

"Step after step the ladder is ascended."—George Herbert, *Jacula Prudentum*.

THE TROPICAL AGRICULTURIST

A Monthly Record of Information for Planters

OF

TEA, CACAO, COFFEE, CINCHONA, SUGAR, COTTON, TOBACCO,
PALMS, SPICES, RUBBER, RICE,

AND OTHER PRODUCTS SUITED FOR CULTIVATION IN THE TROPICS.

COMPILED BY

A. M. & J. FERGUSON,

of the "Ceylon Observer," &c.

"It is both the duty and interest of every owner and cultivator of the soil to study the best means of rendering that soil subservient to his own and the general wants of the community; and he who introduces, beneficially, a new and useful *Seed*, *Plant*, or *Shrub* into his district, is a blessing and an honour to his country."—SIR J. SINCLAIR.

VOL. XII.

[Containing Numbers I. to XII. : July 1892 to June 1893.]

Solombo, Ceylon :

A. M. & J. FERGUSON.

LONDON :

MESSRS. JOHN HADDON & Co.; KEGAN PAUL TRENCH, TRUBNER & Co., Ltd. ;

MADRAS : ADDISON & Co. ; CALCUTTA : THACKER, SPINK & Co. ;

BOMBAY : THACKER & Co., LTD. ; AUSTRALIAN COLONIES : GORDON & GOTCH,

◁ TO OUR READERS ▷

In closing the Twelfth Volume of the "**Tropical Agriculturist**," we would once more direct attention to the large amount of useful information afforded and to the great variety of topics treated in our pages. From month to month, we have endeavoured to embody in these pages the latest results of practical experience and scientific teaching in all that concerns tropical agriculture; and our ambition has been to make this periodical not only indispensable to the planter, but of service to business men and capitalists, never forgetting that agriculture trenches upon every department of human knowledge, beside being the basis of personal and communal wealth.

While directing our attention chiefly to the products prominently mentioned on our title-page, we have always taken care to notice minor industries likely to fit in with sub-tropical conditions; and our readers have an ample guarantee in the pages before them, that, in the future, no pains will be spared to bring together all available information both from the West and East, the same being examined in the light of the teachings of common sense as well as of prolonged tropical experience in this, the leading Crown and Planting Colony of the British Empire.

The Tea-planting Industry has sprung into so much importance in India and Ceylon, that a large amount of attention is naturally directed to this great staple, and we think it will be admitted by impartial judges that the *Tropical Agriculturist* should be filed, for ready reference, in every Tea Factory in this Island and India.

"The Manual of Chemical Analyses" prepared by Mr. M. Cochran specially for the benefit of planters, and which was begun in our January number, cannot fail to instruct all who give it a careful perusal.

A full and accurate Index affords the means of ready reference to every subject treated in this, the twelfth volume, which we now place in our subscribers' hands, in full confidence that it will be received with an amount of approval, at least equal to that which has been so kindly extended to its predecessors.

We are convinced that no more suitable or useful gift can be made to the tropical planter or agriculturist, whether he be about to enter on his career, or with many years of experience behind him, than the twelve volumes of our periodical which we have now made available. They are full of information bearing on every department and relating to nearly every product within the scope of sub-tropical industry.

In conclusion, we have to tender our thanks to readers and contributors, and our wish that all friends may continue to write instructively and to read with approval; for then, indeed, must the "**Tropical Agriculturist**" continue to do well.

A. M. & J. FERGUSON.

COLOMBO, CEYLON: 1ST JULY 1893.

INDEX.

[s after certain figures stands for *Supplement*, meaning the "Magazine of the School of Agriculture," which was paged separately for eleven months, and is stitched at the end.]

SUBSCRIBERS

TO THE

“TROPICAL AGRICULTURIST”

are reminded that with the June Number, already received by them, and the Index and Title-page now issued, the TWELFTH VOLUME (1892-93) is closed.

SUBSCRIPTIONS are due payable in advance for 1893-94, at the following rates:—

For Ceylon { Yearly ... R12	For Europe, &c. { Yearly £1 6s. R17.
or India { Half-yearly ... R8	

N.B.—Subscribers to the *Ceylon Observer* or *Overland Ceylon Observer* R4 (6s.) LESS in each case.

Single Copies, R1; back copies, R1½.

Price of each Volume, elegantly bound, to Non-Subscribers, R14.

Those who have not settled for past subscriptions are requested to do so by return of Post, and to send Cheque, Post Office Order, or Bank Draft, in favour of A. M. & J. FERGUSON, Colombo.

Covers for binding the Twelfth Volume, July 1892 to June 1893 (870 pages), can be obtained for R1. Cost of binding and cover R2.

WHAT IS THOUGHT OF

THE “TROPICAL AGRICULTURIST.”

A gentleman resident in the Central Province, who has as good opportunities of knowing what is of benefit to planters as anyone we know, sent us the following explicit testimony to the value of the “T.A.”:—

“Since its commencement, I have regularly seen and perused the *Tropical Agriculturist*. There can be but one opinion that its scope and object are highly important, and that it supplies a distinct desideratum, which it is to the interest of every estate proprietor to have available in the bungalow for the use of his *locum tenens*, or superintendent. As a magazine it provides interesting and instructive fresh literature at intervals, deprived, as most in Ceylon are, of easy access to libraries; and as years go by it will growingly become ‘The Ceylon Encyclopædia,’ with reference to agricultural operations. Viewing estate property as practically a permanent investment, to any proprietor, the trifling charge of R12 per annum—a rupee a month—is certainly of no account, provided the separate numbers are kept, and bound together yearly as a book of reference, for the benefit of the manager and his successors. In that light, as the property of an estate to be handed over just as much as its office furniture, few proprietors would probably refuse to authorize its being taken and filed regularly (if the periodical was brought under their notice), more especially as on looking over the most recent volume one cannot fail to see how much valuable information on ‘Tea’* has been collated. In the belief that ‘Tea’ will restore prosperity to Ceylon, and that plantation property is a good investment for capitalists, such should not omit the office and connected equipment so advisable on all ‘pukka’ estates, a part of which should be the *Tropical Agriculturist*. I find I have gone on writing, but as I am getting the numbers for the past year ready to be bound, the volume is before me.”

THE VALUE OF THE “T. A.” TO CEYLON ESTATE OWNERS.—A planting correspondent wrote some time ago:—“I think proprietors should supply every tea estate with the T. A. The information in it with regard to everything in connection with tea, &c., is invaluable: it would pay its value over and over again. Owners of estates should not leave it to hard-up superintendents to take it in.”

* “Tea” is the subject of a very large number of references to papers and articles in the volume for 1892-93 now closed.—ED.

☞ Every Tea Factory ought to have a file of the **Tropical Agriculturist**, which contains a vast amount of information about Tea, and a Record of the Tea and other Produce Sales.

ORDER FOR THE
"TROPICAL AGRICULTURIST."

.....1893.

Sirs,

Please forward the above publication from the beginning of Vol. XIII. 1st July 1893.

Please send also (lettered as for..... Estate)
Vols. I., II., III., IV., V., VI., VII., VIII., IX., X., XI., ^{AND}_{OR} XII.,
for 1881-2, 1882-3, 1883-4, 1884-5, 1885-6, 1886-7,
1887-8, 1888-9, 1889-90, 1890-91, 1891-92, and 1892-93.

I am, Sirs,

Yours faithfully,

Messrs. A. M. & J. FERGUSON,

"Ceylon Observer" Office,

COLOMBO, CEYLON.

THE TROPICAL AGRICULTURIST MONTHLY.

Vol. XII.

COLOMBO, JULY 1ST, 1892.

[No. 1.]

THE REPORT OF THE EASTERN PRODUCE AND ESTATES COMPANY.

We have made a point hitherto of specially noticing the reports of those companies whose operations have included what may be termed the transitional period of planting in Ceylon. Occupying

perhaps the foremost position among those has been the Eastern Produce and Estates Company, which, our readers will doubtless bear in mind, was formed to take over from the liquidator of the defunct Ceylon Company the estate properties possessed by the latter at the date of its winding up. It is true that when the transfer took place some progress had already been made in the supersession of the exhausted coffee trees by tea bushes; but the bulk of this operation, we believe, has had to be performed by the new Company, the report of which for last year now lies before us. Our London Letter by this mail briefly reviews the very onerous conditions under which this Company had had to work since the transfer of the properties was made to it. It is not necessary, therefore, that we should here recapitulate these. It will suffice to remark that those conditions have not only been fully met and complied with, but that the time has arrived when the holders of ordinary shares in the Company are able to obtain some return for the money invested by them. All of us must be ready to endorse the remarks by our London correspondent that this fact is not alone creditable to the management, but highly satisfactory to all who feel an interest in the prosperity and progress of our tea-planting industry. We observe that the profits made during the year amounted to about £22,000, there being, with £4,752 brought forward from the last account, an exact sum of £26,608 13s 4d available for fulfilling all the conditions imposed by the articles of association under which the Company was formed and registered. These having been, as we have said, fully complied with, the directors are yet in a position to propose a first dividend at the rate of 1½ per

cent per annum, free of income tax. We have no doubt that while this much-desired point has been reached, a liberal expenditure has been made to bring the efficiency of all the properties up to the highest modern standard, and that so much has been accomplished during the relatively few years throughout which the Company has been working, is a fact that cannot fail to be regarded as most satisfactory by all who have watched the progress of the undertaking. Year by year we have seen the cloud under which this Company and similarly situated companies commenced their working clear away, until even that placed under the most restrictive of conditions is able to appear before the public as a paying concern, and with ample grounds exhibited for anticipating a bright future for those who have had so long to wait for it. The fact furnishes an additional commentary—if any were needed—upon the pusillanimity of those who decided upon winding up the affairs of the old Oriental Bank; it is perfectly well-known that it was in consequence of that act that the Ceylon Company, which was the child of that institution, had likewise to follow suit; and great dread was felt at the time that this was done that the forced realization of that Company's properties would flood the market, and would heavily depreciate the value of estate property throughout the island. We now can see that, if the Bank had stood its ground, not only would it ultimately have attained the success which now attends the New Oriental Bank's working, but the Ceylon Company under judicious management might have been tided over all its difficulties, and that the assets which the Bank directors regarded as comparatively valueless would have been made in the end to contribute largely towards the maintenance of the prosperity of the foster mother. We have no doubt that much of the credit due for the results now obtained and disclosed must be assigned to the able managing director, Mr. Ralph A. Cameron.

NOTES FROM OUR LONDON LETTER.

LONDON, April 29.

THE EASTERN PRODUCE AND ESTATES COMPANY, LD.

Very considerable interest must be attached to the report of the Eastern Produce and Estates Company, which is herewith forwarded to you. You will recollect that this Company was formed to take over and work the numerous properties which were possessed by the Ceylon Company at the time it was wound up and its existence finally closed. Very stringent conditions were imposed at the time

of the formation of the Eastern Produce and Estates Company by the liquidators of the Ceylon Company when handing over these properties. With regard to these it may be as well to quote as follows from the report under notice. Referring to the articles of Association, that document states that "as the shareholders are aware provision is there made for the appropriation of profits, after payment of Debenture interest and Dividend on Preference Shares:—first, for the creation and maintenance of a Reserve Fund of £10,000, applicable if required for the payment of said interest and dividends; secondly, for the redemption of debentures to the value of £3,000 each year, and thereafter for the payment of dividend on the ordinary shares, not to exceed the rate of three per cent per annum, until the debenture stock be reduced below £50,000. Any surplus profits after payment of dividend at that rate to be applied in further redemption of debentures." It will be regarded as most satisfactory that although but a short time comparatively has passed since the Eastern Produce and Estates Company took over the estates on the stringent conditions above-mentioned, the present report—that for last year—is able to announce that all these conditions have been fulfilled, and that, notwithstanding the heavy cost of doing so, the directors are able to recommend that a first dividend on the ordinary shares shall be paid at the rate of 1½ per cent per annum free from income tax. Although this liberal first instalment can be paid, there will yet remain the substantial sum of £7,690 15s 4d to be carried forward to next year's account. Out of the profits of last year no less an amount than £10,010 was drawn and paid off the debenture stock of the Company. These facts indicate how prosperously the properties have been worked. We all recollect that at the time of their being taken over it was commonly said that a large— an unduly large—proportion of these was comparatively worthless. During the years of forced economy necessary to the Ceylon Company it can hardly be doubted that the estates were greatly starved, and that their upkeep must consequently have been greatly neglected. That estates in such a condition should have been by judicious management brought into a condition to yield good results speaks highly for those to whom their management has been entrusted, and the Ceylon public may be congratulated on the fresh evidence afforded by this report of the prosperity and payingness of the leading industry of its island. It is stated that 9,236 acres of the Company's properties is now under tea, of which 6,700 are over four years old. In all 2,008,000 lb of tea was obtained, the gross price at which it sold being 9½d per lb. The crop for 1892 is estimated at 2,240,000 lb. Three estates, Belgodde, Montefiore, and Sinnegodde Belle Vue, have been sold during the year, the proceeds being credited to the Estates Reserve Account. We observe that exclusive of its tea acreage the Company has 108 acres under coffee, 624 acres under cacao, and 358 acres under cinchona, cardamoms and sundries, with a balance of 6,465 acres, consisting of forest, grass and uncultivated land, the whole making up a total acreage of 16,791 acres. The meeting to consider this report was to be held yesterday, but at the moment of writing no account of the proceedings at it has reached me.

COLOMBIAN CINCHONA BARKS.

The specimens of new kinds of cinchona bark from the Republic of Colombia to which Mr. Holmes drew attention at the Pharmaceutical Society's meeting last

Wednesday (see below) were exceedingly interesting in themselves, but unhappily, from a commercial point of view, the existence of the cinchonas is, at the present time at any rate, of no value. For all practical purposes they might just as well flourish, along with political economy, on the planet Saturn. For, assuming that the supply of the rich Negra and Tuna barks is large enough to warrant their consignment to Europe, the expense of bringing them over will far exceed their appearance in the market for a considerable time to come. Colombia is one of the most backward countries on earth in the matter of inter-continental communication. There are practically no roads, and although short tracts of railway have been made here and there, and numerous concessions for other lines have been given, there is no prospect whatever that efficient railway communication will be established this century with the region where the barks grow. A striking instance of the cost of transport in the country was given in a recent paper on the resources of Colombia, published by the "Bureau of American Republics" in Washington. It is stated there that a bale of goods sent from the Port of Cartagena to Bogotá (the capital of the Republic) has to be unloaded, loaded and warehoused twelve times, the last part of the journey alone, and eighty-mile run by mules across the Andes, taking "from five to twelve days in good weather." The cost of bringing merchandise from Honda (over 600 miles inland) to Bogotá alone is from 2½d to 3¼d per lb. This route inverted would have to be taken by Mr. Thomson's cinchonas, and it is safe to calculate that the freight upon them alone from Bogotá to London, would cost not less than 5d per lb. As 6-per-cent cinchona is worth about 7½d per lb. at present, the happy grower is not likely to flourish on the proceeds of his discovery just yet. At the time when the bark prices began to fall Colombia was almost the first country from which supplies ceased to come, and it is believed that unless prices attain at least double their present figure this Republic will not resume its cinchona exports on a scale of any magnitude. But as economic commercial considerations have to take a very hack seat at the Bloomsbury Square meetings, such matters can hardly be expected to find education there.—*Chemist and Druggist*, April 23.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.

EVENING MEETING.

As briefly reported last week, the members of the Society were invited to a pharmaceutical evening at Bloomsbury Square on Wednesday, April 13th. The attractions were unusually bright—a whole year's collection of museum donations exhibited in the old way, and with microscopic illustrations under the lens, and enlarged by lime-light lantern. It was a brave show truly; still, it might have been an ordinary monthly meeting so far as mere number of specimens was concerned. The audience was a fair one, with a good sprinkling of Mincing Lane people on the front benches, but the representatives of historic wholesale houses were conspicuous by their absence.

Mr. CARTEIGHE, in opening the proceedings, suggested that the best way to arrange the menu of the evening would be, first to let Mr. Holmes read a portion of his paper relating to the donations received by the museum during the year, and then to ask Dr. Paul to interpose with his notes on solution of strychnine after which Mr. Holmes would be invited to resume his paper.

