines, which we ate, I shall not say greedily, for I left tired and sulky, keeping a suspicious eye upon the Jesuit priests. We had resolved before leaving home that we would never move on Sunday, but when next day dawned we saw the absurdity of sitting in that old damp sepulchre longer than we could help.

We were told, by the way, that the bones of Athawalpa, so treacherously murdered by Pizarro, but in Peru, of course, every such tale must be taken *cum grano salis*. A start was again made, without much regard to toilet, and on we rode for a few hours till the path the government of Peru had prepared for us came abruptly to an end, and we were not sorry. This path, which we had the pleasure of wading along for some twenty miles at a gradient of one in three up and down, is looked upon as a great piece of engineering for a Peruvian, and so delighted were the authorities in Lima with the achievement, that they actually bestowed upon the engineer-in-chief the degree and title of Doctor. I have in other countries travelled in tracks traced and made by elephants, and had reason to admire their gradients, and marvel at the topographical knowledge displayed, but anything so perfectly idiotic as this atrocious path I had never before been doomed to follow so far. It was a relief to leave it, and cut our own way through the jungle or follow occasionally the paths of the Chunchos who come hither for salt. The Cerro de Sal, or mountain of salt, lies a few miles to the west, providentially placed here for the benefit of the poor natives who come from many hundreds of miles around. The supply is said to be practically inexhaustible, and as to its savour and purity, I can well vouch, having for months used it as it was quarried out of the hill. Soon after leaving the Peruvians' path we found ourselves upon an extensive Pajonal or "Patena," as we call it in Ceylon, where the great forest abruptly and completely ceases, and we have instead a grassy sward, it may be from a few acres up to a few thousand acres. Here there are about 500 acres, and our

"Scottish farries never tread
A greener nor a souter sod."

But our chief delight was in the glorious view. I shall never forget that calm, bright Sunday afternoon, when we looked out for the first time on the great interminable forest of the Upper Valleys of the Amazon. Right in front of us as we stood with our face to the east, were evergreen hills of various altitudes, all richly clad, and undulating down towards the great plains of Brazil. We were standing at a height of 4,600 feet, but even in that clear atmosphere, could see but a comparatively short distance; still it showed better than any words can

convey the extent and richness of this vast reserve and the absurdity of the cry that the world is getting overcrowded. Why, we have only as yet been nibbling at the outside borders, and now trying to peep over the walls of the great garden itself. The extent of this forest is probably three million square miles, equal to about 40 Great Britains.

"From Plymouth to Peterhead," said Mr. Stanley, in describing the extent of forest he came across in Africa—but here is a forest stretching as far as from Plymouth to Timbuctoo—with a few hundred miles to spare! In estimating this, I adopt the figures of that very reliable authority, Alfred Russell Wallace, who travelled in the lower portions of this forest for some three years, and whose definition of the upper Peruvian boundaries I can confirm. Behind us tower the snowcapped Cordilleras from which the ever watchful condor swoops down in search of prey; and woe to the unwary traveller who may be found sleeping or exhausted on these distant and dismal mountain passes; but our immediate surroundings are mild and peaceful to a degree, the faint buzzing of bees, the subdued chirping of finely feathered birds, the flutter of brilliant butterflies being the only commotion in the air, itself the perfection of summer temperature. What a glorious spot in which to form a quiet, comfortable home! Quiet, it certainly would be. Lonely it might seem to those accustomed to town life, but healthy it could scarcely fail to be at this altitude, where the climate seems similar to that of the best parts of Great Britain, say Braemar, in August. Imagine this all the year round, every month seed time and every month harvest. What crops of vegetables and fruit might not be produced in such a climate and in such a soil! Had poor old Malthus only been permitted to look upon a country like this, so rich, and yet so tenantless, his pessimistic fears of the population outgrowing the means of sustenance would have quickly vanished.

Right below we could see the River Perene wending its way to swell the mighty Amazon, and our object now was to get down to this tributary. Unfortunately, we had lingered rather too long over this view and it was four o'clock ere we felt inclined to move. Better for us had we pitched our camp there for the night, but we were induced once more, against our better judgment, to believe the padre, who declared he could in two hours take us to the house of one King Chokery, a Chuncho chief. "I know the way," he said, as he mounted his mule, but scarcely had he gone a hundred yards when the so-called way became impassable, each step being something like from a mantelpiece to the floor. For a time we dragged the poor animals after us, but ultimately had to leave them behind, plunging into the forest again just as it was getting dusk. We were now down to about 2,000 feet above sea level. The air was very steamy and the vegetation most luxuriant, but we were past the stage of studying botany. Tantalised by thorny creepers like the "wait a bit" of Ceylon, tripped up by gnarled roots, rising again only to have our hats knocked off by an overhanging branch; elegant fern trees and beautiful palms may be there, but we are in no mood to admire. We now come to a newly-burned clearing intended for Yucca, as we afterwards learned. It is not the first clearing we had scrambled through by any means, but this had been so badly lopped that the fire had only succeeded in burning the leaves and blackening the branches. To scramble through such a confused mass in daylight tries the best of tempers. You can imagine what it was for tired men in the dark. We plodded on, however, ashamed to think how we had again been befooled by the dissembling priest, shouting till we were all hoarse and listening only to the echo from the opposite ridge. Still we knew, if we kept on descending, we must, sooner or later, come to the river. But our strength and patience were getting sadly exhausted and every five minutes we had to sit down to breathe, the perspiration pouring from us in little streams.

The night was calm, and a death-like silence reigned all around; not even a jaguar growled not, a monkey chattered, but we could now hear the dis-

tant murmur of the water, and "Oh Caramba!" a human voice at length answered our call. Nearer and nearer we drew to the spot; and at length, through an opening in the jungle, saw the swinging of a fire stick. A few minutes more, and half our troubles were forgotten in shaking hands with the owner of the welcome voice.

This gentleman turned out to be the king's medical adviser. I do not know if he had taken his M.D., but the learned doctor had at least one European word, which he used to good effect, "Amigo! Amigo!" he said, as he shook hands with us. It turned out the king was prostrate with fever.

The palace was simply a thatched roof, supported by a few jungle trees, and on a raised bench in the centre of the only apartment, lay his Majesty, groaning. Our chief priest cautiously approached, unbuckled his flask, a sort of bladder he always carried well primed with rum (the only spiritual matter he dealt in). The tube attached to this, he placed in the royal mouth, into which he injected a liberal supply of the spirit, which, for the moment, had the desired effect. The king, lifting his head, indicated that we might be permitted to lie down on the earthen floor at his feet, and there we lay, supperless and saturated with perspiration, till next morning. I arose, I need scarcely say, but little refreshed. But then, the surroundings were so intensely interesting, that I soon forgot my aching limbs as I gazed upon the marvellously beautiful vegetation. We were within a hundred yards of the river Perene, and after a bath in its clear tepid water, I felt fit to tackle the Manioca roots upon which we breakfasted. Our surroundings in the palace were, however, very filthy, and the curiosity displayed by the royal family became rather inconvenient as they grew more familiar. They had never, for instance, seen human beings with anything in the shape of beards before, and seemed greatly amused as they looked and came to rather closely handle us. The queen, by the way, seriously suggested that your humble servant would be much improved by being well tattooed, and actually proposed carrying the operation into effect herself, a decoration, however, which, to her great disappointment, I, being a modest man, protested against.

For day after day we had to remain the involuntary guests of this curious household. Our object was to get down the river, and we had to await the recovery of the king before labour could be commanded, and balsas (rafts) made. But the time was not altogether wasted, for we made daily excursions into the forest, with increasing interest and admiration. Never had I seen such a variety of plants. It is one of the characteristics of tropical vegetation that plants of the same family are less sociable as it were, than in the cooler regions of the world; in North America for instance, the same dark green pine covered thousands of square miles and, in Australia, the dingy eucalypti and myrtle monopolise half the ground; or, nearer home, where that most sociable of all plants, our heather, still covers a very large extent of our country. There is nothing of that kind in the purely tropical regions, and here, in the upper tributaries of the Amazon, the variety is almost incredible. Scarcely two plants of the same family can be seen growing side by side. Diversity is the rule, nature delighting both in variety and contrasts, one tree upright as an *Areca* palm, another sloping over a chasm; one with bark, smooth as ivory, the next prickly as "*Acacia horrida*." Exceptions there are, and one may be seen by the river banks, viz., the Balso wood (*Ochroma piscatoria*), as if providentially placed there for the natives, who invariably use its remarkably light wood for their rafts. The *Ochroma* has a cottonlike fruit, which might be used for stuffing mattresses, &c.

The graceful ivory palm (*Phytelephas*), may also be seen in small groups, indicating the very richest spots of soil. Near to this may be found a solitary cacao (*Theobroma*) thirty to forty inches in circumference, and rising to the mature height of fifty feet.

Coffee, of course, is not found wild here, but at intervals we came upon gigantic specimens of the *Cinchona*, both *Calisaya* and *Succirubra*, six feet in circumference. The walnut of Peru an undescribed

species of *Juglans*, is frequently seen in the Perene Valley, growing to a height of sixty to seventy feet. Satinwood there is also, but not the satinwood of Ceylon (*Chloroxylon*); for though the wood looks similar, the family (*Ebenacea*), is in no way related to our Ceylon tree. The indigenous coca, as an undergrowth, we rarely came across, except in semi-cultivated patches. Gigantic cottons, the screw pine (*Carludovia*), from which the famous Panama hat is made, the grand scarlet flowering *Erythrina*, and another tall and brilliant yellow flowering tree—probably the laburnum of Peru—add much to the beauty of the scene. Many other leguminous plants we also noted, particularly *Calliandra* and *Clitoria*.

Innumerable orchids, mosses, and ferns sufficiently indicated the humid nature of the climate. Probably the chief distinguishing feature in Peruvian vegetation is, that it is an essentially flowering and fruit-bearing vegetation, rather than the excessive leaf-producing, which so distinguished the luxuriant greenery in Panama, the West Indies, and Ceylon. Peru undoubtedly possesses a richer soil and a climate more favourable to fruit-bearing; while compared with the massiveness and graudeur of the Trans-Andean forest monarchs, the jungle trees of India and Ceylon are somewhat diminutive. A few plants we missed; the beautiful and useful yellow Bamboo is not there, nor are the Palmyra, talipot, and coconut palms. The jak and bread fruit trees might also be introduced with great advantage. The cultivated grasses of the East, the Guinea and Mauritius grasses are here already, but as a nutritious fodder, they cannot be compared with the "Alfalfa."

There cannot be said to be any cultivation here, but we can see by the well beaten foot paths leading to them that certain plants are more highly prized than others, and Coca (*Erythroxylon*) is one of the chief favourites. Around little patches of this plant the jungle is occasionally cleared away, and the coca leaves are carefully harvested.

Coca, from which the invaluable drug cocaine is obtained, is a native of this locality, a plant not unlike the Chinese tea, though scarcely so sturdy in habit, growing to a height of from four to five feet, with bright green leaves and white blossoms, followed by reddish berries. The leaves are plucked when well matured, dried in the sun, and simply packed in bundles for use or export. Probably tea might be treated in the same way, and all its real virtues conserved in the natural vessels of the leaf till drawn out in the teapot; the fermenting and elaborate manipulation introduced by Chinamen is of doubtful utility.

Of the sustaining power of coca there can be no possible doubt; the Chunchos seem not only to exist but to thrive upon this stimulant, often travelling for days with very little, if anything else to sustain them. Unquestionably it is much superior, and less liable to abuse, than the tobacco, betel, or opium of other nations. The Chunchos is never seen without his wallet containing a stock of dried leaves, a pot of prepared lime, or the ashes of the quinna plant, and he makes a halt about once an hour to replenish his capacious mouth. The flavour is bitter and somewhat nauseating at first, but the taste is soon acquired, and if not exactly palatable, the benefit under fatiguing journeys is very palpable. Cold tea is nowhere, and the best of wines worthless in comparison with this pure, unfermented, heaven-sent reviver.

The chief food of the Chunchos when at home is, however, the *Yucca* (*Jatroba manihot*), the Cassava of the East, which also obtains a certain amount of care and protection, in this case almost amounting to semicultivation. The plant may be freely grown from cuttings, the thickness of one's finger, stuck obliquely into the ground. In about nine months the roots, the only edible part, are fit for use. They look like huge kidney potatoes or roots of the dahlia and taste, when boiled, something between a waxy potato and a stringy yam; roasted they are better. Still, one wearies even of roasted yucca. For weeks I had no other solid food morning, noon, nor night, and though duly thankful of these mercies, I have no craving for another course of yuccas. With the Chunchos, as I have said, they form the chief food. Fish is the favourite accompani-

ment, though they do not despise a slice of wild turkey when obtainable, which is but seldom. Black monkey and white maggots are delicacies set before a king.

They have no regular meal hours, but eat like cattle, whenever they have a mind to, that is to say, if food is at hand; if not, there is always the coca.

The Papaw (*Carica*) is here one of the most abundant of indigenous fruit trees. The eastern world has been indebted to Peru for many good things, and the best variety of papaw is one of them. The pleasant, melon-like fruit is not only very agreeable and digestible in itself, but it has the property of helping the digestion of other foods particularly flesh meats, with which it may come in contact. Even the leaves rolled round tough beef is said to tender it, and the most ancient fowl hung up in this tree for a night will become like chicken. The juice is used by the Spanish ladies as a cosmetic, but the most valuable product of this prolific tree is fibrine, so beneficial to the dyspeptic.

One peculiarity is that its male and its female flowers grow on separate plants, and the tree is thus called Papaya or Mamai, according to sex.

After a weary wait of eight days, the royal patient began to show signs of recovery, his subjects coming in crowds to call upon him, bringing presents, generally large white maggots, about three inches long, which the king greedily ate.

On such occasions it was curious to note how, on the approach of visitors, the ladies disappeared, just as ladies sometimes do nearer home, re-appearing again in all the dignity of the war-paint of their tribe. The preliminaries were soon over, and hunkering down in a circle, the social chat over the latest sensation seemed soon to have full play. No doubt we formed the chief topic, and judging from the loud laughter of the company, we were evidently looked upon as harmless lunatics, frequent allusion being made to bunches of flowers and weeds we had gathered, which caused much merriment.

King Chokery at length gave orders for balsas to be made, and trees were at once cut down and fixed together by pins of palm wood. The balsa, or raft, consisted of seven logs about twenty-four inches in circumference, rather roughly pegged together, but sufficiently buoyant to support three of our party on each. Seven of these rafts carried our company of twenty. The king accompanied us, and as he himself had never been forty miles down the river, it was an interesting voyage of discovery to all concerned.

We started in single file, I electing to sit in the prow of the foremost balsa. It was a glorious morning, and as we glided onward at the rate of four miles an hour through ever-changing, but always enchanting scenery, the effect was indescribably exhilarating. Every nerve seemed stretched to the highest pitch of enjoyment; the eyes, glancing from scene to scene took in more impressions than the mental powers could take note of. Such a wealth of vegetation seems to mock at the idea of a few poor, puny planters ever making any impression upon it. The leafy monarchs may, indeed, be cut down, but who is to keep that interminable undergrowth in check? Beautiful as these creepers are as they hang in festoons from the lofty trees, they almost bid defiance to the progress of explorers, and a path cut, which in other countries would remain open for years, would here close up in a few weeks. Such seems the inexhaustible fertility of the soil, and such the forcing nature of the climate, that there is a mixture of awe in our admiration. In every other country we know the more fertile the soil the more friendly it is to man, but here its excessive fertility has led it to be looked upon as an enemy to his progress. But, as an old planter, I do not despair of its fertility being yet turned to good account, if we could only tap the labour supply of India and China, where there are millions to spare, and conduct the stream hither; the result, if we directed, would bring a wealth of supplies such as the world has not before been blessed with.

Turning a bend in the river we are struck by what seems the ivy-clad ruins of an ancient castle, but it turns out to be only an aged tree, clad from top to bottom with verdant creepers, its huge horizontal arms supporting a perfect screen of living trellis work below, while ferns, lycopods and rare orchids, beautiful

in hue as they are grotesque in form, grow upright from the damp decaying bark; the original tree itself being so hidden that it is hardly recognizable, but from its curious buttresses we suppose it to be a ficus. Right behind, on the steep bank stands a lovely scarlet Erythrina, 40 to 50 feet in height in full flower, while 100 yards to the right a still taller tree with bright yellow blossoms stood out conspicuously—evidently a very near relative of our own laburnum. To the left a group of palms, near to which we can see a grand specimen of the cinchona tree, and another of the cacao.

One of the noblest trees in this forest is the walnut, a variety I never saw, certainly not the *Juglans nigra* of North America. The whole scene is one of surpassing beauty, but it must be remembered that from the river we see it to the greatest advantage; the leaf boughs naturally bend to the light and lean lovingly over the water, while flowers can only bloom in the bright sunshine. Nothing could be more dismal than to scramble beneath the dark forest, and the further one penetrates the more monotonous it gets; scarcely a flower or a bird is to be seen there, is all such life at the top. Not even the snakes will cross your path, for they, too, are children of the sun. It is like living in a dark cellar and longing to get out into the cheerful light again. Merrily our rafts glide down the river; here and there we have a few yards of rocky rapids requiring careful navigation, but beyond an occasional ducking, nothing of importance happens to us. Natives armed with bow and arrows creep from below the trees and look at us with evident wonder and some suspicion, but offer no active hostility. Or suddenly we come upon them as they are shooting their arrows into a passing fish. Our padre here astonished the natives by throwing in a charge of dynamite, the result of which was five or six dozen fine fish on the surface within a minute.

This diabolical and unsportsman-like mode of fishing is, I am sorry to say, daily practised by these convent fathers. There was a tremendous scrimmage in the water after the dead fish, and by the time it was over the sun was sinking behind the trees. Moreover, heavy rain set in, causing us to seek such shelter as was obtainable. We followed the Chunchos into the jungle by tortuous paths for about a mile ere we came to a hut, but before being permitted to enter it, we were first led to witness their prowess as marksmen, the target being a banana tree at about 40 yards distant, which was soon bristling with arrows. Sufficiently impressed with this, we were allowed to enter a hut about 10 by 20 feet, into which we all (about 30 in number) were huddled for the night, and after drinking a little Liebig's extract tried to sleep, *without success*. We lay on the floor like sardines in a box, our hosts crowding on to a rule bench in front watching our every movement. The house was so narrow that my head lay right below the eaves which continued to drip all night. Sleep was an impossibility. The Chunchos drank their abominable masato and soon became uproarious, and evidently cracked their favourite jokes, judging from the screaming laughter. This was varied by an idiotic fan dance, and in other respects their deportment was even more objectionable. We are apt to imagine that man in a perfectly natural state must be a very delightful and interesting creature. On the contrary, my experience is, that no other animal is less lovable or more repulsive in its habits than a thoroughly untamed man or woman. These Chunchos or "Campas" are evidently the remnant of a very barbarous and low caste race of untamable savages, recognising no laws, and killing each other with as little compunction as we kill our rodents. On the night before we passed down the river, a woman and two children were tumbled off a raft and drowned. It seemed the standing joke of the day, and no one more enjoyed it than the woman's husband, who danced with fiendish glee the whole night through, encouraged by the screaming laughter of the native ladies. If loud laughter, by the way, be a healthy and happy sign, the Chunchos are to be envied; my experience of mankind however, is that he who laughs loudest and is most easily moved to tears is not the man to be most trusted.

I was not sorry to see the sun rise next morning,

and did not linger long over our early breakfast, which consisted of tea and Yuuca, the latter like badly boiled potatoes.

Once more on the river we were all alive with excitement. Several tributaries fall in; one, the "Ipuki," equal to the Don in volume, adds palpably to the depth and force of the Perene, upon which we are now carried at the rate of about five miles an hour. Denser and denser became the forest, now no longer relieved by patches of grassy land. Such perfect lands for coffee and cocoa cheered the heart of old planters, while such unheard-of varieties of orchids, ferns, gloxinia, begonias and caladiums, were enough to drive a botanist frantic.

The question here naturally arises, why has this rich country been allowed to remain from the creation to the present day, in a wild and desolate condition? A country capable of supplying many millions of inhabitants with not only the necessities of life, but all the luxuries the most fastidious appetites could desire. When we see so many less favoured countries crowded and cultivated to the utmost, it does seem strange to see this magnificent land left to a few Chunchos, who are really little better than the monkeys that grin on the branches above us. Practically it is *no man's land*, for it has never been taken possession of, the present scattered tribes recognising no laws, no government, no God.

In every other country we know, men have succeeded in subjecting the productive powers of nature to his sway and is there no hope that such will yet be the case with the valleys of the Amazon? Are men always to despair of utilising this marvellous vegetation, and be forever overwhelmed by the excessive bounties of nature? Surely the time has come, or will soon come, when this, the richest portion of the globe, will no longer be entirely left to nature and the few wandering tribes who are so utterly incapable of making any proper use of it.

We had landed for luncheon, under a far-spreading rubber tree, and so refreshing was the shade and inviting the scene, that we vainly would have pitched our camp there for the night, in order to thoroughly explore the locality; but our guides, who were fast becoming an insufferable nuisance, urged us onwards, stating that the cascades were still a long day's journey off and that we ought to push on for a few hours more, so as to reach them next night. So again we started, but had scarcely moved three hundred yards when I, still in the prow of the first balsa, began to feel we were gliding along rather faster than pleasant, and distinctly heard a not very distant roar like muffled thunder. All at once, it dawned upon us that we had reached uncomfortably near the rapids, and the greatest possible exertion was required to heave our rafts. I never jumped on the banks of a river with greater feeling of relief. We had now time to take a leisurely view of the rapids, though not more than four or five feet of a fall in any one place. A succession of these were sufficient to obstruct further navigation, though this only for a few miles, probably under ten. Our aneroids told us we were now 1,050 feet above sea level, and as the water has nearly 3,000 miles yet to run before reaching the Atlantic, the average fall is not great. We would now have naturally wished to work our way down to the Atlantic—by far the easiest and most natural outlet—but we were under orders to visit other tributaries of the Amazon 200 miles to the north, so had reluctantly to wend our way back. We slept that night rather comfortably under a tree, but before going to rest I shot a large snake which hung from a branch above us, and the only one we saw during our sojourn. Next morning we arose more refreshed than usual, explored the country a little, finding the vegetation now gradually assuming a low, country type, took some photos of the rapids, and then prepared to start on our return voyage. We found, however, that something like a mutiny was brewing in the camp. The priests declared that the rum was done, and that it was ridiculous to think that men could live in this country without drink. The king grumbled because the jam was finished, while the Chunchos struck work for no earthly reason at all.

(To be continued.)

Correspondence.

To the Editor.

THE TEA ESTIMATE FOR 1891—AND
WHAT MIGHT HAVE BEEN.

Upcountry, Dec. 10th, 1892.

DEAR SIR,—I see that the battle of the estimates has come round again. I consider that with normal conditions of the weather the *Observer's* estimate for the present season would have been fully recoured; and that with both normal conditions of weather and a continuance of the style of plucking of even a year ago, the estimate would have been considerably exceeded. Had the estimates of individual estates been published at the beginning of the season I fancy the total figures would have made all of us "sit up."—Yours truly,

AN OLD COFFEE STUMP.

CEYLON AND LIBERIAN COFFEE
PLANTATIONS.

Kegalla, Dec. 10 1892.

SIR,—Tea, as the staple product of Ceylon, has taken up the attention of the Ceylon public so much, that the other products hitherto called "minor" have attracted but little attention. Everything is to be done at the Columbian Exposition obviously to boom Ceylon tea. Ceylon cacao, cinchona and even coffee Arabica or the rising Liberian are thrown in the shade. There are two products, however which will need no expositions to help them, and these are cocoa and Liberian coffee. Some ridiculous articles appeared in your columns* by a writer who complained bitterly of his unfortunate experience in his cocoa plantation, and who expected that his wild vapourings would be endorsed by others. If there was much truth in his statements, cacao would have ceased to be a Ceylon product years ago. The exports have been increasing, and so has the price, and who would not now exchange a 400 acre tea totam for 100 acres of cacao. There were a great many wrong ideas about the cultivation of this product now fully exploded, viz., that it can only be grown "in pockets" amongst the hills and on flat and undulating land, &c. Cacao is seen now thriving exceedingly well even on what is called steep land, much in the same way as coconut trees have been successfully raised on hill sides. The only enemy is really the wind and even its ill-effect can easily be prevented by growing belts of trees early in a clearing. There is, however, plenty of land available where the wind does not play havoc and such parts of an estate exposed to winds need not be planted and it must be a singularly very bad plantation where the unsuited portions exceeds 20 per cent. of the average. It is difficult to make folks understand that you cannot "run up" a cacao plantation as you can a tea clearing. Coffee and tea are shrubs, and you can make a showy clearing in a few months, but cacao cultivation is as good as an orchard cultivation. In never so poor or rich soil, if the first steps of making good large holes, removing woody matters when filling the holes, to prevent attacks of termites, shading thoroughly, &c., &c., are carefully attended to, and the plants put down or even seeds at seasonable weather, success must follow

* In a contemporary's.—Ed. T.A.

and the percentage of deaths will be very small, and can be easily set right by a second repetition of the *proper* course. Any ordinary kangani will plant up a tea clearing, and stick in the plants "any way and anyhow" and the weather being favorable, you can feel comfortably assured that the plants are coming up, and view your tea field with your glasses from afar. Cacao planting is a different matter. *Personal*, and may I say close ocular inspection of almost every plant laid down, and that being selected and intelligent coolies is essential. Then only fifteen months of constant care is needed, shading, &c., the plant, and whether the shade trees are well up or not, the plant will be found needing no further attention, save that in poor soils only, after the second or third year, trenching and manuring will be needed and perhaps repeated every third or fourth year. A yield of 3 cwt. per acre is really *very ordinary*. Proper cultivation can raise it to 5 cwt., and with the old prices of R50 per cwt. and the small expenditure needed for upkeep, why should not this product be expected to be in a few years hence considered as the more lasting and more reliable and paying product than tea? The highest price is paid for this product in Europe, and, with little or no booming, has been going on to bring it into the large markets. The quantity shipped is not a fiftieth part of what those in the trade are ready to purchase (at perhaps even the former prices) before they cry "Hold! enough!"

As to Liberian coffee even at R8 per bushel and leaf-disease notwithstanding, there is a decent margin left as profit; but the average local price of R10 per bushel will rule for at least ten years hence, even if there were over 100,000 acres yielding this coffee. Unfortunately for this product, when first introduced prices were low, the yield was insufficient owing to too distant planting, viz., 12 by 12 ft. and 8 by 8, &c. These distances are only good in *extremely* rich soils, extents of 10 to 20 acres of which are hard to find.

In the coming year the Ceylon public will find that more attention is being paid to these products hitherto unnecessarily and thoughtlessly neglected for tea, the all-absorbing topic now. Arabian coffee at R17 a bushel now, and Liberian coffee at R12 is sure proof of a good demand for these products that it will take years to satisfy, and those first in the field can expect something more than ordinary profits.—I am, &c.,

OLD HAND.

TEA BUYERS IN MINCING LANE.

Colombo, Dec. 13, 1892.

SIR,—I am requested by the Secretary of the Ceylon Association in London to hand you the enclosed Correspondence for publication and I am to ask if you are willing to give your authority for the story told by you of the "Tea Buyers in Mincing Lane."—I am yours faithfully,

O. E. H. SYMONS, Secretary.

[The illness of our senior who was responsible editor of the *Observer* in October last, makes a difficulty in regard to the identification of the informant as his name cannot be recalled by our predecessor here. He was a gentleman, we are told, who had then recently arrived in the Colony and who on telling his experience to some one in the Fort, was advised to come to the *Observer* Office and relate it. Pending the attempt still being made to get at the name through the shipping list, and Mr. A. M. Ferguson's recovery,—in the hope that he may recall it—we can only request the gentleman

concerned to communicate with us at once in order that the necessary information, or correction of his story may be afforded. We very much regret if injustice has been done to the Brokers, and we must have something more to say soon.—E.D. T.A.]

4, Mincing Lane, E. C. 21st Nov. 1892.

Dear Sirs,—My attention has been called to a paragraph in the *Ceylon Observer* of 28th ult. headed "Tea Buyers in Mincing Lane—A Queer Story," the gist of which is that at the tea sales the brokers are accustomed to combine to keep prices down. As the truth of the story told is vouched for as being "beyond question" by the editor of the *Observer*, I shall be glad to have your views of the matter so that I may send it for publication in that newspaper.—I am, yours faithfully, (Signed) W. MARTIN LEAKE, Secretary.

Messrs. W. J. & H. Thompson, Messrs. Gow, Wilson & Stanton; Messrs. Geo. White & Co.; Messrs. Wilson Smithett & Co.

31 Fenchurch Street, E. C., 23rd Nov. 1892.

Wm. Martin Leake, Esq. Secretary the Ceylon Association in London, 4, Mincing Lane, E. C.

Dear Sir,—In reply to your favour of yesterday we beg to say that we had noticed the paragraph in the *Ceylon Observer* of 28th ult. to which you draw our attention, but never heard of the transaction referred to before.

Anyone conversant with the circumstances under which the Ceylon tea auctions are conducted in London must be aware that competition among buyers is far too keen to admit of anything of the kind being general and we think the inference which the inspirer of the paragraph intended should be drawn from it is entirely uncalled for. In our opinion the heading "A Queer Story" is very appropriate!!—We are, dear sir, yours faithfully (Signed) Geo. WHITE & Co.

38, Mincing Lane, E. C.

W. M. Leake, Esq.—Dear Sir,—Without fuller details it is impossible to comment upon the "very queer story" you allude to. We have no hesitation in saying that no combination exists among brokers to keep down the prices, and that the huying broker who would let anyone else have a tea under the limit he had for it is unknown to yours faithfully, (Sgd.) W. J. & H. THOMPSON.

P.S.—Was the buying broker in the room when it was sold? Was it a small lot of pekoe dust?

13, Rood Lane, E. C. 23rd Nov.

W. Martin Leake Esq., London E. C.

Dear Sir,—We are in due receipt of your favour dated 21st inst. and in reply we beg to state that we read the paragraph to which you allude in the *Ceylon Observer* with some surprise, as we are ourselves unable to place any credence whatever upon such an extraordinary statement. You are aware that it is distinctly to the interest of the "first hand" or selling brokers to keep prices up and not down, and we do not think that they would be at all likely to combine together, to do that which is manifestly wrong and against their own interest.—We are, dear sir, yours faithfully,

(Sgd.) GOW, WILSON & STANTON.

41, Mincing Lane, E. C., 23rd Nov. 1892.

W. Martin Leake, Esq., the Ceylon Association in London.

Dear Sir,—With regard to your enquiry as to the truth of the story stated as "beyond question" in the *Ceylon Observer* of the 28th ult., we can scarcely think that their readers can regard it as serious we should characterize it as "beyond belief."

It would obviously be very short-sighted policy on the part of selling brokers to combine to keep down prices of tea, as besides destroying their reputation for making best possible sales they would be reducing their brokers (in this case to the extent of some 50 per cent) for it is not suggested, that the broker benefitted by the 4d per lb,

advance so quickly offered, which was duly secured by the fortunate buyer of the tea, whose extraordinary cheapness had somehow or other escaped the attention of a room full of dealers all, of course eager to pick up such bargains! However, seeing that this very "queer story" is anonymously told through the inevitable friend, we think brokers are entitled to demand that the author of it should emerge from obscurity and give us full particulars of this onerous transaction, with date and names of the parties involved in it; and explanation would then, no doubt, be speedily forthcoming which would prove satisfactory to everybody.

In the meantime we are constrained to think that the story has got considerably mixed in its travels.—We are, dear sir, yours faithfully,

(Signed) WILSON SMITHETT & Co.

CEYLON TEA IN NEW SOUTH WALES AND AN OLD PLANTER ON EXISTENCE THERE.

DEAR SIR,—Your staple has had such an extraordinary advance that I am afraid we shall have to do without it for a time, though we are very glad to see the rise both for your sakes and our own. I am getting very tired of passing contracts for half our business—for teas at 5d to 6d per lb. I can assure you we much prefer them at 9d to 10d: it makes a big difference in one's returns. Your improvement is already helping India and China, but they will keep you out of this market until you lose a bit, which you can well afford to do. We cannot sell ordinary Ceylon Pekoe Fouchong at 8d to 8½d, but by all means make hay as fast as you can while London will keep you going. You will do better in the long run with 300 lb. an acre at 10d than 400 or 450 lb. at 8d.