Mr. Holmes, who received a very friendly reception, pleasantly remarked on rising that the difficulty he had was to know where to begin.

* * *

COCA LEAVES.

From senna the Curator proceeded to coca, the botany of which, he said, is still far from being satis-

factorily known. In commerce there are two kinds of leaves, the dark green, strong Bolivian, or Huanoco, and the light green, Peruvian, or Truxillo leaf. A third variety of leaf is that cultivated in the island of Java, which is occasionally met with in the markets of the world, and has the reputation of being a very carefully dried article. About four years ago Mr. Morris, of Kew, in an exhaustive paper on coca, described a variety which he called "Novogranatense," which has narrower leaves and of a paler green colour than the Bolivian leaf, and this is the variety which appears to yield the Java leaf of commerce. With regard to the respective alkaloidal values of the various leaves, Peruvian and Bolivian leaves yielded cocaine and isotropyl-cocaine in almost equal parts, whereas the Java leaves gave less cocaine than the two former. In this country, said Mr. Holmes, cocaine was generally prepared by purifying the crude cocaine manufactured in Peru, and the Java leaves were therefore all used by the German cocaine-makers. So far as cocaine-manufacture is concerned the leaves of the *Erythroxylon Bolivianum* are preferred, and of this variety the pale brown leaves are the best. The leaves of young plants contain more than double the quantity of alkaloid found in the leaves from old shrubs, and moisture caused a considerable loss in the yield of alkaloid. Reproductions of various kinds of coca-leaves were then thrown on the screen. The variety described by Mr. Morris tapers at the base and the flowers have a short stigma. The cultivated Java leaves are not so long as Mr. Morris's "Novogranatense" leaf. They are broader in the middle, the flowers have longer stigmata, and the habit is different from that of the others. The Brown Bolivian leaf, finally, has a more leathery appearance and the midrib shows a distinct ridge.

Having given these notes on coca, Mr. Holmes came to the staple subject of his discourse—viz., certain new varieties of

CINCHONA.

The specimens to which he referred were shown upon the table before him. There were nine varieties of bark, of which the donor was a Mr. R. Thomson, formerly a superintendent of the Jamaica Botanical Gardens, and now engaged as a planter in the Republic of Colombia. Mr. Thomson had discovered some of these barks in the central range of the Colombian Andes while travelling in that region a few years ago; others were cultivated by him upon his plantation. Analyses of the barks showed them to be of remarkable average richness, the following being the figures given:—

	Quinine Sulphate.	Quinine.	Cinchonidine.
Thomsoniana...	.. 5.94	4.45	0.27
Ledger. Verde 4.90	3.68	0.00
Negra 7.30	5.08	0.00
Morada 3.06	2.30	0.00
Tuna 9.04	6.78	0.40
Pombiana 5.88	4.41	0.34
Officialis 6.32	4.74	1.23
Succirubra 5.93	4.45	2.77
Hybrid 3.32	2.49	1.92
	Cinchonidine.	Quinine.	Amorpha.
Thomsoniana..	.. 0.82	0.26	0.74
Ledger. Verde 0.01	0.20	0.44
Negra 9.10	trace	0.78
Morada 0.04	0.50	0.38
Tuna 0.38	0.18	0.42
Pombiana 0.02	trace	0.26
Officialis 0.10	0.07	0.42
Succirubra 0.12	0.02	0.36
Hybrid 0.04	trace	0.52

The three last-named kinds are well-known varieties and not natives of Columbia, any more than the Ledgeriana Verde and Morada. The tree yielding the bark marked "Negra" was discovered by Mr. Thomson in 1893. It grows at an altitude of 8,000 ft., attains maturity with singular rapidity, resembling in this respect, the Succirubra variety, and is exceedingly rare. Both flowers and leaves are very large; the latter have a rich brown colour and hairy underface. They are without the scabberles, or little warts, the existence of which has been held to indicate alkaloidal richness.

Whether, as a matter of fact, rich barks are always collateral with scabberles leaves may be doubted. The microscopical structure of the *Negra* bark indicates a relationship to that of the *Lancifolia*. Mr. Thomson secured a few hundreds of plants of this species, and is now rearing it in his plantation. The tree grows slowly and does not appear to prosper so well under cultivation as in the wild state. It received from Mr. Thomson the name of "Negra" (black), because of its deep claret-coloured petioles, by which the peons are able to distinguish it from other kinds. In the Tuna bark ("tuna" is a native word of uncertain meaning), the richest of all Mr. Thomson's varieties, the resemblance to the Ledger species is very evident. Like all other kinds belonging to the *Lancifolia* group, the bark of this species contains numerous stone cells, fairly well distinguishable under the microscope; in the soft or middle layer there are no stone cells; in the other layers the cells are now arranged in solitary lines, now in clusters. The Pombiana variety was discovered in 1883 in Ecuador by a gentleman living in that country, and whose name had been given to it. Several thousand plants had been raised by Mr. Thomson from seeds and cuttings, but the tree is one of very slow growth. The Pombiana does not in histological structure resemble any of the cinchonas, but is like the myrtaceous plants. Its leaves are small and glossy, and its foliage is very dense. The capsules also are small (a fact which, in cinchonas, is held to presage richness in quinine). The wood-fibres from distinct oblong groups like those of the *C. lancifolia*, the leaves are leathery and narrower than those of the *C. pitayensis*, the flowers are hairy on the under-surface of the corolla, the petals are hairy all over, whereas in nearly all true cinchonas the petals are only fringed with hair. In *C. pitayensis* there are no stone-cells in the middle layers of the bark. The Pombiana may be said to form a link between the Pitayo and the *Lancifolia*, or "soit Colombian" species.

EUCALYPTUS OIL.

The Curator, resuming his paper, came next to essential oils, and eucalyptus oils were the first he spoke of. He referred to the introduction of *Eucalyptus Globulus* oil, and the great differences which were noted in the qualities of commercial oils as soon as eucalyptus began to be popular. Within the last two years a new kind of oil had appeared in the market under the name of *E. oleosa*, which had a cuminalike odour, very different from that formerly known as *oleosa* oil. The fact was that the oil which formerly went by that name was the Mallee scrub oil, a mixture distilled from four species which grow together, and the new *oleosa* is a distinct variety. He expressed the opinion that although the original reputation of eucalyptus oil was based on the *Globulus* variety, it had, in reality, happened that for years the *amygdalina* oil was the only one, which came on the market, and even yet this oil is preferred for inhaling in lung-diseases. He did not appear to be quite sure what the therapeutic properties of eucalyptus oil are due to, at one time suggesting that the peculiar odour of the *amygdalina* oil is probably due to an aldehyde, which may have something to do with its therapeutic properties, and again recommending a comparative trial of phellandrene and eucalyptol.

Speaking of the cocas Mr. MARTINDALE said that although the Bolivian leaf was most liked for cocaine-making, the Truxillo and similar varieties were preferred for galenical preparations, as they did not contain the large percentage of wax which is in the Bolivian leaves, and makes the surface of those leaves quite shiny.

Mr. THOMAS CHRISTY called attention to some plants which he had put upon the table, which included *Pulsatilla nigricans*, and, speaking of coca, said that he had so many kinds in his conservatories that he felt they had not learnt all that was to be known regarding the leaves of greatest value. To this he added a comment that English manufacturers do not know so much about the extraction of cocaine as is known in Germany.

Mr. R. H. DAVIS said, in regard to the oil of *Eucalyptus oleosa*, that he had now been able to confirm Schimmel's statement that eucalyptol can be separated from it by freezing, without previous distillation. He thought there should be no difficulty in getting the question of the medicinal values of the oils settled by submitting samples of phillandrene and eucalyptol to medical men for experiment.

Mr. DRYSDALE, in response to an invitation from the chair, said that there was one point about eucalyptus oil which he might call attention to. The oil from *E. oleosa* and that from *E. cneorifolia* were regarded as from two distinct species, whereas they were, in fact, one and the same product. Formerly Baron von Mueller regarded the latter as a sub-variety of *E. oleosa*, but later observations showed that *E. cneorifolia* was a distinct species. The firm of distillers which he represented had adopted the more common name *oleosa* because of the facility in pronouncing it, but the tree was not widely propagated in Australia.

Dr. F. W. PASSMORE said, he had lately been working on samples of *E. cneorifolia* oil, and found that one specimen contained 50 per cent of eucalyptol. Another sample also contained some. He had observed that the higher boiling fractions had an odour like lemon, this probably being due to the presence of some such body as citral.—*Chemist and Druggist*.

ABOLISH THE TEA DUTY.

BY C. J. ROWE.

We reprint by permission an article contributed to *The Speaker* by Mr. Rowe. These articles constitute a powerful argument for the complete abolition of the Tea Duty.

The reduction of the Tea Duty in 1889 produced an increase in the home consumption of Tea, in 1891, of 17,000,000 lb. It was effective, too, in procuring a great improvement in the general quality of tea, by causing inferior China Teas to be ousted in favour of better leaf from Ceylon and India. In fact, the reduction of 2d was a national gain of more than 2½ per lb. The total abolition of the remaining duty of 4½ per lb. could hardly fail to give the public a greater benefit than four-ponnyworth of value now represents.

Under existing arrangements the duty has to be advanced before clearance for delivery. Firms engaged in the tea trade must possess a capital for duty-paying purposes alone, over and above their trading capital proper. They must also employ a larger staff than unfettered business requirements would demand, in order to transact their Custom House work. Extra capital means extra interest charges, more clerks mean more office room, higher rents, and additional salaries. Probably, under these heads, the duty requires, on an average, the employment of 50 per cent more capital in the distributive tea trade of the kingdom than would suffice if there were no duty. That is to say, the duty sets up a barrier—Protectionist to the core—which shuts out from the trade all but those who can command the extra 50 per cent of capital or credit. *Pro tanto* it limits the number of sellers, and so allows existing ones to reap a high rate of profit. The immediate general effect of the abolition of duty would be the removal of a protective barrier between the trade and the consumer, for the maintenance of which the latter has to pay heavily *beyond* the 4d. per pound that he contributes to the revenue.

There is a still readier illustration of the protective effect of the duty and of the consequent gain to the consumer from its removal. The majority of grocers retail their *ordinary* teas at not less than fifty per cent. profit. The profit is made on the duty payment as well as on the cost price. On the average cost of *ordinary* teas the profit probably works out in equal proportions on duty and cost price, fifty per cent. on each. The tea of the very poor, now sold largely in fractions of a pound, gives an even higher profit, and because of its cheaper cost to the retailer, a much greater share of profit attaches to the duty payment. Proportionately, the benefit of the abolition of duty will be most valuable to those who are least able to pay it, but who now have to pay the biggest share of

the profit it procures for the grocer. Proportionately, also, it will be least valuable to purchasers of the finest teas; those who pay a higher profit on the tea itself but correspondingly less on the duty payment. But, taking one tea with another, we may estimate the gain to the consumer, directly resulting from the abolition, without reckoning improvement in the value of tea given for the money, at not less than 6½ per pound.

Indirectly, the consequent benefit cannot be estimated on a mere poundage basis. Its effect is vastly increasing the tea trade between ourselves and our Eastern possessions must be considered. There, tens of thousands of coolies, now barely existing on the verge of starvation, will find plentiful opportunities for work and wages in the task of extending existing tea areas, and in harvesting the immensely increased quantities of leaf that will be required for the British public. Here the labour market will be largely stimulated by the necessity of paying for the growing imports by supplying home manufactures in exchange. Ships, railways, factories, all forms of industry, must profit by the freshened activity of the tea trade. In fact, the fresh field of employment created by the abolition of the duty will be co-terminous with the enlarged field of consumption certain to result from Free Trade in tea.

It can scarcely be doubted that the removal of the four-pence will bring a rate of increased home consumption of tea greater than has ensued upon any reduction of duty in the past. Hitherto the greatest rates of increase following on reductions have been in 1866 and 1891 respectively. In 1865 the reduction was from 1s. to 6d., and 1866 showed an increased consumption of 10½ per cent. In 1891 the increase consequent on the reduction in 1889 was also 10½ per cent. The reduction by 50 per cent. in 1865 is the readiest gauge we can apply to an estimate of the pace of the increase in home consumption as affected by a 100 per cent. reduction. Thirteen years after 1865, in 1878, the home consumption had doubled. And that, he it noted, although Ceylon and Indian teas, with all the extra attractiveness to the public taste that we now know them to possess, were non-existent. Is it too much to suppose that, with these teas coming forward in fast-increasing bulk, with planters competing against each other to improve quality and cheapen processes of manufacture, and with Free Trade in tea quickening the activity of competition amongst retailers, the rate of increase would be likely to double the home consumption in half a dozen years? The only factor that might, conceivably, have a disturbing effect upon the rate of progression is the certainty that the large extra demand for tea will keep "bond" prices at a high level in the market for some time after the abolition. This is what has happened after all previous reductions. But it has never affected the retail price to the consumer: nor is it likely to do so in the future, because supplies from India and Ceylon can without difficulty be expanded to meet even so large an extra demand as may be expected to result from abolition. At present, producers are fearful of glutting the market. With no duty in the way to check consumption, they will be able to fully supply the market without overflowing it.

The groundwork of the criticism expended by Liberals both in and out of the House of Commons—upon Mr. Goschen's reduction was its insufficiency. It was strongly urged that the duty should have been swept away *in toto*; and we may now consider the Liberal party, as such, pledged to go one better than Mr. Goschen by carrying the abolition of the duty. There is to be no more "tinkering;" the nation is to be no longer forced to pay toll for one of the staple necessities of life.

To say that tea is a "necessary of life" in the United Kingdom is to admit that the Tea Duty is indefensible in principle. All the more so because it forms the keystone of the system which surrounds the breakfast table with a hedgework of taxes. It shelters and gives vitality to the duties on coffee, chicory, and cocoa. No one would trouble to say a word in favour of taxing these last if the Tea Duty were abolished. To delay in pressing forward its abolition would be to

subordinate principle to expediency. Such a course would only mean that it would be considered expedient to continue to make the poor man the milch-cow of the revenue to the relief of the rich; for the poor pay by far the greater portion of the Breakfast Table Taxes while the burden of making up the revenue deficiency caused by their removal would, undoubtedly, be transferred to the rich, principally, let us hope, through the agency of a substitutionary tax on Land Values. The abolition of the duty will afford us the best imaginable opportunity for striking at those values.—*Financial Reformer* for March.

THE TEA DUTY.

When the tea duty was reduced by twopence in 1890, it was prophesied by the pessimists of the tea trade that the reduction would not benefit the public. While they admitted that an increased consumption of tea would follow the reduction, they contended that quality would be lowered in a large proportion than price. Consistently with their belief, they prophesied that cheap China teas, with all their drawbacks, would once again become popular, to the comparative exclusion and at the expense of Indian and Ceylon teas.

We can now look back on twenty months of results. During the greater part of the time we have had to face a great financial crisis, followed by heavy business depression and by a consequent lessening of employment, which has materially diminished the purchasing power of the working classes. For several months we were in the grip of a winter of exceptional severity—to the cost again of the working man's pocket. Further, during a large slice of 1891 we suffered from a positive dearth of Indian teas of the common kind. Scarcity drove them up to famine prices from February to June, and lower grade Ceylons followed their lead. Circumstances, indeed, seemed in a conspiracy to minimise the increase in the consumption of tea, and at the same time to encourage the use of cheap Chinas preferably to their "British-grown" competitors.

Even during the worst of the "famine" the refusal of the public to take to China teas again was very marked. The price of these was driven up by the gamblers of the Clearing House, but only momentarily. It rose like the rocket and fell like the stick. Whatever the height of Indians and Ceylons dealers had to take them, grocers had to buy them—at the extra rates—and to retail them at a reduction of 2d per lb. on the former retail price. Their low-priced Chinas were saleable only on condition of being concealed in blends. The explanation is that competition in the trade was too keen to permit of the consumer being done out of the benefit of the duty reduction. In all probability he lost no part of it even then. And be it remembered that the great rise in market values during this period was entirely confined to the lower-grade teas. At one time there was but little difference between the values of Broken Pekoes, Pekoes, and Pekoe Souchongs.

For the twenty months the total increase of "Home Consumption" has been, in round numbers, 17,000,000 lb. The remission of 2d in the duty was only in operation during the last eight months of 1890, so that the more convenient method of testing the increase in consumption is to compare the completed year 1891 with 1889.

The "Home Consumption" in 1889 was (in round numbers) 185,500,000 lb.

The "Home Consumption" in 1891 was (in round numbers) 202,500,000 lb.

An advantage to 1891 of 17,000,000 lb.

The "poundage" gain is far less on paper than in reality. The increase was exclusively in Indian and Ceylon Teas, and was accompanied by an enormous decrease in the consumption of China teas. It has been estimated that Indians and Ceylons show, on an average, 50 per cent greater strength than China teas; that is to say, they are capable of more economical use. Consequently, we may claim that, had China tea been our only staple last year, the increase for 1891 over 1889, in consequence of the reduction of duty, would have been much more than 17,000,000 lb. Even without counting the increase, the mere

displacement of China teas by British-grown teas would still have argued a far larger number of cups of tea drunk in 1891 than in 1889.

The assertion that the increase is due, not to the reduction of duty, but to greater liking for the new than for the old teas, may be safely rejected. Probably the "greater liking" had little to do with the increase, but it was itself the product of the effect of the reduction of duty in lessening the price of the new teas. If, for argument's sake, we assume that the "greater liking," and not the reduction of duty, was responsible for the bulk of the increase, we are bound to the conclusion that, when the duty was reduced, the public got better value for their money. The cheapened better teas drove out the cheapened worse teas.

Before the reduction, the opponents of the Tea Duties contended that the effect of even a partial reduction must be to give the consumer better quality at a reduced price. They pointed out, at the close of 1889, that the duty was then equivalent to 130 per cent upon average Chinas, to 100 per cent on average Indians, to 80 per cent on average Ceylons; that any appreciable reduction must enable smaller capitals to engage in the tea trade, and that, as a consequence, there would be keener competition between sellers, with the probable result that the public would get even more than the full money benefit conferred by the reduction.

To measure the meaning of an increase of "Home Consumption" in 1891 over 1889, it is useful to note that, in view of the future production of British-grown teas, our Indian and Ceylon planters are congratulating themselves on being able to dispose of 9,000,000 lb. of leaf, annually, in the Australian markets, but the reduction of duty has been given them already a fresh field of consumption in Great Britain equal to *two Australias*. The 17,000,000 increase—effected under singularly adverse circumstances—is about equal to twice the total consumption of an entire continent whose inhabitants drink more tea per head than the inhabitants of any other country in the universe.

Consider, from the producer's point of view, the position at the end of 1889. A fast-rising rate of production in India and Ceylon was met by a home consumption tending towards the stationary stage as regards quantity of leaf. "Bond" values for tea were rapidly declining to a non-paying level. The new teas were more economical in use than the old, and the prospect before producers was that the supplanting of the old teas by the new would be accompanied by an actual decrease in the quantity of leaf consumed, because of the 50 per cent greater strength of the new teas. To supplant 80,000,000 lb. of the old teas only 54,000,000 lb. of the new teas would be required. To the Indian and Ceylon producer the prospect spelt ruin, unless he restricted his output or else confined his manufacture mainly to high-class teas. Either alternative would have been injurious to himself, still more so to the consumer. For cheap teas the latter would have to revert to common China Congous, or if, after having acquired a taste for the new teas, the prospect was unbearable, he would have had to content himself with a smaller allowance of the new tea—so that the worse for the cause of temperance and morality!

If, notwithstanding a fortuitous combination of adverse circumstances, the reduction of twopence has already proved an important benefit for the public and to the producer, we may hope for vastly more favourable results from the remission of the remaining fourpence.—*The Speaker*.

THE COCONUT OIL SITUATION.

The arrival of several vessels that were not expected until some time in April, together with several others that were due and expected, threw the market for Ceylon coconut oil into a condition bordering upon demoralization early in the week. As it was, a most uncertain feeling prevailed for several days, and for a time it looked as though a large decline in prices was inevitable. There were reports that five and three-

eighths cents and possibly five and a quarter cents would buy. This put consumers on the *qui vive*, and although they affected to lack interest, it was evident that they were prepared to stock up liberally as soon as the price reached a figure that would warrant them in such a course.

However, the market did not give way under the pressure of the unexpected large arrivals and there seems to have been good reason why it should not have done so. The stock received aggregated about twenty-five hundred tons. Coming on a bare market, as it did it would ordinarily have been enough to have completely unsettled values. But, if we are rightly informed, only a comparatively small portion of this stock will be available for ordinary trade. At least two-thirds of it was sold before arrival and would not be likely to come, in whole or in part, upon the market unless prices should advance to a point that would warrant resales. We know that at least seven hundred and fifty tons belong to Western consumers and that preparations are now being actively made to ship to it to its destination at the earliest possible moment. Of the remaining seventeen hundred and fifty tons, at least one-half is under contract, leaving not more than eight hundred tons to supply the market for an interval of about two months, when the only vessel on the way, the *Bonanza* with five hundred and twenty-five tons is due. This last is the only vessel due to arrive before July next, and in the ordinary course of events, therefore, the trade would have a stock of but thirteen hundred and fifty tons to draw upon. Under some circumstances this might cause a firm feeling and possibly an advance, but it is offset by the fact that consumers will be well supplied by stock deliverable from the vessels just in. Conservative opinion inclines to the belief that we will have a quiet market for some time to come with prices little or not at all above the present limit.—*Oil, Paint and Drug Reporter*, Feb. 1st.

EUCALYPTUS, ITS PRODUCTS AND THEIR USES.

Of the eucalyptus tree there have been discovered in the neighbourhood of 135 species, most of which are large trees. Eucalyptus was discovered in Tasmania and is found in great profusion growing in that island and in Australia. Nearly two score years ago it was introduced into Europe and has since been extensively planted in northern Africa and in various portions of southern United States and especially southern California. In proportions it is a noble tree, often attaining a height of 300 or more feet. It has a long narrow leaf, from 6 to 12 inches, and from various peculiarities of its leaf and bark has received numerous local names. In Australia it is known as the "gum tree," and the "gums" are locally distinguished as red, white, blue, etc. In California it is commonly known as blue gum. Sometimes the adjective is employed to describe the leaves, in another, the bark, and so on.

Eucalyptus first came into prominence from the fact that its leaves were highly recommended, when properly prepared, as a specific in cases of intermittent fever, but these claims have not been completely established, and it and its products now find their application in other directions. Probably the most valuable of its constituents is the essential oil which exists in the leaf to the extent of 6 to 8 per cent. It is fully believed by many that by planting the eucalyptus tree in malarial regions there can be warded off the attacks of malarial affections. A theory advanced for this action is that the tree, being a most rapid grower, absorbs the moisture from the saturated earth, and through the numerous and prominent stomata of the leaves, evaporation is rapid, and eventually the laud becomes deprived of its dangerous qualities. In addition to this theory there is evidence given to the supposition that the exhalation of volatile oil acts as an antiseptic and disinfectant, this latter theory being probably more tenable than the preceding one.

The most valuable products of the trees are the essential oil and certain medical preparations of the leaves. There has of late come into prominence a

preparation resembling in its method of production the well known distilled extract of witch hazel, viz., the distilled extract from eucalyptus. This is a concentrated double distilled extract from the freshly gathered leaves of trees that are at least 7 years old—the older the better. This is not a particularly new article except in its manner of preparation. Old residence of California, and especially the Spanish and Mexican inhabitants, have for years used infusions and decoctions of the leaf. As a standard remedy for man and beast, they believe eucalyptus to be a panacea. This position can not be substantiated, but, nevertheless, the virtues of the extract are many. It can be employed for most of the ailments that the oil is used for, and has the advantage of being much cheaper. By actual tests it has been proven a cure for headache, nervous affections, and as an antiseptic it has given valuable results in its application to sores, flesh wounds, inflammations of the various mucous membranes, in affections of the stomach, insomnia, etc. It finds extensive application in the external treatment of lame back, bruises, scalds, burns, etc. For cold in the head, sore throat and the like it is also of service. As a disinfectant it is of great utility, it, as well as the oil, substituting a very pleasant, agreeable odour for disagreeable and noxious emanations. A special application is in the treatment of genito-urinary affections. Sheep dealers and poultry handlers find it of benefit in ridding these animals and their houses of vermin and for the treatment of scab and other cutaneous affections.

As before hinted, this distilled extract has been long employed, but its present mode of preparation is not so primitive as that formerly in vogue. The leaves, in suitable containers and with the proper proportion of water, are subjected to distillation, and that portion of the aqueous liquid that comes over at a temperature of 340° F. is saved and the oil allowed to separate from it and rise to the top in a conical separator. The liquid is then put back into the still and redistilled at a temperature of about 230° F., after which it is filtered, allowed to stand about a week, and then decanted into bottles ready for the market. Eucalypta is a beverage which is thus prepared: A certain quantity of the distilled extract is combined with carbonated water and certain flavorings and put up in pint champagne bottles. Then, too, the same company, the Eucalyptus Manufacturing Co., of Los Angeles, Cal., which prepares these goods, also places upon the market a medicated water which is having great success. This is extremely pleasant, and physicians have found it of much benefit in catarrh and certain inflammatory conditions of the stomach.

As the oil has without question established for itself an important place in our materia medica, there would seem to be a valuable field for preparations of the character described. The oil, locally applied, is a powerful irritant, and in proper doses, internally, it is a stimulating narcotic in cases of migraine and other forms of neuralgia. As an antiseptic, some claim for its superiority over carbolic acid, and it certainly has to its credit many cures in the treatment of skin affections and ulcerations where a stimulative antiseptic application is indicated.—*Pharmaceutical Era*, April 1st.

NOTES ON PRODUCE AND FINANCE.

WHY IS IT?—It is unfortunate, to say the least, that Indian planters are usually left behind their Ceylon comrades where any question of organisation for furthering their interest is concerned. While the Ceylon people have their plans cut and dried the Indian fraternity are only thinking about theirs. Take the case of the Chicago Exhibition. Here is the Ceylon Commissioner about to start for Chicago, and his plans have been laid before a meeting of enthusiastic Ceylon planters and their friends in London and approved, while all we know about the Indian proposal is that the Government of India is prepared to follow the lead of Ceylon in the matter of being efficiently represented at Chicago.

The one body is thinking about it and the other has taken action. We attribute this tardy movement in matters of vital interest to the Indian tea industry to a want of unison between the Indian and the home organisations. If this is not the cause, then it behoves those who are mainly interested to discover it. It must be a source of considerable irritation, both at home and in India, to find that on nearly every occasion when enterprise is necessary Ceylon has to show the way.

THE OPENING OF FRESH MARKETS.—In the report just issued by the Darjeeling Company, we read with satisfaction the following paragraph:—"The sum of £375 was originally invested in the Associated Tea Planters, Limited, which had been established for promoting the sale of Indian tea in America and Canada, and ultimately that association repaid £237 10s. of that sum, leaving a small balance of £137 10s. to be carried to debtor of revenue account. The sum of £300 has been invested in debentures of the Palais Indien Tea Houses, Limited, in order to assist that company in further developing the sale of Indian tea in Paris and on the Continent." This we think is worthy of imitation by other companies. A special reference in the report which comes before the eyes of all the shareholders cannot fail to be of some use in aiding schemes initiated for the general good of the tea industry.

NO GOING BACK.—It is hoped that the recent dictum of Sir Andrew Clark that if you want to have tea which will not injure and which will refresh get black China tea "will have the effect," says the *Grocer*, "of restoring its waning popularity in England and infusing fresh life into the China trade." Indian and Ceylon planters certainly do not hope for anything of the sort, nor is there much chance of it. The public taste is entirely won over to Indian and Ceylon teas, and even so eminent a personage as Sir Andrew Clark cannot do much to bring about a reaction. The remarks of the *Grocer* are *apropos* of the tea trade of Wenchow, which has been very good this year, but owing to the heavy freights ruling to Shanghai and expenses of brokerage only small profits have been realised. Most of the Wenchow black tea finds its way to the Hankow market. The unfired tea goes to Shanghai or Hankow, where it is refired and prepared for foreign consumption. When the Chinese had the tea trade in their own hands they abused their opportunity by sending over some very indifferent and unwholesome stuff in order to meet the demand for cheap tea. Gradually from a variety of causes they have practically lost the market, and the tea growers of India and Ceylon mean to keep it.

THE TEA MARKET.—Last week being practically a blank week so far as Indian tea is concerned, there is not much to say about the markets. The *Produce Markets' Review* says:—"There has been a good enquiry privately for medium and Broken Pekoes, and, owing to the somewhat limited selection offering, prices are firm. There may be a more liberal supply of these grades later on, but the demand is too active and general to check the upward movement in prices. The common qualities are still offered plentifully, and are likely to continue to be so, as the bulk of the auctions lately held in Calcutta consisted of these kinds, and prices generally were exceptionally low. This, coupled with an ample supply of similar grades of Ceylon tea, will keep the market easy, as there will be quite sufficient to meet any increase in the requirements that may arise. The finest descriptions are scarce, and fetch very firm rates. The latest reports from Calcutta regarding the coming crop are more favourable, and, although the season may be late, the prospects are encouraging. There is no change in the position of Ceylon tea. There is, however, a fair enquiry, and there seems little likelihood of any relapse in prices for the present. The latest reports from Colombo put the amount exported as slightly less than last year, while the quality of the latest parcels offered has shown a little improvement."

TEA AT THE HORTICULTURAL EXHIBITION.—The large area at Earl's Court will this year be devoted to an International Horticultural Exhibition. Here will be

found examples of the gardens of all ages, including restorations of the ancient gardens of Egypt Greece, and Rome; copies of those in China and Japan; types of the Baronial, Italian, Tudor, Jacobean, Georgian, and Victorian eras. A large sub-tropical garden will also form a feature of the attractions offered. The tea gardens of India and Ceylon will be represented, illustrating the growth of the tea plant, and the manner of drying and manipulating the leaves. A model cottage garden and allotment ground will be shown, demonstrating practically what can be done in a limited area. The services of Mr. P. Macgregor have been secured for the arrangement of the Indian tea garden.

THE COFFEE MARKET.—On the sales being resumed on the 21st inst. a very considerable accumulation had taken place, and the total weight was altogether too large for disposal during the limited time fixed for the auctions. Importers showed themselves fully ready to meet buyer's views, and a further decline of 1s to 2s per cwt. was submitted to the market generally at the opening sales becoming very flat. A rather better tone was afterwards established, the lower quotations attracting orders, and more life given to the market by speculation based on a reduced estimate of the Brazil crops, and a recovery of about 1s. from the lowest point was established. At the same time, any important recovery in values can scarcely be looked for just now. Heavy arrivals have again taken place, and for the next few weeks very considerable supplies will be placed on the market. The following are the French official figures for the three months, as given by Messrs. Wilson, Smithett, and Co.:—Importation; 1892, 37,958 tons; 1891, 32,175 tons; 1890, 30,262 tons. Consumption: 1892, 18,250 tons; 1891, 18,251 tons; 1890, 17,416 tons. Exportation: 1892, 6,100 tons; 1891, 11,473 tons; 1890, 8,276 tons.—*H. and C. Mail*, April 29th.

FROM THE METROPOLIS.

April 29th, 1892.

CEYLON TEA IN AMERICA AND THE CHICAGO EXHIBITION.