I always get a pleasant half-hour reading the Ceylon papers when the mail arrives: what a wonderful little place it is, and what an interest everyone in it takes in its welfare; it ought to be called "The Pivot of the World." If people here exhibited similar proportionate energy and patriotism America wouldn't be in it.

Propos of the foregoing the following anecdote is worth repeating. I was dining one evening at The Bristol during my visit to Ceylon in 1890 with a small party, mostly old acquaintances. The conversation led on to the relative merits of Ceylon and Australia, and one member of the party (a regular Ceylon patriot) said to me "Look here, Rowbotham, wouldn't you be very glad to get back to Ceylon if you could get a decent billet or saw your way to making a decent living?" With the idea of drawing him a little more I replied that for every hundred a year I could earn in Sydney I should require a thousand in Ceylon. For half a minute he was speechless at such an awful insult to his beloved land, and then roared out: "Well, you must be making d—d little in Sydney then." Nevertheless I should like to be dining with him again at the same place tonight. Still there are points which make Sydney not the worst place in the world to live. The community in general undoubtedly take life easier than any other collection of the Anglo-Saxon race, and get more ease and pleasure out of existence than any other nationality. You can pick out the Sydney native or long-standing resident anywhere by his self-possession and *laissez-faire* manner, and yet he is very much "all there" if you wish to call his mental powers into operation.

At the present moment I am sitting at a large bay window 150 feet above the sea level—(although within a month of midsummer it is too chilly to sit on the verandah); out of this window I can see at anchor without turning my head nine ships of the Australian Naval Squadron, the P. & O.

'Arcadia' and seven other large steamers, more than a dozen large sailing vessels, and moving about hundreds of yachts, half-decks, canvass dingies and row-boats (it's Sunday afternoon). All the vessels at anchor are within ten minutes pull from my own boat-house. Beyond these is the City of Sydney itself and some of its prettiest suburbs. Not a bad lookout for a poor man and an invalid. I am looking on instead of assisting in this panorama, because two months ago I slipped on that curse of "Fin de Siècle" houses—"a polished floor" smashed up my legs and ankles, and have been on my back ever since. It is this misfortune, and the singing to banjo accompaniment of a pretty sister-in-law that you must blame for this rambling epistle. I started to write a few business lines only, and as I have many other letters to get through I must now wish you a pleasant holiday season and subscribe myself, Faithfully Yours,

H. M. ROWBOTHAM.

VARIOUS NOTES.

NEW PRODUCTS: THE CULTIVATION OF LIBERIAN COFFEE EXTENDING.—We are delighted to learn that Liberian coffee is being planted in more than one district on a liberal scale. Besides the 20 acres occupied with this product on Gikiyankande, Kalutara, we learn that the new proprietors of Arampola estate, Kurunegala district (Messrs. Harper and Davidson) have planted up no less than 100 acres with Liberian coffee. We trust to hear of this example being freely followed elsewhere during the next South-west monsoon. Nor should the extension of cacao be overlooked.

PLANTING IN PEERMAAD.—The operations of manuring and pruning are now coming in for both coffee and tea, and whilst everyone is agreed as to the necessity of doing both to the former yearly, there is still a good deal of variety of opinion as to the methods to be pursued as to tea. For some men doubt the advisability of manuring at all, their theory being, that though the leaf yield is much larger, the quality is correspondingly reduced; many again, differ very much as to the kind of manure, and method of application, whilst as to pruning, though it is admitted that it must be done some time, the greatest difference exists as to severity or lightness required, and the proper season. My own idea is that it is generally impossible to lay down any hard and fast rule, and that what suits a free soil and Southern face at 3,000 feet elevation, may be utterly unfit for a Northern one at 4,000 feet. But, on these operations I hope in some future article to comment more fully.—*M. Times*, Dec. 31.

NOTES FROM PEERMAAD, Dec. 25.—We have been nearly blown away to the Western seas during the last few weeks. A cold, cutting North-East raging at night, and in the early mornings, curling up the tea leaves, as effectually as the finest improved roller could do, but without waiting for them to be picked, nipping off the young shoots, blowing tons of thatch off roofs, and making itself generally as objectionable (only with more damage), as a does in our Northern homes. It has unluckily been unaccompanied by rain, and indeed in the Madurit district and parts round there, something very nearly approaching famine prices have arrived during the last month. Rice has doubled itself in price, and scarcity is very apparent, by the numbers of Tamil coolies who are flocking up daily without advance. Scarcely an estate employing Tamil labour, that is not overstocked now. True we are getting sight of rainy weather now; but this will be too late for the rice, though it may benefit other crops, and will be invaluable for our tea flushes if rain falls. In the last six weeks barely one inch has been registered.—*Madras Times*, Dec. 31.

WOOD FOR TEA BOXES.

4, Mincing Lane, London, E. C., 25th Nov. 1892.
A. Philip, Esq. Secretary, Planters' Association, Kandy, Ceylon.

Dear Sir,—I have the pleasure to forward for the information of your Association copy of a letter from the London Wholesale Tea dealer Association on the subject of the wood used in Ceylon for packing Tea.—I am, yours faithfully, Wm. MARTIN LEAKE, Secretary, London Wholesale Tea Dealers' Association, 4, Fenchurch Street, E. C. Nov. 21st, 1892.

W. MARTIN LEAKE, Esq., Secretary, The Ceylon Association, 4, Mincing Lane, E. C. Dear Sir,—The attention of my Committee has been drawn to the objectionable flavour in some cases imparted to Ceylon teas by the wood used for the packages, and I am informed that in particular gardens, saw mills are frequently part of the plant, and when the wood used is in too green a state, the juices produce in contact with the lead, an acid, which perforates through minute apertures into the tea itself and creates what is commonly known as a "cheesiness" in the flavour.

May I ask you to be good enough to bring this subject under the notice of tea growers with the view of their recognising the necessity of only using wood which is properly seasoned, and this request I venture to make, both in the interest of the importer as well as the buyer.—I am, dear sir, yours faithfully,
(Signed) R. SEDGWICK.

CEYLON TEA ON THE CONTINENT OF EUROPE.

The Secretary of the Planters' Association sends us for publication the following letters and annexure regarding Ceylon tea in Russia, Switzerland and Austria:—

4, Mincing Lane, London, E. C., 18th Nov. 1892.
A. Philip, Esq., Secretary Planters' Association,

Kandy.

Dear Sir,—I have today received your letter of 29th ult., a copy of which shall be forwarded to Messrs. Watson & Farr, as requested.

I have the pleasure to enclose a copy of letter just received from Messrs. Wilson, Smithett & Co. on the subject of the lining of tea chests for export to Russia.

I am sending you a sample of the lining required.—I am, yours faithfully, Wm. MARTIN LEAKE, Secretary.

Copy.

41, Mincing Lane, London, E. C., Nov. 18th 1892.
W. Martin Leake, Esq., The Ceylon Association in London.

Dear Sir,—In the Ceylon papers received this week we notice a letter from Mr. Street with reference to the Continental demand that teas should be packed with a lining of paper between the lead and the leaf. As it seems desirable that further particulars should be furnished, we think it may be advisable to acquaint planters through the medium of their Association in Ceylon with the causes which have led to this request being made.

Some years ago the authorities both in Russia and Germany had their attention attracted to a case of lead poisoning in Odessa, which was alleged to be traceable to tea taken from an ordinary lead lined chest; probably in this particular instance the tea was sea damaged or tainted by the action of "cheesy" wood on the lead which has been ascertained to produce both acetate of lead (sugar of lead) and carbonate of lead (white lead); but whether the case of poisoning was really due to tea or not it made some stir at the time, and the zeal of the sanitary authorities was aroused without any definite ukase being enforced; representations were, however, made in China as to the desirability of an inner lining of paper, and for some time past China teas have been shipped with paper on both sides of the lead as per sample, which we send you herewith. Within the past few

months, owing no doubt to the development of the trade done in Ceylon and Indian teas and perhaps to the consequent jealousy of the large importers of China tea in Moscow, the attention of the Russian authorities has again been directed to the matter, and the exclusion of all tea packed in simple lead-lined chests will be enforced in May next. All the firms through whom we send samples to Russia are of opinion that it would be highly desirable if Ceylon planters could manage to pack their teas in the manner indicated, as this stringent Customs regulation will otherwise entail repacking with paper in London before shipping. We may add that in the case of teas which are habitually bulked here, there would be no need to insert the paper, as after bulking in London warehouses the lead casing is always lined with paper before the packages are refilled. Many growers may not, perhaps, consider it worth while to incur any extra expense in order to satisfy a Continental Customs regulation which may be complied with by re-packing here; but, on the other hand, we think it would be to the advantage of those high-country estates whose teas so often sell for Russian account if they could fall in with the suggestion; anyhow with the full facts before them planters will be able to decide for themselves what course to pursue.—We are, dear sir, yours faithfully,

(Signed) WILSON, SMITHETT & Co.

N.B.—The difficulty could not be overcome by using metal chests, as there is a duty on these on the Continent, and teas thus packed have, as it is, to be repacked before they are allowed to pass the Customs.

Winterthur, Sept. 30th, 1892.

To the Secretary of the Planters' Association of Ceylon, Kandy.

Dear Sir,—I beg leave to refer to my letter of June 10th, by which I took the liberty of asking you to refund me £23 1s 7d for duty paid on 500 pounds of tea granted by you as samples for my friend, Mr. Weiner of Vienna.

Although I suppose that Mr. Rogivue will inform you of all that is taking place in Russia with reference to tea, I nevertheless send you herewith a translation of an information contained lately in an Austrian newspaper, which may be of some interest for you.—Believe me, dear sir, yours truly,

CHARLES OSWALD.

It is intended to establish a *Tea Museum in St. Petersburg*, which will contain everything referring to the culture and commerce of tea, beginning with tea plants and ending with the ready produce in the different kinds of packing. There will be also a separate department containing all kinds of vessels and other things used for the preparation of tea, such as Samowars in the various shapes, tea pots, tea sieves, etc. The purpose of the museum is to give a complete view of the tea industry in its entire extension. The greatest part of the objects to be exhibited is already on the way from Kiachta to St. Petersburg.

Winterthur, October 14th, 1892.

To the Secretary of the Planters' Association of Ceylon, Kandy.

Dear Sir,—I last had the pleasure of writing to you on Sept. 30th, and received on the 9th instant your letter of Sept. 15th, covering your remittance of £23 1s 7d on demand on London, against my payment of the Austrian import duty on the 500lb tea granted kindly by your committee as samples. I am much obliged to you for this payment.

The sale of tea in Switzerland and Austria progresses favourably. Later on I intend giving you a more explicit report.—I am, dear sir, yours truly,

CHARLES OSWALD.

CEYLON TEA IN GERMANY.

Secretary's Office, No. 42, King Street, Kandy, December 13th, 1892.

Sir,—At the request of the committee, I enclos

for publication copy letter regarding Ceylon Tea in Germany.—I am, &c., A. PHILIP, Secretary to the Planters' Association of Ceylon.

The Secretary of the Planters' Association of Ceylon, Kandy.

Dear Sir,—We beg to acknowledge with thanks the receipt of the shipment of 2,500 lb. of tea per s.s. "Hobenzollern", being one half of the grant of 5,000 lb. made to our Mr. Schrader by the standing committee of the Ceylon Tea Fund, and are now expecting the second 2,500 lb. to arrive in a few days per s.s. "Salier" at Bremen.

Owing to different circumstances we have not been able to make a start with the tea business before this, but intend to commence operations within the next few days. We have taken an office with stores in the business centre of Berlin, and our preparations being nearly complete, we shall now try what can be done with Ceylon tea here.

We have made use of our leisure to get all the information obtainable about and have come to the conclusion that the Ceylon produce will stand a good chance in Germany. It must be admitted, that Germany so far is not a tea drinking country, but tea is gaining ground steadily and becoming more popular year by year. It is in the Northern parts, on the coasts of the German Sea and the Baltic, that most of the teas now imported into Germany are consumed, and it is there where we shall in the first time have to look for a market. In Middle and Southern Germany tea is only being used in winter time, mostly at supper and it is an exception, if tea is taken at the breakfast table. However, much progress has been made of late and it is the medical profession, who in first place advocate the use of tea. We have, therefore, made up our mind to supply this profession liberally with samples, from the grant, and are confident that they will recommend our teas. The consumption of tea in Germany may roughly be estimated at 2 million kilos, equal to 4½ millions English pounds, or about 1-12th of a pound per head of population. The Berlin consumption amounts to 125,000 kilos a year, or about 1-6th of a pound per head. To our opinion the small demand for tea is a consequence of the high prices charged by retailers, and of the poor quality generally sold by them. Whoever can afford it buys so-called "Russian Tea", viz., tea coming from Russia, whether it is alleged to be sent by the overland route from China, it being supposed that the transport overland gives it additional flavor. Big prices are paid for these Russian or Caravan teas. Who requires cheaper stuff buys so-called China tea, which is in fact a blend of China with Indian or Ceylon tea. These are sold to the retailers at from 1m. to 1-75 m. respectively to m. 2. utmost and resold by them at from m. 2 to m. 4. the so-called very finest qualities at m. 5. The grocers sell mostly in packets of 50 or 100 grammes and they have consequently to make a big profit; in fact we know of instances, where a retailer bought at m. 1.80 and sold at m. 4. We had half an intention at first, to take some rooms in the principal thoroughfares for the sale of tea in packets and for free distribution of tea in cup, but on further inquiry we had to abandon the idea, as it would have made all the retailers our enemies; and as they are after all the chief buyers, we have to count with them. The first importance for Germany is that we get leafy teas; Broken Pekoe for instance will not be liked for a long time to come, as people will always believe it mixed up with dust. The conclusion we have come to is that in Germany a fully favored, but not too pungent tea of leafy character, and at a price, which can compete with China teas, will be the most asked for; with such teas we are confident to do a good business and to be able to push the Ceylon produce in Germany. We shall report more fully after we have had some practical tests.

Samples of our packets, showcards, pamphlets, etc., will be sent you by an early opportunity as the showcards are too big to be sent by post; and we therefore prefer to wait until everything is complete to be sent by parcel-post. The packets we believe will be a success, as they are very neatly made and are showy, without being gaudy. The showcards we trust will also be much liked; they are of artistic appearance and especially the larger kind quite a novelty. Our pamphlet which is now being printed, will contain several illustrations, showing the preparation of tea; we have spared no expense or trouble to make everything attractive in order to make the Ceylon tea known.

We beg to add, that we had several samples of Ceylon tea analyzed by Government authorities with the following result:—

	Ceylon Tea		
	Orange Pekoe.	Assam Tea.	China Tea
Moisture ...	6.10	5.81	8.37
Total extracts	42.50	38.40	34.38
Tannin ...	17.2	13.19	10.14
Salts ...	5.	5.6	5.7
Salts soluble	3.6	3.5	3.
Salts insoluble	1.4	2.1	2.7
Theine ...	2.4	2.4	2.7

As we were told by the analyst, other Berlin firms have had Ceylon tea analysed several times already, with about the same result.

We still beg to bring the following matter before the standing committee of the Ceylon Tea Fund:—

We have had to pay for duty on the 2,500 lb. ex s.s. "Hohensollern" (half of the grant to our Mr. Schrader) the sum of £54 3 10 (m. 1104.90 at the exchange of m. 20.40 pr. £) and shall have to pay the same amount on the second 2,500 lb. pr. s.s. "Salier." As we have according to the conditions of the grant, to give away these 5,000 lb. as samples, we don't think we can fairly be expected to pay the duty for same. We may add that our Mr. Schrader when he first applied for a grant, was asked to state, what duty tea has to pay in Germany, which certainly conveyed the intention of the standing committee to refund the duty. We believe this to be a reasonable contention, and trust the committee will kindly authorize the payment of the duty. We are quite prepared to take the equivalent in tea against it. — We remain, &c.,

KRONING & SCHRADER.

Berlin, O, October 8th, 1892.

UVA PLANTING REPORT.

WEATHER—COFFEE—TEA—CINCHONA.

Badulla, Dec. 11, 1892.

THE WEATHER is dull and misty with a great deal of wind. The monsoon proper has disappeared, and the days are cold; except on the eastern slopes of Namunakula there is no sun, and we are having no heavy rains in the afternoons at all. There is no doubt lots more rain to come and Christmas and earlier portions of January will probably be very wet, as they so often are. Everyone is busy finishing off clearings, planting grevillea and supplying; and a considerable acreage is going into tea this year, though not so much as in the past few seasons.

COFFEE PICKINGS are coming in well, and autumn crop estimates will generally be secured: while the sample is a good one and prices magnificent. Spring crops, on the contrary, are woefully short and bug—now rampant in the higher portions of the district—will reduce them still more. Poor old coffee is having a hard struggle just now and bug certainly looks as if it was going to get the upper hand at

last, on many fine fields. That coffee may pull through this attack as it has done through others, is the wish of everyone.

TEA on the contrary is looking particularly well; and, for the time of year, flushing excellently; far better than usual. This product is really doing wonderfully well up here; I hear of some very extraordinary yields, notably two hundred and fifty pounds made tea per acre in the past three months. This, too, over a considerable acreage. I can't give you any such figures from my own experience, worse luck. That with the splendid prices Uva teas are now fetching, those with estates in full bearing must be having a real good time. As far as I hear now estimates all promise to be secured.

CINCHONA has practically disappeared from the district, though a few of the higher estates have some quantity left.

THE NEW ROAD to be cut this season in the district in conjunction with the opening of the Railway to Haputale will mark a new era in the province. They will really make a great change, not only to the estates but also to the villagers; and life will be rendered pleasanter to all residents in these parts, while proprietors will at last be able to reap some profits from land they have opened in tea. There will be no pleasanter residential district in the island, than Badulla under the new régime; and it always did and always will hold its own in productiveness with the rest.

RICE is dear, and supplies somewhat doubtful; an early opening of the railway is much looked forward to.

IMPROVED TEA MACHINERY:—SOUTAR'S
PATENT ROLL-BREAKER;
A NEW SIFTER WANTED.

We omitted the other day in referring to Great Western Tea Factory to note the good work we saw done by "Soutar's Patent Roll Breaker." It appeared to be a most useful machine and the general appreciation in which it is held is shown by their being turned out at the Hatton Works just now, at the rate of three or four a day.

As regards an improved Sifter, which some planters consider a want, notwithstanding existing patents,—it is reported that the busily inventive brain of Mr. Jackson is at present engaged in perfecting one with a circular motion, which it is expected will come as near the perfect article as anything can.

TEA SALES IN MINCING LANE: "THE
QUEER STORY."

We have now heard from the gentleman who related the "queer story" in this office which was reproduced in the *Observer* of Oct. 28th last, and we find him to be above all suspicion of having invented the tale, or tampered with the "facts" so far as they go. He makes one correction, however, on the printed version, in stating that the tea was bought at 8d not 7d. From his letter to us, we extract as follows:—

"I see that what I told you, and what you subsequently printed, about the sale of one particular lot of tea in Mincing Lane has caused quite a little storm in the London tea market. Mr. Shand does not appear to have understood what I said, for he writes:—'How anyone who has ever been at the public sales could imagine that a stranger could go in and without trouble turn 7d (I said 8d) into 11d passes the wit of man.' Now I told you that a informant, so far from being a stranger, was a tea dealer, having an office and staff of clerks, within half a mile of the saleroom,—that he is a regular attendant

at the tea sales,—that the tea he bought in at 81 (not 7d) was his own tea grown on one of his own estates in Ceylon, and that on his telling the man who stood next to him that the lot had been knocked down to him, that person offered him first 9s, then 10s and finally 11s a pound for tea which while under the auctioneer's hands he had declined or at least had failed to bid more than 8d."

We have also heard from London by a recent mail to the effect that those concerned do not allege, that the circumstances stated would be impossible of occurrence, though they deem it to be extremely unlikely that they can have been altogether correctly reported. But, on the other hand, they hold that, supposing the facts to be as stated, these could not justify the conclusion that there exists any combination among the brokers to keep down prices at the sales. Even if it might pay buying brokers to enter into any such combination, it would be distinctly adverse to the interests of the selling brokers to join in it. Now, on this point of "combination" we, having lately returned from Mincing Lane, can give the fullest assurance that from all we saw and learned of the mode in which business is transacted, such a suspicion can at once be dispelled. At no sales in the world we suppose are there fiercer competition and therefore less chance of combination effecting any result than in Mincing Lane. Of course the particular Broking Firms who have been addressed by Mr. Leake and whose letters we published the other day, can never have had been thought of in connection with the "queer story." What may have happened may, we suppose, be indicated by what we learned many years ago from an Anglo-German coffee buyer whose acquaintances we made in Eastcheap. He had never seen Ceylon nor a Ceylon Directory, but he was accustomed to buy in the Lane a good deal of our coffee for the Continent and the way he ran over marks and names of estates classifying the coffee very fairly (according to altitude) astonished us. Well, he told us that, occasionally at the end of a very extensive and prolonged sale (alas! over 15 years ago) when the big English buyers had got all they wanted, if there were small lots (2 or 3 casks) at the end of the catalogue, they were sometimes sold distinctly below value from want of competition. But this was a rare occurrence; and on the average, our friend added, nowhere could producers be more certain of a sale according to value than in Mincing Lane coffee sales. Well, we believe the same is true of tea; but there may be an exceptional case now and then—we should want to know the size of the break and the time of day at which the tea was offered and whether "the broker" (a buying broker we suppose) who cried out, was the only one, or one of two or three stragglers in the room left at the end of a long afternoon's sale,—before we attached importance to the experience. We are giving, as we say, the impressions we have gathered after being back and fore in "the Lane" at intervals during twelve months. During this time we could not but form the highest opinion of the mode in which business was done considering the enormous quantities of produce passed through the salerooms. Of course no system can be perfect: and just as a cask or two of coffee now and then dropped through below value on big sale-days, so may it be with a small break of tea, for we cannot believe that the lot bought at 8d and for which 11s was refused, could be otherwise and one too sold at the close of the day? On this point we will now ask our informant (in whose *bona fides* we have perfect confidence—but he is not a tea-planter himself) to communicate with the gentle-

man whose experience he related, to ask if he has any objection to further inquiry such as is indicated as to size of break and time and date of sale, and further to the giving of names? Of course it rests now with the London tea estate owner to decide; but as to "combination" among brokers to keep down tea prices, our personal experience of the Lane and the sale-rooms shows it to be absolutely impossible.

A "VINTAGE YEAR" FOR TEA.

(To the Editor of the *Leeds Express*.)

Sir,—As "Tea" interests everybody, we venture to submit the following, as possibly worthy of the attention of your numerous readers.

About half of this season's crop having now arrived, and having been seen and sampled, we are happy to assure the tea-loving British public that 1892-93 is fairly entitled to rank as a "Vintage Year" for Tea—a season of exceptional quality. The crops gathered in the fertile valleys of Assam and especially on the rich lands bordering on the Bramapootra River are of marked merit and strength. This is mainly due to the ample rainfall but moderate heat of last summer.

Such propitious weather induces the tea-bush to grow vigorously, but not rankly. Its medium-sized leaf contains less water and more "sap," meaning, when dried, exceptional strength and fragrance. In a season of temperate warmth, too, like the present, the skilled picker plucks mainly the richer tip and the ends of the leaves, leaving the lower halves on the plant to protect its coming buds from being unduly checked by possible cold.

The yield of '92 is consequently smaller than was estimated before the growth matured, and, as a rule, a lesser crop is of finer quality than a larger. The Indian teas which have hitherto been placed upon the market display the greyish leaf with bright yellow tip which experts know to be characteristic of a season such as this.

An excessively wet season unduly stimulates the "flushing" of the plant, producing a somewhat rank foliage, drying ultimately into a Tea of a weak, watery, "sapless" type, with characteristically black leaf and yellowish-white "tip." In an excessively dry year, on the other hand, the plant is very shy of "flushing"; and owing to the scanty yield of the older bushes planters are reduced to stripping the younger plants to excess. The expert at once identifies a dry-season's Tea by its brown-red tinge and bright-yellow tips, yielding, on infusion, a liquor of clear ruby red.

Of the vast bulk of more than two hundred million pounds of Tea consumed in the United Kingdom during the current year more than two-thirds come from our own possessions in the East, from India and Ceylon, while less than a sixth is drawn from China. Only a generation ago the Celestial Empire sent us all our Tea. Even at this reduced rate, the Tea tax produced, last year, the stupendous total of three and a half million pounds sterling.

Owing to the qualities being finer and the crops smaller than anticipated at the beginning of the season, Teas, especially the kinds preferred by the masses, have suddenly and considerably advanced in price during the last three months. On the Mincing Lane market they are now fetching nearly twenty-five per cent. more money than they could have been bought at in August last.

Thanking you for permitting us to occupy so much of your valuable space with these notes,—We are, Sir, Yours faithfully, BROOKE, BOND & CO., LIMITED.

November 21st, 1892.

CEYLON TEA IN THE LONDON MARKET: WHAT THE REPORTS SAY.

The following is the cream of a number of Reports by a recent mail on Ceylon tea;—
Geo. White & Co. from 25th Nov. to 1st Dec

On the whole, prices were well maintained, although Broken Pekoes were irregular, and occasionally easier. Considering the small sales, more breaks than usual were withdrawn, owing to low offers, this being especially the case with Colombo-bought invoices.

Ewart, Maccaughy & Co., London, Dec. 1st.

The absence of tip in the Broken Pekoes, too, was very much against quotations, even the finest liquoring parcels, with few exceptions, being very wanting in this respect. The continued shrinkage in the qualities offered naturally led most operators to look for an increasingly strong market. This, however, has not been the case, and on the last few days of the month the enquiry was very dull for everything except tea for price, and the market closed flat.

I. A. Rucker & Bencraft, Dec. 1st.

Fine broken pekoes from 1s 1d to 1s 4d are irregular, and so very cheap in comparison with leaf kinds below 1s that they are sure to have their turn. So far they have not advanced in anything like a fair proportion, and we should say are by far the best value of any tea in the market.

Wm. Jas. & Hy. Thompson, Dec. 1st.

CEYLON.—In spite of continued very moderate supplies at auction, the tendency of prices has been to droop, following the course of the Indian market: Broken pekoes over 1s per lb., showing the greatest reduction. Dealers complain that the country trade has been checked by recent rates, and that the amount of business is exceedingly limited; however, the month closed with rather more firmness, and an improved demand in tea for price. The average is now about 10³d per lb. Telegraphic advices from Colombo place the export at 5,360,000 lb. for Nov. against 4,436,000 lb. last year, which is about the increase that was looked for. Deliveries in Nov. were 5,500,000 lb., against 4,788,000 lb. last year.

Stenning, Iuskipp & Co., Dec. 1st.

The quantities at auction have been very moderate but have met with little animation in the biddings, until a day or two ago, when the low range of prices caused more attention and values became steadier. The quality generally is without improvement, and really fine Invoices have been scarce.

VARIOUS NOTES.

A NEW ANESTHETIC.—It is stated that a new anæsthetic has been discovered by Professor Von Mering, Director of the Medical and Polytechnic College in Halle, which he has named Pentol. This new compound is very volatile, combustible and has been found to contain five atoms of carbon, whence its name. It is administered in the same way as chloroform, taking effect in about three minutes after administration, but possesses as its most important characteristic freedom from any deleterious after effects. It is especially suited for use in small operations, and for producing unconsciousness during the extraction of teeth.—*Chemical Trade Journal*.

COLONIZING AND PLANTING IN PERU.—The Peruvian Corporation held its annual meeting on Dec. 15th, 1892, Sir Alfred Dent in the chair. One sentence of his speech alone refers to the colonizing-planting experiment which follows on the exploration and reports of Messrs. Ross, Sinclair and Clarke:—
After some detailed remarks respecting the various lines of railway, the chairman spoke in encouraging terms of the expedition of colonists, under the charge of Mr. Mackenzie, which had reached the lands of the corporation on the banks of the Perené river. It was confidently hoped that Mr. Mackenzie would be able to make the colony a success. The dispute with Messrs. Antony Gibbs about the quality and condition in which some of the guano had arrived was now forming the subject of arbitration, and they had little doubt that an amicable settlement would be arrived at. Matters in connexion with the Cerro de Pasco concession remained *in statu quo*, but negotiations had been initiated with a view to placing it on a footing beneficial to both the Peruvian Government and the corporation.

KAPOK or TREE-COTTON, formerly a despised export article in Java, now comes into greater prominence there since leaf disease has checked coffee cultivation. Lack of suitable means to clean the fibre has hitherto stood in the way of the industry advancing, but this obstacle is said to be now almost overcome by the introduction of newly invented machinery for the purpose utilised in East Java.—*Straits Times*, Dec. 6.

TOMATO FRITTERS.—Pare six ripe tomatoes of good size and set them near the ice to chill. Put into a bowl half a pint of flour mixed with one teaspoonful of baking powder, one teaspoonful of sugar and half a teaspoonful of salt. Beat the yolks of two eggs well and add a gill of milk to them. Stir this into the dry mixture. Add two tablespoonfuls on salad oil or melted butter, and set this mixture away until the time comes to cook the fritters. Cut the tomatoes into slices about half an inch thick and cut these slices into four parts. Season with a little pepper and one teaspoonful of salt. Beat the white of the eggs to a stiff froth and stir them into the batter. Dip the slices of tomato, one at a time, into the batter, and fry in hot fat until brown—which will be in about three minutes. On lifting them out, drain on brown paper. Serve at once on hot plates.—*American Grocer*.

CEYLON MANUAL OF CHEMICAL ANALYSES:

A HANDBOOK OF ANALYSES CONNECTED WITH THE INDUSTRIES AND PUBLIC HEALTH OF CEYLON FOR PLANTERS, COMMERCIAL MEN, AGRICULTURAL STUDENTS, AND MEMBERS OF LOCAL BOARDS.
By M. COCHRAN, M.A., F.C.S.

(Continued from page 444.)
COFFEE AND TEA SOILS.

GIVE four pretty complete analyses of soils from contiguous estates in the Dolosbage district of Ceylon. These formerly produced good crops of coffee, and now yield satisfactory returns as tea soils.

These soils were subjected to a physical as well as to a chemical examination. The specific gravities varied from 2.25 to 2.64. The specific gravity was highest when the proportion of gravel was greatest.

The apparent specific gravity or relative weight of the soil, *i.e.*, the ratio which the weight of a given volume of the soil, including the interstitial air, bears to the same volume of water, was not determined. Such a determination, however, is of use for calculating the weight of a soil per acre for any specified depth.

The soil, as a whole, is seldom submitted to chemical analyses, only the finer portion of it being analysed, and the amount of available plant food is usually calculated on a basis of 1,000 tons per acre to a depth of nine inches. Thus, 1 per cent in an analysis is equivalent to 10 tons per acre, and 1 per cent to 1 ton per acre.

Analyses of Dolosbage Soils.

Physical Examination.	No. 1.	No. 2.	No. 3.	No. 4.
Specific gravity	2.64 per ct.	2.43 per ct.	2.25 per ct.	2.37 per ct.

	100.000	100.000	100.000	100.000
* Containing Nitrogen	.167	.141	.140	.192

The moisture in the air-dried samples of the different soils varied considerably. It was highest in No. 3, in which the soil was in the finest state of division, and which had the lowest specific gravity. It was next highest in No. 4, which was also second lowest in specific gravity, and in the second finest state of division. No. 1, although of higher specific gravity, and in a coarser state of division, had more moisture than No. 2; but No. 1 was richest of all in alumina (the base of clay) and its insoluble silicates were lowest.

The water required to completely saturate the air-dried soil, varied inversely as the specific gravities.

The moisture given off when the saturated soil was spread out and left for 24 hours also varied inversely as the specific gravity in the three surface soils; but it was lowest in the subsoil. Of course in comparing quantitatively the power of different soils to absorb, retain, or give off moisture, results will be affected by the state of the atmosphere as regards humidity at the time when the experiments are made.

It will be observed from the mechanical analysis that, while the state of division of the four soils is very varied; the proportions of the total mineral and organic matters differ only to a very small extent.