Before a gathering of about 20 gentlemen more or less connected with Ceylon and its tea enterprise, your Commissioner, Mr. Grimlinton, on Monday afternoon last displayed the plans for the Ceylon Court at the Chicago Exposition and explained the position and prospects of his mission so far at present possible. This was in the room of the Ceylon Association, and I will leave your regular correspondent, who was present, to give an account of the meeting, while merely touching here on some of the impressions formed. First of all it was pleasant to see several veteran ex-Ceylon residents looking so well, Sir G. W. R. Campbell has always been a well-preserved, strong-looking man, and he has become so florid and stout in the English climate that no one would suspect that the larger part of his life was spent in Western India, Ceylon and Penang. He passed quite a eulogium in supporting the vote of thanks to Mr. Grimlinton, referring to his energy in the Gas, Wharf and Hotel Companies, in the latter two of which he (Sir George) was one of the largest shareholders, holding at one time one-seventh of the Wharf Company's shares. Mr. Mosse and Mr. Churchill both looking well, were present, and so was the evergreen Mr. Tom Gray ready with his jocular "aside" or "Hear, hear," to everything good. Still more ancient is Mr. Thomas Dickson, who did most of the speaking in clear but decided Doric, more particularly in giving us a graphic account of his experience in loading a 220-ton brig so far back as 1852 in Colombo with a general cargo of "products"—something of everything—and voyaging in her to New York, where at Sandy Hook, the officials would insist they had come from

tainted "Sierra Leone," and for some days fought shy of the vessel. But Mr. Dickson, though full of faith in the future of the Ceylon tea trade in America, doubted if merchants ever in the present day make so much profit, as he cleared from his miscellaneous assortment of Ceylon goods forty years ago. Again, the veteran Mr. John Capper, now in his 78th year, was at the meeting, reporting for his journal and apparently as hale and active with his pencil at the desk as I remember him in the Legislative Council thirty years ago. Mr. Grinlinton's explanations were all clear and generally approved of, especially the arrangement to supply cups of Ceylon tea properly infused and with good cream and sugar, free of charge to visitors; it was feared though that the Court buildings (including dagoba) were scarcely extensive and large enough to arrest attention in a place built on so enormous a scale as the Exhibition is to be; while it was generally agreed that the total amount of money available or in prospect so far was inadequate to doing justice. The increase of the British vote was mentioned apparently as a reason why the Ceylon official vote of £50,000 should be increased; but I suspect that in proportion to total amount of revenue, Ceylon stands better in its vote than either the United Kingdom or India. Mr. Whittall, who presided and who discharges the duties of Chairman at such gatherings, so far as I have seen with business-like precision, tact and courtesy—supported as he is so well by the experienced Secretary, Mr. Leake—was anxious that a subscription list for London friends should be begun in the room; but eventually he decided to leave the circulation and management of this list to Mr. Leake, who would, he felt sure, arrange the business with his usual tact. Mr. A. A. Delmege, who has recently returned from a shooting expedition in the far West of the Rockies, gave an interesting account of how he and his companions were served at a remote station with capital tea which turned out to be from a chest of the pure Ceylon article, and how the railway engine-driver, stoker and the train conductor declared they got such tea nowhere else. This bears out what I have always said about the good opening in the Central and Western States, where the people are free of prejudice and many of them fresh from the old country, for Ceylon teas. But then Mr. Delmege (whose firm was one of the earliest to enter the American trade) proceeded to show how over and over again he had urged on their New York and Philadelphia friends who were so ready to do a business in Ceylon oils, plumbage, coffee, &c., to place Ceylon teas, *but in vain*. The large tea dealers in the Eastern States hold a monopoly and making their profit of 6d and more per lb. out of China and Japan teas they do not see why they should encourage a new and dearer article, allowing a profit of perhaps only 2d a lb. It is the Australian case over again; and this was fully acknowledged by Mr. Elwood May, who, being called on by Mr. Whittall, gave an account of his Company's work, in its careful, substantial mode of procedure, so as to lay a good foundation in educating the taste of the consumers, rather than in attempting a mere show course which, while securing a sudden consumption of 2 or 3 million lb. of Ceylon tea, would in reality prove a mere flash in the pan. Mr. May appreciated Mr. Grinlinton's mission and is sure that if utilized properly the Chicago opportunity should help forward the good work of making the American people understand the superior quality of Ceylon teas—that is of the good grades. [It is satisfactory to learn from Mr. Stanton that as a matter of fact, the demand for

Ceylon tea in America is steadily progressive, although of course, comparatively, it is still the day of small things.] It was satisfactory to hear that the Commissioner hopes to realize a good deal by the sale of Ceylon tea in the Exhibition and also of the Court material—Ceylon woods for instance—and exhibits. It is possible, too, that money may be saved by articles being lent from the Imperial Institute (some of the Colinderies' Exhibits for instance).

A further suggestion I have since made to Mr. Grinlinton has reference to a paragraph I have come across in the London Letter (of six weeks ago) of a Manchester paper in which it is stated that at the Horticultural Exhibition shortly to be opened at Earls Court (with "Buffalo Bill's Show") among other attractions will be a model tea garden showing the cultivation of tea in all stages in the field, and the preparation of the leaf all through the factory. This ought also, undoubtedly, to be a feature at Chicago.

Mr. Grinlinton has been busy in other directions, meeting the American Minister, Mr. Lincoln, and obtaining letters for influential citizens in New York and Chicago. I have myself been sending intimation across the Atlantic to journalist friends about his mission, so as to create interest in advance; for clearly, the bigger the "advertisement" Ceylon and its tea gets in this matter the better. Mr. Grinlinton leaves Wymondham, Rutlandshire, on Saturday (tomorrow), going to Edinburgh on the 2nd and then back to Liverpool to **embark on the S. S. "City of New York"** on the 4th May. That he will not have a long passage may be judged from the following paragraph now going the round of the London press:—

THE TRANSATLANTIC RECORD AGAIN BROKEN.

The Inman liner "City of New York" arrived at Queenstown on Tuesday at seven o'clock after a remarkably fast passage, having broken the record for the distance on a single day's run east bound by making 482 knots (555 statute miles) in a day of twenty-three hours and ten minutes. Her sister ship, the "City of Paris," has also made a record passage by arriving at Sandy Hook before 6 a.m. This is the first occasion on which two steamers of any line going in opposite directions have together averaged considerably over twenty knots.

After a few days in New York, the "Commissioner" will go on to Chicago for his work occupying two months or so, since he expects to be back in London by July and out in Ceylon in October—back again with a staff of some 12 to 20 Ceylonese (who will not be the least attraction in the Court or advertisement of the Colony) by February-March 1893.

MAHOGANY CUTTING is one of the chief industries of British Honduras. The export of timber varies from about 4,000,000 feet to about 6,000,000 feet per annum. The annual value is about a quarter of a million sterling. The mahogany forests are cut over once in about fifteen years. The trees are selected and cut down generally above the large slab-like buttresses which grow out of the base of the stem. They are then squared into convenient logs and drawn on heavy trucks to the nearest stream. The broad, massive wheels of these trucks are sometimes cut out of the slab-like buttresses of the mahogany trees or by sawing pieces across the stems of Santa Maria trees (*Calophyllum Calaba*). Recently Sir Alfred Moloney, K.C.M.G., Governor of British Honduras, forwarded to Kew two truck wheels that have been in use in the mahogany forests, consisting of cross sections, about 12 inches thick of mahogany and Santa Maria trees. These are roughly trimmed and pierced for the axle.—*Kew Bulletin*.

THE COMMERCE OF INDIA FOR THE
YEAR ENDING MARCH 31ST, 1892:

THE PROGRESS OF THE TEA ENTERPRISE
AND THE REVIVAL OF COFFEE.

Our own copy of the figures compiled by Mr. O'Conor having reached us, we naturally turned first to those which represent the position now occupied by the great tea enterprise of India. Although the discovery—fraught with such important and beneficial consequences to the Indian Empire and so disastrous to that of China—of the indigenous tea plant of Assam dates back more than sixty years, the enterprise itself is not more than a generation old. The cultivation of this indigenous product was at first hindered for years by the persistency of the eminent botanist, Dr. Wallich, in the error that the large-leaved trees—for trees they were of forty-five feet high and more—were not tea at all, but true camellias. Then came the more serious and prolonged hindrance arising from the belief entertained that the Assam species of tea was inferior for purposes of cultivation to those grown in China. Mr. Fortune was therefore deputed by the Government of the East Indian Company to visit the tea districts of China and bring thence seeds and plants of the best species and varieties. This was successfully accomplished; and in 1848 Chinese tea manufacturing experts were also introduced. Since then the revolution has been so complete that Commissions have been sent from China and Japan to India and Ceylon, to learn the secrets of the better teas sent into the markets by those British possessions. Government plantations of the China tea plants were established on the eastern and northern slopes of the Himalayas; and to this day China tea is cultivated on many of the private plantations in the districts of Darjiling, Kumaon and the Kangra Valley. The superior quality of the indigenous tea began to be recognized, however; and in the low-lying valleys of Assam, Cachar and Sylhet it was largely cultivated and with great success, as far as growth went. Col. Money and others contended that great harm was done by the introduction of the China tea plants, from the consequent hybridization which took place; With this view we could never agree, and we suppose it is now generally abandoned. The native habitat of the Assam and Burmese teas is low and hot; and the plants were delicate in proportion and impatient of high altitudes. The China teas, on the other hand, contrary of popular ideas, were (and are) grown up to high altitudes and in latitudes where snow and frost prevailed. The plants introduced to India were hardy in proportion, and good hybrids between the two species are now obtained suitable for all altitudes and a vast range of climate. For the higher altitudes in Ceylon a good hybrid with long, thin, pointed leaves, is certainly better than the large, broad, deeply-corrugated-leaved Assam indigenous. That is our personal experience. We have planted indigenous tea at 5,000 to 6,000 feet, and now the bushes have so assimilated in appearance to the hybrids in their neighbourhood that it would be impossible to distinguish them merely by their foliage. To return to the history of the Indian Tea Enterprise. Its next great hindrance was the ruinous crash which followed a wild "boom," during which estates were perfunctorily opened to be sold at fabulous prices, while there were neither labour nor appliances to work them properly. But phoenix-like the enterprise rose from the ashes of the dead past, and has advanced all along the line of northern India, with a few outposts in the south, until the figures for 1891-92 are 120,000,000 lb. exports

valued at R59,681,000, even at present low prices. Of the exports 111,000,000 lb. went to the United Kingdom; nearly 5½ millions to Australia, which was only struggling into existence when in 1830 tea was discovered in the jungles of Assam; and 2,789,000 lb. to Persia. Only 83,000 lb. went to the United States, and 903,000 to other countries. The latter are now appreciably supplied from London; and some portion of the Indian crop (far less than well wishers of the country could wish) is consumed in India itself. Even at the present depreciated value of the rupee, 60 millions of rupees are the equivalent of about four millions sterling, contributed to the commerce of India by a product which thirty years ago scarcely entered into the accounts. In Ceylon, where all the experience of India was available as well as the labour supply created for the coffee enterprise and the fields on which coffee had been grown, the progress of the tea enterprise has been beyond all comparison rapid, so as to be really marvellous. Our export of last year was very considerably more than half that of India which had preceded us by a quarter of a century or more in this culture,—while indeed our almost undivided allegiance was given to another king, even COFFEE, to which we now turn, in these accounts. While tea is principally grown in the north of India in latitudes extending beyond 28°, coffee has been cultivated commercially exclusively in the south of India, where the conditions are, like those of Ceylon, tropical. The disaster which almost annihilated coffee in Ceylon affected the coffee districts of Southern India very seriously, but not quite with the same deadly virulence, and coffee is still the staple product grown by European planters in the Wynaad, Travancore and especially Mysore. The figures for the past three years show a very remarkable recovery last year, thus:—

1890	...	239,795 cwt.
1891	...	233,457 "
1892	...	311,864 "

This is far and away better than Ceylon, which, in 1869, exported over a million cwt., while we believe India scarcely ever exceeded one-half of that quantity. The value of the coffee exported last year from India is given at R19,986,588, say in round numbers twenty millions of rupees, or exactly one-third the value of the tea crop,—in sterling nearly £1,333,000. Coffee, therefore, is still an article of very considerable importance in the commerce of India. For total crop considering how largely coffee is consumed in the country, we may, we believe, add at least another 100,000 cwt. to the 312,000 shown as exported. Some of the coffee is exported from Bombay (to Australia and Egypt, to be drunk as best Mocha?) but the whole is grown in the Madras Presidency, where all the signs point to a revival of the coffee enterprise, rather than a large extension of tea cultivation. With reference to ulterior action in Ceylon it will be well for our planters to watch carefully the history of coffee for the next few years in the neighbouring Indian Presidency.

We next turn to the great staple article in Ceylon commerce, coconut oil, of which the Cochin product is a formidable competitor. The exports from India last commercial year were 1,396,000 gallons, valued at R1,549,000, or about £100,000. The exports of raw coir were insignificant compared with ours,—only 29,204 cwt., valued at R204,000, but of coir wholly or partially manufactured the exports were:—Coir (excluding rope) 289,343 cwt. valued at R2,449,000 or about £81,000. Besides this of cordage and rope of vegetable fibre (ex-

cluding jute) there were exported 38 808 cwt. valued at R378,000. The exports of coconuts were only 349,000 valued at R9,000; of copra 36,265 cwt. value R360,000. Coconut ponnac is mixed up with other "oil-cake." The cardamoms exported were only 278,000 lb., value R319,000, but cardamoms are largely consumed in India. Of "spices" (pepper and condiments for curries, we should think) 4,545,000 lb. were exported to Ceylon, valued at R418 000. Of tobacco India exported, unmanufactured 7,514,000 lb. manufactured 764,000 lb. only. The exports are of course a mere fraction of the proportion locally consumed. The quantity of salt fish exported to Ceylon is not shown; but in the case of grain we have:—

Rice, 4,145,000 cwt. R18,321,000.

Add to this for paddy (rice in the husk), gram and other cereals and pulses, and our tribute to India for grain must closely approximate on twenty millions of rupees, or nearly £1,334,000. Salt fish, animals and poultry, curry stuffs, gingeli ponnac, cotton cloths, &c., make up a sum exceeding one and a half million sterling, for which in a shape direct or roundabout we have to pay with the proceeds of our tea, coffee, coconut produce, arca-nuts, &c.

We observe that gold to the value of R141,000 was imported into India from Ceylon, and of silver R705,720; but this is exclusive of the large sums carried from Ceylon by native merchants and coolies on their persons. If money alone, as reported, were considered, the balance would be terribly against our island, to which coins worth R7,691,500 were exported, against R846,734 imported. As our readers are aware, we are indebted to India for our silver currency of rupees,—with the parts of the rupee, half quarter and one-eighth—equivalent to 50 cents, 25 and 12½; while our subsidiary bronze coinage of 5 cents, 1, ½ and ¼ of a cent is minted for us in Britain.

We have thus dealt with the articles in the Indian export commerce, which are identical with articles in our own commerce, or which are of special interest to us otherwise. There is much else in these tables of general interest, to the consideration of which we may address attention, should time and space permit.

THE INDIAN TEA TRADE.

INDIA AND THE CHICAGO SHOW.

CALCUTTA, May 15.—The *Englishman* says it is gratifying to learn that the leaders of the tea interest in Calcutta are alive to the immense importance of making a good fight for the American market on the occasion of the Chicago Exhibition. The Indian Tea Association is publishing a paper written by a well-known Indian planter, and read before a meeting of the Indian Tea Districts Association in London, which contains practical suggestions with regard to the financial side of the question. Ceylon will be represented by a company in America, with a capital of a million dollars, and with agencies in all the large towns to aid in the work of pushing Ceylon tea. Already the general committee of the Indian Tea Association has appointed a sub-committee to collect subscriptions, which, added to the money collected in England, should amount to a considerable sum. All gardens are invited to subscribe two annas per acre, which should bring in about R25,000, and subscription lists will be circulated in all the districts among the agents, managers, etc. A good beginning has been made in Calcutta, where ten of the leading firms have subscribed R1,000 each. On former occasions when a combined action in the interest

of the Indian tea industry has been called for, the matter had generally been left to the Calcutta agents and brokers, but now it is hoped that the whole industry will be fully represented, and that all connected with it will combine to ensure the success of the Chicago project.—*Times of India*.

THE CEYLON TEA PLANTATIONS COMPANY, LIMITED.