For the chemical analysis only that portion of the soil was taken which passed through a sieve of ten meshes to the lineal inch. This excluded the coarse gravel. For ordinary analyses it is commoner to exclude the fine gravel also. Thus at Cirencester Royal Agricultural College the portion of soil taken for chemical analysis is what passes through a sieve of 6 millimeter (one-fiftieth of an inch) mesh. This includes the coarse sand, fine sand, and finest particles with the accompanying organic matter. The coarser ingredients are examined, or analysed separately when it is considered desirable to do so.

In the portions taken for the chemical analyses, the proportion of moisture varied in the same order as in the mechanical analyses.

The organic matter in the chemical analyses is not notably higher than in the mechanical analyses except in the case of No. 1. In this case there was a considerable proportion of coarse gravel associated with only a small proportion of organic matter, which is not included in the portion of soil taken for the chemical analysis.

In two of the surface soils the amount of protoxide of iron was higher than in the subsoil; but the proportion of protoxide to peroxide was higher in the subsoil. There have been too few determinations of the former in Ceylon soils to enable one to fix a limit above which the presence of protoxide of iron is to be regarded as injurious. In his numerous analyses of Ceylon soils, Mr. Hughes does not appear to have made a separate determination of this ingredient, but only in conjunction with peroxide, of which the amount may be very high without any detriment to the fertility of the soil, and a large percentage of which is even desirable, on account of its property of fixing the atmospheric ammonia brought down by the rain.

The available lime was lowest in the subsoil. In No. 2 it was well above the average of the older estates. The magnesia in these contiguous soils was higher than the lime.

The potash is present in good proportion, the quantity available being highest in the three surface soils.

In soil No. 3 the amount was phenomenally high for a Ceylon soil. The sender of this sample stated that it was drawn from a new clearing, and not according to either of the two methods of sampling described. The probability is that it contained an undue proportion of wood ashes due to the burning of the forest. The available soda was found to vary in the same order as the potash, only a trace being found in the subsoil.

The phosphoric acid was present in good proportion in No. 1 and No. 2, in fair proportion in No. 3, and in the highest proportion in the subsoil.

The nitrogen was present in fair proportion in all four soils being highest in the subsoil.

Analysis of soil from an old *coffee estate* in the *Matale district*, Ceylon, together with that of the prevailing rocks, and of the fertiliser used.

Only the more important ingredients of this soil were determined, the following being the results obtained:—

	per cent
Organic matter and combined water ...	12.84
Nitrogen197
Phosphoric acid098
Potash179
Lime150

This soil, the sender said, "represents a field of about 3,500 feet elevation, western aspect, rather steep, comparatively free from wind, with a rainfall of 100 inches, well distributed, full of small stones same as sample No. 1. The field lies on a slab rock of much the same nature. There is also a pretty fair proportion of stones same as No. 2."

Stone No. 1 was a piece of light-colored metamorphic rock with a distinctly stratified structure. Stone No. 2 was a piece of metamorphic rock much darker in color than No. 1, the stratification being also much less distinct. Another stone marked No. 3 was also sent with the remark that it was a chip from a boulder near which the coffee was very flourishing. These three pieces of rock were analysed with the following results:—

Analyses of stones from a Coffee Estate in Matale.

	No. 1.	No. 2.	No. 3.
Silica ...	65.55	51.04	61.19
Alumina ...	19.79	19.99	21.78
Oxide of iron ...	4.61	10.02	5.51
Lime ...	1.96	9.47	5.40
Magnesia50	5.75	1.15
Potash ...	4.74	1.20	3.12
Soda ...	2.72	2.05	1.80
Phosphoric acid13	.12	Trace
	100.00	100.00	99.95

No. 1, it will be observed, has the highest percentage of potash, No. 2 the highest percentage of lime, while No. 3 has a considerable proportion of both of these, but is poorer in phosphoric acid.

Of the soil the sender remarked "that it had been thirty years in coffee, and had given originally large crops without manure. It had gradually declined from average crops of 8 cwts. per acre to less than an average of 4 cwts. per acre. By the application, in alternate years, of a manure, at one time well known in Ceylon, called *Sombreorum*, the crops had been increased in a series of eight years from 4.68 cwts. per acre average, in the first four years, to 5.54 cwts. per acre average in the last four. The *Sombreorum* had been regularly applied in semi-circular holes round the trees one foot from the stem. The sender had been careful in drawing samples of the soil to take them at some distance from the holes. His mode of taking a sample was to scrape the surface slightly in four different parts of the field, near to each other, and of the same physical appearance, and to take the soil from under these spots, to mix the four samples together, and to send a portion for analysis."

A sample of the *Sombreorum* manure was submitted to me for analysis by my correspondent, but which he was careful to state was not in the same dry condition as when received, having

been lying at the estate for a considerable time. The sample, as I received it, had the following composition:—

Analysis of Sombreorum.

Moisture	18.65
* Organic matter and water chemically combined	6.29
Calcium sulphate	13.94
Magnesium sulphate	3.25
Potassium sulphate	8.53
Sodium sulphate	9.78
Sodium chloride88
Insoluble earthy matter96
† Biphosphate of lime	6.29
Tribasic phosphate of lime	12.21
100.00	
* Containing nitrogen	1.80
Equal to ammonia	2.19
† Equal to tribasic phosphate of lime	9.84
Total phosphoric acid equal to tribasic phosphate of lime	22.05

Another sample of soil from the same, and one from a contiguous estate, were analysed by Mr. A. C. Dixon with the following results:—

Analysis of Matale Soils. (DIXON.)

	per cent.	per cent.
Organic matter	17.483	11.525
Nitrogen205	.174
Lime134	.113
Potash121	.090
Phosphoric acid089	.104

The percentage of plant food in this old property compare favorably with that of many much younger estates. The phosphoric acid, however, is somewhat deficient, hence the increased yield produced by a phosphatic manure. The manure Sombreorum has, however, been manufactured to serve the purpose of a general manure for coffee, as it supplies nitrogen, and more especially potash, in much larger proportion than is found in ordinary superphosphates.

The unnecessarily high proportion of sodium sulphate is no doubt due to the difficulty of getting potash salts free from soda at a cheap enough rate for manuring purposes.

The rocks on the estate cannot be regarded as very deficient in lime; but this constituent

in an available state has disappeared from the soil to a greater extent than the two other important mineral ingredients; thus, while the rocks contained from about 2 to 9½ per cent of lime, only .150, or, according to Mr. Dixon's analyses, only .134 and .113 per cent respectively, remained in an available state in the soil.

The following are average analyses of *Dimbula, Maskeliya and Matale soils*, computed from the analyses made by Mr. John Hughes, F.C.S., F.I.C., and published in his "Report to the Ceylon Coffee Planters' Association of 1879." The samples of the Dimbula and Maskeliya soils were selected by the Association, those of the Matale soils were sent by private individuals:—

Average Analyses of Dimbula, Maskeliya and Matale Soils, computed from the Analyses of Mr. John Hughes.

	Average of 9 Dimbula Soils.	Average of 6 Maskeliya Soils.	Average of 6 Matale Soils.

* Containing Nitrogen	.143	.292	.089
Equal to Ammonia174	.355	.094
Moisture in air-dried sample ...	3.24	12.130	1.780

The mechanical condition of B was probably very different from A and C, as there is nothing in the chemical composition of B to account for its high percentage of moisture in the air-dried state, as compared with A and C.

On the above analyses Mr. Pringle recommended the conservation of moisture in A and C by means of shade, and the use of 'as much good cattle manure, made by bedding the cattle with ferns and leaves, as possible.' Both being deficient in potash he recommended 1 cwt. per acre of nitrate of potash.

A requiring nitrogenous manure as well as potash, and also phosphoric acid to prevent soil exhaustion, he recommended for this coffee land 2 cwts. bone meal and 1 cwt. nitrate of potash per acre, the manure to be mixed with one cubic yard of burnt earth, or 2 bandy loads of cattle manure.

B being deficient in phosphoric acid, and rich in nitrogen, he recommended for this land 4 cwts. bone meal, to be succeeded 6 months later by an application of lime. The application of oil cake to such land he would regard as waste.

C being a poor sandy soil, deficient in moisture, in nitrogen, in potash, and not very rich in phosphoric acid, he recommended for this soil thick shade, and for manure, cattle manure 2 tons; fine bone meal 1 cwt.; good fish manure 2 cwts.; and nitrate of potash ½ cwt. per acre.

Mr. Pringle also made the two following analyses to illustrate the changes produced in soil by burning the same. The general effect is the dissipation of the organic matter with the nitrogen, and the increase in the available amount of all the mineral ingredients; part of the augmentation, however, and especially in the case of the potash is attributed to the ashes of the wood used as fuel.

Fiji Soil.

The following analyses of a sample of soil sent to me from Fiji in the year 1880 may have an interest for Ceylon and Indian planters. The soil was from *Gt. Amalgam Estate*, where coffee leaf disease first made its appearance in Fiji. The sample was taken from different depths and represents the composition of the soil from the surface to a depth of three feet:—

Analysis of Soil from Great Amalgam Estate, Fiji.

Water expelled at 212° F. ...	3.998
* Organic matter and combined water ...	12.848
Soluble in standard hydrochloric acid	
Silica194
Protoxide of iron887

Soda063
Phosphoric acid128
Chlorine026
Carbonic acid ...	Trace
Insoluble Silicates ...	64.386
	100.000
* Containing Nitrogen201

The chemical composition of the part of this soil extracted by acid is upon the whole very similar to that of our Ceylon Coffee Soils. There is no marked deficiency of any of the elements of plant food as compared with other coffee soils, while the phosphoric acid, although not very high, is above the average proportion. The insoluble silicates, however, are of a more argillaceous nature than is the case with Ceylon Coffee and tea soils. The numerous crystals of quartz, so noticeable in the insoluble silicates of Ceylon soil, were absent from the sample Fiji soil. The insoluble residue in the latter, after being freed from organic matter, consisted of white clay.

The air-dried soil required 40 per cent of its weight of water for complete saturation, shewing thus a greater capacity for water than the 4 Dolosbage soils examined in a similar way. The reaction of the soil was distinctly acid, as the sample, however, represented a depth of three feet, this acidity was probably in the subsoil.

Classification of Coffee and Tea Soils.

A sufficient number of these soils has been analysed to warrant a classification being attempted on the basis of the proportion of nitrogen present, and also of the amount of the two important mineral ingredients of plant food that are soluble in hydrochloric acid, viz., potash and phosphoric acid. Those that contain nitrogen under .1 per cent, potash and phosphoric acid each under .05 per cent might be described as poor soils. Those that contain from .1 to .2 per cent of nitrogen and from .05 to .1 per cent of potash and the same of phosphoric acid might be described as of fair or medium quality, while those containing above .2 per cent of nitrogen, above .1 per cent of potash and the same of phosphoric acid might be described as rich soils. Of course soils may be of poor fair or rich quality in respect of one or more of the three most important ingredients. This classification or comparison of Ceylon soils with each other might be drawn out in tabular form thus:—

Classification of Ceylon Coffee and Tea Soils.

Quality of Soil.	Percentage.		
	Nitrogen.	Potash.	Phosphoric Acid.
Poor ...	under .1	under .05	under .05
Medium1 to .2	.05 to .1	.05 to .1
Rich ...	above .2	above .1	above .1

Rocks or Stones founded on Ceylon Estates.

The following are analyses of rocks or stones found on Ceylon estates. The first three analyses are of pieces of quartz which were sent to me to be tested for gold and not to ascertain if they possessed any agricultural value. They are inserted here, as such rocks or stones abound on many of the Ceylon estates, and fuller analyses of them were made than were necessary merely for the purpose of finding out whether or not they were auriferous:—

Analyses of Quartzose Rocks.

Silica ...	99.810	94.57	97.00
Alumina and oxide of iron020	5.20	3.00
Lime628	.02	
Magnesia054	.13	
Alkalies088	.08	
Gold ...	absent	absent	absent

Analysis of Metamorphic Rocks.

	Light colored.	Dark colored.
	Silica ...	82.63
Oxide of iron and alumina ...	18.51	34.45
Lime ...	1.19	9.48
Magnesia23	3.49
Potash ...	3.86	.80
Soda ...	3.40	1.14
Phosphoric acid18	.29
	100.00	100.00

Three other analyses of Metamorphic rock have already been given; see page 17.

The next two analyses are by Mr. J. H. Wilson. They are quoted from the *Ceylon Observer*:—

Analysis of Ceylon "Orthoclase Granite." (WILSON.)

Silica ...	69.26
Peroxide of iron ...	4.50
Alumina ...	15.20
Potash ...	6.75
Soda ...	2.10
Phosphoric acid05
Magnesia ...	1.75
Lime49
	100.00

Analyses of Decomposed Ferruginous Gneiss. (WILSON.)

Moisture and combined water ...	8.38
Organic matter ...	12.26
Silica ...	33.26
Alumina ...	21.02
Peroxide of iron ...	20.64
Lime ...	1.51
Magnesia50
Alkalies ...	1.50
Phosphoric acid44
Loss49
	100.00

I also analysed a sample of decomposed rock from *Dimbala*, which differed from the preceding in not being ferruginous. The following were the results obtained:—

Analyses of Decomposed Rock.

Moisture ...	10.00
Organic matter and combined water ...	10.07
Alumina with traces of oxide of iron ...	37.95
Lime34
Magnesia06
Phosphoric acid35
Potash61
Soda22
Silica ...	39.00
	100.00

For the analyses of Ceylon limestones see the chapter on Mamures.

(To be continued.)

CEYLON TEA FOR NEW ZEALAND.—So far as the Colombo Customs are aware, the direct shipments of tea to New Zealand last year were 96,002½ lb; but we suspect a good deal more of the 5 million lb. sent to "Australia" was transhipped thence to the Britain of the South. We are glad to see that during January this year our tea exports to "Australia and New Zealand" are more than double what they were in the same month of 1892.

COFFEE PLANTING IN MEXICO AND GUATEMALA BY AN OLD CEYLON PLANTER.

WESTERN MEXICO, Nov. 1st, 1892.

To the Editor "Tropical Agriculturist," Ceylon.

I still read with great interest the movements and writings of ex-Ceylon Planters; and feel anew the obligations of writing what I have learned lately, thinking that possibly some other planter may be interested equally with what I communicate as I have been with other contributors.

I write from the district of Soconuxo, State of Chiapas, Mexico. This district formed part of the neighbouring Republic of Guatemala; but was ceded to Mexico about thirty years ago.

This estate, which I am at present engaged in opening, is situated only ten miles (10) from the boundary line which separates the two countries.

The character of the country for 200 miles along what is known as the Pacific slope of the mountain range is very uniform indeed.

The lands rise with a gentle slope upwards from the sea coast to an elevation of about 5,000 feet, then rise abruptly to their highest ridges 12,000 to 15,000 feet above sea-level.

The distance throughout the whole coast from sea shore to beginning of coffee belt is about the same 30 miles.

In the neighbouring Republic, Guatemala, there are some very fine coffee estates. *El Porrenir* is one of the largest if not the very largest of all I know the property well, and if agreeable will relate some of the figures in connection with the opening and production of the estate.

El Porrenir (in the future) was a pet place of the late President, General Rufino Barrios. It was purchased and opened by him, and at the time I knew it best, from 1883 to 1886, was already a large concern. His unfortunate death at the battle of Chalchiapa checked the development; and it was recently sold to a German Syndicate, who have added greatly to the concern.

The following figures were Notes taken by me in 1886, and are still interesting:—

The total area of land was 12,915 acres, which covers everything, and so made up in the following way:

416	acres	of	7	years	old	coffee
315	"		5	"	"	"
315	"		4	"	"	"
210	"		3	"	"	"
315	"		2	"	"	"

1,571 acres planted up with coffee in 1886.

At that time there were approximately about 2,500 acres of virgin forest lands eminently suitable for coffee, which it was Barrios's intention to cover with coffee. The land was good and rich, soil a deep chocolate-colored volcanic loam. The balance of the lands are rough and high, and also slope downwards to the hot country, too low for coffee; but which has been planted up with grass.

Barbacues.—There were thirty barbacues 25 yards square each made of stone, paved, and well cemented, offering a perfectly smooth surface and floor.

Driers.—There were four No. 4 Guardiole driers, each capable of drying 75 quintals of coffee daily.

Peelers.—Three Smoot's peelers of the largest size, one Gordon peeler, and one Mason peeler. The latter was not very popular and little used.

Pulpers.—Six Gordon cylinder breast pulpers disposed of all the coffee cherry.

Receiving Cistern.—The receiving cistern for coffee cherry was a very large concern, all stone paved and cemented; the actual dimensions I have not got.

Fermenting Cisterns.—Eight fermenting cisterns for wet parchment, 6 × 8 yards and 8 × 10 yards stone work.

Washers.—Two Guardiole washers and one Mason's washer for wet parchment after fermentation.

400 working oxen and 65 carts; 37 mules, 15 carts. Power to work the whole concern in the height of picking was furnished by one waterwheel 40 feet in diameter, one of 24 feet diameter, and one of 12 feet diameter. Two blacksmith's forges and a saw-mill.

The Building.—The building which contained all this machinery was L-shaped or one-half of a square, one side was 204 feet by 48, other side equal, namely 204 by 48. House and office for accommodation of clerks and managers contained 8 rooms. Telegraph office, and cottage of 10 rooms for accommodation of the President when he visited the estate.

150 houses for the accommodation of the resident labourers; also scattered throughout the coffee estate were additional houses to furnish sleeping room for the extra number of hands needed during crop. There were 18 of these houses 90 to 120 feet long by 24 to 30 feet wide.

Roads.—The whole estate was interlaced with paths cut 6 feet wide, the total length of which would record many miles; 12 miles of good cart road too led from the store to the Pueblo of Rodco.

Harvest.—In the year under notice there were 21,000 quintals of clean coffee picked; each quintal is equal to 10½ lb. English measurement. A very large estate compared with the size of our Ceylon and Southern Indian plantations. The manager was also busy at work lining and holing 300 acres of land more which he purposed planting up as soon as the rains began. This estate to me was very interesting indeed, and I am sure would have been equally so to any Ceylon planter who might have had the fortune to see it; I must admit I extended the field of my knowledge greatly, and learned much of the ways of working in these countries.

I raised 600,000 cinchona plants on the property and distributed them throughout the place, chiefly on the lee side of the roadways, which greatly added to and adorned the estate. All the coffee cherry was brought by carts, or carried by men to the central curing establishment, where it was pulped, fermented, dried and cured, and despatched ready for market. I was present during crop time 1886, and saw by far the largest number of people engaged picking I ever beheld. There were about 3,000 hands on the estate at that time; and the stir in the evening when the cherry was measured was great and exhilarating. The room was cramped indeed, and the time taken to measure palm twice as long as we take in Ceylon. However, these defects are matters of detail, and improvements were made next year.

When the pulpers began their work, a stream of parchment coffee was concentrated and focused, when it issued into the fermenting tank, that did one's heart good to see. All the coffee was not measured in the evening at the receiving cistern, not by a great deal. During the day, carts were arriving and leaving regularly filled with cherry, to and fro, from the coffee fields; yet, in the evening, the number of pickers seemed innumerable, and the palm they brought immense. The figures alone tell a good tale. Allowing 9 bushels of cherry to 1 quintal or cental of coffee, then 21,000 centals equals 189,000 bushels of cherry. The figures I take from Ferguson's Directory, page 154, for year 1883-4, for the calculation, allowing also an average turn-out of labor equal to 2,000 pickers, and that each picker averages 1 bushel per day, 94½ days would be employed from beginning to end of the harvest. This is not the case, however. The season began with I suppose about 200 pickers, and as the harvest called for more men more were engaged, so as I have stated about 3,000 pickers turned out daily. A German Syndicate purchased the property from Madame Barrios after her husband's death, and have added

very largely to the estate. Mr. Charles Schultz, the managing partner, is a friend of mine, and has sent me an invitation to see the estate, which I shall avail myself of when the dry season advances and, if agreeable, will let the readers of the *Tropical Agriculturist* know further particulars of this large and excellent property.

Throughout these countries a very different system of coffee planting is employed to the method we are acquainted with in Ceylon and Southern India.

The elevations best for the cultivation of coffee are from 2,000 feet to 5,000 feet, much the same as in Ceylon. From 3,000 to 4,000 feet is considered the very choicest elevation of all. It is very difficult to introduce any new method in work; much more so than it would be in Ceylon. The very crudest work is all the Mozo, Indians, of this country can understand; hence the agriculture of these countries is also of the very crudest kind. Unlike the Tamil cooly the Mozo is a very stupid person. The tool he uses, which they all use, and the only one they have any knowledge of, is called a machète, a long-bladed knife 22 inches long by $3\frac{1}{2}$ inches broad at the point. The point is very broad and shaped exactly like an ordinary sailor's sheath knife, or butcher's knife. With this instrument they can do almost anything. I have seen them picking their teeth, digging jiggers out of their toes, felling fairly-sized trees, and flatwise flogging their wives. They are never without their machète journeying or at home, they have it ever near them. It constitutes all their belongings. Their whole worldly possessions are concentrated in a machète. Hence the machète is a force in the land. All agriculture is guided according to what this instrument is capable of accomplishing. I can fairly state without the least exaggeration that nearly all the work of a coffee estate, from the very beginning to end, outside of picking and curing, is done by the machète.*

It must be very patent therefore that any planter coming to these countries with a view to open a coffee estate must not have too iron-bound notions about how to go about his work. Not by any means must he sacrifice and put away all his previous knowledge and experience. This would be foolish and needless; but he would have to, of necessity, adopt the general principles of planting as it is conducted here, which would force him into strange and new channels of working.

Firstly, although the coffee country is all very heavily forest-clad, like the jungles of Ceylon, we planters here never burn, or rather very rarely, and when a planter does burn he is careful not to make a big one, what we in Ceylon would call a bad burn. To accomplish this he watches his chances carefully, after the clearing is dry enough to fire he waits still further until a heavy shower has fallen sufficient to fairly damp the ground, then scorches off the worst brush. The usual way, however, is altogether different. The jungle is felled down and allowed to lie for not less than two years. During this time a second growth begins and shoots up very densely throughout the branches of the fallen jungle. This growth is rapid, spongy, sappy, and has a strong tendency to assist in rotting the fallen jungle. In two years, that is two rainy seasons and two dry ones, the most of the branches of the jungle are rotted away, in three years or four entirely so. The soft spongy wood that has taken its place is easily cleaned off again, or rather fallen, lining is then done immediately afterwards, 12 x 12 feet apart. A base line is run as is usual in Ceylon, between each peg, or stake, a distance of 12 feet is carefully measured. Then a gang of four men are furnished with two straight sticks 12 feet long. These sticks are placed each one end at the bottom of a peg on the measured line, then at the apex of the angle formed by joining the other two ends together a peg is put, and so on the process is repeated until the whole is lined up. This method is very simple, easily learned, and difficult for men strange to the work, to go wrong in. In fact the whole process is a repetition of the first propo-

sition in Euclid (to which refer): given a straight base line a, b, and a triangle raised to c, then the angle a, b, c, is equal to the angle a, c, b; and the whole an equilateral triangle.

This method has an agreeable look; all the lines in which ever way the person looks are straight.

Holing.—Holing is done the same as in Ceylon. A task for each Mozo is 80 holes per day 18 x 18 inches. We are able to get a much larger task out of our people here than in Ceylon, because of the nature of the soil; being very free, friable, it is easy to dig, much more so than with you.

Before dismissing the burning of jungle I should like to say that I am quite a convert to the rotting way against my earliest teaching of burning. I believe most thoroughly that burning, however right, scorches and ruins the surface mould, especially in these countries, whereas the gradual decay of the forest timbers assuredly returns to the ground more and retains the virtue of the soil better than the ash, that is the residue of the fire.

I notice from the five letters that have come to my notice through the *Tropical Agriculturist*, written by Mr. Scott Blacklaw, the information he gives of the *modus operandi* of coffee planting as conducted in Brazil is very much the same as the process in vogue in these countries. I have not seen all of that gent'eman's contributions; and there are great gaps in the process of work that I have missed; which I have no doubt he has most exhaustively described.

Nurseries.—Especially is this true in regard to nurseries, I have not seen anything he has written on this section of the subject, therefore shall describe them as done here. This work differs so widely from the way you raise the coffee plants, that I am not far off in saying the work is entirely reversed. We select a piece of land flat and entirely open to the sun, if possible. It sometimes happens in a virgin forest, no open clear place is conveniently available for the purpose. Then the smallest natural tree shade is selected. The ground is cleaned thoroughly of all surface rubbish and the surface merely broken to rid the soil of strong roots. The Mozos (coolies) are then each furnished with a stick 9 inches long (nine), and beginning at one end of the land selection measure the distance equidistant between each plant and work backwards until the whole is filled up. No beds are formed, simply a drain is made to carry off the surface water in the event of heavy rainfall. The seedlings are sprouted in a small bed and are set out in the extended nurseries before they expand into anything like plant form. While the form of the coffee berry is still on the delicate stem, it is considered the safest time for transplanting into extended nurseries; when the two leaves expand first they are called Mariposa (butterfly) to which insect they have quite a likeness. The seedling is never transplanted until it has passed the Mariposa, and has produced four or more leaves. But the most of the transplanting is done before ever the leaves open at all. The shade is gradually reduced, and the plants hardened off in the usual way. The planting, when the season arrives, is what is benefited by the form of nursery as described. The cooly cuts around each plant, in a very skillful way, with the point of his machète, and extracts a plant with a ball of earth the size of a good flower pot. These plants are then carefully carried out into the field and placed into the bottom of the hole, and the seeds packed with earth mould carefully. A nursery of plants, planted wide apart certainly produce themselves infinitely better than when crowded together. A two-year old plant is considered the best of all, although for my own part I have been more successful with a hardy 14 or 16 months plant.

I have described the method ruling the labor supply of these countries to my old friend T. A. Cockburn of Rathkelle estate, and as he usually sends you notes that may be fitted for printing, I daresay he has already furnished you with a description. It is too lengthy a subject, therefore shall shunt it for the present. Suffice it to say no way is more unsatisfactory.

* An axe is used of course for felling big trees.

I am busily engaged opening a large coffee plantation. We have nearly 3,000 acres, mostly good for coffee. In 1891 I planted 250 acres, this year I planted another 150 acres, and next year I shall plant another 100 acres and finish by June 1893. I have 300 acres of virgin forest fallow, which is rotting away, and which I shall plant up in 1895 and 1896. I shall not do any planting in 1894. I am just now beginning to build my receiving cisterns, store, and barbaenes. My power is furnished by a Pelton wheel, with an 80 feet fall of water.

W. J. FORSYTH.

[We hope to hear soon again from Mr. Forsyth—Ed. T.A.]

NEW PRODUCTS.

We are glad to find that the attention of Planters is being prominently directed by the Editor of the *Observer* since his return to the Island to the wisdom of extending the cultivation of other products than Tea. Dr. Trimen has in annual Report after annual Report pleaded against the practical restriction of upcountry cultivation to Tea; and we have ourselves—whether in reviewing Administration Reports on the Botanic Gardens, or in dealing with Customs and commercial statistics—condemned the apparent devotion of Planters to a single product. To be sure Cocoa, Cinchona, Cardamoms and Coffee are cultivated in a fashion; but there has scarcely been any extension to mention in any of them. The acreage under Cardamoms may have increased somewhat; but not to an extent to arrest attention; and perhaps wisely so. Spices must be reckoned among luxuries; and the demand for them does not expand with the supply—as Cinnamon Planters know to their cost. It is doubtful whether there has been any increase in the acreage under Cocoa. Even allowing for the delicacy of the plant, at least in its younger stages, its love for sheltered nooks, and its impatience of wind, there is not a sufficiently determined effort, we fear, in any district to find out spots suitable for its cultivation. At the prices which have ruled throughout the year if not beyond it, Cocoa ought to pay handsomely. Why then is it neglected to the extent that it is? The chief reason probably is, that its returns are not as quick as in the case of Tea. It is the old story of hastening to be rich. Without being able fully to endorse the views of a correspondent who has just been singing the praises of Cocoa most lustily in the pages of our contemporaries, we do think land may be found in which experiments might be undertaken with almost the certainty of success, not only in upcountry districts, but also in the low country. Its gradual extension among the Natives in sheltered gardens, is a pleasing feature; but this cannot, at any rate for a considerable time, appreciably affect the Exports. With regard to Coffee, it is most difficult to form or pronounce a decided opinion. The prices which the fragrant bean now commands in the markets of the world are such as should encourage its cultivation. And it has the advantage—if it be an advantage—like Tea of yielding quick returns. But *Hemelia vastatrix* is not the only enemy with which the shrub has to contend, as the few who own coffee land can sadly testify. If "Once bit, twice shy" explains the unwillingness of Planters to commence planting new clearings with coffee, or to extend the acreage they already have, the explanation does not apply to the maintenance of the land under the product without shrinkage. How is it that the acreage is steadily dwindling and the exports decreasing? Black bug, green bug, unfavourable seasons are turn about offered as explanations; and the Planters are too hard-headed a race to offer them without just cause. But is this really conclusive against fresh experiments? May not the conditions under which the plants have grown and borne fruit—their productiveness having been stimulated by topping and pruning—be fatal to their longevity? Because these can no longer survive or be profitably cultivated, does it necessarily follow that cultivation on fresh land—on virgin forest—should not be tried? To be sure, with Tea regarded as a

certainty, and Coffee, even if our theory be accepted as a risky experiment, people naturally prefer the former to the latter. It is to be hoped, however, in the interests of the community generally, and the prosperity of the planting enterprise particularly, that wealthy Companies and well-to-do individuals will make experiments, even on a small scale, to test the practicability of reviving Coffee cultivation in new fields. Even Liberian Coffee fetches prices which are abundantly satisfactory; and although we cannot say we are believers in the immunity of this species from leaf-disease or even in its ability to resist attacks better than the Arabian variety, we do not despair of its continuing to flourish, if it be allowed to grow as it does in its native habitat. In our limited experience, trees which have not been topped resist attacks of leaf disease better than bushes which have been topped and pruned; while there has not been the same mortality—if indeed any trees have died—among them from that specific cause.

In writings as we do, we do not mean to imply that Tea is in a bad way; or that the cry of over-production is a valid one, at any rate here. New markets are taking away all that we are producing at remunerative rates. Those who speak of the small margin of profit which Tea leaves, in order to secure some concession in transport or otherwise, unconsciously do much harm to a very promising and, we may add, profitable enterprise. Tea pays generally, and very handsomely in particular cases. Plantations which do not pay are those which should never have been opened; and it is impossible to treat any product in a way that all who engage in it, whether wisely or unwisely, should be able to grow rich on it. To the warning that Tea is profitable because of the depreciated value of the Rupee, the simple answer is that there seems to be no prospect of its appreciation. The world is prepared to take up all the Tea we can grow; and to pay better prices for it, too, than for the product of any other country. Still, the unwisdom of placing all one's eggs in a single basket has been demonstrated again and again in other countries, and very painfully here in the case of Coffee. It is for that reason we should be glad to know that other products are not neglected while Tea is being attended to. And that suggests the need of real attention. Are Planters doing justice to their bushes, on which a very unusual strain is placed by the severe pruning and the continuous plucking to which they are alternately subjected? The returns of manure imported, and the information touching cattle establishments on Estates, do not point to any general appreciation of the need of giving back to the soil some part of the constituents regularly taken away from it. It may be too late, in many cases, before this is realised; and it behoves the Planters' Association and the Press to draw very serious attention to the matter.—Ceylon "Examiner."

RATS!—Talking about rats, says the *Nilgiri News*: these at times make their appearance in ravenous swarms that stop at nothing. We were informed the other day, by a planter of long standing, that even the very calves and cattle on his estate were not exempt from their depredations. On one occasion, by the attractive bait of a little gram, placed in juxtaposition to his cattle shed, he succeeded in killing as many as twenty by a single shot, and he repeated the experiment with success.

THE CURRENT CROP OF COFFEE IN BRAZIL has been reduced by about 300,000 bags in consequence of the want of labour. This want tends to increase in a very sensible degree, and causes a large advance in the wages paid by planters. The disorganisation in the transportation service adds another very serious difficulty in the way of cultivation. The next crop has been estimated provisionally by a delegation of coffee factors of Rio de Janeiro at 2,700,000 bags, subject to the character of the season up to February next.—*Capitalist*, London, Jan. 7.

THE REPORT OF THE LANKA PLANTATIONS COMPANY.

Had the seasons been more favourable to the cultivation of coffee and cacao than were those of the period covered by the report of this Company for 1891-2 up to 30th of June last, we should doubtless have been able more fully to congratulate its shareholders upon the issue to the working of that period. The Lanka Plantations Company is one of those which we may characterize as of the old régime, for it has had to gradually change the character of the cultivation it started with, and the cost entailed by doing this has hardly even as yet been wholly surmounted. Still the report under notice evidences that the time approaches when the change from coffee to tea as the main production of the Company will have been fully effected, and the heavy annual charges incurred for making this change will have become a thing of the past. It is certain that all estate proprietors will feel sympathy with the directors when making the statement contained in the report that, as regards coffee and cacao the weather during the blossoming season for both products, was "most unfavourable" and "most unpropitious." Planters generally will bear evidence that this statement is warranted. In the case of the Lanka Company we find that its production of coffee fell off from the figures of 2,031 cwt. in the year previous to little more than 914 cwt. in that represented by the report. Similarly with regard to cacao there was a decrease from 1,106 cwt. to 707 cwt. We are sorry to observe that the directors declare that their cultivation of cardamoms is to be abandoned as being unprofitable, a like declaration being made with regard to cinchona, the statement being added that "as the trees are very injurious to the tea nearly all have now been uprooted." *Sic transit gloria mundi.* An industry which at one time promised to go far towards the redemption of the prospects of our planters when overshadowed by the prevalence of coffee leaf-disease has been declared to be not alone "unremunerative," but distinctly injurious to the new cultivation which has superseded that of the nearly wholly abandoned coffee. The failure of the coffee and cacao crops on this Company's estates would not perhaps have been so trying, were it not for the fact that, as yet, the acreage planted by it with tea has not come into full bearing. It is this fact which constitutes the great difference between the Lanka Company's operations and those on the great mass of our island estates. The change from coffee to tea has had, in this Company's case, to be proceeded with gradually, so that while surrounding their properties there is a large area covered with tea that has long attained maturity, a very considerable proportion of the Company's connected acreage is as yet immature. Had it not been for this fact we should certainly have had to welcome a report which, in spite of reduction in the yield both of coffee and cacao, would have shown a most favorable result to the operations of the year. Even as it is, and notwithstanding the adverse circumstances narrated, the directors are able to announce a dividend of 6 per cent. on its preference shares and one of three shillings, per share (free of income tax) on the ordinary shares. All things considered this is not a bad result to have attained, and as the returns of Companies now working plantation properties in Ceylon are carefully and critically watched by our opponents in tea-growing throughout India, it is as well that the circumstance under which a restricted dividend is declared in the case of the present Company should be fully

set forth. For if it be not so, the uninstructed might be led to the conclusion that tea-growing could not be profitably pursued in Ceylon, and upon this would be based a conclusion that might injuriously operate against the investment of public capital in Ceylon agricultural enterprise.

The tea production announced seems to us to be very satisfactory. The amount of it during the twelve months covered by the report was no less than 377,327 lb. against 248,574 lb. of the year preceding. When the cash return, however, comes to be looked at, we see the effect of diminished prices on the amount obtained. These averaged for the year under review only 8½d per lb. against 9½d mentioned in the previous report. As matters have gone the average now announced is not a bad one, considering how much the home market was disorganized by the mistaken estimates formed of the general outturn of tea for the present year. A table given in the report shows that the company is possessed altogether of 4,157½ acres of land, of which 528 yet remain under coffee, while 1,899 are cultivated with tea, 412 with cacao, and 18 with areca. The shareholders are to be congratulated on securing the services of one so well acquainted with Ceylon and its planting enterprise and of such good business attainments as Mr. Henry Bois. The place worthily filled by Sir Herbert Sandford could not be more fitly occupied now. We sincerely hope that the directors in their next report will be able to show a progress undiminished by the comparative failure of either coffee or cacao crops.

THE LANKA PLANTATIONS COMPANY, LTD.
REPORT.

To be presented at the Twelfth Ordinary General Meeting of the Lanka Plantations Company, Limited, to be held at the Offices of the Company, on Wednesday, the 7th December, 1892, at 12 o'clock noon.

1. The Directors submit their Report for the twelve months ending 30th June last, together with the Balance Sheet and Accounts of the Company made up to that date.

2. The coffee crop was only 914 cwt. 3 qr. 4 lb. (against 2,031 cwt. last year), and the amount realised therefrom was £4,509 10s 11d. The season was most unfavorable for this product owing to the excessive rainfall in Haputale, which caused the berries to drop prematurely. The best fields on Thotulagalla and the other Ouwah estates are being kept in a good state of cultivation, in the hope that they will give more satisfactory returns. All other fields were either planted, or ready for planting, with tea on the 30th June last.

3. The Cinchona Bark shipped has been 71,897 lb. which realised £668 7s 11½d. This cultivation is no longer remunerative, and as the trees are very injurious to the tea nearly all have now been uprooted.

4. Cocoa realised £3,120 2s 4d, the quantity gathered being 707 cwt. 0 qrs. 26 lb., against 1,106 cwt. last year. The weather during the blossoming season was most unpropitious, and to this alone the lessened yield may be attributed. Such weather as that which prevailed in Matale at the critical time is, fortunately, quite exceptional, and the Directors look upon the future of this product with confidence. The trees are reported to be in excellent heart, and the arrangements for curing have been perfected. Fifty acres of jungle have been felled and are now being planted. The Superintendent reports very favorably of the suitability of the land for cocoa.

5. The Cardamoms produced 1,200 lb., realising £80 5s 1d. The cultivation has been abandoned as unprofitable, and the land planted with cocoa on Yatawatte and tea on Rillamulle.

6. The tea received from the Company's estates (without purchase of outside leaf) amounted to 377,327 lb., which sold at an average of 8½d per lb., and realised £13,028 0s 3d, against 248,574 lb., averaging

9½d last year. The very heavy supplies which came forward during the first half of the year led to very exaggerated estimates of the Ceylon tea crop for the season, and quite disorganised the market. These estimates have proved much too high: deliveries have lately exceeded imports, and the statistical position is now decidedly strong.

7. The following statement shows the acreage and state of cultivation of the Company's estates on the 30th June last.

Estate.	Coffee.	Tea.	Cocoa.	Nuts.	Grass.	Pattina.	Forest & Timber Trees.	Total.
Ampitiakande	.. 110	178	39	332
Arnhall	.. 40	140	173	20	373
Fruit Hill	225	12	..	237
Fordyce, Garbawn, Gonagalla and Paramatta	} 31	731	39	135	936
Rappahannock	.. 35	290	25	43½	..	80	473½
Rillamulle	.. 15	215	2	6	..	20	258
Thotulagalla	.. 297	120*	126	..	53	601
Yattawatte	412	18	95	145	277	917
	528	1899	412	18	166	50½	629	4157½

* Partly in Coffee.

8. The directors regret that the result of the years' working is not more satisfactory; the reason being the diminished receipts from both coffee and cacao before the acreage under tea is in full bearing. The profits for the past year amounted to £4,235 19s 10d, and after writing £1,499 off the suspense account, and reducing the machinery account by £307 10s 8d, they recommend the payment of the dividend of 6 per cent on the preference shares and a dividend of 3s per share (free of income tax) on the ordinary shares, carrying forward a balance of £76 14s 2d to the next account.

9. The Directors regret to have to report the death of their esteemed colleague, Sir Herbert Bruce Sandford, K.C.M.G., who was a large shareholder. The vacancy thus caused has been filled by the appointment of Mr. Henry Bois, who is now permanently resident in England. Mr. Bois, having been elected in the place of the late Sir H. B. Sandford, retires on this occasion, and being eligible, offers himself for re-election. It is hoped that his long connection with Ceylon will be of great value to the Board and of material assistance to the Company.

In the Balance Sheet, the estates are valued as follows:—

	£	s.	d.	£	s.	d.
Ampitiakande	26,225	5	0
Arnhall	18,521	6	9
Fordyce and Garbawn	..	16,149	2 0

A NEW TEA COMPANY.

LONDON, Dec. 9th, 1892.

BANDARAPOLA CEYLON CO., LIMITED. (37,603.)

This company was registered on the 23rd inst. with a capital of £50,000, divided into 5,000 shares of £10 each, to cultivate tea, cinchona, coffee, tapioca, indiarubber, cocoa, and fibre-producing grasses, plants and trees in the island of Ceylon, India, and elsewhere; with power to farm, cultivate, prepare, manufacture, treat, and carry on any trade or business for making marketable the same and such other products as may hereafter be approved of by the company. The subscribers are:—

	Shares
J. Anderson, 16, Philpot Lane, E. C., merchant	1
G. G. Anderson, same address, merchant	1
J. D. Campbell, same address, cashier	1
N. Aunum, same address, accountant	1
G. C. Thompson, same address, clerk	1
M. R. Hall, same address, clerk	1
G. T. Robinson, 19, Eastcheap, E. C., solicitor	1

The number of directors is not to be less than 3 nor more than 5; the first being Messrs. G. W. Paine, C. J. Scott, and John Anderson; qualification, 50 shares; remuneration, £200 per annum until the company earns 15 per cent., then at the rate of £300 per annum, or such further sum as the shareholders may vote to them at a general meeting. Registered by Messrs. Robinson & Standard, 19, Eastcheap, E. C. Registered office, 16, Philpot Lane, E. C. The prospectus is as follows:—

This Company has been formed to purchase from Mr. Hugh Fraser the properties of Bandarapola and Mundeniya, situated in the district of Matale in Ceylon, within 3½ miles by cart road, and 1½ miles by bridle path of the railway terminus.

The Estates consist approximately of 1,340 acres of Freehold, and 130 acres of Leasehold land of which

300 Acres are under Tea in full bearing	
25 do do do partial bearing	
40 do do do recently planted	
32 do do do Cocoa	
6 do do do Grass	
1,067 do do do Forest and Chena	

1,470 Acres.

The price Mr. Fraser has agreed to accept for the properties is £21,000, payable:—

£7,000 in fully paid up Shares
7,000 in Debentures at 6 per cent.
7,000 in Cash.

£21,000

Bandarapola is equipped with a complete Factory and Machinery sufficient for twice the present acreage and has ample water power. There are also two excellent Bungalows with outhouses, and permanent brick and tiled lines for a sufficient supply of cool labourers. The Forest and Chena is all available for Tea, and it is intended to open up some 600 acres as soon as it can properly be done, leaving the balance as a timber and firewood reserve. The facilities for transport, and the cheap and abundant labour, enable the produce to be delivered in Colombo at an exceptionally low cost, and this will be a material factor in the earnings of the Company. The yield of the Tea in hearing was 650 lb. per acre for 1891, and this yield will be exceeded for the year 1892. Mr. William Mackenzie, a recognised authority as a valuer of Ceylon property, has valued and reported on the Estates, and his report is appended. It is proposed to take over the properties from 1st January, 1893. No promotion money whatever has been, nor will be paid, and the Vendor will pay all charges up to date of allotment of the shares.

FINE TEA

which to a great extent reviews the little pamphlet *Theine vs. Tannin*, recently forwarded to you. The writer of the article believes that the authors of the letters cited in that pamphlet had reasons for being biased in favour of China tea and is disposed therefrom to largely discount the opinions expressed in them. He goes on to remark that grocers have to consult the public taste, and that this is pronounced in favour of Ceylon and Indian teas. At the same time he thinks a vigorous effort should be made to impress upon the British public that fine tea cannot be purchased "at the absurdly low prices that one now often sees advertised in the general press." Owing to the system of blending Indian with China teas of a low grade, the article declares that a taste for the former has superseded the latter, fine teas from China being now scarcely procurable. The idea that the public health is affected by the drinking of British-grown teas is laughed at as a fallacy, the increase in consumption being pointed out as a refutation of the notion. It is argued that "if the late Chancellor of the Exchequer was correct in thinking that one pound of Indian tea when infused would equal one and a half or two pounds of China, then the weight of Indian tea referred to by Professor W. Dittmar, as containing 2.16 per cent tannin, would, in the case of an equal quantity of China tea when liquored, be 2.70 per cent tannin."

NOTES ON PRODUCE AND FINANCE.

THE TANNIN BEGGY.—The pamphlet to which we referred some months since, issued by a Glasgow firm, calling attention to the excessive amount of tannin in Indian and Ceylon teas, has not been a success. Scarcely any notice has been taken of it in the Press, and even the *Grocer* has not referred to it, unless we may take some remarks appearing in its last issue as reference. It says:—"The attention of the public has recently been conspicuously drawn to this subject, several letters having been published and leading articles written in the daily papers, generally with the view of proving that really fine teas can only be grown in China, while Indian and Ceylon teas contain an excessive quantity of tannin, which is not only injurious but, as the writer of a pamphlet entitled '*Theine versus Tannin*' contends, is actually

dangerous to the public health. The late Professor W. Dittmar gave an opinion, based upon the results of a number of analyses, that there is larger amount of theine in Indian than in China tea, but this advantage is more than counterbalanced by the greater amount of tannin they contain. The experiments upon time infusions were as follows:—China tea which had drawn for ten minutes produced 1.0 theine and 1.35 of tannin; in Ceylon tea the figures were 1.0 theine and 2.21 tannin, while Indian tea produced 1.0 theine and 2.16 of tannin; and the results from five minutes' infusion went to confirm the impression that the relative weight of tannin is less in China than in Indian or Ceylon teas. The conclusion to be drawn from reading the correspondence is that the writers of some of the letters are either personally interested in the importation of China teas, and their minds are biased to a certain extent, or that they are ignorant of the fact that grocers and other retailers of tea have to study the taste and requirements of the public. It would be well, too, if a vigorous attempt were made to educate the public to an appreciation of the fact that fine tea cannot be purchased at the absurdly low prices that one now often sees advertised in the general Press.

THE ECONOMICS OF INDIAN TEA.—The teas from China which came to this country fifteen or twenty years ago varied both in strength and quality, and grocers, by judiciously blending certain kinds, could produce a delicious cup of tea at what was considered a reasonable price then; but the circumstances have entirely altered since, continues the *Grocer*, and grocers now must be up to date both as regards price and the public taste. When India first, and Ceylon of late years, sent strong, pungent kinds, which, when blended with low-priced China teas, produced at a lower cost a flavour which the public appreciated, it was not a matter of wonder that the demand for fine, high-priced China teas declined, and the bulk of the trade was diverted to Russia, where the public pay a good price, and generally drink tea with lemon, whereas in Great Britain a deep colour is necessary to stand the addition of cream or milk. As regards the alleged injury to health, previously alluded to, the case has, of course, been ridiculously exaggerated, for the consumption of tea per head of the population has yearly increased with rapid strides, and no evidence is produced to show that the community at large are any the worse for using Indian and Ceylon teas; more over, despite the fact that the custom of drinking an additional cup of tea in the afternoon had become fashionable, no statistics have been cited to indicate the slightest increase in diseases arising from the consumption of tannin, either as affecting the digestive organs or the nervous system. It should be noted, too, that Indian and Ceylon tea goes farther than China, and if the late Chancellor of the Exchequer was correct in thinking that one pound of Indian tea, when infused, would equal one and a half or two pounds of China, then the weight of Indian tea referred to by Professor W. Dittmar as containing 2.16 per cent tannin would, in the case of an equal quantity of China tea when liquored, be 2.70 per cent tannin.

AVOID INFERIOR TEA.—But, in the opinion of the *Grocer*, the reason of the increase in the use of Indian and Ceylon teas must be traced to other causes; the first is the relative cost of the teas, and this is most important, as touching the pockets of the public, more particularly as consumers have been educated to drink teas at prices ranging from one to two shillings per pound, whereas, allowing for the difference in the duty, they formerly were content to pay two or three shillings per pound. Thus now the finest China teas cost more than the public will generally pay, and consequently they are neglected and attention is only given to the lower grades, which will blend with strong, thick Indian or Ceylon teas; and, in many cases, China tea is avoided altogether. Another reason, is owing to milk being added to tea, it is necessary to have not only a pungent flavour, but also a dark colour to withstand

its effect, and fair-priced Indian teas supply these conditions, which are frequently wanting in low-priced China teas. This subject is of importance to the public generally, but more especially to retail grocers—particularly at a time like the present, when a substantial rise has taken place in India teas—but we have full confidence in our readers being able to gauge the wants and tastes of their customers, and, by carefully studying the art of blending, be in a position still to produce, tea at a price which will not only leave them a reasonable profit, but also please the palates of consumers. The great thing, however, is to avoid the tendency to deal in inferior tea because the price is low. The public will pay a fair price if the article be good enough.

TEA IN AUSTRALIA.—While on the subject of tannin, there is a miserable picture drawn in a new book called "Australian Life," published by Messrs. Chapman and Hall, of the way they drink stewed tea at all times in the Australian bush and the results arising therefrom. It is quite time that something was done for Australia in the way of introducing Indian and Ceylon teas in place of the miserable compressed rubbish they drink upcountry. The writer of the book, Mr. Francis Adams, says:—"The heathenism of the bush is intense. Everyone is at heart a pessimist. The horrible condition of the coatings of stomachs perpetually drenched with tannin (speciously termed 'tea') doubtless counts for something in the action and reaction of body and climate. After a good spell of drought, endured on a diet of mutton, bread, jam, and stewed Bohea, one's indifference to life becomes remarkable. There is nothing wild or hysterical about it. It is merely a deep, quiet, stoical heedlessness of danger and death. In certain natures it becomes combative, and the drawing 'blow' (Anglice, boasting) of the competitive bushman borders on an anger which is so high-strung as to threaten insanity. Gordon, with the acute impressionability of a poet, absorbed, all the natural influences of the climate and the life, and has become the absolute spokesman of its morality." This is not drinking tea, it is making and consuming soup. In the first place the tea is bad and in the second it is stewed. The man who can drink stewed tea and not become a pessimist must possess the constitution of an elephant.—*H. and C. Mail*, Dec. 2.

TEA ESTIMATES AND RESULTS FOR 1892.

(By a tea planter.)

J. L. Shand has good reason to be proud of his estimates for this year. I agree with him in thinking pruning was too long delayed in many instances, 14 months in the lowcountry and 18 on the hills, seem to be the best system of pruning.

I cannot say that if each and every planter had got his estimates this year the total would have reached 85,000,000, or that only two or three months' bad weather and fine plucking prevented estimates being got. The weather has been blamed throughout the year, sometimes, I think, without reason: certainly it was wet, cold and ungenial from July to October; but I do not think the plucking, as a rule, had much to do with it.

The curious thing is, that estates can be selected in almost every district that have done well, much better than last year.

But apart from these few lucky places, the falling off between results and expectations on the same acreage is so great that one wonders how the total has exceeded that of last year. Even in the Kelani Valley, where the excessive wet and wind did not prevail, several of the largest estates are giving absolutely less, and considerably less than last year. This, too, with a larger area in bearing.

Our P. A. Chairman may find the cause in the actinism of the sun's rays. In the declining years of coffee, between '81 and '85, this principle

often did duty as an explanation why crops were short.

Increased age and area have saved us from a total export considerably less than that of '91.

AMERICAN TEA.

MR. HENRY COTTAM AGAIN TO THE FORE.

Now and then we hear the term "American grown" tea. It is not usually taken seriously however. The brief, fugitive newspaper paragraphs in which it is met are treated by northerners in much the same way as sensational news from remote lawless regions, whose bad name gives probability to the fabrication, and whose remoteness makes it hard to disprove. Thus often very readable news is coined. But American grown tea is not the figment of a press agency's fancy. It is a reality, neglected instead of exaggerated by the authors of despatches. The production of it is likely to become an important Southern industry, an industry that has already emerged from its experimental stage. Its growth is worth looking into.

Summerville, South Carolina, has the distinction of being the place where the initial attempt to grow tea in America was made. There at Pinehurst, an estate of 600 acres, twenty-two miles from Charleston, the State capital, Dr. Charles U. Shepard renewed the experiment that the United States Commissioner of Agriculture had begun on the same ground shortly after the war. The efforts of the Commissioner were premature, as the South was in a state of industrial and financial prostration unfavourable for any economic departures of this kind, and tea culture was abandoned until Dr. Chas. U. Shepard undertook it at Pinehurst. He succeeded in bringing tea to maturity at four years of age. Export knowledge was necessary, however, to bring his experiments to their most successful issue, and this was applied by Mr. Henry Cottam, who at the critical time in Dr. Shepard's labors at tea cultivation was taking advantage of colder climates to recruit his strength after attacks of fever. Mr. Cottam had spent twenty-five years in the island of Ceylon as a tea and coffee planter, and consequently was just the man to render the assistance Dr. Shepard needed. Mr. Cottam has written thousands of columns for the press on tea subjects, and is the author of books on tea. He has few equals in this department of knowledge. He gave to Dr. Shepard the modus operandi of growing and preparing tea for commerce. He corrected a mistake in the mode of drying, sun-drying having caused the tea to be red leaved instead of a good black tea, a result which spoiled its value. After shadewithering, careful rolling, firing at a proper temperature of 280 degrees, and sifting through proper sieves, made specially for the purpose, Mr. Cottam succeeded in turning out as good a tea, he claims, as was ever produced in India or Ceylon, and shows samples that either of those dominions might be proud of. He believes that the United States can produce all the 90,000,000 lb. of tea it consumes, and does not consider that conditions of climate, soil or economy stand in the way. There are millions of acres that in his opinion are suitable. These lands are inside the yellow pine belt, where the camellia japonica grows to a height of 30 feet. The tea plant being a sister (camellia thea) it will do equally well. Tea will stand all the cold it is likely to suffer in the South, because, he argues, it grows successfully in high elevations in tropical climates, and he holds that the same amount of rainfall is not so necessary in countries so distant from the equator. The average rainfall of 60 inches in S. Carolina he regards as equal to 80 or 90 inches in the tropics. The Indian planters at the outset said that tea could not be grown in Ceylon because of the cold of high lands, but now Ceylon produces half as much tea as India. Dr. Shepard will have no difficulty in securing cheap labor, which is supposed to be the chief advantage in favour of Asiatic teagrowers. He has a school on his estate in which he gives a free education to the children of the district, and thus has them

assembled so as to bring their labor to bear easily and cheaply upon picking. Men are required only to look after the machinery. Dr. Shepard has planted far apart so as to be able to use the plough instead of the hoe.

The tea turns out well in the cup. Its retail value is 75c. a pound for Orange Pekoe, 50 to 60c. for Pekoe, and 30 to 40c. for Pekoe Souchong. It is an Assam hybrid, a cross between China and India tea. The Assam tea is a higher jet. Mr. Cottam, who has the honor of being the pioneer in making American tea, is now with Steel, Hayter & Co. of this city.—*Canadian Grocer.*

VARIOUS NOTES.

MOSQUITOES AND KEROSENE OIL—Mosquitoes cannot multiply without a breeding pool of stagnant water. If householders take care that there is no pool, no marshy hollow, or other damp corner in their compounds, they ought not to be persistently troubled with mosquitoes. But sometimes, the pool is not easily got rid of. In that case here is the next best cure apparently, according to the *Globe* :—

Kerosene has been tried in the United States for destroying mosquitoes, the old idea of keeping down their number by dragonflies having proved a failure. Four ounces of kerosene were poured on a breeding pool 60 square feet in area, and for the next ten days the pool, which had before swarmed with the insects, was cleared of them.

PLANTING PROSPECTS IN WYNAAD are not very bright to judge by the annual report of the Wynaad Planters' Association, which has just reached us; and yet one of the first items in the report is the statement that "coffee stealing is still as flourishing a trade in the district as ever." Farther on, however, we come on the following paragraphs of considerable interest to Ceylon planters :—

During the past two years considerable attention has been directed towards the possibility of discovering a cure for leaf disease; numerous experiments have been tried in the district, and Government was approached with a view of getting the services of an expert. After giving the question their careful consideration and consulting with Dr. D. D. Cunningham, Government decided that an investigation would be of value merely from a scientific point of view, and would not be likely to result in the discovery of anything which would be of service to the planter, and I fear that most of us coincide in this opinion.

Amongst other matters to which the Association has directed its attention during the past two years has been to the encouragement of Tea growing in the district. With this object a prize of R200 was offered last year for the best essay dealing with the question of small acreages under different proprietors with a common factory. This prize was won by Mr. W. M. Standen of Noddiwattam.

As for the general prospects of the district, the periodical ravages of leaf disease have so diminished the profit from our staple product, notwithstanding the high prices and low exchange that have ruled during the last two years, that planters have been forced to turn their attention to other cultivation. Liberian Coffee is on many estates replacing the Arabian; tea is now being widely planted, and an experiment is being made in growing *Fourcroya Gigantea* for fibre, the result of which, whether successful or not, will be reported for the benefit of the Association. At any rate I think we may congratulate ourselves that there is no lack of capital in the district, or of energy to work it.

The Associations of Southern India have very properly asked the Madras Governor to have an M. L. C. of their own, and they are anxious to have railways extended. Mr. J. W. Hoskin is Chairman and Mr. Geo. Romilly, Hon. Secretary of the Wynaad Association; we wish it a long career of usefulness.

THE MANURING OF TEA.

The receipt of an interesting communication from Mr. John Hughes of Mark Lane on the value of coir dust as a manure to the tea planter, affords a good opening for touching on the subject of the manuring of tea in general. Since our return, we have been making inquiries as to how far liberal cultivation in this way has extended, and the result is a series of rather contradictory replies. For, while we have on one side not a few practical men maintaining that if tea will not pay without manure, even on old coffee land, it had better be left alone,—on the other we have indubitable evidence afforded of the advantage of manuring in the paying returns from land which without such cultivation, could not be saved from abandonment in view of the fall in prices. There are old coffee estates now in tea which come under this category in several districts; and without going so far in other cases as to say the choice was between "abandonment" and "manure," yet the results in these instances of less worn-out land have been exceedingly satisfactory to the proprietor. This is the case in the high and medium districts,—in Dimbula and Dikoya as well as in Dolosbage. One manager in a high district, reports :—

"Manure ($\frac{1}{2}$ ton to acre) pays splendidly on medium soil, but don't put it in till say 7 or 8 months after pruning. I would not manure tea that will average 450 lb. per acre without. Tea at 300 lb. per acre with London price at 7 $\frac{1}{2}$ d will pay about R50 per acre; but bad soil and bad situation are always to be avoided."

Another still higher up, writes :—

"We have still a large cattle establishment and manure tea on a pretty extensive scale; but you know I have a large acreage of old soil to work with, which was put under coffee over 50 years ago, and all my labour and cost of manuring does not, I fear, do more than bring our yield up to the average of younger places receiving no manures. So far I see no reason to change our system, and if the average price would only keep about 10d gross a pound and exchange at about 1s 4d to 1s 5d per rupee, present owners, believe me, should have no reason for complaint with their tea investments."

Of course, in both cases, we take it that land once under coffee is referred to. We suppose in the case of tea planted on virgin forest land, at any rate in the lowcountry, little or no manuring has as yet taken place. We do not forget the case of Mariawatte with its splendid facilities easy lay of land and proximity to Gampola—advantages equally possessed, no doubt, by Bandarapolla in reference to Matala. Most tea planters, however, with comparatively unexhausted soil to begin with, must share what is the more general opinion, namely, that for the present, manure is not required, nor should it be touched until its necessity becomes quite apparent. And yet there may be such a case as delaying too long. At any rate Mr. Hughes' proposal to the Planters' Association about collecting the leaves off a few tea bushes of different sizes; "weighing the green leaf and drying in the sun and again weighing so as to note the loss of weight in water; then sending him samples of the dried leaves and the particulars of the original weights, and number of trees per acre," so that he, Mr. Hughes, might calculate what exhaustion was caused by severe pruning, should receive attention. We trust now that the hurry incident to the Chicago Exhibition, is drawing to an end, Mr. Hughes' wish as above expressed will not be forgotten by the Planters' Association Committee; for he is assuredly worthy of all support in his endeavours to throw light on problems of great practical importance connected with tea culture. The

question has been asked: have the Chinese found it necessary to apply manure to their tea? As among the best horticulturists in the world and as their gardens are generally small holdings, we may be sure the Chinese do not overlook the advantage of returning fertilizing matter to the soil in the case of tea as of their other cultivated plants. Meantime, we append the useful information afforded by Mr. Hughes in regard to "Ceylon Coir Dust as a Manure for Tea," which is sure to be read with interest by planters:—

CEYLON COIR DUST AS A MANURE FOR TEA.

Attention having recently been directed to the utilization of coir dust as a manure for tea and coffee, it may be of interest to publish an analysis of this material which was made by myself in connection with a special inquiry into this matter in conjunction with the late Mr. Borron, in March 1891. In general composition, coir dust as represented by this analysis closely resembles that of ordinary farm-yard manure so far as the actual quantities of nitrogen, potash and phosphoric acid, except that, unless the coir dust has fermented by being allowed to remain in a moist state in a heap for some time, it is not likely to decompose and become available as plant food as rapidly as ordinary dung. It is obvious, therefore, that such a material will not pay for removal any great distance, the percentage of the important plant food elements being small, while there is always the possibility that the native ingenuity towards fraudulent adulteration would cause the proportions of water and sand to become unduly increased above those shown by this analysis. Provided, however, that caution be observed in this respect, there is no reason why coir dust should not be used as a means of supplying useful plant food on tea estates situated near the railway, assuming that a low rate for carriage could be obtained. Of course, it could be used for mixing with more concentrated fertilizers such as castor-cake, fish guano, dried blood, or bones, though the fact of being mixed with more valuable materials would not increase the natural intrinsic value of the coir dust itself.

On soils such as those of Ceylon tea estates, which are not particularly rich in humus or vegetable organic matter, the addition of a material such as coir dust, containing at least 67.27 per cent of organic matter, must be beneficial, not only on account of the plant food constituents directly supplied, but also as furnishing a plentiful store of carbonaceous matter which on decomposition would become resolved into carbonic acid; and this would exercise a solvent action on the mineral resources of the soil which would be rendered available as plant food more rapidly than under ordinary circumstances when such organic matter was supplied.

Indeed this is a special advantage which organic matter of a carbonaceous character always possesses; hence the value for shrubs, of dead leaves for making leaf mould, and we find that planters approve of the plan of allowing the prunings of the tea to remain on the surface for a time, because they furnish a protection from sun and rain, while the leaves are gradually decaying and forming suitable food to be afterwards covered up and afford nourishment to the feeding roots.

JOHN HUGHES.

ANALYSIS OF COIR DUST FROM CEYLON.

Water (lost at 212° F)	12.50
* Organic matters	67.27
Phosphoric Acid27
Lime	1.20
Poash78
Soda43
Oxide of Iron, Alumina	}	..	2.89
Magnesia, Sulphuric Acid, etc.			
Sand	14.66
			100.00

equal to Ammonia68

From the above results one ton of this coir dust would contain as follows:—

Nitrogen	12½ lb.
Potash	17½ "
Phosphoric Acid	6 "

TEA IN UPPER AND LOWER DIKOYA—
SPECIALLY BOGAWANTALAWA.

DEL REY—THE FLATS—AND KOTIYAGALA.

(From an Old Planter.)

I was up to Bogawantalawa the other day, and on my way I kept my eyes open; and I must say that taking the appearance of the tea into consideration, say from Abergeldie up to Kotiyagala, the yield for the next six months is bound to be heavy. Every place I went through seemed in grand trim for flushing. Del Rey is a sight, and, all the flats (that used to be "patana") from Tientsin Bridge to Kotiyagala are also well worth the journey to see. No doubt Bogawantalawa is the place for tea in Ceylon. The coffee—and there is still a good lot about—is very poor as far as crop is concerned; and it does not look as if it would do much the coming year. So I fear its days are numbered.

I see you have been advocating planting timber trees on all estates. You are again right, for we do want a lot of shelter and also firewood. The Great Western Rajah is also right when he told you that there has been a great deal planted already which only wants time to show. Last year there must have been millions of plants put out. I have put out some thousands myself and will put out more next year.

Kotiyagala estate is the place you ought to see. There you will find all the fields laid out with original jungle belts and any number of other trees—in fact it is a model estate.

THE TEA PLANTING ENTERPRISE AND
MANURE.