We have received a full report of the annual general meeting of this Company taken from the *Money Market Review* of April 30th, 1892. We have already quoted the full text of the Chairman's speech in moving the adoption of the report, and we now give the remainder of the proceedings in full:—

Mr. D. Reidsaid:—In rising to second the resolution which has just been submitted, I desire to congratulate the shareholders on the satisfactory results of the past year's working of the business of the company. Mr. Rutherford has so fully reviewed the position and prospects of the estate under the company's management that I need not trouble you with any remarks on that subject, but I cannot refrain at the present time from saying a few words to the shareholders on the very great loss which the board and the company have sustained by the wholly, I might say, unlooked-for death of my cousin and namesake, the former chairman of this company. Although not resident in London, Mr. Reid was a frequent visitor, and kept himself in close and constant touch with every detail of the work of the office, and also with the management of the estates in Ceylon, and it is largely owing to his enterprise and to his great good judgment that the company has acquired such valuable estates, from which we have been able to return you in five successive years very satisfactory dividends. Whilst those of us who were intimate with the late Mr. Reid, and who came into close communication and touch with him, deeply mourn his removal from amongst us in the prime of life, I am sure it must be a satisfaction to all of you to know that he has left us a company which he has brought to such a high position of prosperity that it may be surely said that it stands second to none in tea cultivation in Ceylon. In Mr. Rutherford, who has taken the chair today, although it is a sad position, we have a gentleman well-known here and also to those residents in Ceylon, and who is intimate not only with the company's estates but with every detail of the company's business, and therefore, I am sure, it is a satisfaction to you to know that in having him as our managing director that the business of the company will be well managed. In Mr. Talbot, also, who is known far and wide in Ceylon as a recognised planter of great ability and business capacity, we have a guarantee that the business will be carried on in Ceylon with that marked success that has attended it heretofore. Therefore, although we have sustained a great loss by the death of Mr. Reid, we feel that he has left behind him those who will labour on behalf of the company just as well as when he was in the chair. (Hear, hear.) I beg to second the motion.

The resolution for the adoption of the report was then put and carried, without discussion.

The CHAIRMAN said that the next business on the agenda was to elect a director in the place of Mr. H. Tod, but, as he had informed them, Mr. Tod had withdrawn his resignation, and they would have the advantage of seeing him on the board. No doubt many of the shareholders knew that Mr. Tod was one of the original founders of the company, with Mr. Reid and himself, and he had a thorough grasp of everything connected with it, and therefore it would have been a great loss to the company if he had resigned. He now had the greatest pleasure in moving the re-election of Mr. Henry Tod as a director of the company.

The motion was seconded, and carried unanimously.

The CHAIRMAN next proposed the election of Mr. G. A. Talbot as a director of the company. Mr. Talbot,

he said, was a very able Ceylon manager, and when he came home, they would be glad to learn from him various matters about their property which they could not obtain by means of correspondence.

Mr. HERBERT ANDERSON seconded the motion, which was adopted.

After the reappointment of the auditor,

Mr. LUCAS proposed a vote of thanks to the chairman for his conduct in the chair, and for the satisfactory account he had given them of the affairs of the company.

The motion was seconded by Mr. HARVEY, and carried.

Mr. O. J. SCOTT then proposed a vote of thanks to the officers and staff in Ceylon and London.

The motion was seconded and agreed to.

The CHAIRMAN stated that the board would inform the managers and staff in Ceylon that a vote of thanks had been unanimously accorded to them, and he was sure that they would highly appreciate it.

The proceedings then terminated.

NOTES ON PRODUCE AND FINANCE.

A GOOD INVESTMENT.—Shareholders in the Ceylon Tea Plantations Company have reason to be well pleased with the result of the past year's working, as shown in the dividend just declared. A company that can pay 15 per cent. in bad times may be reasonably expected to do still better things if the market should prove kinder.

TRAVANCORE PLANTERS' ASSOCIATION.—We recently referred to the newly formed Travancore Planters' Association in London, of which Mr. Even Cattanaach of 3, Great St. Helen's, is the hon. secretary. The object of the association is to watch and protect the interests, in London, of tea, coffee, and cinchona planters, &c. The president is Mr. Patrick Grant. The committee is as follows:—Messrs. Hugh Crawford, 6, Shakespeare Road, Bedford; Leopold F. Davies, Messrs. Gow, Wilson, and Stanton; J. B. Keith, Messrs. Arbuthnot, Latham, and Co.; Patrick Leslie, Messrs. Leslie and Anderson; W. B. Miller, Travancore Plantation Company, Limited; W. Cotton Rohde, 17, Bishopsgate Street, E.C.; and Sidney Wilson, Messrs. Wilson, Smithett, and Co. The present members are:—Messrs. Arbuthnot, Latham, and Co., Hugh Crawford, Fleming, Milligan, and Co., Gow, Wilson, and Stanton, Patrick Grant, Harvey Brothers, Leslie and Anderson, Nagamally Tea Company, Limited, Patry and Pasteur, W. Cotton Rohde, and Wilson, Smithett, and Co.

PARAGUAYAN TEA.—Although the cultivation of Paraguayan tea produces about 25,000,000 lb. yearly, and the qualities of this tea are spoken highly of, no attempt has yet been made to introduce it into this country. It takes an ordinary consumer some time to get used to maté, and people are in too much of a hurry in these days to apprentice their palates to a new beverage. Maté, having no resemblance to any of the breakfast drinks now in vogue, and not being particularly palatable to a strange tongue, is not likely to find a market here.

THE TEA TRADE.

Tea is such a universally accepted friend and comforter to our mortal race, that those of us who have hitherto been accustomed to sip it morning and afternoon, without a thought, perhaps, of the vastness of the trade it represents, and the enormous capital involved therein, may be interested by a few remarks on the subject. The position of the tea trade at the present time is well worthy of attention, not only by the outside public, but by those more intimately connected with its production, importation and sale here and elsewhere. There has been during the last few years a perfect revolution, not only in the public taste for tea, but in all that appertains to it, from the circumstances attending its plucking and manufacture to the time and manner of its being offered, either wholesale or retail, for sale on this market. The public taste has generally turned

from the delicate flavoured China teas to the more full-flavoured British-grown Ceylon and the strong pungent Indian teas; for the latter are mostly of this description, although some fine, delicate invoices arrive from the Darjeeling districts. The general quality of the China teas has rapidly declined during the last five years, and the bulk of the imports remaining here, after the best chops have been selected for export, have been year by year more difficult to dispose of at profitable rates, until, during this past season, China teas may be said to have received their final *coup mortel*, and the average sales, especially of the medium and fine leaf teas, have often shown very disastrous results to shippers. When last July and August imports have had to be realised, real losses of from 8s. to 10s. per lb. have not been uncommon experiences. The finest teas from Hankow twenty or thirty years ago were of rich, full Pekoe flavour, and delicious to drink, but they could not be sold under 2s. and 2s. 6d. per lb. in bond, and being in limited quantities, only reached a certain portion of the public in their pure state, the price being prohibitive. This class of tea has chiefly gone direct or been re-shipped from here to Russia, &c., the British public requiring a much stronger drink and at a less cost. At the present time they can easily obtain this, very good to fine blends of Ceylon only or of Indian and Ceylon teas being procurable at from 2s 4d per lb. downwards, duty paid.

There are three special sorts of Ceylon teas—broken Pekoe, Pekoes, and Pekoe Soucheons. The leaf of the former is generally too small and the liquor too strong to drink alone, and it is, therefore, used almost entirely for blending with the two other leafy kinds, and with similar Indian or China teas. The Pekoe Soucheong is generally too bold in leaf, and, like the common and medium grades of Pekoes, too light in cup for separate use; but the finest Ceylon Pekoes, realising now in the Mining Lane auctions from 1s 1d to 1s 4d per lb. in bond, are mostly of delicate and choice Pekoe flavour, similar to that of the finest China Ningchows of days gone by, but possessing more body in liquor. These, again, are in small supply, and the public see little of them in their pure imported state, the general call being for something stronger, a want which is met by buying them blended. In 1882 the home consumption of China teas was 114,462,000 lb. and of Indian teas only 50,426,000 lb. In 1886 the chief supply of tea to this country was still from China; but since 1887 the importation and consumption of China teas, so far as this country is concerned, have steadily declined, and during last year (1891) the total consumption of all tea was 202,500,000 lb. of which 150,000,000 lb. were Indian and Ceylon, and only about 52,000,000 lb. China. In 1891 the consumption of Ceylon teas alone increased 50,000,000 lb., while that of China showed a reduction of 40,000,000 lb. Whatever the cause, whether it is what has been termed by those only interested in China teas "the coarse taste of the average British consumer," or, more probably, the natural requirement of something more stimulating, the cry is more and more pronounced for Indian and Ceylon teas—which is highly encouraging and satisfactory to our British tea industries in those colonies. The change in the customs duty in 1890 from 6d to 4d per lb. has enabled grocers, and especially the principal blending firms, to give to the public by means of blending a much more useful flavoured tea than they were a few years ago able to provide. Formerly, when little else but China tea was used, the fine and finest qualities were too expensive, and the poor could only obtain the inferior sorts. Now, by this blending system, which has become of late a large industry itself, the working classes can buy a very superior tea at much less cost than they paid a few years since for a very inferior substitute. The quoted prices one generally sees now range from 1s 2d to 1s 6d per lb. for good useful to medium, and from 1s 9d to 3s per lb. for better to finest blended teas. Were this fact, which is already attracting attention, is still more fully recognised, we shall, without doubt

see a further marked increase in the consumption of an article which, being so largely produced by British enterprise, has the good wishes of all interested in British industry.

To give an idea of the enormous extent of the tea trade here, it may be stated that about 1,250,000 packages of Indian (valued at £4,887,000), 756,000 packages of Ceylon (valued at £1,890,000), and 667,500 packages of China teas (valued at £1,223,000) were catalogued and sold last year under the hammer in Mincing-lane over and above the very large quantities sold by private contract. The auctions of Indian, Ceylon, and China teas are held, as a rule, in separate halls in the Commercial Salerooms, and a stranger entering during one of these sales would be scared by the thundering noise caused by some dozen or more men shouting at the very top of their voices all at once, each endeavouring to secure the attention of the selling broker to his bid first. Where a lot of low-priced tea is put up, the exact value of which is well known, the unanimous shout is like the report from a cannon, and the stranger might well come to the conclusion that the very last lots of tea available in this world were being competed for. These scenes, however, are of almost daily occurrence in Mincing Lane. It is not at all unusual in the busy seasons for some 15,000 to 20,000 chests and half-chests of a particular growth to be sold in one day, the sales generally lasting from 12 to 3 o'clock, or later. The imports from June 1st to March 31st, 1891-92, were of China tea 59,975,000 lb, Indian 107,861,000 lb., Ceylon 52,105,000 lb., and Java 2,538,000 lb., as against during the same period in 1889-90, China tea 59,174,000 lb., Indian 96,384,000 lb., Ceylon 26,775,000 lb., and Java 2,412,000 lb. The total tea delivered for home consumption in 1891-92 was 150,971,000 lb., against 129,581,000 lb. in 1889-90.

The Chinese for so many years had the monopoly of our tea trade that they became utterly careless of the preparation or proper maintenance of their plantations, thinking anything they sent to this country, so long as it paid them well, would do for us. They regarded the ramour of competition from other countries with ridicule, and have only just commenced to learn, by sharp and painful experience, what it is. To allow a serious and steady decline in the quality of their staple export article was a costly error, especially at a time when our British-grown tea from both India and Ceylon were arriving in quantities sufficiently large for them to be widely spread amongst, and quickly appreciated by, the British public. India, it seems probable, may remain a good tea-producing country for many years to come; but not so Ceylon—from the fact that the soil or climate, or both combined, quickly exhaust the good qualities of the plants. From observations during the past five years it is evident that few, if any, of the higher-class tea producing gardens maintain a high standard of quality after three years from their first bearing and year by year they decline into producing only common and medium teas. At present new ground is continually being opened up, so a certain fresh supply of fine teas continues to come forward: but the common invoices largely increase month by month, many being from gardens conspicuous three or four years ago for the fineness of their teas. This being so, the Chinese if they look out, may yet have another innings. They will have time to replant, modernise their workings, learn to use machinery, get free from export taxes; and in a few years hence, when, possibly, Ceylon teas may not be regarded with the favour which they enjoy today, the Chinese may be ready to bring some newly grown young Chinese leaf of fine quality and at reasonable prices to compete with their late formidable rivals.—*Financial News.*

BARK AND DRUG REPORT.

(From the *Chemist and Druggist.*)

LONDON, April 27.

ANNATTO.—Seeds rather dearer, 2½d per lb. being paid today for 6 bags of good bright quality from Ceylon.

COCA-LEAVES.—There was one 28-lb.-bale of small dark-

green dry coca-leaves from Ceylon, which was bought in at 1s 6d per lb., no bids being forthcoming.

NUX VOMICA.—Several parcels of recent arrival were offered today and partly sold at a slight decline in value. Eighty eight bags bold pale grey to rather dark seeds from Ceylon sold at 9s to 9s 6d per cwt., partly subject to approval, and for 104 bags fair polish but small from Southern India the same price was paid.

ESSENTIAL OIL.—Of Lemongrass oil in bottles sales have been made privately at 1 9-16ths d. per oz at auction, and an offer of 1½d was refused for 20 cases.

LONDON, May 5th.

CINCHONA.—The London cinchona auctions were resumed on Tuesday, after a four weeks' interval. The quantity of bark offered was rather small and consisted almost entirely of poor and medium qualities. The catalogues included

	Packages	Package	Package
Ceylon cinchona.....	1,117	of which	1,041 were sold
East Indian cinchona..	1,002	do	950 do
Java cinchona.....	148	do	148 do
West Africa cinchona	279	do	279 do
South American cinchona	563	do	225 do

Total ... 3,109 do 2,613 do

There was very little competition, and especially towards the close of the sales, the tone flagged considerably. There is scarcely any quotable alteration in the unit price, which remains 1½ per lb. for barks of fair quality, but taken all round the market has an easier tendency.

The following are the approximate quantities purchased by the principal buyers:—

	Lb.
Agents for the Brunswick factory	... 153,011
Agents for the Auerbach factory	... 151,726
Agents for the Mannheim and Amsterdam works	... 88,202
Agents for the Frankfurt a/M and Stuttgart works	... 80,731
Messrs. Howard & Sons	... 54,279
Agents for the American and Italian works	... 49,670
Sundry druggists and others	... 42,785

Total quantity of bark sold	... 620,434
Bought in or withdrawn	... 64,127

Total quantity of bark offered ... 684,561
COCA-LEAVES.—Seventeen cases (of 28 lb. each) good green thin Ceylon leaves sold at auction last Friday at 1s 4d to 1s 5d per lb.

COCCULUS INDICUS is rather dearer, 11s 6d per cwt. being paid last Friday for fair quality.

THE AMSTERDAM CINCHONA SALES.

(Telegram from our Correspondent.)

AMSTERDAM, May 5th.

About one-fourth of the Java cinchona offered at today's auctions was bought in, only 2,900 bales being sold at lower prices, the average unit value being only 6 cents, or between 1d. and 1½d. per lb. Manufacturing bark in quills whole and broken and chips brought from 8 to 63 cents (1½d. to 11½d.) per lb.; ditto in root, from 14 to 40 cents (2½d. to 7d. per lb.); druggists' bark in quills, broken quills, and chips, at 8 to 47 cents (1½d. to 8½d.) per lb.; ditto root, 10 to 11 cents (1½d. to 2d.) per lb. The principal buyers were the Brunswick Quinine Works, Mr. Gustav Briegleb, and the Auerbach Factory.—*Chemist and Druggist.*

CHINA TEA AND TEA TRADE

(By Consul Bedloe, of Amoy.)

By whom and when the use of tea for drinking purposes was discovered is lost in antiquity. The famous herb is referred to in the Chinese annals as far back as 2000 B. C., at which period it was cultivated and classified almost as completely as today.

One ancient legend says that its virtues were learned by accident by a Chinese monarch, King Shen Nung, "The Divine Husbandman," who flourished forty centuries ago, and who, in boiling water over a fire made from tea-branches on which the leaves still hung, allowed some of the latter to fall into the pot.

During the reign of Sheu-Nung-She, B. C. 2737 to 2696, he not only discovered the curative virtues of plauts, but first fashioned timber into ploughs and

taught the people the art of husbandry, and instituted the practice of holding markets for the exchange of commodities.

Tea was highly esteemed in nearly every ancient Asiatic city near the sea and was used as a royal gift from the Chinese monarchs and great merchants to the potentates of the East. To the Rajahs of Kandy, the Sultans of Ceylon, the Shoguns and Daimios of Japan, were sent gifts of carefully selected samples of the leaves packed in precious boxes. Some of these presents must have been worthy of a crown. One is thus recorded: "It weighed 40 catties (about 50 pounds,) and each leaf was perfect in color, size and age. The leaves were divided into parcels of five macles each (a little over half an ounce,) and each parcel was wrapped in fine white paper, and these in turn wrapped in pure silver foil and put into little bags made of bright colored silk. A hundred bags were placed in a porcelain jar, whose lid was securely fastened and sealed, and each jar was protected by a box of camphor-wood trimmed with silver hinges and ornaments."

In the list of the Princes to whom these presents were made are many whose identity would be otherwise lost in history. From the old writings many curious facts are thus obtainable. Among other things it appears that Korea was at one time a formidable power, military and naval; that the Japanese at long intervals changed from peaceable neighbors into marauders and free-booters; that Manipur, Assam, Burmah and Tong-Quin at various epochs were strong belligerent communities in the far east; that Cambodia and Cochin-China were populous, rich and war-like civilizations, where now the tiger prowls and the serpent glides; that the Island of Ceylon was the scene of brilliant and brave dynasties which followed one another like the waves on the shore, and that at times the Tartar nomads who live to the North, Northwest and West of Asia, were gathered into great armies and nations by unknown Tamerlanes and Zenghis Khans. The presents of tea from the Flowery Kingdom to kingly neighbors are humble monuments to the wash of dynasties and empires.

Before the time of Confucius it had supplanted every other fluid for assuaging thirst. Its sanitary excellence was appreciated by Shen Kung, a celebrated scholar and philosopher, who said: "Tea is better than wine, for it leadeth not to intoxication, neither doth it cause a man to do foolish things and repent thereof in his sober moments. It is better than water, for it doth not carry disease, neither doth it act as a poison as doth water when the wells contain foul or rotten matter."

That the use of tea was universal is borne out by one of the maxims of Confucius, the wisest man of China, when he said: "Be good and courteous to all, even to the stranger from other lands. If he say unto thee that he thirsteth, give unto him a cup of warm tea without money and without price." At the time of Buddha, China was enjoying as large foreign commerce in tea. It was carried by her junks to Japan, Korea, Tong-Quin, Anam, Cochin, Burmah, Siam, India, Ceylon, Persia, and Arabia. According to one record it was sent to a great flat river country west of Arabia, which must have been Egypt, from which it was separated by a long and very torrid sea. It was carried by caravans to Manchuria, Mongolia, Kuldja, Tartary, Thibet, Persia, and Northern India. This commerce flourished for centuries and culminated in the dynasties of Hung-Fung-Chi about 1600 A.D.

From that time there was a slow but steady decline to the reign of the present sovereign, Kwang Hsi. In the past twenty years the decline has been something terrible, the trade today being scarcely one-quarter of what it was in 1870. Nor is the outlook promising to the tea-planter and patriot in any respect. In every district the industry is on the verge of bankruptcy; the demand from abroad yearly diminishes; the people themselves are taking to other beverages; while the taxation necessary to Government which in the former years of prosperity was a mere trifle, now threatens an utter extinction of the tea trade of China.

There are many interesting facts to be gleaned from the old books in relation to the tea trade. For example, there is no doubt that China was far more liberal in her commercial policy when ruled by her own people than she was after the Manchu Conquest, 1641 A.D. Before that time are many allusions to traders and merchants from various countries, and to the exportation and importation of goods of all sorts. I find references to bronze works and porcelain from Japan, weapons and pottery from Corea, cloths and other woven tissues from Indo-Chinese territories, and ivory and tortoise shell from Ceylon and Arabia.

The transactions were on a large scale and required quite a navy of junks and cargo-boats. In several instances are references which can only be explained upon the theory that the mercantile classes of the East had established some system of marine insurance. After the Manchu Conquest, there was a very great change. Foreign trade seemed to drop out of existence, as it were, and foreign traders lost all status. The condition of affairs continued for nearly two centuries.

In reading between, the lines of the tea trade, the most striking fact is the profound change wrought in Chinese life by the influence of Europe, and especially the European steamer in the present century. It is a peaceable revolution. In the early part of the eighties the great cities were in the interior and only a few communities on the seaboard, and these of no political importance. Today everything is just opposite. Canton, Kowloon, Hong Kong, Swatow, Amoy, Takow, Shanghai, and the Yangtze River cities are drawing to themselves the trade and wealth of the empire, and the old inland cities are visibly falling into ruin.

Peking, the present, and Nanking, the ancient capital, are scarcely half as large as they were a hundred years ago. They display all the symptoms of decay and death. In the seaports the population is comprised chiefly of "Young China," energetic, enterprising, and commercial, and offers a marked contrast to the conservative and literary communities of the interior. From the form r will come the rulers and policies of the next century. Even today their power is so great as to be a stumbling block to the Madarins and a menace to the imperial Government. The tea market in Amoy, and, I am informed, in nearly all the tea cities of China, opens according to the agreement of the dealers and speculators, who either hold it back or rush it forward, according to circumstances. This is one of the tricks of the trade, and there are more tricks in the tea trade of the East than in any other civilization known to man. The true inwardness of this particular trick is as follows: Two-thirds of all the tea growers in this province, including Formosa, are poor men who have to borrow money to raise and move their crops. They obtain the needful money from heathen usurers, native merchants, and Christian tea exporters. It makes little difference to whom they apply, as each charges 10 per cent per month on the loan, and takes the land and growing crop as collateral security, and imposes the hard condition that he shall have the first choice of buying the new leaf at the market rates. As the crop comes in the money lenders hold back and bear the market as much as it will stand, and do nothing until there are signs of revolt among the farmers.

Then they buy largely at the lowest figures, and shortly afterward jump the prices up so as to prevent interference from less long-headed operators.

This year the quality is slightly better than last. In fact there has been a steady improvement during the present decade.

While Formosa is, practically, a new tea country, it appears to possess unlimited possibilities. Its crops increase in quantity as well as quality. Formosa produces three crops of tea annually. The first and second crops for the present season are already in, and estimated as follows: First crop, 200,000 half-chests, each averaging forty-three pounds. The second crop reached 100,000 half-chests, a very heavy advance on that of last year, which was only 45,000. The price

then ran from \$45 to \$100 per picul. This year, on account of the superior quality, the prices range a little higher. The third crop, now coming in, will, from the present enormous yield, go as high as 150,000 and possibly to 200,000 half-chests. The three crops, or annual output of Formosa for the season of 1891, may be figured between 400,000 and 450,000 half-chests, or, in weight, between 19,000,000 and 20,000,000 pounds. This, in value, will figure up to \$5,000,000. It pays an internal revenue to the Chinese government of an equally large amount.

The packing and transportation from Formosa to Amoy and Hong Kong, from whence it is exported to the United States and Great Britain, cost from \$1,500,000 to \$2,000,000.

The Chinese merchants and officials with whom I have conversed state that the crops this season are larger and very much finer than ever before in the history of Formosa. This will be good news to Americans. Formosa tea is, without doubt, the best in the world, and Americans almost monopolize its use, consuming 95 per cent. of the total output. It is so superior and popular that unscrupulous dealers in Japan, Korea, and especially Indian and Ceylon teas have been doing a large business in sending to the American market their own goods put up in imitation of the Formosa article. The new law compelling importers to brand each package with the name of the place it comes from has struck a blow at the evil and given much satisfaction to merchants in China. It may be questioned, however, if the statute goes far enough, and if further legislation is not necessary. I have had the opportunity of studying tea culture in Ceylon and Formosa, and find there is great room here for the improvement and cheapening of the curing processes. The Chinese still cure the leaf in small bamboo baskets over charcoal fires in the same way as did their ancestors thirty centuries ago. The new processes invented chiefly if not solely, by Englishmen, use copper, iron, or porcelain plates, hot air, and more or less labor-saving machinery. The result is great saving in time and labor, and the production of a very uniform article. The Chinese object to the process on the ground that they destroy the bouquet of the fine leaf and add unpleasant metallic flavor to the tea. They make the further objection that the new system would throw thousands out of employment, and so injure the nation.

Amoy teas are still on the downward path. Last year (1890) the output was 50,000 half-chests, and the average price \$13 per picul, or 10 cents per pound. This year (1891) it will not exceed 48,000 half-chests in quantity, or \$12.50 per picul. When it is remembered that Amoy at one time was the greatest tea country in the world, and exported as high as 500,000 half-chests (10 times its present production), the decay of the industry is easily realized. This tremendous change is due, I regret to say, almost entirely to dishonesty and rapacity on the part of the trade, native and foreign, and especially the European houses. At one time the Amoy teas were excellent and the tea districts correspondingly prosperous. The tea planters fell into debt to the usurers and merchants, and were so fleeced that they lost all interest in their calling. The quality of the leaf fell off, as did the quantity. Then, to carry out contracts as to specific amounts, the leaf was adulterated with other leaves, with sweepings, and even in some instances with dirt. By degrees its reputation fell until it became known as the vilest and filthiest compound in the market. Today no tea drinker knowingly uses it.

In those days Formosa did a business of 26,000 to 50,000 half-chests per annum, when Amoy was doing 400,000. Now the figures are exactly reversed.

The decadence of the Amoy industry has taught one good lesson. It showed the usurers that Amoy did not and could not monopolize the culture of tea. Today they are afraid to apply the screws to the full limit to the Formosa planters, knowing that if they do the trade will die off as it did in Amoy and will revert to Japan, Korea, Ceylon and India. Further than this, the countries named are encroaching every year upon the China tea export trade.

Thus, for example, in 1878 the exportation of tea from Ceylon was 25,000 pounds; this year (1891) the estimate is 61,000,000 pounds; while the consumption of China tea in England fell from 125,000,000 pounds in 1879 to 61,000,000 pounds in 1889.

Such a change in trade so alarmed the Chinese merchants that five years ago the Chamber of Commerce at Shanghai sent a commission to Ceylon and India to investigate. The commissioners returned, reporting that if China did not send better tea from her shores and open her gates to the foreigner with his machinery, she must eventually lose her export trade.

The same state of affairs, though not upon so large a scale, exists in regard to India, Assam and Japan. Each of these is competing with this empire, and is depriving it by degrees of its commerce. The condition of affairs is well illustrated by two grocery circulars that lie before me. One is of New York, in 1868, and announces the merits of Hyson, Oolong, Souchong, Gunpowder and English Breakfast. The other is of Philadelphia, in 1891, and refers in similar language to Ceylon, India, Assam, Chinese and Japanese teas. There could hardly be a better practical commentary upon the decadence of a great industry.—*American Grocer.*

NOTES FROM OUR LONDON LETTER.

LONDON, May 13th.

MR. J. L. SHAND'S STRICTURES ON TEA PLUCKING IN CEYLON.

The letters which you have published from several planting correspondents complaining of Mr. J. L. Shand's strictures upon the system pursued in Ceylon of constant tea plucking have awakened much of interest here, and it has been my endeavour, whenever opportunity has offered, to learn how far the experience of gentlemen formerly resident in Ceylon inclines them to lean to one side or other of the argument. So far as I am able to judge, it is undoubtedly the fact that by far the greater majority of those who have discussed this topic with me adhere to the views expressed by Mr. Shand, and they think that in mentioning these he has tendered very useful advice to your planters. The total ignorance of the subject, and my entire want of personal interest in planting matters, fit me, it may be believed, to receive and decide upon the opinions expressed to me with full impartiality, and my record of the conclusion forced upon me may therefore be possessed of a value it would not otherwise have. It was only within the last day or two that I conversed on this topic with a former planter of very large experience, my remark to him being that there was every reason to think that the prosperity now attending Ceylon might be reckoned upon as certain to be continuous. He observed in reply:—"I wish I could adopt that view, but candidly I don't and cannot. It is true that apparently the tea bush is far better suited to the soil of Ceylon than was the coffee tree; but to my mind man seems hastening to undo all that might be secured by natural advantages. I don't believe that any course which is diametrically opposed to the natural habits of any growth can tend to its perpetuity, and I entirely concur in what Mr. Shand has said about the ill-effects of too constant plucking. My belief is that, if it is persevered in to the extent that is at present practised, we shall witness with regard to tea quite as great and as ruinous a fiasco as we had to face with regard to coffee. How can it go on? Directly a bud makes its appearance it is nipped off, and never allowed even to open. It is absurd to tell me that anything in nature

can be exposed to such an arrest of development without loss of strength and vitality. It is on this account that, despite all that experts have told us about the suitability of Ceylon soils for tea growing,—and about that I presume there is no doubt,—I confess I have no great faith in the continuance of the present prosperity of Ceylon, and that I dread the advent of a second great collapse, though it may not take place either within your days or my own." This outspoken opinion, coming as it did upon the remarks made to me by other friends, is certainly disquieting. It would be useless for me to attempt to recommend any change of system as the result to the several conversations had by me with Ceylon men on the subject. But you are in a different position. You yourselves have a planting experience, and will be better able to weigh what has been written by me as the result of those conversations. At the same time every outsider must know sufficient of natural laws to be aware that they can never be violated without any after-penalty being exacted, and it is such a knowledge which induces me to hope that you will endeavour to lead the planters of Ceylon to give consideration to the remarks made by Mr. Shand on his recent visit with respect to the effects he observed to too constant plucking. One of your correspondents' letters, we noticed, rather sneeringly referred to Mr. Shand as having been absent from the island for several years. To my mind that is the greater reason why his observations should have the clearer result, and we doubt exceedingly if his trained judgment would under such circumstances be likely to go much astray. Another friend lately remarked to me:—"Yes, poor Shand is getting it hot in the *Observer*, but don't you recollect how Sir William Gregory pulled a wasp's nest about his head when, shortly after first reaching Ceylon, he permitted himself to express a doubt as to the permanency of the coffee enterprise. To my mind Shand's advice and Sir Wm. Gregory's doubt stand pretty much on the same lines, and if our Ceylon people are wise they will spare Shand any more of their invective and recollect that Sir Wm. Gregory proved to be right after all, though he was so tremendously abused."

SCOTTISH CEYLON TEA CO.

With this letter you will receive a copy of the report of the Scottish Ceylon Tea Company. You will be pleased to hear of the success which has attended this undertaking throughout the year reviewed by that report, the profits made amounting to £8,799 14s 11d. An interim dividend of 5 per cent, free of income tax, was paid during last year, and a further dividend of 13 per cent (also free of income tax) is now proposed, making a total division of 13 per cent for the year. £1,000 will be added to the Reserve Fund, which will then amount to £2,000, while £807 0s 6d will remain to be carried forward. It is stated that all the estates belonging to the Company are in excellent condition, and promise well for its future prosperity. The area of all the properties possessed is put down at 1,948 acres. Of these, 1,498 acres are of tea in full bearing, 62 acres are in partial bearing, 14 acres only are under coffee and other products, while 374 acres are of forest and waste land. The total tea harvested was 574,481 lb., coffee producing 120 cwt, and cinchona 13,925 lb. Mr. R. W. Forbes retires from the Board of Directors and offers himself for re-election. The report, it is to be observed, does not state the average price secured for the tea obtained during the year. This is an omission which might usefully

be altered on the occasion of the next report. We feel it can hardly have been intentional, because it is believed the teas of the Scottish Ceylon Tea Company have always sold well in the market here. A company that can pay in the third year of its existence only a dividend of 18 per cent, and that free of income tax, will, it is certain, be looked upon by all investors here as a very successful one.

LADY TEA MERCHANTS.