We are now enabled through the courtesy of the General Manager to give the figures showing the quantity of manure carried upcountry by the railway for a series of years. The statement appended goes back to 1882, when there were not 7,000 acres of tea in bearing in the island. The figures for that year and indeed up to 1885, we should say, show manure which must have been used for coffee rather than tea fields. The tonnage of manure carried by rails, is as follows:—

Years.	Tons.	Years.	Tons.
1882	.. 4,173	1888	.. 2,098
1883	.. 5,332	1889	.. 2,519
1884	.. 3,928	1890	.. 5,576
1885	.. 2,093	1891	.. 3,355
1886	.. 1,881	1892 (11 months)	3,011
1887	.. 2,507		

The minimum was reached in 1886, and since then there has been a satisfactory increase especially in 1890, when a total was reached in excess of that for last year or, we suspect, for the present year though we have the figures for eleven months only. We suppose the whole of 1892 will show about the same return as 1891.

NEW PRODUCTS—AND THE NEED FOR THEIR
DEVELOPMENT TO COUNTERBALANCE TEA.

The letter (on page 521) which "An Old Coffee Stump" sends us in answer to our correspondent, "Wanderer," is a truly alarmist one! To remind the planting world of Ceylon that

there are 40,000 acres available in private hands in what we used to call the "Southern Coffee Districts" for extended tea cultivation is to give them the very reverse of welcome or reasonable intelligence. We cannot contest the special illustration afforded by an "Old Coffee Stump" as to the success of tea on the Balangoda chenas; but certain we are that there is as much prospect of the difference between the total and cultivated area on all our plantations (namely 353,879 acres according to last Directory) being transformed into tea fields, as that, of the private reserves in Balangoda, Rakwana, Kukul and Morawak Korale, there should be 40,000 acres fit for profitable cultivation.

But it is surely time, in view of speculation as to farther large extents available for tea, to urge on all desirous of a field for planting enterprise and capital in this island, to give their attention to other products, rather than our staple. To open more tea plantations until at least there is increased encouragement in new markets, will probably be as suicidal on the part of the investors as it will prove injurious to existing interests. The intending investor in new tea land should ask himself seriously what the prospects are in the face of a considerable fall in prices and the certainty of increased production.

Now we should like to plead for renewed attention at this time both to Cacao and Liberian Coffee. With the early prospect of the railway to Uva being opened, we think there is room for prospecting in that province for land—in small blocks perhaps—suitable for these two much-required products. It is with regret that we see no encouragement to try clearings with ordinary coffee: on the contrary we much fear a farther contraction of area under cultivation when we have to face such a doleful account as the following from an Uva planter:—

"My wish has been to keep in a good deal of the old staple. I have been taking the utmost care of the coffee for the last twelve months; and although the weather at the flowering season was not particularly favourable, the trees set an excellent crop. Just as the berries began to swell up, a fearful attack of green bug came on, which will rob me of half the crop. We read of the olive leaf before the deluge, of the grape and the vine in ancient classic lore, and are we to believe that the coffee hush, as a sign of Heaven's displeasure, has been smitten to rise no more. What theories have been urged to explain the ruin that has come over a splendid cultivation in less than a life-time. One scientist declared that an almost microscopic fungus would kill every coffee tree in Ceylon; were he alive now he would moderate his prognostication of absolute ruin; others wrote of excessive inbreeding, unnatural electric action, variation in the magnetic earth currents, excessive stimulus, more waste than supply; while the philosophic geologist said plants die out, the coffee's race is run and it has ever been so, since the creation of the world. Poor blind mortals, we are only groping in the dark; perchance, a score of years hence, as science advances, the mist will be rolled away and we shall see clearly what natural law violated brought on us this destruction and misery. It is true that small coffee clearings have been put out in this district. The time has not yet arrived, however, in my opinion to do so with any chance of success. *Hemiteia vastatrix* does not now

do much damage, but this green bug is a dreadful pest much more destructive than any other. I hope that a remnant of the coffee in Uva will yet be saved; but it will be a smaller portion than I at one time believed. Time flies and the financial situation presses, so that we cannot afford to wait for the change which sooner or later, be the cause what it may be, will come and will enable coffee again to be cultivated successfully in Ceylon."

We can only hope, even if against hope, that green-bug and *hemiteia* will disappear and leave us still, especially in Uva, a certain and profitable area under the old staple. But be that as it may, surely the news of success at the Straits with Liberian coffee ought to stimulate Ceylon planters to make further experiments in this direction. Mr. T. H. Hill, formerly of Matale, has been giving some wonderful figures in statements published in the *Kevo Bulletin* (which we are taking over in full into the *Tropical Agriculturist*). Returns of 9½ cwt. and 11½ cwt. per acre must be enough to make young planters desire to share in so good a thing, and it is impossible that Ceylon cannot have land in considerable area as suitable for Liberian coffee as that taken up in the Straits. We have mentioned the Uva province with the facilities in many ways which the railway will offer to extended occupation. The same may be said of the Southern Province which can by no means be played out or fully settled in the districts suitable for planting. But still more what about the expanse of rich land north-east of Matale, beyond and around the Minneri tank? We had a visitor the other day who, with special knowledge of the country, declared that in that direction lay the very richest reserves of Crown land for agricultural purposes in the island, and he strongly protested for that reason against Mr. Waring's route for the Northern railway being adopted, in so far as it ran in a straight line from Kurunegala to Anuradhapura. In the public interests as well as in the interests of traffic, the line ought, in his opinion, to tend Eastward to the point that would best command the route to Trincomalee and from which a road or branch railway could easily be run into the heart of the fertile reserves referred to. He did not think, too, that the actual outlay per mile of the Northern line would be much if anything increased. This is a matter for the Government in connection with the Surveyor-General and Government Agents to decide. Mr. Waring has to do his work as Engineer, but he will only be too ready, we suppose, to adapt his line to fresh industrial and revenue claims, if these are pointed out to him and he is asked, to serve them. Meantime we have surely, among our younger generation of planters, men of enterprise, who will not shrink from thoroughly exploring this region with reference to the cultivation of Liberian coffee, cacao, &c. The question of rainfall will have to be answered, and yet in rich soil with shelter and shade, fruit trees can get on well with a limited rainfall. The distance and climate should not deter pioneers; for the difficulties would be trifling compared with those encountered in the early days in

the lower and remoter planting districts before the era of roads and bridges, and of a reliable labour and food supply.

We would fain hope, therefore, that further new investments in planting in Ceylon may take the direction of cacao and Liberian coffee rather than of tea; and that proprietors with considerable reserves in the lower districts may consider well whether sheltered pockets of good soil, where such exist, would not be a safer investment if put in the products in keen demand, and for which high prices are available, rather than in the one in danger now of being over-produced and of falling in value to actual cost of production.

LOCAL AND HOME TEA SALES.

The letter of our correspondent, "A Local Seller," (on page 521) appears at an opportune moment when, with the figures published for the total of tea offered and sold in Colombo during 1892, we are considering the comparison between the Baillie Street and Mincing Lane Sales. The growing importance of the former cannot be denied: they take off considerable percentage now of our total output as may be judged from the figures compiled by a contemporary and given on page 513. That 15 million lb. should have been sold in Colombo this year and still more that so much as 6½ millions should be sent to other countries than the United Kingdom—mainly Australasia—are very satisfactory features. The more rapidly our direct exports to "other countries" increase, the better chance of Ceylon teas holding their own in the Lane, and as direct exports are chiefly fed by local sales, it must be the wish of our planters to see the Colombo tea sales extend and flourish. In this light, the experience of "A Local Seller" will be regarded as extremely satisfactory and will no doubt encourage other producers to think of trying the Colombo sales. Nevertheless, it must not, of course, be forgotten that considerable as the number of local buyers has become, there is a limit to what they can take off. A continuous steady increase of a few million lb. each year in the quantity locally offered is the most we can expect or desire. We suppose that nearly all the finer teas are sent to Mincing Lane, and though for small parcels (such as those from the little Naseby garden giving a total crop of only 16,000 lb.) there is nearly always a better demand and price than could probably be realized in "the Lane"; yet we recognize the fact that no such competition could be anticipated for a continuously large supply of the finer teas. Our correspondent's experience, however, refers to considerable quantities of ordinary teas and the result, as he says, tells strongly for the local market. Let us hope that during 1893, the direct order to Colombo "from other countries" may so increase as to still further stimulate local sales and business generally in a way satisfactory to planters and brokers as well as to buyers.

DRUGS, &c., IN THE LONDON MARKET.

(From the *Chemist and Druggist*.)

London, Nov. 30.

THE CINCHONA SALES.—The London auctions of December 13th will be the last of the current year. The first cinchona sales of 1893 are fixed for January 10th. The dates of the ten cinchona sales to be held in Amster-

dam in 1893 have been fixed as follows:—January 19th, February 16th, March 23rd, April 27th, June 1st, July 6th, August 31st, October 5th, November 9th, and December 14th.

CINNAMON.—At the quarterly auctions on Monday the comparatively small supply of 2,181 bales of Ceylon cinnamon (including some 700 bales unworked) was offered. There was a fairly steady demand, which improved as the sales went on, and about 1,650 bales sold at 1d to 2d per lb. advance for good to superior, and ½d per lb. for ordinary grades. The following are the present prices:—Firsts: Superior, 1½d to 1s 5d; ordinary to fine 7d to 11½d per lb. Seconds: Superior 1s 2d to 1s 3d; ordinary to fine 6d to 10½d per lb. Thirds: Superior 11s to 11½d; ordinary to good 6d to 9d per lb. Fourths and unworked 5½d to 8½d per lb. Cinnamon chips sold steadily at 1½d per lb.; quillings at 4½d to 5½d, and broken quills at 6d to 6½d per lb.

CINCHONA.—Tuesday's auctions were larger by a long way than their predecessors for several months back. The catalogues comprised of:—

	Packages.	Packages.
Ceylon cinchona	1,381	of which 1,235 were sold
East Indian cinchona	434	" 420 "
Java cinchona	107	" 107 "
West African cinchona	466	" 466 "
South American cinchona	301	" 250 "
	2,719	2,476

The assortment of bark offered was a fairly good one, though there were no very rich parcels, only one or two lots realising over 7d per lb. The Indian bark consisted almost wholly of officinals, and there was an unusually large quantity of West African bark (succinbra character) of poor quality. Competition was anything but brisk, and only two of the German agents bought considerably. The result of the auctions may be summed up as showing an average decline of 5 to 10 per cent, reducing the unit to ½d at the most.

The following are the quantities purchased by the principal buyers:—

	Lb.
Agents for the Mannheim and Amsterdam works	251,112
Agents for the Frankfurt-o/Main and Stuttgart works	72,433
Agents for the Brunswick factory	54,374
Agents for the Auerbach factory	33,295
Messrs. Howard & Sons	26,091
Agents for the American and Italian works	22,955
Agents for the Paris factory	22,140
Sundry druggists	41,288
Total quantity of bark sold	524,188
Bought in or withdrawn	49,610

Total quantity offered ... 573,798
ESSENTIAL OILS.—Citronella: A parcel of 24 cases in auction last week is held for 3d per oz. Sales of Lemon-grass oil are reported privately at 1½d per oz.

THE TEA PLANTERS OF ASSAM, like the Indigo Planters of Behar, and the Coffee Planters of the South—who besought the Viceroy the other day not to touch the exchange question on the ground that a rise would be disastrous to the imperial interests of Coorg—are, says the *Pioneer*, jubilant over the high prices they are getting for their tea. We hear of one concern which with a capital of two lakhs of rupees is expected to turn over a profit of Rs60,000 on this year's working. This indicates a beautiful state of things no doubt from the manager's point of view; and may be satisfactory enough to the shareholders as long as they desire to draw and employ their dividends in this country. But the satisfaction would vanish so soon as they should desire to take their money to England: and one does not quite see why anyone living a European life in India should prefer earning a comparatively large number of low value rupees to a comparatively small number of high value ones. It is true that the labour and raw material which the planter employs are paid for in rupees at prices which are tolerably constant; but the shrinkage in the real value of the planter's income (which he cannot escape any more than his fellows) amply takes off, as far as his individual prosperity is concerned, from the increase in its bulk.

But planters are on the whole well content with the prices paid in sterling for their produce just now.

MANURING TEA: A QUERY.

(From a Planter in a High District.)

Is there any objection to putting fresh cattle manure mixed with much litter to the tea, applied in shallow holes in the centre of the lines, 18" x 18" x 4": I mean on a gentle slope, not on steep land or on absolutely flat land on which pools of water stand. My own experience is that this is the best way of applying cattle manure. The extra cost of transport I leave out of the question, as if taken by estate carts and applied, within easy distance of the road, it does not amount to much. Of course, well rotted manure has quicker effect: but it is not so lasting.

I ask this question as, on page 404 of the T.A. for December, Mr. Shelton is reported to have said "he would not put the manure direct to the roots unless the manure was thoroughly rotted." He was speaking of manuring an orchard.

[What do the planting authorities whom we quoted yesterday say to this?—ED T.A.]

ON THE PRONUNCIATION OF TEA.

In Gay's *Trivia*, bk. ii. l. 249, "prey" and "sea," and l. 297 "pay" and "tea" are given as rhymes. Were "sea" and "tea" ever pronounced in this way generally? G.H.T. (*Notes and Queries* 6th S. vi., Aug. 12, 1882, p. 129.)

In his *English Grammar* Ben Jonson illustrates the diphthong *ea* by the words *earl*, *pearl*, *meat*, *seat*, *sea*, *plea*; then adds:—"To which add *yea* and *plea*; and you have at one view all our words of this termination." That is, according to Jonson, there are only four words ending in *ea*. Prof. Earle (*Philology of the English Tongue*, p. 171) continues the list thus: "He forgot the word *lea*, or perhaps regarded it as a bad spelling for *ley* or *lay*. This makes five. A sixth, *plea*, has come into existence since. To these there has been added a seventh, viz. *tea*." It seems likely that the diphthong *ea*, from the 15th century onwards, was sounded like modern *ay*. * * *

The word *tea* is, of course, comparatively modern, the pronunciation in the 18th century being due to French influence. Here again, however, one cannot but note the coincidence there is in that pronunciation with the original sound of the diphthong in the small class of words with which *tea* is grouped. Pope was not only using a fashionable utterance, but also speaking in accordance with the genius of the language, when (*Rape of the Lock*, iii. 7) he apostrophized the queen thus:

"Here thou, great Anna! whom three realms obey,
Dost sometimes counsel take and sometimes tea."
See Archbishop Trench's *English Past and Present*, pp. 120, 292-3.—THOMAS BAYNE, HELENSBURGH, N.B.

This question strikes a student of English as a little odd, but it is probable that many Englishmen have never even heard of Mr. Ellis's wonderful book upon early English pronunciation, in which it is only too conclusively shown that the pronunciation of modern English differs in every conceivable way, and always for the worse, from that of Middle English and Anglo-Saxon. The word *sea*, spelt *see* in Middle-English, was universally pronounced for many centuries precisely as we now pronounce *say*: and the pronunciation of the Anglo-Saxon *se* did not greatly differ from that. The German *see* and Dutch *zee* have preserved the true sound of the *ee* to this moment. The word *tea*, being, comparatively, a late word, is in somewhat a different case, but was certainly pronounced like *Fr. the. Gar. thee* in the 17th century and later.—WALTER W. SKEAT.

As rhyme to "tea" Pope gives *away* (*Rape of the Lock*, i. 62), *obey* (*ibid.* iii. 8), *stay* (*Misc. Poems*, ix. 28); and to "bohea" way R. of the L. iv. 155. Dr. Watts, in his *Lyric Poem to John Locke*, make *day* and *play* rhyme to *sea*.—WILLIAM PLATT, CALLIS COURT, ST. PETER'S. ISLE OF THANET. (*Notes and Queries*, 6th S., vi., Aug. 26, 1882, p. 171-2.)

It may be worth while to note the few survivals in good English speech of the former sound of the diphthong, *great*, *bear*, *wear*, *tear*. Are there any others? The cause of the survival is, I presume, to be found in the awkwardness of the confusion with other words in familiar use which would have been produced in these cases by the change to the modern sound. In the popular speech of Ireland, as we all know, the old sound of the diphthong is generally preserved, *bate* for *beat*, *mate* for *meat*, &c. This usage, therefore, is not a vulgar correction, but a survival amongst an isolated people, whose talk in this particular has remained stationary, being separated from the main current of English speech. Matthew Prior, in his ballad, *Down Hall*, written in 1715, says:—"Near a Nymph with an urn, that divides the highway, And into a puddle throws mother of tea."

W.H.HUSK.
(*Notes and Queries*, 6th S., vi., Sept. 9, 1882, p. 213.)

That *tea* was even spelt *tay*, between 1608 and 1650, might be proved from the record of the old East India Company. I have a distinct recollection of a visit I paid to John Stuart Mills, many years ago at his office at the India House in Leadenhall Street, when he pointed out to me a framed autograph letter from the authorities there to their agent (at Bantam, I think) desiring him to send home twenty-five pounds of the "best *tay* he could get." The date of this letter was within the above-mentioned years.—FREDK. HENDRIKS. (*Notes and Queries*, 6th S., vi., Sept. 30, 1882, p. 277.)

THE COLOMBO TEA SALES FOR THE YEAR 1892.

DETAILS OF SALES AND AVERAGES.

The last public sale of tea to be held in Colombo during the year 1892 took place yesterday—Tuesday December 20th—and brought up to the total quantity of tea sold in *sale* during the year to 11,518,869 lb., equivalent to 16½ per cent upon the total shipment for the year, say, 70,500,000 lb. The figures showing the quantity of tea offered and sold in Colombo during the last three years compare as follows:—

	Offered lb.	Sold lb.	Percentage to total shipped.
1889	6,841,529	4,627,762	14
1890	8,897,510	6,114,525	14½
1891	13,933,793	9,578,611	14½
1892	15,060,681	11,518,869	16½

The figures are taken from the brokers' weekly reports; but it would not be far out if we calculated that *all* the tea offered was sold locally, for much that is withdrawn from sale is sold afterwards privately. We feel certain that over 14,000,000 lb. has been actually sold in Colombo during the year now closed. In calculating the percentage sold to total quantity shipped, however, we have only taken into consideration the actual amount which passed the hammer in the sale room. It will thus be observed that the proportionate quantity of tea sold locally to that shipped has increased a good deal during the past year, the percentage having risen from 14½ to 16½, more than half the quantity (6,500,000 lb. out of 11,518,869 lb.) being shipped to countries other than Great Britain.

The following table compiled by us will show the weekly quantities offered and sold; whilst the average for each sale may be relied on as accurate, taken as they are from Messrs. Forbes and Walker's price cur.

rent, and know that they are very carefully worked out. The table below will be found very interesting;—

COLOMBO TEA SALES.

1892.	Date.	Offered lb.	Sold lb.	Forbes & Walker's Weekly Average.	39 cts.

"	20	281,414	176,547		47

Total 15,060,681 11,518,869

That the quantity of tea offered for sale in Colombo during the year 1892 should aggregate as much as 15,000,000 lb. will probably surprise a good many of our readers. The quantity is greater than the total shipment from the Island five years ago (in 1887, and we are extremely pleased to see that the tendency is towards an increase in the relative amount of tea offered for sale in Colombo, as shipments to other countries than Great Britain can only increase with the increase of local sales. The year is not yet closed for shipments; but the total will probably work out much as follows as compared with the year:—

	1891	1892.
To United Kingdom	63,744,987 lb.	64,000,000 lb.
To other countries	4,529,433 lb.	6,500,000 lb.

Total 68,274,420 lb. 70,500,000 lb.

The significance of these figures ought not to be lost! Shipments to the United Kingdom this year show no real increase upon those for 1891; but those to other countries, such as Australia, India, the Continent of Europe, &c., have gone up nearly 50 per cent! May this growth of shipments to new Markets yearly increase.—Local "Times."

COFFEE IN THE MALAY NATIVE STATES.

(From a Correspondent.)

The latest publication dealing with the Malayan States is the "Kew Bulletin," the official organ of the Director of the Royal Gardens at that botanical station, which deals with a number of interesting questions, affecting agricultural interests. Amongst others it takes up the subject of Liberian coffee in the Malay Native States. This product, which has proved so disappointing in other parts of the tropical world, is evidently about to become an undoubted success in the Malayan peninsula, where it seems to have found both soil and climate adapted to its requirements. As an admirable substitute for the Arabian variety it was introduced into Ceylon when leaf disease first played havoc with the plantations of that island, and much was hoped from it. At first it gave good promise of successful results, but at the end of a year or two these hopes were doomed to failure and now the cultivation has almost ceased. This was a terrible blow to many a planter who had invested largely in the product, for the bean was full flavored and has made a mark in the London market.

In Ceylon, although the early crops of Liberian coffee were fairly abundant, they were not lasting, whereas in the Malayan Peninsula they range from about 9 cwt. to 1½ cwt. per acre annually. The Editor of the "Bulletin" says of these estates: "Important plantations yielding regular crops of Liberian coffee are established in Java and in the Straits Settlements. In the latter the yield of per acre in full bearing is given as ranging from 9½ cwt to 1½ cwt per acre. Placing the price of Liberian coffee as low as 90s per cwt this would show a gross return of from 42½ to 52½ per acre. This is a higher return than is obtained from almost any plantations of Arabian coffee. These figures, it should be remembered, are based on returns supplied to Kew by an experienced and competent planter."

The returns to which the "Kew Bulletin" refers give the following results in crops:—Linsum Estate in Sungei Ujong, average yield per acre for 4 years in full bearing 2½ cwt per acre. S'Lian Estate, in Sungei Ujong, average for three years full bearing 10.7-16th cwt. Weld's Hill Estate, in Selangor 8 cwt. Batu Caves Estate, in Selangor, for one year in full bearing 1½ cwt.

In the report accompanying these returns I find it stated that Batu Estate has not been manured until 1891, because the soil was so much superior to that of the other estates as to render it theoretically unnecessary to apply manure. In future the same system will be followed as on the other estates.

The secret of the abundant yields of some of the above estates lies in what is stated in regard to the climate, which was one of great heat and plentiful rain supply, which latter quality was so greatly wanting in Ceylon, Linsum and S'Lian, in Sungei Ujong, estates are surrounded by forest, and the atmosphere there is generally laden with moisture (rainfall from 90" to 120") and rain falling on over 200 days in the year, with heavier and more continuous rains in October, November and the early part of December. The older fields on these estates are manured yearly, and weeds are allowed to grow and have been for many years for a large portion of the year. This latter practice is so opposed to the system almost universally adopted in other coffee-growing countries as to need some explanation; of the results however there can be no doubt. The cost of cultivation is reported as from 70 dols to 90 dols per acre per annum. It is stated that the younger fields on one of these properties are finer than the old coffee was at the same age, all having been planted from "selected" seed from the finest trees, thus obtaining "pedigree seed" some of the clearings being planted from the fourth generation of this selected seed. —Pinang Gazette.

MR. JOHN BROWN'S VIEWS ON THE CEYLON
TEA INDUSTRY.

LONDON, Dec. 9th 1892

During a long chat with Mr John Brown this week—whom I then met for the first time since his recent return from Ceylon—he obliged me with many remarks upon what he observed during his last visit to your island. He had little to tell me but what was hopeful, and in high praise of the energy and skill of the present generation of your planters. At the same time he felt, he said, somewhat doubtful as to tea remaining a remunerative planting industry if prices were continued at their late low level. He remarked that the cost of bringing land into cultivation with tea was very heavy; and that there were often to be seen instances of too early planting-out that he thought would be sure to produce bad results. He told me that this planting-out was often done when the seedling was but a twelvemonth old, and that he believed it would be far wiser to delay this until the plants were fully double the age. He was of opinion that bushes planted out at so tender a period of growth would have but a weakly maturity. Then he observed that a very large area of inferior land, with but little depth of soil, was now being taken up for tea planting. He feared very bad results from this:—"If," he said, "we get large acres of weak trees, I can imagine no condition of things more likely to bring upon us the visitation of some pest or other, such as worked such havoc with us in the old coffee days." Mr. Brown further said that tea growing on some exceptional estates must be still very remunerative even at the present low prices, but that such instances must not be taken as forming a general rule. He asserted that it required a strong capital to properly plant out a tea estate and to wait for its profitable maturing. If haste were made to force young trees into bearing by planting out too early, he believed there would be but a short life before the trees, and that nothing could be more dangerous for the future of the whole industry than the presence of any considerable area of weakly growth. Mr. Brown tells me he has now no symptom left of the malarial fever that hastened his departure from Ceylon. Sleep and appetite returned to him, indeed, the very first night he passed on board ship; but he is troubled with a bronchial delicacy which may be the result of the feverish attack.—*London Cor.*

THE HON. ALFRED DEAKIN OF VICTORIA
ON IRRIGATION IN CEYLON.*(From his forthcoming book.)*IRRIGATION IN CEYLON: PAST
AND PRESENT.

Irrigation has been practised in Ceylon for many hundreds of years, and upon a scale that, considering the size of the island and the difficulties which it presents is truly surprising. "Excepting the exaggerated dimensions of Lake Moeris in Central Egypt, and the mysterious basin of Al-aram, the bursting of whose embankment devastated the Arabian city of Mareb, no similar constructions formed by any race, whether ancient or modern, exceed in colossal magnitude the stupendous tanks of Ceylon," says Sir Emerson Tennent. One or two illustrations will convey an idea of the extent of these ancient operations.

THE PADIVIL DAM.

is 11 miles long, 200 feet wide at the base, 30 feet wide at the crest, and in places 70 feet

high. It was faced along its whole length with steps of large squared stone, and at the rates for native labour is estimated to have cost £1,300,000.

THE KALAWEWA TANK.

was 40 miles, in circumference, with an area of 6,000 acres, and contained over 3,000,000,000 cubic feet, or three times as much as the Yan Yean.* The work requisite to retain this quantity was much more than three times that required on the Plenty. The dam had a length of 12 miles, averaging 50 to 60 feet in height, and was 20 feet broad at the crest. Anuradhapura, the former capital city, was supplied from this site by means of a channel 40 feet wide and 53 miles long. In addition to this it fed innumerable tanks of varying capacity and constituted in itself a storage of no mean order. Two schemes in the north are of such dimensions that their restoration at the present time would absorb £200,000. They are now recommended to be carried out upon the old lines, which are still discernible. The Ambanganga River was dammed by a solid work of masonry 99 feet in top width, and rising 40 feet above the ordinary high level of the stream. An embankment was carried thence, from 40 feet to 90 feet in height, for 24 miles, forming a series of navigable lagoons, and then further prolonged by a canal for 57 miles more. Even allowing for the despotic authority exercised by the kings over their subjects, who were required in many cases to give their labour, the boldness of these designs and their massive execution are still the wonder of the modern engineer.

IRRIGATION IN THE TIME OF THE SINHALESE MONARCHS.

A report of a committee of the Legislative Council in 1867 states that "the Sinhalese monarchs vied with each other in the construction of irrigation works and in giving every possible encouragement to agricultural enterprise. Vast tracts of country, now covered with the vegetation of centuries, once abounded in grain." The truth of this statement may be supported by the record of one of the kings, Prakrama Bahu I., who flourished about the middle of the twelfth century of the present era. This king constructed 1,470 tanks and 534 canals, and repaired 1,395 large with 960 smaller tanks and 3,621 canals. Some of the older works which he put into working order are believed to date back to 500 B.C., their original constructor being the son of a chief of the Ganges valley, well acquainted with irrigation in his own country, who landed with a small body of followers and made himself master of Ceylon. The feature of the Sinhalese system of supply, however, is akin to that of Southern Madras, and differs entirely from that of Bengal, since it relies very largely upon storage. There are today more than 5,000 reservoirs in the island, from which the cultivators derive their streams for irrigation, and almost the whole of these are situated upon the sites of former works constructed ages since. Its monarchs of that far time were faithful Buddhists who sought to give those practical proofs of their religious zeal which the great founder of their creed required of his followers. They decided, and wisely, that to a vegetarian race there was nothing so important as the assurance of certain and abundant harvests, and consequently put their whole strength into an irrigation policy. The works remain monuments to their piety and wisdom, combined perhaps with a natural proportion of personal pride in leaving such memorials behind them. Even British Governors and engineers in modern times have nourished a similar and not ignoble ambition.

BRITISH TIMES.

Irrigation has been a chief article in the programmes of successive Governors, and their provincial officers have pushed it enthusiastically. There are six honorary titles in the gift of the Crown which are much prized among native notabilities, and by their means it is said that irrigation enterprise is rewarded and schemes are encouraged. The planters are inclined to complain that the paternal solicitude of the State is devoted too much to this one branch of in-

* The great water reservoir for Melbourne.—*Ed. T.A.*

dustry, but taking all things into consideration it is hard to see how it could be otherwise. Other products might be encouraged, it is true, but rice is likely to remain first in the needs and tastes of the people.

RICE GROWING IN CEYLON.

The natural difficulties in the way of the cultivation of rice are naturally made much of by the opponents of irrigation, and even its advocates are unable to ignore their seriousness. It is a thirsty crop, and the provision of a sufficient supply of water by means of storage is therefore most expensive in proportion to area affected. Then again the rich deltaic soils of the Ganges and the Brahmaputra, with their annual floods richly laden with silt, secure crops which are fifty fold to eighty fold of the seed sown. There is much argument as to what may be considered a fair return in Ceylon, and as rice is grown almost everywhere, there are, as is natural, very different returns. In some districts it is insisted that the harvest gives only four or five fold, while the average claimed is not more than fifteen to eighteen fold. It is confessed, therefore, that the island is heavily handicapped in this regard, and cannot compete with the mainland. In 1888-89 India exported nearly 27,000,000 cwt., while Ceylon imported 3,330,000 cwt. Sometimes it has been questioned whether rice growing does not involve an absolute loss to the Sinhalese farmer, and very careful estimates of his working expenses and profits have been made. The result appears to show that in certain districts which are well irrigated, such as Matara and Batticaloa, it pays well, but that in others it yields only a bare profit. The doubt has arisen whether the limit of its payable production has not been reached, and certainly, the fact that some 6,000,000 bushels annually have been brought from India during the past few years would seem to lead to such a conclusion. On the other hand Mr. Elliott, the Government agent at Batticaloa has conducted some careful experiments in rice growing by means of hired labour in two districts with which he is intimately acquainted, and gives a balance-sheet which shows a profit of 40 per cent. in the one instance, and 70 per cent in the other. If such profits are open to the average cultivator, as many believe, there is still a fine future before the Sinhalese and Tamils of the low country, and the Government policy is abundantly justified.

HOW THE POLICY WAS DEVELOPED.

That Ceylon should have adopted an irrigation policy at all is somewhat remarkable, but the form which it has taken is perhaps more remarkable still. Though separated from India by but a narrow channel of sea, the island has developed upon its own lines independently of its great neighbour. While in both countries the State has stepped in to aid the cultivator, and has undertaken costly works to provide his fields with an unfailing water supply, yet in Ceylon, owing to the cautious character of Lord Grey, it has done so with certain reserves, and only upon conditions of local responsibility. When it is remembered that the population to be dealt with is entirely Asiatic, and that the forms insisted upon are those associated in Europe with responsible Government, the difficulty of the task imposed may be appreciated. A short reference to the circumstances under which the policy was developed in the first instance may lead up to a better understanding of its present character, and of the important conclusions to which it points.

PORTUGUESE AND DUTCH PERIODS.

During the earliest ages the Sinhalese had developed an irrigation system on the greatest scale. As the official report for 1888 says:—"There is no part of the island, except the central mountain districts, in which the remains of canals and tanks are not found; but whether the whole island . . . was ever at any one time under cultivation, as some suppose, or whether the population, abandoning or driven from ancient centres of habitation, gradually migrated from one district to another, erecting new works where they settled, and allowing the old ones to decay, is a disputed question. The fact, however, that almost all irrigation works are found on investigation to form but parts of large connected systems, affecting

great stretches of country, would appear to favour the former supposition. . . . The Yodiela (canal) itself, 54 miles long, is only one link in a connected chain of tanks reaching far north and westward. . . . Another system, as yet only partially explored . . . extended from the foot of the Central Mountains to the sea on the south coast; while the remains of ancient cities, which are frequent in Uva, show that the country was once highly cultivated by the agency of canals, the remains of which are often crossed when traversing the forest." During the period of the Tamil invasions of the thirteenth century many of these were destroyed and others neglected so as to soon destroy themselves. The Portuguese were blind to their value and guilty of wilful vandalism, though the Dutch who succeeded them were enabled from their own experience to appreciate the navigable canals and take some steps for their maintenance. Still little was done, and the island which had maintained according to the records no less than 5,000,000 people, was unable when its irrigation was restricted to support more than 750,000.