The *Daily Telegraph* must be responsible for the accuracy of the information conveyed by the following extract from its issue of the 10th inst. If the statement be correct, the ladies are to be congratulated upon the novel start made by them. It has not been possible for me to learn who these enterprising ladies may be. Of course we all know ladies have long been actively canvassing as agents, to push Ceylon teas, and they have doubtless done much towards spreading a knowledge of, and liking for, them in many domestic circles. The paragraph referred to reads as under:—

Among the latest evidences of women's enterprise is the formation of a firm of lady tea merchants. Seven dames have joined in partnership, bought a tea estate in Ceylon, and set up in business to sell their product, the whole business being carried through by female hands. They have lady blenders, lady packers, and lady agents, in town and country. Not only does this firm sell the essentially feminine luxury from their own estate, but they will, if required, provide China and Japan teas, and make blends to suit all tastes. There is but one son of Adam in this commercial Eden, where afternoon tea is the principle article of faith, and to him is allotted the drudgery of the position of manager. The greatest difficulty for the ladies is that of packing: this they are fast conquering under skilled male instructors. Blending and tasting are favourite branches of the business with the fair proprietresses, and an inducement is offered to customers of the sterner sex by the fact that favourite blends are called "The Ladies' Own."

DAYS FOR SALE OF TEA.

The *Times* has announced that the selling brokers of tea have arranged that until August next Mondays and Wednesdays shall be devoted entirely to the sale of Indian teas, while Tuesdays and Thursdays shall be exclusively given up to those of Ceylon teas. It may be noted here that there exists a much firmer tone this week for really good Ceylon teas, and that prices have advanced fully $\frac{3}{4}$ d to 1d the lb. The stocks of inferior teas are kept low and there is little demand for qualities under 6d per lb., while for India and Ceylon of the better sorts of common kinds there is a strong demand. Very little common China remains in stock, and advices from the Chinese ports render it very doubtful if these will be replenished at all this year. Prices there are ruling fully 25 per cent below those paid last year, and even with this reduction it is questionable if the agents will buy for exportation to the London market.

THE CINCHONA ASSOCIATION (LIMITED).

The formation of a syndicate to control the world's output of cinchona-bark appears to be nearer realization at this movement than it has been before. We do not mean to say that the negotiations now in progress are certain to succeed. A definite and elaborate scheme, however, has been propounded to some of the leading firms in the cinchona trade by a gentleman (acting presumably on behalf of others) who has been associated with quinine and cinchona for many years. The scheme involves the formation of two companies—"The Trading Founders (Limited)," es-

established for the purpose of obtaining offers (to hold good for six months after receipt) from all the cinchona-planters in the world of the entire quantity of bark already taken off the trees, or still on the wood, for a period of three years, and "The Cinchona Association (Limited)," which is to acquire and work the rights secured by the Trading Founders for the benefit of cinchona planters and dealers. The scheme is fully set forth in a lengthy document, which the promoters call a "draft scheme," and of which copies have been distributed lately to a select number of planters' representatives, brokers, and others. We have succeeded in securing a copy of this document (not from the promoters), and give below the salient passages of the scheme. The promoters, in what we may call their "argument," set forth that the present price of cinchona is unremunerative, but that if properly regulated its cultivation and sale might be made profitable to all concerned. In order to effect their object it is proposed that planters and traders should associate to buy the world's crops or shipments of cinchona during the three years following the formation of the Association. The traders are to provide the cover to enable the raising of the capital for this purpose by guaranteeing that they will subscribe for shares in the Cinchona Association (Limited).

The planters are to engage to sell their three next crops of cinchona at the price of 5½ cents, or 1d per unit, subject to an engagement on the part of the Association to pay the planters one-half the net profits which the Association may make on the quantities supplied. The planters will also bind themselves, under penalties, not to dispose of any cinchona to anyone outside the Association.

Profits are to be divided between the growers and the traders as follows:—the whole of the net profits on sales at or under 2d. per unit are to be divided equally between the planters and traders without any deduction for the expense of forming the Association; but from all sales at over 2d. per unit a deduction of 10 per cent. of the excess profit shall be made; and this 10 per cent. is to form the sole remuneration of the Founders.

It is provided that meetings are to be held in Amsterdam and London, at which leading members of the trade will be formed into committees to represent the two chief centres, respectively. The scheme apparently suggests the appointment of six commissioners in each city, each with a secretary, officers, bankers, and so forth. Should the co-operation of the planters be withheld, the scheme will, of course, fall through. The planter is therefore earnestly adjured to join, and the anticipated advantages to both growers and traders are then detailed.

THE ATTITUDE OF THE QUININE-MAKERS.

Whether the planters—who, as we have repeatedly pointed out, hold the key of the situation—will consider the inducements held out to them sufficient, may be left an open question at present. The quinine-makers, however, are quite left out in the cold, and in this respect the scheme is a distinct innovation. What attitude will these gentlemen take up? "It is expected," say the promoters, "that they will welcome the Association, and give it their support, as it will secure for all concerned a stability in price, and a remuneration for work done, which have been wanting for many years past."

Should, however, the quinine manufacturers stop working bark for any lengthened period, the consumption of the present stocks of manufactured quinine would necessarily follow, and their removal would place the Association in the possession of a monopoly of the supply, and thus enable it to obtain its own price.

The question is next mooted whether the rise in price contemplated by the Association will not lead to a reduction in the consumption of quinine, or to an increase in the future cinchona shipments. In dealing with this point the promoters state that, up to the year 1885-6, the quinine manufacturers of the world have been in the habit of receiving from the wholesale trade a yearly sum which has decreased from a little over 3,000,000*l.* in 1880-1, to about 1,000,000*l.* in 1885-6, in this latter sum was considered to be a small sum out of which to pay all the plant-

ers, traders, and quinine manufacturers, and was a sum which the wholesale buying trade was quite satisfied to pay (and on which it made its profit), and the retail equivalent of which the consuming public was perfectly willing to give for its then yearly supply of about 7,000,000 oz. of sulphate of quinine.

The promoters thereupon calculate that "if the Association should now offer yearly only sufficient cinchona to produce 7,000,000 oz. of sulphate of quinine, the wholesale buying trade will, doubtless, pay their 100,000*l.* for it just as well in 1892 as they did in 1885-1886, and if out of this 1,000,000*l.* the quinine manufacturers take for their share 250,000*l.* there would remain annually 750,000*l.* for the Association, being about three times the proposed purchase price."

BUT WILL "WILD BARKS" SPOIL THE GAME?

The fear of an invasion of hordes of "wild barks" from South America, attracted by the higher prices, is next discussed. It is held that if the collection of wild barks ceased before the unit fell to 6d, it is not likely that 3d will induce its recommencement.

There are no accurate figures, say the drafters of the proposal, to show the exact annual consumption of quinine or the "normal yearly yield of cinchona—i.e., the true yearly crop." We do not quite gather what is meant by the latter expression, but, whatever it may be, the directors' first duty will be to find it out. The result of their investigations in this direction, it is expected, will be to show that the existence of the present excessive production is due either to temporary or to permanent causes—a conclusion which seems obvious. But, having ascertained what unit price will permit the cultivation of a rich bark, whilst leaving that of a poor bark unremunerative, the Association will regulate their transactions accordingly. If, for instance, present cinchona supplies shall be found to be one-third in excess of the demand and that such sales may be made notwithstanding present stocks then the Association will sell out of each of their three years' arrivals two third parts at a gross profit of 33 33 per cent., and, at the end of the three years, would have a stock equal to one year's purchases on hand costing nothing. This would be on the assumption that holders of outside stock were selling at the same time as the Association, but if the formers should be allowed to realise first, the result would be so much better for the Association. The calculations are said to be made on the worst possible assumptions which the Association can have to deal with.

In arriving at the proportion of profits to be paid to the planters, the Association will not attempt to trace particular parcels of bark, but will pay each planter on the basis of the proportion which the money value of the sales he will have made to the Association during the year at 5½ cents (one penny) per unit, shall bear to its total purchases of the year, but for public sale purposes the identity of the parcels will be preserved, and the names of the importers and brokers made known as at present.

All traders who shall introduce planters' offers are to be entitled to preferential allotment of ordinary shares to a face value equal to the full amount which shall be paid by the Association for such cinchona so introduced by them.—*Chemist and Druggist*, May 7th.

BARK AND DRUG REPORT.

(From the *Chemist and Druggist*.)

London, May 12.

COCA-LEAVES.—Seven bales good stout green and brown mixed Huanoco leaves were bought in at 2s per lb. today. One small bag of small dark leaves from Ceylon was bought in at 1s 6d per lb.

ESSENTIAL OILS.—For twenty-one cases Cinnamon leaf oil, each of 36 bottles, there was no bid at 1½d per oz. Three tanks brown Citronella sold cheaply at 9d per lb.

CACAO: ITS NATURAL HISTORY,
CULTURE AND PREPARATION.

It is just possible, indeed probable, that Trinidad may have been the original home of some of the varieties of the cacao plant. In any case this valuable vegetable product was introduced at early date from the adjacent American continent into the West Indian island, which is far and away the most important scene of its culture in the world. It is only in quality that Ceylon competes, and in price obtained for the more carefully prepared beans. In quantity we are no where, as yet, when our export of less than 20,000 cwt. average is contrasted with 200,000 or more, valued locally at over £600,000, which Trinidad sends into the markets of the world. It was only natural that in taking up the enterprise we should at first trust to the lessons of Trinidad experience; but, as in so many other cases, the Ceylon planters improved on the lessons taught them, so that, judged by the test of price in the London market, the Ceylon cacao "beans" are the best and finest flavoured in the world. Something may be due to soil and climate; but there can be no doubt that the superior quality of our product is mainly owing to the care and scientific skill with which the seeds are fermented, washed and dried. In the thorough washing of the seed which prevails in Ceylon a considerable proportion of weight is lost, and the Trinidad planters contend that the greater number of cwt., for which they receive a somewhat lower price, compensates them and leaves little inducement to follow fully the Ceylon mode of preparation. All such points and indeed all the details connected with the natural history, species or varieties of the plant, its culture and preparation, the properties of the fruit and its value as a food (food of the gods!) are given in a carefully prepared and illustrated handbook, prepared by Mr. J. H. Hart, F. L. S., Superintendent of the Trinidad Royal Botanic Gardens. This gentleman, besides his experience in Jamaica and other West Indian colonies, has had the advantage of travelling on the American continent, and seeing the cacao plant in its native habitat in Venezuela and other places in which it is indigenous. Added to all this are the special advantages for research and correct conclusions enjoyed by him in the position he occupies in Trinidad; and it will be acknowledged that few men could be better qualified than Mr. Hart for the task he has undertaken and performed so well. The book in its printing and get-up does great credit to the Port of Spain Government Printing Office. The illustrations are faithful and well executed portraits of the objects intended to be represented. On the front cover there is a longitudinal section of a cacao pod, showing the mode in which the seeds are embedded in pulp and mucilage, and at the end there is a picture of the cacao hook used for picking the pods, which is described as follows:—

The instrument is made of a shape to be used either by a push, a pull, or by a side cut, and when kept well sharp, and affixed to a light bamboo rod, serves admirably for collecting the pods from the higher branches of the cacao tree, but a sharp cutlass or knife is used for taking the pods from that portion of the tree within reach of the arm. Care should always be taken not to cut too close to the "cushion" or point where the Cacao pod is borne, as the tree presents a succession of flowers and fruit from—at or near—the same point each season, and if the part is wounded

by a cutting instrument or bruised by a blunt one the supply of flowers, and consequently fruit, will be reduced during the following season.

But the chief interest of the reader of the book will centre in a lithographed sheet of portraits of the pods and beans, with sections and measurements of the four great varieties recognized in Trinidad:—

- | | | | |
|--------|--------------|---|-------------------------|
| No. 1. | CRIOLLO | (synonymous with creole or indigenous), | colours red and yellow. |
| No. 2. | FORASTERO, | " | " |
| No. 3. | AMELONUDO, | " | " |
| No. 4. | CALABACILLO, | " | " |

Mr. Hart thus describes the representations of the different kinds:—

ILLUSTRATIONS.

In selecting the Cacao pods for our Illustrations we have been at considerable trouble to get what must be considered a fair type of each variety and not extreme forms.

No. 1 represents a fair sample of Red and Yellow Criollo. As will be seen this is always more bottle-necked and pointed than any of the other forms. The section is drawn from an actual section of the pod represented, cut from the centre and laid upon the paper. It will be seen that the outer covering is very thin in comparison with other varieties, and this forms one of its chief characteristics. The measurement of the pods may be taken from the scale. This variety certainly produces the finest quality of Cacao produced in the West Indies.

No. 2 shows the character of the Forastero varieties. The Red variety as a rule shows a more worted appearance than the Yellow. As shewn by the section also drawn from actual section of the fruits, the thickness of the skin is rather greater than in Criollo. This is sometimes called the ten "furrowed" Cacao, while the smoother varieties are called the five "furrowed," as the intermediate furrow all but disappears in the larger proportion of the pods of that class. The furrows are much more decided in Forastero than in Criollo, as will be noticed by the depth shewn in the sections of both the Red and Yellow varieties.

No. 3 as will be seen, there is a wide margin of difference between No. 3 and the two preceding numbers, but in the text it will be found that this is covered by the insertion of the ordinary Red and Yellow Forastero as Nos. 5 and 6. There is really a large number of forms included between these two types, but none however, which are considered of sufficient prominence to be treated as a typical variety. The Amelonado is conspicuous by its thick-skinned, smooth and five-furrowed pod, but its seeds are almost identical with those of Nos. 3 and 4, except when met with as an extreme form approaching Calabacillo, into which it frequently runs upon the same tree.

No. 4 shows "Calabacillo" Red and Yellow. The pods are small, smooth, thick-skinned, and contain little else but flattened beans, small, and containing a large amount of the bitter principle and purple colouring—slightly rounder pods should perhaps have been selected to represent faithfully the character of this type.

The figures are not ideal drawings of what we consider to be a type, but are drawn from individual pods of the major types collected from an estate in one of the best districts of the Island.

The varieties are fully described in Mr. Hart's chapter on the "Botany and Nomenclature of Cacao, with Description of Typical Forms, &c., &c.," which we have previously extracted from the Trinidad Agricultural Record in which it was separately published. There are several species of the genus, which is a native of tropical regions extending from Mexico to Brazil, all said to be distinct from the cultivated kinds, which have doubtless altered much in the processes of culture and hybridization. In America the indigenous trees grow to a height of forty feet, but the usual size in Trinidad (and in Ceylon) is about eighteen feet in height and

lateral growth. While holding that the finest cacao is produced by a variety known as Criollo, Mr. Hart states that Mr. D. Morris appeared to be of opinion that they had no longer the true Criollo variety in Trinidad, while Messrs. Sinclair and Ross, when they visited the West Indian island, informed Mr. Hart that the cacao which fetches the highest prices in Ceylon was different to anything they had seen in Trinidad. At the risk of repetition, we quote as follows:—

Dr. Trimen of Ceylon, in his annual Report for 1890, falls into the error of interpreting the word "Criollo" as being synonymous with "wild."

It is well-known, however, that the word is never used in this sense in the West Indies, the true interpretation of the word "Creole" being—one born in a country or one belonging to a country. With European Anglicans the word "Creole" is generally supposed to have reference to a mixture of races, but it is not used in that sense here.

For instance, a child born of white parents in any West Indian Island, or even on the mainland of Central and South America, is a "Creole," and just as much so as a black or coloured child would be. In fact, "Creole" would be better translated as "native" than as "wild" or coloured, a black or coloured child being just as much a Creole as a white one or a mulatto. An English clergyman lately travelling in Trinidad was much surprised to find that the word Creole was used in this sense here, and even when shown that the use of the word in his sense would often subject him to ridicule, still he said he was not inclined to allow that the West Indian interpretation was right, but felt inclined to follow his own. This gentleman was "writing a book," and possibly we may hear more of his conservatism later on.

It is important that the sense in which the word "Creole" is used should be fully understood as we have "Criollo" as our first variety of Cacao.

If we interpret the words criollo cacao as native cacao, and Forastero as foreign cacao, and Calabacillo cacao as calabash cacao, we shall have a better definition of terms, and prevent further misapplication of the word "Criollo." The Calabacillo is so named from its fruits resembling those of the calabash tree (*Crescentia cujete*, L.).

Dr. Trimen (Annual Report 1890) remarks that these names appear to have had their origin in Trinidad, and doubts whether the first or Creole was "ever really a native plant there." The misunderstanding of the word Creole probably leads him to this conclusion, for how could it be *Native* or *Creole* (Criollo) if imported into Trinidad, unless its name was imported from South America with it, and if so it should be known as the Criollo of South America and not simply *Criollo*. The word Forastero is also applied on the Main to the same cacao as in Trinidad, for they term it "Tritinario" in contradistinction to their own Criollo, and certainly a plant of Trinidad would be Forastero or foreign in Venezuela or any other part of Central America, and therefore their Forastero being a foreign cacao and supposed to have its origin in Trinidad would properly be the Criollo of Trinidad if the word was used in the correct sense.