RESTORATION OF WORKS BY THE BRITISH.

The British had scarcely taken possession before the cause of the national decline was discovered, and proposals were made even as early as 1800 for the restoration of some of the works. With customary deliberation successive Governors debated the question, and in 1832 it was referred to a commission, which, actuated by a laudable desire to free the people from the oppression of the *corvée*, or contribution of forced labour, recommended that not even her Majesty should be authorised to demand it for the future without payment. As it was by this means that the works had always been maintained, the ruin of many of those remaining speedily resulted. "Each cultivator was ready to grumble and complain that his neighbour would undertake no work of repair; but he was firmly resolved to do none himself so long as his fellows refrained from doing their part also." In 1846 Sir Emerson Tennent, then Colonial Secretary, endeavoured to awaken his superiors to the necessity for action. In 1847 he obtained a recommendation from a committee in favour of the repair of old tanks, and immediately afterwards tabled a proposal to apply portions of the road funds to this purpose.

LORD GREY'S MINUTE.

Lord Grey emphatically refused to follow a diversion exactly equivalent in Australia to the application of municipal rates to water supply purposes, and in a minute of 1849 laid down the principles upon which he would insist before authorising a new departure in State interference. His first condition was that the cultivators themselves must be consulted and form for the purpose a local body, and the second was that the works, being for the benefit of a particular body of persons in a particular locality, those thus favoured must bear at least a portion of the cost and maintenance of the scheme. The immediate effect of these requirements and of political exigencies was to delay the initiation of legislation for six years; not that it was impossible to comply with the conditions, for, indeed, in some respects they had long been anticipated.

VILLAGE COUNCILS OF IRRIGATION.

Every village in the island had possessed for centuries a kind of assembly of notables and elders, to whom all questions of common interest were referred. The absolute necessity for joint effort in connection with irrigation had been felt, and at a remote period a complete system of administration had sprung up, of which the tradition remained where the works had been destroyed, and the practice where they were still in existence. All land-holders were compelled to do their share of repairs or else they were refused water. They were forbidden to irrigate fresh fields unless there was a surplus available, and in a season of drought were allotted only a fair proportion of the diminished stream. The rotation of watering and the order of supply were strictly determined, and thefts of water or breaches of the custom promptly punished. This

communal system was readily revived when the need arose. The mere fact of its existence and persistence in the island, reiterating as it does the lessons of French and Italian experience, is full of significance for Australia. It offers another evidence that, to parody a French saying, if local bodies did not exist for other purposes it would be necessary for the sake of irrigation to create them. There must be some organisation such as that of the Victorian Trusts, no matter what part the Central Government may take in securing or distributing water supply.

IRRIGATION DURING SIR HENRY WARD'S ADMINISTRATION.

Sir William* Ward was the Governor to whom Ceylon owes its first ordinance on irrigation, dated 1st January, 1857, and in force for five years afterwards. The measure was tentative in character, and provided for little more than the revival of the ancient customs for obtaining and regulating a water supply whenever a two-thirds majority of the landed proprietors of any district approved. It was really applicable only to parts in which rice cultivation was already proceeding, in which there were comparatively few proprietors, and they happened to be unanimous. It was successful, therefore, only in one or two places, and supplies a parallel in several respects to the first Victorian Irrigation Clause of 1833. In 1861 the same ordinance was renewed, with slight amendments, for another period of five years, during which time the same difficulty that was and is felt at Victoria, when an influential minority opposes the legalisation of any scheme was keenly realised. Sir Hercules Robinson, who was in office in 1867, accordingly endorsed a measure in that year which destroyed the power of the minority to permanently obstruct. It provided for a vote of the land-owners for and against the establishment of irrigation districts to decide the issue, and for their control by a village council or headman under by-laws supported by penalties. Most important of all was the authorisation of the advance of money by the State for expenditure upon private lands. This at once indicated a new departure of a momentous kind. Taken as a whole this ordinance resembles the Victorian Act of 1836. Curiously enough it was largely founded, as that was, upon the report of a commission whose recommendations were more generous to the cultivator on some points than the Act itself proved to be. While free grants were suggested in Victoria, the free construction of minor works costing less than £100 was urged in Ceylon,

SIR HERCULES ROBINSON

remained faithful on the whole to the policy of Lord Grey, making one concession, however, which is more liberal than anything yet granted in Victoria. The capital required by the farmers to construct irrigation works was to be obtained from the State and repaid by 10 per cent instalments in 10 years, but the advance was made for that period without any interest. The representative of the Tamils in the Council contended that even this treatment was not sufficiently liberal, inasmuch as, in his opinion, the rice excise and increased land rents would amply repay the Government for its outlay. As it stands, the Government of Ceylon, by its gift of interest and by its departmental expenditure, will have probably paid as much towards a scheme ten years after its execution as have the farmers who directly benefit by it. This is handsome treatment.

SIR WILLIAM GREGORY AND HIS SUCCESSORS.

The success of the Ordinance of 1867 has been unquestionable. During Sir Hercules Robinson's term of office £105,000 was advanced or expended under its provisions. Sir William Gregory proved as energetic in this direction as his predecessor, a further £121,000 being provided under his administration. His successor, Sir James Longden, was a less vigorous ruler, but £117,000 was spent during his reign. Sir Arthur Gordon, who took office at the end of 1883, imparted fresh life to the policy involved in this class of public works. In 1884 a further concession was made to the irrigators, who were allowed

the option of accepting a permanent rate of 2s per acre in lieu of the obligation to repay the capital advanced to them in 10 years. This rate also provides for maintenance and repairs. In other words the Government made a permanent loan of the sum spent on the works, contenting itself with the receipt of its bare interest and cost of management. This is the Victorian system, minus its sinking fund and its compulsory acceptance of, and payment for, water. Assuredly if the operation of the rice tax and land rent be rendered equitable in themselves, the native farmer of Ceylon who irrigates cannot complain of the treatment he has received from his Government. There is nothing so liberal to be found in America, Europe, Egypt, or Australia.

CONSOLIDATION OF THE IRRIGATION MEASURES.

In 1889 the existing ordinances, five in number, relating to irrigation and rice cultivation were repealed and replaced by a consolidating measure which today embodies the law in Ceylon upon these subjects. It commences by establishing a series of provincial irrigation boards and a Central Irrigation Board. As is natural in a Crown Colony, these boards are nominated, consisting of Government officers and any other person or persons whom the Governor chooses to appoint. The settlement of the question as to whether an irrigation scheme shall be adopted or not, is left to be decided by a two-thirds majority of the local land-holders within its boundaries, who must represent at least one-third of the acreage to be benefited, or by the votes of those who own at least two-thirds of the acreage to be watered, irrespective of their number. This is exactly parallel to the Victorian law, which more strictly requires in each case the endorsement of a majority in number of proprietors, owing at least one-half of the area to be included. The application from owners to be lodged with the provincial board, like that furnished to the Victorian Department, must give the names of the proprietors and the allotments proposed to be watered. The preparation of plans and estimates rests with the provincial board, and if these involve an expenditure of not more than £250 they are empowered at once to make the advance; if the cost exceed that sum the proposal, with all necessary particulars, goes to the Central Board, whose decision is final on the question, just as that of the Executive Council is final in Victoria. That assent in our case is conveyed to the public through the *Government Gazette*, while in Ceylon the law requires that it should "be published in each village affected by the work by beat of tom-tom."

THE FUNDS.

The funds available for irrigation each year are apportioned among the provinces. It was for some years the practice to charge the watered land with only the estimated cost of the works but that has now been abandoned in favour of the Victorian system of charging the exact cost. Farmers in Ceylon are giving the option of executing certain earth-works themselves so long as they are done to the satisfaction of the officer in charge. This enables them to claim a grant of a certain amount of money or its equivalent in works, at the expense of the State, and in a provision of which much advantage is taken. Land required for any scheme may be acquired on payment of compensation. The capital cost of a scheme may be repaid in ten yearly instalments and in that case the works are maintained by the Government for 2½d. per acre, per annum, or a perpetual rate fixed by the Government, but not exceeding 2s per acre, may be paid for both interest and maintenance. The debt as in Victoria is a first charge upon the land, which may be seized and sold if the proprietor be in default. The setting aside of one-fourth of the grain tax as a special appropriation for irrigation works, and the appointment of village councils or headmen, are peculiar to Ceylon, but in other respects the ordinance bears a most remarkable likeness to the present Victorian law. Our Parliament has never suspected that the main principles of our act were anticipated in this Crown colony, but such

* Sir Henry G. Ward.—ED. T.A.

is the fact. The similarity speaks strongly in favour of the principles thus mutually but independently approved. The last addition to the policy in Ceylon is the appointment of a Central Board charged with the function devolving upon the Minister in Victoria. It is within the bounds of possibility that the admitted success of the ordinance in this particular may be hereafter worthy of very careful consideration by our own Legislature.

A CONTRAST.

The great difference in point of practice between the two countries is that the State in Ceylon not only offers greater inducements to its irrigators, but that it does more for them. It is the State that constructs and maintains the works—instead of the Trusts. All that the individual does is to undertake to pay the rates levied upon him. Although the village councils are greatly relied upon in the island it is, of course, impossible to compare their capacity for self-government with that of Australian shires. The authority which is properly placed in the hands of the Victorian farmer over the design and management of the scheme in his district, like that of the irrigator in Lombardy, Piedmont, and the south of France, is very considerable. Such a power could not with safety be entrusted to the Tamil or Sinhalese. They must be content to remain under control for some generation to come. The native can accept or reject a scheme, and provide for its minor administrative duties, but beyond these he must trust to those who are placed over him, and accept their judgment as to what is most for his interest.

In one other respect the experience of Ceylon is worthy of remark. It was the suggestion of Lord Grey that

THE IRRIGATING SYSTEMS OF OTHER COUNTRIES

should be studied with a view to their application so far as they might be suitable to Ceylon, and Sir Arthur Gordon notes that it was to the inquiries of Mr. J. Bailey into Indian and Italian methods that much of the first success of the movement was due. The first ordinance was based upon his report, and it proceeded upon lines which experience has amply justified. If we are not as successful in Australia it will not be from any want in this direction. The articles of Mr. J. L. Dow, M.P., and of Mr. T. K. Dow, together with the reports published and circulated gratis by the Victorian Government, including the recent letters of Mr. West, have familiarised those who read them with the practices in the United States, Egypt, and Italy, while Mr. Ward has preached the gospel of irrigation with graphic power in New South Wales.

LARGE TANKS.

The one hostile criticism offered in the island against its policy of irrigation has been levelled only against schemes which were new and large and against the undue encouragement alleged to be offered to rice growing. Smaller works and restorations of a minor kind have been expressly approved even by opposition critics. The general public appears to be well contented with the policy. Those who can claim to speak on the subject free from all official trammels, such as Hon. J. J. Grinlinton, M.L.C., an old resident who enjoys the confidence of the natives to a remarkable degree, and who has taken an active and independent interest in public affairs for many years, assert that the system as a whole, whether from a political or professional point of view, is a complete success. The task of the Central Board was declared by itself to be one of no early or easy fulfilment. "It is to the gradual and patient renewal of the ancient irrigation systems of a whole district, utilising every drop of water available, that our efforts should be directed. It is by this means that the crops of a district are multiplied manifold and secured from failure; that many forms of disease and extreme want are banished; and that the health, wealth, and comfort of the people are permanently assured." With what has been done to give effect to this programme its members have expressed their cordial satisfaction in one of their published reports,

in which they testify that in Ceylon irrigation has already "meant health instead of sickness, comfort instead of starvation, in many cases life instead of death."

The circumstances of the island have called for

DESIGNS OF A SPECIAL CHARACTER.

The rivers of Ceylon are solely rain-fed, for though hail is occasionally seen, there is no snow. The largest of its streams has a drainage of 4,000 square miles, is 134 miles in length, and reaches the sea near Trincomalee. It was not because of the deficiency of precipitation that irrigation was employed in the east and to the north, where it most flourishes, but because its timeliness could not always be relied upon. The rainfall on the coast is 88-85 inches. The cultivated areas of the low country have a mean of 82 inches, while in the mountains 2,000 feet above sea level it rises to 217 inches as the average of nine years. The important circumstance connected with the rainfall is the largeness of the fall in very short periods; 9 inches to 12 inches during the twenty-four hours being experienced occasionally in many parts of the island. Eight inches per day for four consecutive days has been actually measured. The monsoon pours itself over the land in torrents, which cut for themselves deep channels of rapid escape, and at times flood a whole country side, though dry for the rest of the year. It is this condition which renders storage essential to all irrigation, and the immense reservoirs of the past were constructed accordingly to impound these enormous downpours for the use of farmers during the dry season.

It may be noted in passing that the violence of the rainstorms necessarily denudes the higher lands and heavily charges the streams with silt. This collects at the mouth of each river, and forms a bar which diverts it at last for some distance parallel with the sea, though from time to time it forces a new outlet. Along the coast there are stretches of lagoon country closely resembling the sea-fringe of Gippsland from Lake Denison to Cunninghame, with its chain of shallow and brackish waters divided from the ocean by a narrow strip of made ground. A somewhat similar phenomenon may be observed on the eastern shore of India, from Madras northwards to the Godaverri. Both there and in Ceylon these lagoons have been improved and utilised for navigation.

THE BASIS OF IRRIGATION IN CEYLON

is the tank. There exist throughout the low country an immense number of minor storages, from each of which one or more fields are watered. Often the smallest are dependent upon their own little catchments only. The larger, however, both in ancient and modern times, were seldom constructed unless it was possible to supplement the supply from a stream or to connect a chain of tanks so as to minimize the possibilities of failure in dry seasons. The tanks themselves were always rudely built and often insignificant in capacity, but the headworks of the system consisted, and consist, of a large reservoir or an expensive weir, with probably channels of considerable size to or from it. In the past, according to the testimony of more than one district engineer, by means of elaborate connections and distributors, every dribble of water was employed, and it has been the best hope of recent Administrations to be able to restore the schemes which made this economy possible hundreds of years ago. There have been already 2,250 small tanks repaired by British engineers, without counting those which have been indirectly benefited.

THE RECENT RESTORATION.

These restorations have involved the reconstruction of 9 large reservoirs, of 245 anicuts, as weirs are here termed, and of 700 miles of canal either partially or wholly renewed. Many of these works are of notable dimensions. The Kantalai reservoir irrigates 25,000 acres, the Walawe-ganga weir commands 10,000 acres and the Tissamaharama tank 2,000 acres. The famous Kalawewa storage has been once more brought into use. Its by-wash has been raised to

20 feet, giving a water surface of 3,300 acres, a contour of nearly 32 miles, and a capacity of close upon 2,000,000,000 cubic feet. By raising the by-wash another five feet the quantity retained can be increased by over 50 per cent. It can irrigate 23,000 acres, and if enlarged could do so through the longest drought ever experienced in its neighbourhood. It feeds eighty tanks and commands a large area of country. Such works as these may be taken as illustrative of the scope and character of the engineering ability of the ancient Sinhalese and of the present Department, which has in Mr. McBride a highly competent chief, whose name is already associated with a reform of the system of macadamised road-making by which 50 per cent has been saved to the State, and the reputation of the island for the excellence of its high-ways fully maintained. Much, however, remains to be done before the work of restoration is completed. Mr. Grinlinton considers that £500,000 would finish all the schemes that are at present called for, but this would probably prove to be under the mark. Mr. Vine, the able engineer in charge of the chief province speaks of a native canal, 40 feet wide and 40 feet in depth, of which he has traced the course, and it would require but a few works of this class to be added to increase the present estimate.

UNDER-ESTIMATES AND MISCALCULATIONS.

It is not to be assumed that Ceylon has proved an exception to the universal rule that experience has to be paid for in the inauguration of any new enterprise. The history of its engineering discovers miscalculation, such as that with regard to the capacity of Tissambarama, which proved to be but one-fifth of the estimate. The surveys at Adichchikalm were so faulty that the progress of the undertaking was stopped altogether. The Elahera canal by no means realised expectations, while more than once the Governor has had to complain of the under estimate of the cost of works in one part, or the indifferent execution of in another part. Sir William Gregory, speaking upon this point in 1874, said, "I cannot attach blame to any person connected with these works for these insufficient estimates. I blame the system. The great object of the then Government was to get irrigation set on foot without delay." There has been the same anxiety in Victoria, but the errors discovered pertain less to the works than to the purposes to which they were limited.

LIBERAL CONCESSION BY GOVERNMENT.

Neither is it to be assumed that the great works constructed have been immediately successful. As a matter of fact in every case the utilisation of the supply provided has been gradual. Recognising this the Government has made liberal concessions to those commencing to irrigate. It charges no rates for four years, foregoes interest for ten years, and makes free grants in connection with small tank construction. If the natives construct the earthwork of a tank the Government gives them gratis a masonry by-wash, or spill water as it is termed, and an outlet of cement pipes. These concessions are greatly appreciated by the inhabitants, especially the last, one officer reporting that in the Matale district during 1888-89, while the Government expenditure was £1,295 that of the natives in labour was worth £1,998. Up to 1889 the earthwork done by them in this way amounted to over 6,000,000 cubic yards. Yet even with these concessions, those who are most satisfied with the policy pursued consider that time must be allowed in every instance for the development of every considerable work. Several of those now classed as successes were held to be failures for some time after their completion, and one district controller goes so far as to say that twenty years is necessary to determine the true value of each great scheme. Impatient critics in Australia are not likely to be persuaded by him to hold their peace for such a protracted term.

So many of the Ceylon works are restorations that the sums expended occasionally appear

DISPROPORTIONATE TO THE RESULTS.

obtained, since no allowance is made as in Madras for the value of the original work embodied in the new scheme. Then the expenses of maintenance require to be deducted from the annual totals, so that the total capital invested, and upon which interest should be earned, can be roughly set down, making allowance for all kinds of outlay, at £500,000, for which 100,000 acres are being permanently watered. This is a high rate per acre; higher than that of the Victorian authorised schemes and national works, in spite of the fact that labour can be obtained for a wage of fewer pence per day than we pay shillings. The explanation is that rice is a thirsty crop, requiring according to Mr. J. R. Mosse, M. Inst. C. E., late director of public works, a cubic yard of water to every square yard of ground, or thrice as much as is likely to be required in Australia. This of course, increases the acreage cost proportionately.

LABOUR IN CEYLON.

is not merely cheap, but in many respects good also. The present head of the Irrigation Department considers that for either earthwork or stonebreaking the Tamil is equal to the European. But the labour has its peculiarities. It is not males only who are employed; whole families work together. On the roads, in the rice fields, or in the plantation, the women are side by side with the men, taking the lighter share of severe exertion but bearing most of the burdens. Children, so soon as they are able, work with their parents. None of them are violent in their exertions, but their efforts are sustained, and are continued in most cases, with little intermission, from dawn till dusk.

OTHER CONDITIONS

are equally novel to us and render comparisons unprofitable. Communal labour is frequent and there is a good deal of communal proprietorship among the villages. Inheritances of real estate are often, on the French method, divided equally among children, and joint partnership becomes so complicated that a suit has been conducted in the courts in which the subject of litigation was the 2-520th part of ten coconut trees. Machinery is unknown, except the rudest kind of water lifters, and the implements of agriculture are of the simplest. The native is a stolid conservative in opinions and practices, and though thus evidencing the limited range of his ideas cannot be condemned altogether for his adherence to traditional practices. He knows what just suits his present style of living, and has no ambition to alter its general character. If he possesses sufficient for the day he is contented and prefers to obtain that sufficiency in a time-honoured way, rather than venture upon a change that promises a better return to greater perseverance.

UNUSED TANKS.

Irrigation has therefore in Ceylon a series of obstacles in the way of its progress, owing to the inherent conservatism of the irrigators. Some fine tanks constructed by the Government, notably those in the western districts, Magalawewa, Galgamuwa and Mahawewa, have remained for some time unutilised, because the Sinhalese decline to leave their present homes, which are at a little distance, in order to take advantage of the storage. Fortunately the Tamils are more enterprising, and the force of their example operates, though slowly, upon their neighbours. Another and greater difficulty arises from indolence and greed. Even rice, though an amphibious plant, may be overwatered, and partly from carelessness and partly from the desire to take all the water they can, many of the Sinhalese drown rather than irrigate their crops and suffer accordingly. The low yields often complained of, arise as much from bad farming as from any other cause, for when skill and caution in the use of water go together, the best irrigators obtain twenty fold and thirty fold. The silt in the low country is a valu-

able addition, but in the mountains the streams are clear, except when there are plantations above. The clearing and cultivation of the planter occasion a sediment in the streams near his estate, which is distinctly traceable below; a fact which has a direct bearing on the influence of forest cultivation, and the necessity for reservation of land above all town supplies.

THE SINHALESE BAD FARMERS AND ENGINEERS.

The Sinhalese is sometimes a bad farmer, and very often a bad engineer. Thus a Government agent is compelled to report that "The distributing channels have apparently had no attention paid to them, the old native courses have been adopted, and the development of new ones left nearly altogether in the hands of the Vanniys. These men know nothing of levels, and consequently do not always select the best line, though the people are very energetic and willing to spend money to obtain water. To secure this in many places the level of the surface of the fields is reduced several feet, with a loss, of course, of the best soil which is heaped up in banks." There is little or no excuse for such blindness as this discloses. Water will reach its own levels. Other conditions are quite favourable. The red soil of the uplands must be very stiff since it permits channels to be constructed with a fall of over ten feet to the mile without erosion. The narrow checks made to retain the flow in the rice fields appear to maintain their consistency very satisfactorily, so that the natives have an easy task before them if they supplement these many natural advantages by knowledge, judgment, and energy.

The problem in Ceylon relates for the future less to irrigation than to the irrigator. The law is liberal; its administration intelligent, and its results admirable. The market is favourable, and success is only limited by the courage and capacity of those for whose use the water has been diverted or stored. Fast as rice cultivation has extended, population has increased faster, and the imports grow year by year in spite of the duty. Everything, therefore, waits for the cultivator, everything is ready to his hand, he has but to stretch it out to grasp his reward. Before we reproach him for his tardiness and timidity we had better, perhaps, assure ourselves that in Victoria we are not open in some degree to a similar criticism even at the present moment.

UVA PLANTING REPORT.

BADULLA, Jan. 3.

WEATHER is most extraordinary and most unseasonable. The wind is N.-West instead of N.-East and is very strong. A bright and hot sun has taken the place of the clouds and rain we should have at what is usually the wettest time of the year. While the western slopes of Namunakula had a fair amount of rain and mist in December, the eastern slopes had practically none. This is a pity in more ways than one. We want rain to ripen up the remaining coffee crop, and the unexpected break has played havoc with those clearings which were planted in the early part of December. It has been the most treacherous planting season I remember.

COFFEE still looks bad. Bug is in the black stage, and fields affected with this pest look particularly unhappy; all coffee however looks bad just now, for at this dead season of the year, there is, as always, a heavy fall of leaf, which makes ridges and weak features look thin and poor. The wind has accentuated this.

TEA.—Tea never does much in this district in the end of December-January, and this year is no exception. There is very little leaf coming in, and factory hands are having an easy time of it. A few weeks more, however, and they will have quite as much as they can do. A little pruning is being done and a considerable acreage will be down before the end of the month. The past six months have been very favourable for growth of leaf, and returns are everywhere better than last year. There has been a much smaller acreage put into tea this year

than usual—due probably to the splendid prices coffee is now fetching; and what has been planted will not all be very regular at a year old, I fancy.

GENERAL.—The work on our new roads has not been commenced yet, but I understand that they will be in full swing in another few weeks. The railway cuttings are now visible almost to Baudarawela, and 1893 will be a great landmark in the history of the province; energy and progress are visible everywhere; and if only tea will keep at a moderate paying figure the next ten years will see a wonderful change in "Outcast Uva." There is, I hear, to be a great function at the railway opening in April.—The general meeting of the Association is fixed for 11th February.

TEA CHESTS IN PEERMAD.

It is curious how the tea chest industry has sprung up of late, and how competition has cut down prices. When it first began, full chests of mango wood cost Rs. 14 annas on the coast, or wherever they were made; gradually they went down, till now you can obtain the same kind for 11½ annas at Alleppy, and though some firms are keeping up their prices they will, of course, have to reduce. Probably 11 annas is about the margin they will pay at. Besides the coast firms, innumerable natives have also undertaken the trade, and if only they could be relied on to execute the orders punctually, would monopolise the trade, being nearer the hills and consequently being able to put them on the estates cheaper. But this, and the regular native failing of being unable to resist a little extra profit by infirm timber, is fatal to their doing as well as they should do. I have made chests myself on the hills, with native carpenters; but could never turn them out under 12 annas on the place, and then the time required to season the timber, and difficulty at above 3,000 ft. in getting suitable timber in large quantities, would always be a bar, though, at a little lower elevation with a circular saw worked by power, it should pay. Chests are always made of light wood of the Mango or Cotton, which is of little use otherwise; so it is a source of revenue to the Sircar caused by the planter, which I am sure the Forest Officers appreciate. The chests are of 3 sizes, called full, half and quarter and contain about 100 lb., 50 lb. and 25 lb. respectively. Many Estates put these exact amounts in, and this, I think, is the simplest and best way. If the weights are really correct, the Customs people take it as bulked, otherwise with uneven weights, they rebulk the whole break. All packages are called chests, unless otherwise stated clearly by the shipper (*b*) stands for boxes i.e. $\frac{1}{4}$ chests, ($\frac{1}{2}$ c) for chests, (*p*) for packages i.e., full chests, (*x*). Prices marked thus represent the biggest offer made. All brokers stick to these rules, and send circulars weekly, with the price of each grade of tea, and the average price of the whole break. In calculating the average, a chest is taken at 100 lb. 2 half chests or 4 boxes to equal a chest.—*Cor. M. Times.*

TEA PROSPECTS.—Two items of considerable interest to the growing body of shareholders in Indian tea companies are published, both relating to railway enterprise. One is that the Bengal-Doonars Railway is likely to be ready for passenger traffic in April and for the conveyance of goods rather earlier, while the fact that the line is one of the cheapest in India gives promise of easy rates. The Doonars being one of the leading tea districts in India, the construction of this railway is of no little importance to the industry. The Assam-Bengal Railway, which will bring the Assam tea gardens much nearer the ports of shipment, is also being actively constructed.—*Financial News, London.*

Correspondence.

To the Editor.

CEYLON CACAO PLANTATIONS.

Kegalla, Dec. 18th, 1892.

SIR,—With reference to the letter of "Danger" commenting on mine, I apologise to him and to you for describing certain letters as articles. As to my description of those letters, I think I can count a majority of those who have had experience in cacao endorsing my view of those letters. It strikes me that "Danger's" letter, if not a "wild" one, is to say the least, very peculiar and deserves little notice. He says "Let the bare simple truth be told, and if the enterprise cannot stand, by all means let it fall;" and then lower down he upholds the gist of my contention by saying "cacao wants no writing up, but it has some special requirements that have been duly noted both by old and modern agriculturists, and for any young investor to ignore these and local experiences as well would be extremely foolish," and so say I.

In my letter I did not make anyone believe that fortunes can be made in this cultivation as did after all only a fraction of the coffee planters in the best of times. Nor did I intend to insinuate that there are no enemies to contend with. Would the fact that occasional droughts or the appearance of red spider deter tea being planted in Ceylon now? As to Government railway rates, thieves, and the refusal of Government to lash them, these are minor matters that can be to a great extent remedied by preventive measures and agitation and combination on the part of those interested.

I still maintain that the price of cacao has increased considerably, the occasional rise and drop of prices from 125 to 105 notwithstanding. Compare the present average annual price with those of former years, commencing from the earlier years of this cultivation, and my contention will be found to be correct. "Danger" says the crop is short by 2,000 cwt.; but the year is not out, and the cacao crop is late this year in ripening. The cultivation, I maintain, is increasing though I regret to say chiefly by the natives, as the returns at the K'chocheries will show. As to the destructive agencies in the West Indies, we are not concerned about them, and if that is to be a deterrent, tea planters had better let their enterprise fall, because red spider plays havoc in the Assam-gardens. Even years ago a sturdy coffee planter of Dimbula, who in his earlier years had travelled and was in some business in China, described the tea enterprise in Ceylon as adding more "coals to fire" when leaf-disease was impoverishing the island! Poor man, if alive now, how astonished he would be? I certainly never advocated planting cacao alone: there is too much waste ground that could be utilized interplanting other products till the plantation is well established, and what is to be interplanted depends on soil and locality. Liberian coffee is about the best for the purpose. Come down from your wind-blown soil-washed dismal hills, where even weeds and mana seem loath to grow, and select lands in the lower hill ranges and valleys, leaving questions of delightful climate aside, and you may get the land that will yield that you want. I have heard some ask what is the trenching system. It is this. Cut a circular trench 2½ to 3 feet from the tree 15 to 18 inches deep. The soil raised should form an outer bund or walling. Fork up carefully the soil left between the trench and the tree. Throw in a compost of everything available: cattle dung, ashes, leaves, twigs, coarse bones, husks, &c. Trees that after yielding their maiden crops have fallen back will again develop and yield nearly double their former crop, and the cost of this system once in three years is not more than that was spent annually in manuring 3,000 to 4,000 coffee trees.

OLD HAND.

TEA SALES: THE HOME V. COLOMBO MARKET.

DEAR SIR,—Is it better to sell your tea in the Local Market or ship it to London? To enable your readers to answer this, allow me to state that X, Y, Z three different properties—have their leaf manufactured in one factory as if all belonged to one estate. X ships to England all its tea in breaks of about 7,000 lb.—Y and Z sell in the local market under their respective marks, in breaks of about 4,500 and 3,000 lb. each.

X London sales averaged.. 7-80d.
Y Colombo do do .. 39-33 cts.
Z do do do .. 43-34 "

If you deduct 1½d per lb. for freight and all London charges, X's net average is 6-30d; and as exchange for 3 months' credits during 12 months ending 30th June 1892 averaged about 1s 4½d, you have 37-80 cents for X's tea against 39-33 cents and 43-34 cents with the advantage of cash on delivery less the small local charges.—Yours truly,

A LOCAL SELLER.

[We notice from last volume of our *Tropical Agriculturist*, page 282, that the same experience pretty well was recorded for 1890-91. A's tea getting 44-36 cents at home; while B's sold for 47-03 cents and C's for 49-56 cents locally.—ED. T.A.]

LAND AVAILABLE FOR THE EXTENSION OF TEA CULTURE IN CEYLON: TOO MUCH OF A GOOD THING.

Upcountry, Dec. 20th.

DEAR SIR,—“Wanderer” in your issue of the 17th inst. says “there is not much to increase in the hill districts” and further on “there is any amount of land in native hands in the low-country quite suitable for the tea weed.” Now, as to the former it depends on what he considers “hill districts:” but if from 2,000 to 4,000 feet can be considered such, I think there is still a large extent available for tea in private hands (not natives.) I take from your Directory for 1891—the only one I have at hand at the moment:—

	acres.
Balangoda ..	17,015
Rakwana ..	12,903
Kukulū Korale ..	5,895
Morawak'Korale ..	13,258
	<hr/>
Total ..	49,076
Cultivated ..	8,871
	<hr/>
Balance ..	40,205

Mr. Mantell can give you the quantity available in the hands of Government, which will be a nice addition to the above. Where then could there be a better field for “Creepers” to try their hands at reducing the price of tea. As for chena land, this is the home of it, and dozens of Mariawattes can be carved out of it. Anyone wishing to see for themselves what can be done in the way of tea-growing in this quarter, should visit Chetnole estate. I mention this estate as it is a very handy one to get at from Balangoda, and is in the heart of the chena country.

AN OLD COFFEE STUMP.

TEA CHESTS WARRANTED AGAINST DESTROYING FLAVOUR OR WARRANTED NOT TO DESTROY THE FLAVOUR.

DEAR SIR,—The arrival of the Acme Tea Chests is most opportune, as they are made of steel, and therefore cannot impart any foreign flavour to the tea. They are made by machinery and are there-

fore same in weight and capacity—ensuring even tares. They save 20 per cent in freight and 10 per cent on the inland carriage.

They are put together in four minutes by an ordinary coo'y, and are opened and closed in two minutes, and conveniently sealed against pilferage. The chests when emptied have a return value of 81 per chest and 61 per half-chest.

I was informed that the grower will actually save 2½d per chest, although the primary cost is greater, no lead, hoop iron or nails being required; but this is not borne out by experience—see figures below.

Here is the comparative price:—	s. d.
Aome 100 lb. chest ...	3 6
Saving on inland carriage 2d ...	0 11
Saving on freight 9d ...	2 7
Cost of wooden chest R1 ...	1 3
Lead and solder ...	1 3
Nails and hoops, &c. ...	0 3½
	2 9½

In reply to your query as to cost of tea chests, here are my figures for year ending 30th June 1892:—

	Per lb. of made tea.
	Cents.
Cost of Japanese full-sized chests } delivered at Matale	.992
Hoop iron and nails..12
Lead, solder fluid, stencil ink761
Cart transport to estate ...	1.0
Carpenter's wages097
	2.090

Packages have therefore cost 2.09c. per lb. of made tea.—Yours truly,
PLANTER.

COFFEE PLANTING IN MEXICO.—We received by yesterday's mail, a long and most interesting account from our well-known correspondent, Mr. W. J. Forsyth (formerly of Maturata) of his experience as a coffee planter in Mexico. It is addressed to the *Tropical Agriculturist* and covers some 13 pages of post, giving full particulars of his experience, with figures for cost and results, and a description of the lands available for coffee. These are chiefly on the Pacific slope and the beginning of the coffee belt is distant only about 30 miles from the coast. The Guatemala coffee districts are not far off. The jungle is very fine and the soil rich: the mode of working very different from that in India and Ceylon. Mr. Forsyth is busily engaged opening a large coffee plantation himself out of some 3,000 acres of fine forest land: he planted 250 acres in 1891; 150 acres this year and he will have another 100 acres in by June 1893—300 more acres (the forest now decaying away after only a slight burn) to be planted in 1895-6. But we must refer to the letter itself for the full particulars and further letters are to follow. It is quite clear that in Mexico and Guatemala, besides Jamaica, the Straits and the East African hillcountry there is plenty of scope still for the experience and energy of Ceylon coffee planters; and it will be our business to keep them fully apprised through the *T.A.* and *Observer*, of the chances open to them, and to collect the best information respecting these new coffee countries from our own correspondents and other reliable sources.

THE DRAINAGE OF OUR ESTATES AND PADDY CULTIVATION.

A correspondent asks us if we have ever considered how seriously the change made from coffee to tea as the main growth on Ceylon estates has affected the paddy cultivation among our higher ranges. He tells us that stories have reached him of long cultivated lands having had to be abandoned because of the cessation of the supply of the manurial element which in days gone by used to be washed down from our coffee estates. We cannot cite any instances known to ourselves of such abandonment, but it is not difficult to imagine them as the result of changes made within the last twenty years. In the early days when coffee was king, not much attention was given in the lower planting districts to systematic drainage on estates. The leaves and cuttings from the trees were turned into the soil loosened by the mamoty, and during heavy rains a large proportion of such admixture was washed down the steep hill-sides until it found a resting-place in the paddy fields cultivated at their base. No doubt this wash was of a particularly fertilizing description, and must have been most valuable to the cultivators of fields so situated. It is alleged that this supply is now altogether stopped, and that the adoption of systematic drainage, which has stayed the denudation of soil from the uplands under cultivation with tea, has become a serious matter for the paddy growers in the lower country. However, this may be, it is certain that improved methods of drainage had become a vital necessity for our planters. Denudation of the soils of our hillsides, which no longer enjoyed their natural protection of long grasses and undergrowths, had been proceeding for a long series of years, until it became a question as to how long there would remain any depth of soil upon them sufficient for cultivation of any kind to be carried on. Now one of the chief outlays that has to be made where new land is being opened for tea, or old coffee-growing is being abandoned for it, is upon the establishment of a thorough system of drainage. The tea bush does not yield to the soil that return of leaf which the coffee tree did, and which in some degree compensated for the waste due to the carrying-off of soil by the heavy surface wash. If any soil at all was to be retained, therefore, it became an absolute necessity to put a stop to this surface wash, and the care taken to lead off the waters by accurately graded drains that is now apparent on most estates, proves how thoroughly alive our planters have become to the duty imposed upon them by changed conditions. No doubt, however, some wash, in spite of all the care taken to prevent it, still reaches the lower levels in which the paddy fields we have alluded to are situated. But, as we have pointed out, such wash does not contain the same manure as it did in the days of coffee cultivation, and we therefore think it likely to be correct that many paddy fields that in the olden time were reinvigorated by the drainage off the coffee estates, and flourished exceedingly as the consequence, are now suffering so greatly from its absence as to render it not worth the while of their owner to continue to cultivate them. It was time, as we have before remarked, that some steps should be taken to maintain a depth of soil upon our hills. The fallen coffee leaves no doubt contributed towards this end. With tea, even though mainly a deep feeder, it was necessary to adopt a more scientific method; and although we may sympathize with the paddy growers, we can hardly regret the loss they have now to put up with.

PROGRESS IN BORNEO.

For several reasons we in this island have always felt much interest in the affairs of what has been called the sixth continent, though Joseph Hatton dubbed the Northern and British portion as "New Ceylon." A good many of our planters as well as of Ceylonese have, from time to time, left their native soil in order to take up occupation of some kind or another in Borneo, and this fact alone would go far to account for the feeling with which its affairs are watched here. Then, again, Borneo has not at any time threatened to become a rival in any of our chief local products. At the time when tobacco cultivation on a large scale was thought to be likely to become an important industry among us there was, perhaps, reason why some slight feeling of jealous rivalry might have been entertained, but with the collapse of our own hopes in that respect, there came the feeling that we had no competition to dread from the cultivation pursued by the several Companies which have been striving to develop the resources of North Borneo. We need therefore feel nothing but sympathy with the shareholders in these Companies when, year after year, their directors have to meet them with the statement that it is as yet impossible to give them any return upon their investments, a disappointment which can only be partially solaced by the hopes annually held out of better things to come. Unfortunately, the latest information received of affairs in Borneo differs in no respect from that which it has been the painful duty of the directors of the British North Borneo Company to submit to their shareholders for the past ten years. It is still a case of hope deferred and of renewed disappointment. It can hardly be wondered at that the shareholders are beginning to turn restive under such provocation, though the insinuations made that the directors are to blame would seem to be hardly warranted by the facts made public. Indeed, when some two years back there was a rush for land belonging to the Company with the intention of planting tobacco on a large scale, it seemed as if the days of its difficulties were over and that a bright future was in store for its shareholders. But then came the increase in the rate of the American tariff, and that vast field for disposal of produce became as completely closed to the tobacco planters of Sumatra and Borneo as it had for the buttons of some French towns and for the cutlery of Sheffield. An idea may be formed of the disastrous effect that the MacKintley tariff had on the tobacco planters of Sumatra from consideration of the fact that the annual yield of their produce for the present year is estimated at 120,000 bales only, against the 240,000 bales of 1891. Half the land formerly cultivated with tobacco in Sumatra has been thrown out of cultivation owing to the effect of the increased duty imposed in America. Naturally, such a result was felt with equal, indeed with even greater, stress among the planters in North Borneo, who were then struggling with the difficulties of a newly-commenced industry. It can hardly surprise us to learn that under such conditions estates have had to be abandoned in great numbers, and there seems to be but little chance of their again being cultivated while the Americans continued to impose a duty of two dollars per pound upon imported tobacco. This rate of duty is alone equal to the retail selling prices of the finest tobaccos in the London shops, and so long as this tariff is retained, the planters of Sumatra and Borneo can hardly look for a revival of hope. Tobacco is now indubitably the staple of

production in Borneo, and until its growth can be made to pay, we fear the shareholders in the several companies working there will hardly obtain a return upon the money invested by them. It is not the case, however, that tobacco is the sole cultivation of Borneo. We are told of hemp, Liberian coffee, and gambier, all doing well; but these industries, although said to be full of promise, are but yet in their infancy, and cannot be said to hold out any prospects of early profitable return to those who have taken up land for the purpose of pursuing them. Then the search after gold has also proved disappointing. The metal is found in paying quantities, but sickness has struck down in large numbers the Chinese diggers who have immigrated in the hopes of making rapid fortunes. Year after year, when the directors have met the shareholders, there have been hopes expressed that railways would soon be commenced and their construction prove a panacea for most of the ills with which the territory is afflicted; but as yet this scheme has not gone beyond the discussion stages, and it is with reference to this delay that so much of blame is attributed to the directors of the British North Borneo Company. It is impossible for us to say how far the hopefulness these express for the future may be justified, but it is certain that hitherto the results to European enterprise in North Borneo have been discouraging in the extreme.

◆

THE CEYLON LAND AND PRODUCE
COMPANY, LIMITED.

Your Directors beg to submit the annexed Profit and Loss Account and Balance Sheet for the year ending 30th June, 1892, duly audited.

The amount at credit of Profit and Loss Account, after reducing the mortgage over North Ma'ale Estate, &c. by £2,015 7s. 5d., is £6,118 14s. 11d., which, with the sum of £1,096 15s. 2d. brought forward from last year, leaves £7,215 10s. 1d. to be dealt with.

On the 20th of July last an Interim Dividend of $7\frac{1}{2}$ per cent. on the Ordinary Shares, and 3 per cent. on the Preference Shares was paid, and your Directors now propose to pay on the 31st day of January next the balance of the fixed cumulative Dividend on the Preference Shares (3 per cent.), making 6 per cent. for the year, and $7\frac{1}{2}$ per cent. on the Ordinary Shares, both free of Income Tax, making 15 per cent. for the year. It is also proposed to take from the Profit and Loss Account a sum of £500 for the further reduction of the North Ma'ale Mortgage. This will leave a balance of £1,903 10s. 1d. to be carried forward, subject to the Directors' remuneration for the year under review, to be fixed at the General Meeting, and to the payment of Income Tax, &c.

The result of the operations during the past season has not been quite so favourable when compared with that of the preceding year, and this is largely owing to the abnormally wet and cold weather that has prevailed. The Tea bushes have been prevented from flushing to their average extent, and, as a natural consequence the estimates of the crops have not in all cases been reached. The Cocoa crop rather exceeded the forecast, but the yield of Coffee was very deficient.

TEA.—During the first six months of 1892 the sales of Ceylon Tea showed an increase over those in the same period of 1891 of nearly 55,000 packages, but the average price was disappointing, being $1\frac{1}{2}$ d. per lb. less. For the last eleven months (January–November) the total quantity offered at auction was 753,000 packages, sold at an average of 9½d per lb., against 695,600 packages in the previous year, which realised 10½d per lb. Heavier supplies, and the expectation of a considerably increased yield, combined with the dullness of trade generally, kept our market depressed, until the lowest point was

tonched in July, when the monthly average declined to 8½d per lb., being about the lowest yet recorded. From this time, however, better teas commenced to come forward, which together with advices of smaller shipments from Colombo, gave buyers more confidence, and a gradual reaction took place. Later on this developed into a strong demand, especially for all the lower grades, when the trade realized that the monthly deliveries were exceeding the arrivals by about 1½ million lb., so that by the end of November the monthly average had risen to 11½d per lb.

No doubt the abnormally low rates current during several months for clean sweet liquoring pekoes and pekoes souchongs were instrumental in forcing these on the notice, not only of the London dealers, but, as the export returns testify, also of Continental, Canadian and American buyers. On the whole, therefore, recurring periods of depression in prices appear beneficial to the trade generally, as by these the teas from the island are made more widely known, and the area of consumption is increased.

Your Directors are pleased to report that notwithstanding the lower prices ruling for Ceylon tea generally during the past year, better results have been obtained for the produce from the Company's Fetteresso and Rickarton estates; on the other hand, however, the low-grown teas have shared in the general depression.

COFFEE.—The market for this article has been good throughout the year, and very satisfactory prices have been obtained, but the production from the island appears to diminish rather than increase. The fears of reduced prices generally expressed at the end of last year, happily proved groundless, as the large Brazil crops were absorbed without seriously increasing the stocks of the world. The high prices which have now existed for over six years have, however, rendered the expansion in consumption slow, and planting in various countries, especially in Columbia, has been pushed forward during recent years, so that increased supplies may in due course be anticipated. In the near future, however, no great change can be looked for, as the large estimates of this season's Brazil crops are being reduced.

The highest price paid for Liberian Ceylon coffee this year was realized for a parcel of the Company's from North Matale Estate on the 6th October, when 98/ per cwt. was obtained.

Cocoa.—A good demand has prevailed throughout the year, but prices are lower than those ruling last year, although the production of the island has been less. This falling off in value is partly attributable to the competition of Java which was anticipated in last year's report, and also to the pernicious system of making direct offers from Colombo to the various Markets, thus stifling competitive orders; as a consequence the output of Java being almost entirely sent to Holland, the price of "good red" has rather stopped that of Ceylon. The outlook, however, is still encouraging, the consumption continues satisfactory, and prices are much above those existing for Western growths. It is satisfactory to report that the sales of the Company compare favourably with those of other estates, in many instances the prices obtained being above those of similar quality of other marks.

From reports by the Visiting Agent, Mr. W. Forbes Laurie, your Directors are able to assure the Shareholders that all the Estates belonging to the Company and buildings thereon are in excellent condition, also that the factory accommodation is quite equal to requirements during the current year; in fact it is not expected that any important additions or alterations will have to be effected for some years to come. It will, however, be necessary to sanction some expenditure, in order to keep our machinery well abreast of the times.

The Mortgage Account, which originally stood at £15,000, has now been reduced to £9,500.

Your Directors have every confidence in the continued prosperity of the Company:

Your Board have to record their appreciation of the services rendered by the Managers in Ceylon Messrs. D. Edwards & Co., of Hatton.

TEA IN MATALE IN 1892.

Our rainfall for 1892 is 141·38 inches,—24 inches over our 14 years' average, but 2½ inches less than 1891, which was also largely in excess of the average. Taken as a whole I should say 1892 has been rather unfavorable for flushing. The heavy rainfall of January, some 43 inches, preceded by a cold and wet December affected the fields in that and the following month; dry cold winds in May and June brought on a severe attack of the yellow tea mite *Acarus translucens* on all tea six months from pruning and seriously reduced the yield for these months; then the cold wind and wet of the south-west monsoon continued into the north-east and gave us a poor yield for October which is usually a hot, steamy, wet month, good for flushing. December, on the other hand, has been more favourable than usual. The rest of the months of the year were, I think, normal. Anyhow the result is that we are fully 5,000 lb. short of the original estimate, though we have exceeded the revised figures in June.—Cor.

NOTES ON PRODUCE AND FINANCE.

OCEAN FREIGHTS AND TEA.—An important meeting of the Indian Tea Districts' Association was held this week, at which there was a fair attendance. The members present almost unanimously expressed a strong feeling against entering, in future, into any arrangement with the Steam Conference, which would tie their hands or tend to prevent free trade and open competition in freights. A feeling was expressed, however, that, within reason, there was no desire on the part of shippers to drive down freights below a certain point, so long as the rate of freight for tea was not out of proportion to what was charged on other classes of cargo. A reversion, however, to the old rebate arrangement was strongly deprecated

and eventually, after some discussion, a resolution was passed, placing on record this view. It was also decided for the present to await the course of events, but to carefully observe the position taken up by the newly-re-formed Steam Conference, so that, if necessary, tea shippers and members of the Tea Association might be prepared to act on the defence. Instructions were given to the Secretary to forward a copy of the resolution to the association in Calcutta for distribution to the various agency houses and others interested.

CHEAP TEA.—There is a strong feeling amongst the leading grocers that the advertising and sale of cheap rubbish called tea is likely to prove very injurious to the tea trade generally unless it is checked. One correspondent, writing on the subject, says:—"Form a union over the length and breadth of the land for the purpose of raising a common fund to be used in defraying the cost of inserting an advertisement in every journal and periodical in which these misleading advertisements appear—such announcements to set forth the danger incurred in drinking low-priced rubbish as advertised; and if it were vouched by some high medical authority, so much the better. This is a matter of vital importance to growers and wholesale dealers, even more so than to retailers. I say, let it emanate from the growers and wholesale dealers' associations; and, whatever remedies may be proposed for what is no longer a personal crisis, but a trade one, the first antecedent condition to be fulfilled is to organise the trade interest into one compact body, because otherwise they would never attain their wishes, but end where they had begun. Without this we can get no nearer the desired goal. It is imperative, in view of the present great crisis, for the trade to form itself into one great advertising union, in which all interested, from grower to petty retailer, can find membership, with its headquarters in London."

TEA IN PERSIA.—In the report of Consul-General Elias, of Meshed, on the trade of Northern Khorasan the following reference to tea in Persia occurs:—"A larger quantity of both green and black tea was imported. Nearly the whole of the green tea is from China and passes on to Central Asia. The Indian green tea is considered of very inferior quality, and is used only by the Meshed traders to mix with the Chinese tea they despatch to Merv, Bokhara, &c. Nevertheless, about 100,000 lb. of this tea were imported into Meshed last year. In Persia black tea is almost universally drunk. The favourite tea now is what is called 'elai,' or golden, and is Assam tea sent from Calcutta. There is another tea also called here Indian black tea, which comes from Kangra via Bombay, and for which there is a good demand."

"HOME MADE" GERMAN COFFEE.—Pity the poor coffee planter! Between periodical blight and adulteration he is not as happy as he might be, and now his soul is to be vexed by German manufacturers of "home made coffee," in which malt plays an important part. The malt is first soaked in water at 40deg. C., and dried in a coffee-roaster until the grains assume a glossy brown appearance. It is then sprinkled with hot water and the roasting is continued until the skin of the malt is loosened. A liquid having the aroma of coffee, and prepared as described below, is then sprayed into the roaster, which is kept revolving; when the spray is discontinued, the malt is further heated until it becomes quite dry. The roaster is removed from the fire and when the contents have cooled somewhat, a little cocoa-butter or some similar fatty matter is introduced, and the roaster is rotated until the "malt coffee" has become covered with a very thin layer of grease. The coffee liquid above alluded to is made by condensing the vapours which arise when genuine coffee is being roasted. The condensed liquid is concentrated by boiling, and neutralised with a little bicarbonate of soda. Sufficient sugar is then added to make a syrup, when the liquid is ready for being sprayed into the roaster. Instead of going to the trouble of preparing this liquid, the manufacturers sometimes use extract of coffee for spraying into the roaster. The finished product, when ground, is said to be a passable coffee substitute.—*H. and C. Mail*, Dec. 23.

RUBIES IN QUEENSLAND.

Messrs. H. L. Davis & Co. have just received the first ruby ever found in Queensland. The gem was discovered at Withersfield, on the Central Railway. Its present weight is fifteen carats; it is somewhat flawed, but of beautiful colour, and it is estimated will cut into a stone of from four to five carats, having a value of something like £70. Mr. Davis has no doubt that there are other rubies where this one was found.

Concerning the discovery Mr. Davis writes:—"The recent finding of a true ruby (red sapphire) of fifteen carats on Richardson and Fisher's gem selection at Withersfield adds so vastly to the importance of the gem districts of Central Queensland that I ask permission to offer through your columns a few remarks with the view of directing attention to the possible value of this discovery. Streeter in 'Precious Stones and Gems' describes the ruby as 'not only standing in the very foremost class of coloured gems, but as occupying among precious stones in general a position which is unquestionably supreme. It seems probable that all the finest rubies in the world have been derived either directly or indirectly from Upper Burmah. When a perfect ruby of five carats is brought into the market a sum will be offered for it ten times the price given for a diamond of the same weight, but should it reach the weight of ten carats it would be almost invaluable.' Of late years the value of rubies has been greatly augmented by failure of supply from the Burmah mines, but the rarity as compared with diamonds coupled with the singular beauty of this gem when of pure 'pigeon blood' tint has always given to it a special value. In 1875 two rubies weighing respectively 32 5/16 and 38 9/16 carats were sold, the former in London for £10,000 (about £330 per carat), the latter in France for £20,000 (about £500 per carat). The Withersfield ruby (which I shall be very pleased to exhibit to any one curious in the matter) is a hexagonal crystal weighing fifteen carats. It is somewhat flawed, has a semi-opaque protuberance on the base, and a decided blue tint at one corner (defects which will be removed in cutting), and should furnish a gem of very fine colour weighing from three to four carats. It may be confidently affirmed that the district which has produced a ruby of such size must contain many others, and will ultimately confirm the opinion expressed some months ago in my report on the Oriental Gem Company's ground, that 'the occurrence of small rubies in the finer drift obtained indicated that larger specimens would be met with.' The present discovery certainly adds vastly to the value of all gem-bearing ground in the Withersfield district, which, in the event of large rubies being found in only very moderate quantity, would equal, if not exceed, in value the celebrated diamond bearing district of South Africa. Referring to the so-called rubies of South Australia, a parcel of these gems is in my possession, and are only spinels of very small value, soft, and readily scratched by the Withersfield gem, which may claim to rank as the first moderate-sized true ruby ever found in Australia."—*Queenslander*, Dec. 3rd.

THE RICE-CROP IN INDIA.

(Dated Calcutta, the 20th December 1892.)

An average full crop being represented by 16 annas. In Bengal the season was generally favourable. Except in Behar, the rain at the end of October and the beginning of November was general and plentiful, and the extension of cultivation is ascribed to the more favourable season. The outturn is rather under, than over, stated at 14 annas: thirty-four out of forty-five districts report a better crop than that of 1891, five districts report a crop as good, and only five a worse crop.

In Madras the area under crop shows an increase of 12 per cent over that of last year. Reports as to condition and probable outturn are very favourable for

the Northern, Deccan and West Coast districts, good for the bulk of the crop in Tanjore and Trichinopoly, but elsewhere standing crops are suffering owing to the failure of the November rains.

In Burma the prospects of the crop are everywhere good, and it is estimated that there will be available for export 27,118,000 cwt. of cleaned rice, including the quantity required for consumption in Upper Burma.

ANOTHER CEYLON PLANTER IN EAST AFRICA.

We are glad to learn that good news has been received of Mr. W. H. Cowley, formerly of Opalgalla, who some time ago left for German East Africa. Mr. Cowley reports himself to be in good health, enjoying the country and his work which has not been trifling, seeing he has opened no less than 400 acres with cacao. Well done, the Ceylon planter. Mr. Cowley's labourers has been Chinese who were introduced last year and he declares that they are capital workers and he gets on well with them. What a revolution—to have Chinese planting up East Africa!

PAVING BLOCKS OF COIR.

Mr. J. Hart-Davies, 186, Fleet Street, London.—(J. McDonnell, *Chilau, Ceylon*.)

Coir or coconut fibre is compressed into blocks with the fibres arranged vertically. The fibres or blocks may be steeped in or treated with tar, pitch, resin, creosote, or with a solution of indiarubber or gutta-percha. Brick dust or fine sand may be mixed with the tar, and the blocks may be bound round by bands.—*Patent Journal*, Dec. 14, 1892.

TEA IN AMERICA.

Indian planters are, I think, observes a writer in a Calcutta paper, not altogether hopeful of the Chicago Exhibition doing great things for their tea. The Americans have already got accustomed to cheap inferior tea, and it is a slow and difficult process to change the public taste. This was the difficulty experienced in Australia. All large employers of farm labour are obliged to give their men tea along with other rations, and it is obviously in their interest that the tea should be as cheap as possible. The country is, therefore, flooded with China tea and cheap Indian tea, but the superior infusions have no chance. It was long before pure Indian tea could be purchased in London, and some people argue that the "blends," with which the public were imposed on for many years, were a necessary education before the public could be got to drink the pure Indian beverage. The seller of the blend may have been unconsciously educating the public taste, but their chief aim, I am afraid, was to make an unfair profit for themselves, and they deserve no praise for any good which resulted from their evil. Anyhow, the preference for Indian tea has got a hold on the English public now, and China is being steadily driven out of the market. It is to be hoped that in America the process of education, if slow, will be equally sure, and that the Exhibition will serve as a primary school. America is really a more promising market than Australia, and if once a start is made great things may be accomplished.—*Times of India*.

ECHOES OF SCIENCE.

(From the *Globe*, Dec. 16, 1892.)

Professor Forbes, who occupies the enviable position of consulting electrical engineer to that greatest of modern electrical undertakings, the utilisation of the water power of the Niagara Falls, delivered a most interesting lecture on Wednesday night, at the Royal Society of Arts, and illustrated it with numerous photographs of the actual state of the works, many

of which were taken by himself. Most people acquainted with this enterprise had supposed that the power of the Falls would be disseminated far and wide by means of electric wires, but the Cataract Construction Company has no immediate intention of doing this, for the simple reason that all the 100,000 horse power of which it will presently avail itself, and probably also the 350,000 it holds in reserve through its concessions for a second hydraulic tunnel on the American side and others on the Canadian side, will most likely be taken up in the industrial city which it is building at the Falls and in Buffalo, twenty miles distant. Niagara is apparently destined to become the nucleus of a great city which may rival Chicago, and become the most important commercial centre in the United States if not on the entire continent.

It is a compliment to British electrical engineering that Professor Forbes has been chosen consulting electrician by the Cataract Construction Company. He is Scotch by origin, and a son of the celebrated Principal Forbes of Edinburgh University. For some time he was Professor of Natural Philosophy in Anderson's College, Glasgow, and he took part in one of the great eclipse expeditions. He also acted as special correspondent for the *Times* with the Russian Army in Asia Minor during the Russo-Turkish War, and he has travelled widely in Russia. In 1881 he was created a Chevalier of the Legion of Honour in connection with the Paris Electrical Exhibition. Professor Forbes is about to pay another visit to Niagara, and the Cataract Construction Company has given him a free hand to go to any part of the world he likes and report upon the electrical systems there. American business men apparently shun doing things by halves, and the directors of the company wish to have the benefit of all the best experience the world can offer them.

Maize, or Indian corn, according to Mr. C. J. Murphy, was first cultivated by white men on James River, Virginia, in 1608. Although much used for food in America it is still neglected in Europe, yet its nutritive value is estimated at five-sixths that of wheat. When maize was the staple grain of America 50 years ago dyspepsia was almost unknown. Numerous delicate dishes are now prepared from it, there being 130 receipts for cooking it. The surplus crop is usually given to cattle and hogs, while glucose, starch, beer, whisky, and oil are made from the corn. The fodder of the plant can be eaten by animals, or burned as fuel on the treeless prairies, and the husks are made into paper, or used as stuffing and wrappers. The "corn-cob" makes a pipe which has been patronised by Mark Twain.

The Pinna oyster, found in warm seas, especially on the coast of Sicily, is a wing-shelled bivalve, one species of which is two feet long, and attaches itself to the rocks by a cable of strong filaments of silken texture. Hence it has been called the "silk oyster," and mummy cloths, as well as other fabrics, were formerly woven from the silk. The animal is scarce, but it seems to contain the germ of a textile industry, and might repay cultivation.

BARK AND DRUG REPORT.

(From the *Chemist and Druggist*.)

London, Dec. 15.

CINCHONA.—At Tuesday's fortnightly auctions (the last of the current year) a moderate quantity was offered. The catalogues comprised of:—

	Pkgs.	Pkgs.
Ceylon cinchona ...	1,351	of which 1,155 were sold
East Indian cinchona	317	do 317 do
Java cinchona ...	64	do 64 do
South American cinchona	208	do 208 do

1,940 1,744

With a very poor assortment of bark, the highest price paid for any lot was only 6½d per lb. At the beginning of the sale the tone was rather quiet, but gradually it improved somewhat, and, upon the whole, it may be said that the prices obtained were slightly above those of the auctions last preceding, the unit being 13-16ths d. per lb upon the average.

The following are the approximate quantities purchased by the principal buyers:—

Agents for the Auerbach factory	...	Lb.	90,358
Agents for the Mannheim and Amsterdam factory	...		73,778
Agents for the Frankfurt o/M and Stuttgart factories	...		61,741
Agents for the American and Italian factories	...		55,250
Agents for the Brunswick factory	...		48,506
Messrs. Howards & Sons	...		13,489
Agents for the Paris factory	...		7,610
Sundry druggists..	...		46,330

Total quantity of bark sold	397,102
Bought in or withdrawn...	48,640

Total quantity offered ... 445,742

At the Amsterdam auctions on Tuesday last, 25,318 kilos hark, representing 1,187 kilos sulphate of quinine were bought in. About 10 per cent of this quantity so'd immediately after the sales. The following equivalents of quinine were bought by the principal buyers:—

The Auerbach factory	..	5,432	Kgr. sulph. quinine
The Brunwick factory	..	3,529	do
The Mannheim factory..	..	3,497	do
Mr. Gustav Brierlegh	..	1,562	do
The Frankfurt-o/Main factory	..	1,092	do
Messrs. Matthers & Bormeester.	..	461	do

The agents for Messrs. Böhlinger & Sons assure us that the quantity of bark exported from Ceylon to Amsterdam and Hamburg does not by any means represent the total of their direct purchases in the island, as much of what they buy from the growers is forwarded to London and transhipped.

ESSENTIAL OIL.—Oil of Lemongrass is quoted 19-16ths d, per oz, on the spot.

CACAO, TEA AND LIBERIAN COFFEE
IN CEYLON.
THE UKUWELLE ESTATES COMPANY,
LIMITED.

CAPITAL.—R150,000.

Provisional Directors.—A. Collingwood-Smail, Esq., J. R. Fairweather, Esq., F. M. Maackwood, Esq., and T. O. Owen, Esq.

Secretary.—T. B. Campbell, Esq.

Agents.—Messrs. Mackwood & Co.

This Company is formed to acquire, in the first instance, the Ratwatte Estate, belonging to the Ceylon Tobacco Company, Limited (in Liquidation), and the investment is particularly recommended to shareholders of that Company as a means of closing the liquidation. It is further proposed to bring up the present acreage under Tea to 220 acres, and speedily to open 100 acres in Cacao in 1893 and another 100 in 1894-95, if sufficient approved land is available. It may be also stated that a successful cultivation of Cacao is its main object, Tea being only a secondary consideration to be utilized as a means of bringing Cacao into bearing.

SITUATION AND OUTLET.—The estate is situated on a Government minor road which runs through it, about 1½ mile from the Ukuwelle Station on the Matale Railway line, and within three miles of Werispola Estate.

ACREAGE.—There are 320 acres more or less at present forming the Ratwatte Estate, belonging to the Ceylon Tobacco Company, Limited (in Liquidation). A further area of 147 acres has been negotiated for by the late Tobacco Company (advances having been made to owners), and the purchase of which can be completed for about R5,200. It is proposed to buy these lands, and with one or two other suitable available lots the area could be brought to a little over 500 acres.

ELEVATION.—From 1,300 to 1,600 feet.

RAINFALL.—From 60 to 70 inches well distributed.

LAY OF LAND AND SOIL.—The land is undulating—about one-fifth of the 320 acres is forest, balance good chena. The soil is of deep good loam, admirably suited for either good Tea, Cocoa, or Liberian Coffee cultivation.

CONDITION OF ESTATE.—120 acres were opened by the Tobacco Company in 1891; but though this is all roaded and drained, there are only about 20 acres of 1891 Tea successful. The balance was again planted by Mr. C. Gibbon in 1892, and is fairly successful.

The jât of the Tea is good, being mostly Kerrimettia, Indigenous.

ESTIMATED YIELD.—Of Cocoa for 5th to 8th year is estimated to yield at an average of 1½ cwts. per acre and after that at 2½ cwt. per acre; the upkeep from the 5th year should not exceed 50 rupees per acre. The Tea is estimated to yield at 500 lb. per acre in the 4th year from January, 1892.

ESTIMATED EXPENDITURE.—A detailed estimate has been made out, and can be seen on application to the Secretary. It provides liberally for establishing Cocoa, in view of the fact that in the Ukuwelle district the weather is somewhat precarious, and white-ants troublesome.

The upkeep of the existing Tea in 1893 is estimated at R6,550; Planting up 100 acres Tea, 1893 R15,225; Planting up 100 acres Cocoa, 1893, inclusive of cost of buildings R10,200; 1894 expenditure on Tea and Cocoa, with tea factory and machinery, estimated at R35,600; 1894 planting up 50 acres Cocoa R4,000; 1895 up-keep Tea and Cocoa R23,750; 1895 planting up 50 acres Cocoa R3,700; 1896 up-keep Tea and Cocoa R35,000. Or a total for the 4 years of R139,025. Against this it is expected that the Tea clearings will produce at least 200,000 lb. of Tea, at, say, 36 cents per lb =R72,000, and enabling a dividend to be declared in 1896. It is not yet quite certain how much of the land will be available for Cocoa; but it is thought that 200 acres of such land will be the minimum.

BUILDINGS.—Small temporary bungalow and temporary lines only at present.

LABOUR.—Ample labour facilities exist.

VALUATION.—Messrs. Deane and Fairweather visited the property in July, 1892, and again in December, 1892. On this latter occasion Mr. T. N. Christie and Mr. T. C. Owen accompanied them. They value the land at R45 per acre, and the Tea at R140 per acre all round. They consider R25,000 would be a fair price to pay for the property as on 1st January, 1893.

A large proportion of the land is well suited for the successful cultivation of cocoa.

PROMOTION MONEY.—None has been, nor will be paid.

ESTIMATE.—Estimate of aggregate cost to end 1896:—

	R
1. Purchase of property from Tobacco Company	25,000
2. Purchase extra lands from natives	5,200
3. Probable expenses re formation of Company	3,000
4. Secretariat in Colombo, 4 years	4,000
5. Directors' fees, &c., 4 years	10,000
6. Expenditure on property, deducting value of produce to end 1896	67,025
	<u>R114,225</u>

At close of 1896 the property on present date of exchange and prices for tea and cocoa should be worth:—

	R
220 acres Tea, at R450 per acre	99,000
100 ,, Cocoa, 3 years old, at R360 per acre	36,000
100 ,, Cocoa, 1 and 2 years, at R240 per acre	24,000
80 ,, Waste land and reserves, at R45 per acre	3,600
	<u>R162,600</u>

It will thus be seen that at the end of 1896 less than 75 per cent of the proposed capital will have been spent should all the shares be taken up, and a dividend of at least 10 per cent could be declared that year, when the company would own the property the value of which would be 50 per cent. in excess of paid up-capital.

ELEPHANTS AND IVORY.

The subject of elephants and the supply of ivory has been receiving a good deal of attention of late in the leading English papers. Remarks which had been made by Capt. Lugard with regard to the African pachyderm called forth an appreciative letter from Mr. Arnaldo Girolamo Povolero, F.Z.S., in which he gave some most interesting information and pointed out a way in which what he described as "the unnecessary and brutal butchery of vast herds of valuable, inoffensive and tractable animals which takes place year by year" might be avoided. He said:—

"The African animal is valued in his native land solely for the sake of his pair of tusks. For their ivory alone elephants are annually slaughtered in Africa to the number of at least 75,000. Since an elephant's tusks, which are solid, can be cut off with a sharp saw without causing pain to the animal, and an elephant once captured by the methods employed in the Government Kheddahs in India can be easily secured for this process, it seems to me that the ivory traders would gain time, save labour, and avoid the criminal folly of exterminating their source of revenue, if they could be induced to resort to this more humane method of obtaining ivory. When it is remembered that reproduction in the African elephant does not commence until the animal is over 20 years old, and that the period of gestation is three years, and, further, that the female elephant produces but one calf at a time, and that only at rare intervals, it will at once be seen that we are well within measurable distance of the date of the annihilation of the 'Ivory King' of the Dark Continent."

In this letter the *Globe* saw a further argument for the retention of Uganda and said that by establishing Kheddahs and adopting the methods suggested by Mr. Povolero we might simultaneously preserve the sources of the ivory-harvest, and obtain a means of transit, which will be almost as efficient as a railway, and a good deal less expensive. The *Standard* also expressed the opinion that the taming of the African elephant would be one of the most important steps in the civilisation and opening up of Africa which could possibly be taken. A correspondent in the same paper was of opinion that for most practical purposes a smaller, handier, and cheaper animal was wanted. As the African buffalo is tsetse proof, he suggested it was worth while to make once more an experiment with his Indian congener, and find out whether a domesticated creature so useful for draught cannot be successfully introduced into Southern and Central Africa. If it could be done, Mr. Cecil Rhodes might find the Indian buffalo of immense service in the development of Mashonaland, and it might go far to settle the question of Uganda.

Another correspondent in the *Standard* mentioned that in a Sheffield trade report he had seen it stated that the scarcity of ivory was causing quiet stocking of the material in that district. In one Sheffield cellar alone was ivory to the value of twenty thousand pounds, and it was further stated that the annual produce of eight hundred elephants was, a few years since, required by one firm alone to keep them supplied with ivory, but the demand had now so greatly grown that they required no less a quantity than the tusks of one thousand two hundred and eighty elephants every year. Referring to this letter Mr. Povolero said it might be worth the consideration of the wealthy manufacturing outlers of Sheffield to adopt a suggestion which he ventured to make—viz., that they should take steps to secure the preservation of the African elephant by purchasing as many living

specimens of the animal as can be obtained in Africa, and conveying them either to Cape Colony or to Algeria, to be placed upon preserves where their safety can be insured. Thus the African elephant and the ostrich would stand side by side as monuments of British enterprise, rescued from extinction, and converted into valuable sources of revenue to their preservers. The ivory collectors he thought would probably sell a living elephant for very little more than they now require in payment for a single pair of tusks. A Mincing Lane ivory broker in an interview he had with a representative of *Cassell's Saturday Journal* said he could see no indication at present of the ivory supply failing. "Most of the ivory was got from Africa, and, of course, when civilisation spread over the Dark Continent, the herds of wild elephants that now roam in the forests of the interior would be annihilated. That, however, was looking a long way ahead; meanwhile, the extension of railways would enable traders to bring produce more readily to the coast, so that for a time increasing quantities of ivory should come into the market. The question of transport was the difficulty at present, ivory for shipment having to be carried hundreds of miles on the backs of negro porters. It must be remembered in considering this matter, that there were known to be hoards of ivory of immense value in Central Africa, apart altogether from the tusks that still remained the property of living beasts. He had also seen ivory offered for sale in London that, from its condition, must have positively been lying about in the open air for centuries. London was, of course, the principal market, although since the establishment of the Congo State sales had been held on the Continent. There were four sales in Mincing Lane every year, and during 1892 the total amount offered was 423 tons. In 1891 the total was 430 tons, but between that and 1885 the quantity never came up to 400 tons in any single year, although in 1884 531 tons were offered. The temporary falling-off was largely due to the anarchy which has prevailed in the Soudan, and the consequent closing of trade routes. However, ivory was now coming forward again through Egypt. The demand for ivory had largely increased and the price had also risen to a remarkable extent. He had seen cut pieces for billiard balls sold in London for £40 the hundred-weight. They had since been up to £120, but the price fell away again, and at the last sale the highest figure was about £80 the hundred-weight."

THE FIJIAN BANANA IN AUSTRALIA.—Mr. H. Rieck of Coff's Harbour, in the Clarence River country (N.S.W.), has demonstrated that the Fijian banana can be successfully grown on the Australian coast. He lately sent a large bunch to Grafton, the first taken from his grove raised from Fijian plants, which bore 217 fine bananas, and this was exceeded on some other bunches. Hitherto the Plantain, Lady's Finger, and Cavendish were the only varieties produced on the Clarence River, and these were completely run out of the market by the superior fruit imported from Fiji. As a consequence, planters ploughed out their groves, some of which were from 15 to 20 acres in extent, as the fruit, at 3d per bunch net, would not pay. But if the Fijian variety can be successfully cultivated the Clarence farmers, with the advantage of near proximity to market, will outstrip the Fijian planter, and cut him out of the running. It may be added that the soil at Coff's Harbour is of volcanic formation, and not so fertile as the alluvial of the Clarence Valley.—*E. Mail.*

FREE POLICY TEA COMPANY, LIMITED.

Registered by T. T. Hull, 22, Chancery-lane, W. O., with a capital of £20,000 in £1 shares. Object, to adopt and carry into effect an agreement, made November 25, between John Carty of the one part and James H. Marsh, on behalf of this company, of the other part; generally, to carry on business as tea and colonial produce merchants in all its branches. There shall not be less than three nor more than seven directors. The first are E. W. Humphreys, A. G. Goodwin, and J. Pritchard. Qualification, £100. Remuneration, 50 guineas each per annum.—*Financial News*, Dec. 15, 1892.

THE MANNHEIM QUININE FACTORY AND THE JAVA CINCHONA PLANTERS.

A general meeting of the Java Planters' Association ("Soekaboemische Landbouw Vereeniging") was held at Soekaboemi, Java, on October 14th last. On that occasion one of the members (Mr. A. Massink), a cinchona-planter, read to the meeting a letter dated June 30th 1892, received by him from Messrs. F. O. Böhringer & sons, of Mannheim, of which the following is a translation:—

"Since many years we do an important business with Colombo, as we buy a very large part of the cinchona bark which is brought to market there. For this purpose a friendly firm in Colombo has installed an analytical laboratory, to be able to analyse personally, and on the spot, the barks which are offered.

"The constant increase of our purchases in Colombo appears to us to prove that the majority of the cinchona-planters regard the sale of their produce in Colombo as more advantageous than its shipment to London. As the Ceylon planters, by selling in Colombo, obtain approximately the same price, with the addition of the freight, as they do when their barks are sold in London, they have the very important advantage of saving the heavy sale expenses in London, and of receiving cash for the bark sold immediately after shipment.

"We estimate that our direct purchases in Colombo have for some time amounted to one-half of the entire output. We now propose to establish an analytical laboratory in Java, in order to be able to effect direct purchases in that island also. But before taking further steps in this matter, we are anxious to put to some of the largest plantation owners in Java the questions whether they are prepared to support our intention, and whether we may count upon being able to buy in Java cinchona bark from their plantations. We address these questions to you among others and you will much oblige us by having the courtesy to send us your esteemed answer as early as possible."

The President of the Association commented in a somewhat unfavourable manner upon Messrs. Böhringer's letter. He said that during his visit to Colombo in 1886 his factory did purchase fairly large quantities of bark in the manner described. There was, at that time, a very serious crisis in the bark industry, consequent upon the appearance of cancer, and many of the planters were financially in the hands of Moorish money-lenders. Messrs. Böhringer were in business relation with most, if not all, of these people, and purchased almost all the produce at their own analysis. In 1887 Mr. Böhringer travelled in Java, and on that occasion he concluded some transactions with planters there; but the President had not heard that any further business had resulted. The Secretary advised all the planters strongly not to sell any of their bark outside the ordinary sources but to consign the whole of it to Amsterdam.

It may be remembered that formerly the Brunswick Quinine Factory bought directly in Java, though upon a different basis from that suggested by Messrs. Böhringer & Sohne. As we were anxious to ascertain the effect of the large purchases of bark in Colombo, of which the latter speaks upon the distribution of exports from Ceylon, we looked

up the last statistics from that island. These show that of the 5,428,137lb. of cinchona exported from Ceylon between January 1st and October 24th 1892, London received 4,839,306 lb., New York 62,079 lb., Amsterdam 59,240 lb., and Antwerp 462,450 lb. The insignificant remainder went to Franco and Australia. If we credit Messrs. Böhringer & Sons with the whole of the shipments made to Amsterdam and Antwerp, their direct share of the Ceylon shipments this year amounts to just over 9½ per cent.—*Chemist and Druggist*, Dec. 10th, 1892.

TEA IN MELBOURNE.

The tea market has been quiet. Our special cable correspondence from Foochow reports the sailing on 18th inst., of the "Ching'u." She will, we believe, call at Hongkong, and will probably not arrive here until the end of January. She brings principally common to medium, 300,000lb being destined for Sydney, and 1,000,000lb for Melbourne. The market is practically closed with a total export to the colonies of 14,000,000lb. This is not too large a supply. A provisional summary of the shipments to the colonies for the present season are as follows:—

	Lb.
China tea (June to December)	14,000,000
Indian tea (May to October)	2,400,000
Ceylon tea (May to November)	3,500,000

19,900,000

The consumption of the colonies is 25,000,000lb to 26,000,000lb annually.

The custom-house statement of receipts and deliveries of tea at the bonds last week, together with the stocks in bonds at the close of the week, is as follows:—

	Deliveries.			
	Receipts into Bond.	For Home Consumption.	For Export.	Stocks on Dec. 17.
	Lb.	Lb.	Lb.	Lb.
Ohina ...	1,900	13,467	96,619	4,315,705
Indian	30,921	122,644	448,682a
Ceylon ...	17,699	7,705	26,291	227,538b
Totals ...	19,599	169,093	245,554	4,991,925

a Not including shipments ex "Goalpara."
 b Not including shipments ex "Rome," and a small portion of the shipments ex "Woolloomooloo."
 —Melbourne *Argus*, Dec. 21, 1892.

ZANZIBAR AND TROPICAL AGRICULTURE.

A valuable report on the agricultural condition and prospects of Zanzibar has been sent home by Sir Gerald Portal, and is published by the Foreign Office. The author, Mr. Fitzgerald, is a specialist on tropical agriculture, and is now in the employment of the British East Africa Company. The marked similarity between Zanzibar and the leading West Indian islands—notably Trinidad and Jamaica—in the matter of soil, temperature, and rainfall, he points out, undoubtedly a very important matter, inasmuch as the principal tropical products can with certainty be introduced. He deals with the labour question, suggesting the importation of Indian coolies; but the real difficulty, he tells us, lies elsewhere. Will the Zanzibar landowners, he asks, now that slavery is doomed, face the altered state of affairs? "Ablar judges than himself," says Mr. Fitzgerald, "reply distinctly in the negative; and it is certainly a fact that many of the larger estates are heavily encumbered and entirely in the hands of Indian traders and merchants." The factor required is European enterprise, and the sooner this can be more largely attracted the quicker will development commence. He suggests that the Government should make known the fertility of the country, and he

also recommends the extension of the existing system of roads. The use of cattle as draught animals is further proposed, for at present, he observes, "the only means of sending produce to the coast is on porters' heads." It appears that there is some talk of opening a fruit trade with India by shipping the surplus supply to Bombay. There ought to be a large market for Zanzibar fruit, especially in the Western Presidency, as the seasons of cropping are different in the two countries.—*O. Mail*, Dec. 23, 1892.

CEYLON LAND AND PRODUCE CO., LD.

The shareholders of the Ceylon Land and Produce Company, Limited, held their eighth ordinary general meeting on Wednesday, at Leadenhall House, Leadenhall Street, E.C., under the presidency of Mr. James Wilson. In moving the adoption of the report, the chairman said that the results of the operations during the past season had not been quite so favourable as they were in the previous year, which was largely owing to the abnormally wet and cold weather that had prevailed. The tea bushes had been prevented from flushing to their average extent, and, as a natural consequence, the estimates of the crops had not been reached. The cacao crop rather exceeded the forecast, but the yield of coffee was very deficient. Notwithstanding the lower prices ruling for Ceylon tea generally during the past year, better results had been obtained for the produce from the company's Fetteresso and Rickarton estates. On the other hand, however, the low-grown teas had shared in the general depression. It was also gratifying to the board to report that the highest price paid for Liberian Ceylon coffee that year was realised for a parcel that came from the company's North Matale estate on October 6th for which 98s. per cwt. was obtained. All the estates belonging to the company, and buildings thereon, were reported to be in excellent condition; also that the factory accommodation was quite equal to requirements during the current year—in fact, it was not expected that any important additions or alterations would have to be effected for some years to come. It would, however, be necessary to sanction some expenditure in order to keep their machinery well abreast of the times. The mortgage account, which originally stood at £15,000, had now been reduced to £9,500. The result of the year's operations enabled the board to pay a dividend of 15 per cent. per annum on the ordinary shares and 6 per cent. on the preference shares. Mr. Lewis seconded the motion, which was adopted.—*H. & C. Mail*, Dec. 23, 1892.

IRRIGATED INDIA.

Irrigated India, an Australian view of India and Ceylon, their Irrigation and Agriculture, by the Hon. Alfred Deakin, M.L.A., formerly Chief Secretary and Minister of Water Supply of Victoria, Australia (W. Thacker & Co.), is the work of an Australian statesman who has been officially concerned with the vital question of irrigation works and water supply in the colony of Victoria and has qualified himself for his duties by a personal study of the problem and the means adopted for its solution in other parts of the Old and New Worlds, such as the United States, Egypt, and Italy, and now, finally, India and Ceylon. The book consists of a series of articles, originally written for an Australian newspaper, and now recast and revised for publication in Europe. Mr. Deakin's survey of irrigation work in India is of great practical moment in its bearing on the Australian problem; but what gives his book a special value for English readers is the fact that it is written by an Australian public man with a saving faith in the solidarity of the Empire and a prophetic grasp of the relations which geography and history are destined to establish in the future between Australia and India. Mr. Deakin writes

somewhat rhetorically, and he says of himself that, writing originally in a newspaper, he did not hesitate "to pass judgment upon the gravest issues with an easy infallibility that is almost editorial." But he writes often with clear insight, his prepossessions are Imperial rather than purely British, and he approaches Indian problems with an Australian freshness of view and frankness of comment that are often singularly suggestive. His point of view is well set forth in the following characteristic passages:—

"By the hoary and weary age of India now stands the eager youth of these southern lands, beholding as if in a magic mirror, its rapidly passing throng of peoples, kingdoms, dynasties, and creeds, that have succeeded, and are still succeeding each other, in an apparently endless chain. There is matter for meditation here. Today Australia is full of hope, as Asia of despair. Racially, socially, politically, and industrially, as far as under the poles, their geographical situation, bringing them face to face, may yet bring them hand to hand, and mind to mind. They have much to teach each other. * * *

"Finally, then, the British Government of India is a compound of contradictions, for, while practically absolute in authority and vested in two or three men entirely, it is supposed by many to be controlled by a popular assembly; military in spirit, it is bureaucratic in method, and pacific in end; Conservative in practice, it adopts many Radical principles; and committed, wholly at first, and often still, to the energy, judgment, and initiative of individuals, has created for them a complete system of written regulations embracing the whole field of possible activity. No public service is so enslaved by the pen, and yet even the civil members of it may be said to live in the shadow of the sword. Separated by immense distances which forbid frequent personal association, all business is conducted by correspondence, the affairs of the country, from the most momentous foreign relations to the pettiest details, being set out upon papers which are passed from hand to hand. It is a Government of minutes based upon memos. Even its soldiers command in the attitude in which Boehm has placed the great governor of the Punjab in his bronze statue at Lahore, sword in one hand and quill in the other. It would be hard indeed to say which has now the mightiest influence on its administration. While the soldier, like Henry Lawrence has often done the most distinguished work in times of peace, the civilian, like John Lawrence, has come forward as a warrior in the hour of need to save an Empire tottering under a stab in the back from the treacherous hand of mutiny.

"British India, in short, is British neither in race, religion, language, policy, sentiment, nor aspiration. Garrisoned by a few Britons, and governed by still fewer, it not only retains its Asiatic complexion, but impresses its character to a large extent upon its conquerors. The British in India have themselves ceased to be British in many respects. They have developed castes and curious creeds, walk with troops of retainers, live like Persian satraps or Roman proconsuls, coming at last to think and speak in the phrase of the Orient, and with its vivid colouring. It is they who have adapted themselves to the Hindu, and not the Hindu who has taken their imprint. It was not to strengthen her hold upon her British subjects that the time-honoured title of the Queen was altered to that of Empress of India. Bearing in mind how few are the whites in proportion to the hordes of varied hue who swarm from Cape Comorin to the Himalayas, and the extent to which they have required to stoop to the conditions of life in the tropics in order to conquer, it is not too much to say that the first fact requiring to be fixed in the mind of the inquirer is that India today is altogether Asiatic in the spirit and form of its life and institutions, and British only in flag, in fame, and in name."

There is some exaggeration, perhaps in these latter sentences, but it is not unprofitable for Englishmen to be told how the spectacle of the British "raj" in India strikes a clear-sighted Australian.—*London Times*,

COFFEE.

The principal feature of the week has been the sale of a large portion of the coffee which was damaged by the recent fire at the London Docks. Some of it was so badly damaged that it was comparatively useless, but it was taken with the greater part of the remainder for export. The few lots of Ceylon and East Indian that were only slightly injured, and that externally fetched prices almost equal to those for perfectly sound coffee. In the terminal market values have shown a further decided fall, owing to continuous heavy receipts at the Brazil ports, and low offers to sell for forward delivery by Brazilians, so that quotations are 1s. 6d. lower. This, together with the slackness of the demand from the country, which is always the case during December, has led to slightly lower rates, good Central American sorts being 2s. cheaper, while of the common kinds only lower offers could be obtained for Santos, which holders would not accept.—*Produce Market Review*, Dec. 17th, 1892.

PLANTING IN NORTHERN AUSTRALIA.

A gentleman writing by the last mail from Palmerston states that he has been engaged in an experiment with coconut pines on land at Fanny Bay, and has now eighty trees as fine as any planter could wish them to look. He has also some mangoes, and this year one of the trees is bearing. The writer was so pleased with the success of the coconut trees that he had applied for a block of 640 acres near Night Cliff for the purpose of starting a plantation upon a large scale.—*Adelaide Observer*.

VARIOUS NOTES.

"MOCHA" COFFEE.—That all is not "Mocha" that goes by that name, is a fact well known to those engaged in the coffee trade. Perhaps the following quotation from the *South of India Observer* throws a little light on the matter:—"It is a curious coincidence that native buyers secured nearly every bean of coffee available last month on the Hills and in Mettappolli, and the largest buyer was shipping his purchases to Egypt, the prices paid being quite above the equivalent of London rates." Hitherto most "Mocha" coffee has really been grown in Abyssinia, but apparently India is entering into competition.—*Madras Times*.

ARTIFICIAL GUM ARABIC.—For the preparation of a so-called artificial gum arabic the *Rev. de Chem. Indust.*—through *Novv. Remèdes*, 1892, No. 13 supplement.—gives the following process:—10 kilogrammes linseed are boiled with 80 kilogrammes sulphuric acid and 100 litres of water for three or four hours. The liquid is then filtered, and four times its volume of alcohol is added. The precipitate is collected, washed, and dried. The product is amorphous, colourless, insipid, and gives, with water, a thick mucilage.—*Public Opinion*.

A LUMINOUS TREE.—One of the most remarkable of trees or shrubs (says the *Horticultural Times*) grows near some springs, about twelve miles north of Tuscarora. It is about six or seven feet high, with a trunk which at its base is three times the size of an ordinary man's wrist. It has numberless branches and twigs, and resembles somewhat the barberry. Its truly wonderful characteristic is its luminosity, which is so great that on the darkest night it can be plainly seen a mile away. A person standing near could read the finest print by its light. Its foliage is extremely rank, and its leaves resemble somewhat those of the aromatic bay tree in shape, size, and colour. The luminous property is due to a gummy substance, which can be transferred to the hand by rubbing, and with the transfer the phosphorescent light, while that on the leaf disappears. This luminosity is thought to be due to a parasitic form. The Indians regard it with superstition, and will not come near it, even in daytime. They give it a name which means "witch tree."

BRITISH NEW GUINEA AS A PLANTING COLONY.

ANOTHER ATTRACTION TO CEYLON COFFEE AND COCONUT PLANTERS.

A recent mail brought us some copies of a "Handbook of Information for intending settlers in British New Guinea," published by the authority of the Queensland Government and in fact drawn up by the Administrator, Sir Wm. Macgregor, the very best possible adviser and authority on the subject. In this pamphlet of 34 pages there is a great deal of most useful information and a very good map. It is quite clear that British New Guinea has now got to such a settled administrative stage that there is a desire to have trained planting settlers with some capital to develop the resources of the country. Sir Wm. Macgregor in fact wishes to have men of the type of Ceylon planters with some capital to back them; and it is for them primarily he has compiled this little Guide. For instance, in an introductory letter to the Governor of Queensland he writes:—

As tribes become settled they have on their hands more leisure than was formerly the case. It is very desirable that this should be turned to some use; that they and the European settler should mutually benefit each other, the one by working with his hands for the other, while at the same time becoming acquainted with new products and new industries, the use and advantage of which he would learn from his employer. The difficulty is, however, that it is not easy to find in quantity the practical European settler with a good head, strong arms, some capital, and sufficient experience of tropical cultivation; and when met with he has such a wide range of choice that it is not an easy matter to secure him for such a remote and little-known place as British New Guinea.

He then proceeds to give needful information under the following heads:—

Position and Area of the Possession, Political Condition, Legislation, Administration of Justice, Police, Communication, Health, Domestic Animals, Sport-land, Labour, Tariff, Exports, Meteorology, Map, and in Appendix:—The Crown Lands Ordinance of 1890, Parts IV., V., and VI., The Native Labour Ordinance of 1892, and Tariff.

As to position and area it is evident British New Guinea is well-fitted to develop into a great tropical planting colony:—

According to a return recently prepared in the office of the Surveyor-General of Queensland, the total area of British New Guinea is about 90,540 square miles. It has an approximate coast-line of 1,728 statute miles on the mainland, and of 1,936 miles on the islands, giving a total coast-line of about 3,664 miles. Its northern boundary lies from 5° south latitude at the west end to 8° south latitude on the east end the southern boundary in the west is the sea and the Colony of Queensland, and in the east end it comes as far south as 12° south latitude. The eastern and western boundaries are respectively the 141° and the 155° of east longitude. The western boundary meets Dutch New Guinea; the northern boundary meets Kaiser Wilhelms-land.

The next three heads show there is settled reliable Government, and then we come to a very important matter:—

A contract has been entered into between the Government of the Possession and the firm of Burns, Philp, & Co. to run a regular mail service between Queensland and the Possession for four years beginning with January, 1893. A round trip will be made every eight weeks, starting from Cooktown for Samarai and proceeding thence to visit all ports on the New Guinea coast from Samarai to Mahuduan, and thence by Thursday Island to Cooktown. The vessels employed cannot be less than 100 tons. Other vessels cross at irregular intervals between Australia and British New Guinea, and many small craft trade on

the coast of the mainland and among the islands. Sir Wm. Macgregor is a qualified M.D., so that he can be listened to with respect in regard to "health":—

With the exception of fever the country is remarkably free from disease of a serious kind. But for fever the country would be a very healthy one for Europeans; and the fever is not nearly so severe as is generally supposed. "Old hands" become acclimatised, and, as a rule, suffer from only mild attacks that speedily pass off. Its great characteristic is uncertainty. Frequently it does not follow the greatest exposure to cold, wet, heat, or travelling and sleeping in mangrove country; at other times it arrives under apparently favourable sanitary conditions. It begins with a feeling of cold and uneasiness, with headache and lumbar pains, until the sufferer begins to perspire, when there is almost instant relief. In many cases a man will take his breakfast, will be down with fever at noon, and will meet the muster roll for duty next morning. In other cases, especially in new arrivals, it remains persistent and is attended with much prostration, which, in certain persons, requires a change of climate for a few months. These persistent cases are dangerous to those that cannot tolerate quinine. In the great majority of cases the fever is well controlled by quinine and antifebrine, but the number of people that cannot take quinine seems to be considerable. Natives suffer from occasional mild attacks of fever; but they are soon over. The congestion of the internal organs during an attack of fever causes distress to Europeans, and might be a serious matter to anyone with organic disease of the chest, liver, or kidneys. The most predisposing cause of fever is exposure to a cold wind when one is perspiring; next come great fatigue and exposure to the direct rays of the burning sun. By reasonable care and by taking appropriate remedies whenever fever threatens, the danger from it to a person actively employed and otherwise healthy is not at all great.

We may repeat here, that we do not know a Governor or Administrator in the whole Colonial Service under whom it would be a greater privilege for planters of the right stamp to pioneer and settle, than Sir Wm. Macgregor. He would be certain to appreciate good, honest, practical work, and to make full allowance for the difficulties incidental to the commencement of industry on a big scale in a new country. If any Ceylon planters, with some capital, turn their attention to New Guinea, to try coffee or coconut palms, we feel sure that Sir William will welcome and officially aid them as far as possible in their start. We now proceed to quote further from his little Guide and here are important items in respect of Food and Sport:—

There are in the Possession some two dozen horses and, perhaps, about fifty cattle. Sheep have not been much tried, but they appear to suffer from spare grass. Pigs thrive well, and are probably indigenous. The native pig is a handsome, intelligent, active animal, which largely provides for itself. It would probably, if crossed with more fleshy kinds, produce a very superior swine. Fowls seem free of disease of any kind, and do well if protected from mosquitoes during the hot season, and if guarded from native dogs, carpet snakes, and lizards.

The list of game procurable in the Colony is a varied one, comprising wild swine, wallaby, and the never-failing crocodile. Among birds there are the cassowary, goura pigeon, hornbill, geese, ducks, and smaller water fowl. There are a great many varieties of pigeons. Scrub fowl and turkey are to be found everywhere. There are many birds that are more of interest to the naturalist than to the sportsman, such for example as the Birds of Paradise. No doubt there are many birds in the country still unknown to science. But although game may be abundant, one may, on account of the difficult nature of the country, make only a poor bag after hard work. Fishing has not been much tried, and does not seem to be very encouraging.

But of still more consequence to the intending planter are the rules about "Land and Labour":—

The Government may sell Crown land by private bargain or by public auction. If Crown land is sold by the Government by private bargain on the condition that the purchaser shall introduce some new industry in cultivating the land, and shall carry out some specified extent of improvement within a given time, the price of the land alienated may be as low as two shillings and sixpence an acre. If no conditions as to improvements are imposed, the price to be paid for land cannot be less an acre than—

- (1) For agricultural land, 10s.;
- (2) For pastoral land, 2s.;
- (3) For land for trading or fishing purposes, £5;
- () For land for the planting of coconuts, 5s.

Land in parcels not exceeding 50 acres can be purchased at £1 an acre, this payment being made in instalments extending over a period of five years.

Crown lands, or land in which the Crown possesses a leasehold interest, can be leased to applicants by the Government. If no improvement conditions are attached to a lease of agricultural land, the annual rent cannot be less than 1s. an acre; if the land is leased subject to improvement conditions, no rent may be payable for three years, but after that period the minimum rent would be 6d an acre. Leases may also be granted with a purchasing clause.

Land suitable for planting coconut trees may be leased for sixty years. No rent may be payable for the first five years, but for the next five years it cannot be less than 6d an acre, and for the remainder of the lease not less than 1s an acre each year.

To a person thinking of taking up land in the Possession, the best course would be to visit the country and see what unoccupied land would suit best the particular industry he has in view. As already pointed out, it would be futile to choose land that is occupied by natives; but, as the Government is extremely anxious to have all lands now lying idle turned to some useful purpose, and to procure employment for the native population in their own country, and that the latter should learn to become producers on their own account of articles for export, all legal means will be used by the Government to procure for an agricultural settler the land he may desire to possess.

There is a very great variety of soil in the Possession, but of the quality of the land chosen by an intending settler he should satisfy himself on the spot, and he must take on himself the sole responsibility of judging whether any given place is suitable for his special purpose. There are flat alluvial river lands suitable for rubber growing; flat, wet, marshy land fit for planting wet rice; river bottom land, fit for growing sugar-cane or maize; hilly country of brown soil on limestone conglomerate and slate, suitable for growing coffee and tea; and there are fine forest patches for large shady trees on rich soil, well adapted for vanilla, cocoa, &c., &c.

It may, perhaps, be considered that the indigenous products give trustworthy indication as to what might be cultivated in the Possession. Amongst food articles the natives cultivate a great many different varieties of yams, as many as three dozen kinds being sometimes used by one large tribe; different varieties of taro and of sweet potatoes; and very many different kinds of bananas, some of which are of decidedly superior quality. Sago grows in the swamps all over the Possession, and is used everywhere, more or less, as an article of diet. In some districts maize is coming much into use. Beans seem to be indigenous. In some districts the pineapple is domesticated, and is of excellent flavour. The papaya is ubiquitous, but not indigenous. The orange family has only very poor indigenous representatives, but the introduced trees do remarkably well. Coffee seeds and plants have been obtained free from disease, and their importation from places infected with "coffee-leaf disease" will now be prohibited. There is a native ginger of very strong flavour, as yet untried, which will probably be found to be of commercial value; East