It may be possible, however, that Criollo cacao is a native of both countries, and that one has as good claim to it as another, but the balance of probability appears to be that its origin can be rightly traced to South America as indicated by Dr. Trimen, but there at present appears no ground of proof in support of the proposition.

Dr. Trimen also repudiates the authenticity of the word Criollo as attached to plants sent him from the Trinidad Botanic Gardens, and turns them into Forastero apparently on account of their being dissimilar to "the Old Ceylon Red cacao, also called Caracas" (Report for 1890), but he allows a little later, that the Forastero sent from Trinidad to Ceylon is in the opinion of a large grower gradually changing its character and "becoming more like the Old Ceylon Red," or in other words, is reverting to its original type through the influence of the soil and climate in which it grows.

If therefore it is possible for Forastero to revert into the Caracas or Criollo, this circumstance goes very far to sustain the supposition that Forastero is merely a descendant of Criollo or that Criollo is a descendant of Forastero: the change being brought about by circumstances of soil and climate in each case. That such a change is quite possible and very probable, is shown by the fact that our best scientific botanists do not find sufficient distinctive characters (notwithstanding the differences in the form, size and colour of fruit, leaf and tree) to make more than *one species of all our cultivated varieties*; which as Dr. Trimen truly says, probably trace their origin to a common wild parent.

Those who believe in the ultimate resuscitation of the Arabian coffee enterprise in Ceylon may derive encouragement from the history of cacao in Trinidad. Dr. de Verteuil in his work on the island states that from its first settlement it exported cacao. In 1727, however, a terrible epidemic broke out, which resulted in the complete ruin of the plantations.

"Thirty years later, some Aragonese Capuchin Father was successful in their attempt to revive the culture of Cacao in the Island. They imported from the continent a new species (variety J. H. H.) the Cacao Forastero which, though giving a produce of inferior quality was nevertheless promptly propagated as being hardier, that is the Cacao at present cultivated in the Island."

In Jamaica, also, cacao was, during the last century visited by a "blast" or blight, which led to its destruction, and yet the enterprise was subsequently revived with success. Mr. Hart states:—

The Calabacillo, or that class which gives small, rounded and smooth pods and flat beaus, having a bitter taste, is the lowest type of cacao that is grown, and requires the greatest amount of skill during treatment to bring it into marketable form, the process of fermenting it, taking more than double the time required for Criollo. The tree however is the strongest grower and the hardest of all the varieties, and will thrive on poorer lands and on lands on which it would be impossible to grow the finer kinds.

Trees of the Forastero type are also strong growers, and its varieties are suitable for most lands in which cacao can reasonably be expected to thrive. It approaches the Calabacillo type by the Amelouado variety, both red and yellow, and certainly stands as a large intermediate and somewhat variable type between Criollo and Calabacillo. In general the Forastero type has a thick skin. It approaches the Criollo in form, or runs into Criollo by its variety *Cundeamor verugosa*, red and yellow, but trees may be found bearing pods which are hardly to be distinguished from the Criollo on the one side and the Calabacillo on the other, thus showing the breadth of form covered by this kind.

It becomes a question, therefore, for the planter to ascertain the character of his land with as much accuracy as possible before deciding what variety of cacao he will plant. If very poor he can rely upon Calabacillo only. If from moderately good to fairly rich, he should rely upon the varieties of the Forastero type, but if rich and lasting ground, only the best types of Criollo should be planted.

The generality of plantations are however of so mixed a character that it is difficult to separate one kind from another, though there cannot be any doubt that it would more than pay for any extra trouble were the system of planting each type in separate fields faithfully carried out.

Many writers agree that the flavour of cacao is dependent upon the soil, and in this they are probably correct, but much must also depend upon the surrounding conditions, viz.: moisture, exposure, and temperature, in their respective order, and perhaps more is to be attributed to these than to the soil, although all of them, it is freely admitted, may have a direct influence on flavour and quality.

Mr. Hart fittingly dedicates his Handbook of Cacao to Governor Sir Wm. Robinson, recently translated from Trinidad to Hongkong, who while in the West India island, took the most zealous interest in all that concerned the botany and agriculture of the colony, writing largely and intelligently himself on the subject of cacao. Following the dedication we have the general contents of the parts (3) and chapters (12) into which the work is divided, indicated, and this is followed by a most elaborate index of the contents of each of the twelve chapters. Then comes the preface in which Mr. Hart acknowledges his special indebtedness to Mr. D. Morris's work on cacao in Jamaica, and states that Mr. Morris, when on a visit to Trinidad, gave his undivided attention to the subject and visited the principal estates in the island, paying special attention to those owned and directed by Sir Joseph Needham, then Chief Justice of Trinidad. A Chief Justice in Ceylon is prohibited, as is every high civil servant of the colony, from owning land or directing its cultivation. The character of the services in the occidental and oriental colonies is very different. Mr. Hart adduces as his qualifications for dealing exhaustively with the subject of cacao the fact that he had "over eleven years' service under the Jamaica Government, during the latter part of which I administered the Botanical Department of that island, and five years in my present office, a total of over sixteen years West India service, all spent in Botanical work." From the reports of his predecessor, Mr. Prestoe, Mr. Hart acknowledges having drawn some valuable hints. We have discovered from experience that only in select localities of rich free soil, warm, moist climate and good shelter will cacao flourish in Ceylon. The product is also much more liable to the attacks of insects than are our other great staples, tea and coconuts. Mr. Hart states that a free subsoil sometimes compensates for a shallow topsoil. Good forest is an indication of good soil; and Mr. Hart favours shelter belts of the original trees on the land chosen, as well as shade trees amongst the cacao, to the discussion of which we shall subsequently come. We quote as follows:—

An ideal spot on which to found a cacao plantation is a well sheltered vale, covered with large trees, protected by mountain spurs from the prevailing winds, well watered, and yet well drained, with a good depth of alluvial soil on which rests a thick deposit of decayed vegetable matter, easy of access, and in a district distant from lagoons or marshes for the sake of the proprietor's health. Such a spot in a climate similar to that of Trinidad could not fail to produce regular crops of the finest quality of cacao.

Elevation above sea-level has also to be considered in choosing ground for planting cacao. The higher the elevation the lower the degree of temperature experienced, and the trees make smaller growth and give less in annual produce.

Plantations existing at over a thousand feet above sea-level in Trinidad are few and far between, and cannot take rank among first-class estates. The mean annual temperature of sea-level is 78° 1 Fah. From this the reader can draw the conclusion, which I believe to be correct, that planting cacao at high elevations is not a measure of economy or good practice, unless in specially favoured positions with regard to soil and exposure.

Of course the difference of latitude would justify a higher elevation in Ceylon than in Trinidad, but we believe few of the cacao estates in this island are situated at elevations above 1,500 feet, the range being from 200 feet above the sea near Polgahawela to 1,000 up to 1,500 feet in the valleys of Matale and Dumbara. The chapter on the selection of seed and nurseries commences thus:—

Cacao is invariably raised from seed by the planter. The seed possesses but a short life, if exposed to dry air; if kept in a moist situation, fermentation quickly sets in and the seed becomes useless. It is thus very difficult to transport cacao seed to distant countries, or to keep it for any length of time, unless placed under conditions favourable to germination. Cacao may be sent in ripe pods for short journeys not exceeding 8 or 10 days, if the pods are kept entire and without bruises. A good method of transporting seeds to a distance is to plant them in Wardian cases and allow them to germinate on the voyage.

For nursery purposes seed from the best quality of cacao only, should be used, the largest beans should be taken, and care taken to procure them from well selected pods. It is a great mistake to use seed of inferior varieties, taken from half-ripe pods and from trees in indifferent health. This applies to all varieties from Calabacillo to Criollo.

Some trees are better bearers than others, some produce finer pods, and the choice, for seed purposes, should rest upon those which produce fine large pods, good beans, and annually bears regular crops. In the vegetable kingdom as a rule, like produces like, yet it is well known that variations do occur, but it is certain that the chances of procuring a good class of plants from seed are in favour of the course recommended, rather than by procuring seeds from the refuse pods of a plantation (as is not seldom done) and expect good results to follow.

Seed should also be selected from trees situated at a distance from inferior varieties of cacao, for the purpose of avoiding as far as possible the variation which will naturally occur, where cross fertilization is free to take place; for if poor varieties are near to the seed trees, the latter will be liable to produce a variety having some of the characters of the poorer kinds, blended with their own.

Too much attention cannot be paid to the selection of a proper quality of seed, if it is the planter's aim to improve the quality and quantity of his productions.

Again:—

Nurseries made in a friable soil, well pulverized, in an open situation, the seeds well cleaned and sown regularly their own diameter beneath the surface of the soil, carefully watered when required, artificially shaded from the direct rays of the sun, protected from the trampling of animals, the ravages of rats and mice, and carefully weeded when required; may reasonably be expected to produce strong and healthy plants. With those who prefer raising plants in boxes—a very handy and economical method all things considered—the best method to employ would be to procure well rotted and sifted Coconut refuse and to sow the seeds regularly, about $\frac{3}{4}$ inch below the surface, the boxes being made about six inches in depth and well drained. If Coconut refuse is not to hand, a suitable substitute may be found in well decomposed leaf mould. Immediately the plants have developed their first pair of leaves, they may be potted or transferred to nursery beds—in both cases, shading them until well-established. If transferred to beds, the plants should be put out, about twelve inches apart each way—*taking especial care not to place the plant too low in the ground.* More plants die from this cause than from any other, both in nursery and in the field. No plant whatever, whether Cacao or any other, should ever be placed in the ground lower than the position in which it stood in the soil as a seedling. Many people tell us a great deal about "tap-root." Personally I have no reverence whatever for even the name of "tap-root," but at the same time I have every respect for the principle which has led to the great respect paid to the "tap-root," by the greater number of West Indian planters, and this principle is, that even the slightest damage cannot occur to *any* root without a loss to the plant with which it is connected.

As regards planting, the opinion in Trinidad as in Ceylon is in favour of nursery plants instead of seeds "planted at stake." There is much in the chapter on planting to quote which in Ceylon

would be "carrying coals to Newcastle," but the following seems worthy of attention:—

The distance which Cacao trees should be planted apart will be determined by the planter in accordance with the character of the soil and the elevation above sea-level. The higher above sea-level and the poorer the soil the closer the trees may be planted and *vice versa*—a distance ranging from 12 to 15 feet apart each way will probably meet all requirements, (*i.e.*) 12 feet in poor soil and 15 feet in rich soil.

In Grenada the practice of close planting is followed much more generally than in Trinidad, but successful planters are to be found among those who follow each system. The wide planting cultivator says, I get more fruit per tree and of better quality than the close planting cultivator, while the latter affirms, I get as much from two trees as you do from one, and the quality is as good. Probably more depends upon the judgment of the individual planter with regard to the character of the soil he is working than anything else. If it is poor he will plant close, if rich and deep, he will regulate his planting accordingly. It is not to be doubted however, that where practicable, wide planting gives the advantage of affording easier access to the cultivator for the various operations of pruning, harvesting, manuring, weeding, &c., and the plantations where the practice is carried out certainly assume a much better appearance than those which are crowded with trees.

We refer to Mr. Hart's dictum against our own general experience when he says:—

Cacao is certainly benefited by intermediate cultivation between the rows of trees in their younger stages, and planters who reside near to their young fields—as all should who wish to work successfully—should endeavour to plant crops of which he can most readily dispose and those which are least exhausting to the land.

In the West Indies as herein Ceylon there are wide divergences of opinion as to the question of shade. The general opinion respecting coffee in Ceylon was that if it could not be grown without shade it had better not be grown at all. But cacao is a different product, always grown in a climate of intense sun-heat. This is what Mr. Hart says on the subject:

The question of shade is one upon which much has been written, and upon which there exists great divergence of opinion. In the Island of Grenada the general practice is to grow Cacao without shade. In Trinidad the prevailing practice is to give the plants permanent shade by planting umbrageous trees at regular intervals through the plantations. Each system has its advantages and its disadvantages, and no hard and fast rule can be laid down, but the novice would certainly be safe in following the general practice of the district in which his land is situated, giving due force to any surrounding circumstances which may justify him in using a modification of the prevailing practice. As stated in a previous chapter, the greatest care should be taken in securing "windbreaks" on the side of the plantation exposed to the prevailing winds, and belts of original forest should be left for this purpose if practicable.

In Grenada the land in Cacao is sometimes undulating, but in the major part of the Cacao districts distinctly hilly. Where the aspect of the plantation affords by the conformation of the ground itself, shade or shelter from a particular direction, artificial shade can certainly be dispensed with in a great measure, but on level land in Trinidad the general practice goes to prove that it is absolutely necessary, to produce Cacao to perfection.

For shade in the lower lying lands of Trinidad the tree generally used is the "Bocare," or *Erythrina velutina*, which affords a deep shade. For the higher lands the "Anauca," or *Erythrina umbrosa* is used. Both being known, together with several other *Erythrinas*, as "Bois Immortel." The Bois Immortel proper, however, is the "Anauca," *Erythrina umbrosa*.*

* Mr. Morris remarks on this point as follows:—"This tree is said to store up moisture in its tissue which it is supposed to dole out to the tree in times of drought. This, I fear, is only a planter's sentiment and cannot stand the test of experiment."

The latter grows to a much greater height than the "Bocare" and does not afford so dense a shade. Why these trees should have attained their present high reputation is somewhat difficult to arrive at, but one thing is certain, they answer well the purpose for which they are used.

The wood of this tree for timber or fuel is utterly useless and the branches often fall injuring the Cacao trees beneath. Among the numerous timber trees which flourish in Trinidad it is strange that one could not have been selected which would serve some useful purpose besides affording shade. That such trees exist is not to be doubted, but the difficulty is to find them. The planter, however, should remember that once such a tree is found and planted, it would materially increase the value of his estate—certainly an inducement for him to seek for such. Nearly all trees suggested for such a purpose possess characters which gives them no economic value. Mr. Morris, however, in his work on British Honduras suggests *Castilloa Elastica* as a shade for Cacao, but having seen the plant in its native habitat in Central America, and having had the opportunity of observing it under careful cultivation in Trinidad, I cannot confirm Mr. Morris' good opinion of it, as it appears from our experience that the tree itself requires shade. Timber trees (to be grown for the timber) would be useless for Cacao shade, as it would be impossible to cut them without injury to the Cacao. It is therefore patent that we should look for a plant which produces an annual crop, which could be gathered without injury to the Cacao. The Rubber tree is certainly such a plant, if it would only thrive above the Cacao, and there are doubtless many other fruit-bearing and umbrageous trees, with which it would be desirable to experiment.

The *Heveas* or *Siphonias*, which supply the Para Rubber of the London markets, are likely trees for this purpose, but they are of much slower growth than the Immortel. *Terminalia bellerica* which supplies the "myrabolan" of commerce might also be tried. Both these trees thrive well in Trinidad. It will be seen that although it is desirable to procure a better tree than the "Bois Immortel," it is a difficult task to find one, and the novice had therefore better rest content with what has served the planter so well in the past, and stick to the Bois Immortel, leaving the experimental trials of new plants to the more experienced planter.

Our experience of *Grevillea robusta* leads us to suggest that it might prove valuable as a shade tree. There is a manurial value in the immense quantity of leaves this tree sheds. In Southern India the grevillea, when planted as a shade for coffee, gets the credit of destroying the fungus so fatal to our old staple. Mr. Hart proceeds:—

Having decided upon the question of the permanent shade he will use, the planter should make arrangements to plant it either before or at the same time as the Cacao. The distance and manner of planting will depend a great deal upon the ground, the quality of the soil and the exposure, but the usual distance is from 35 to 40 feet apart each way for the "Bocare," and from 40 to 45 feet apart from the "Anauca."

If the planter believes, what we certainly do not, that "intermediate culture" will do good and not harm to the cacao plants, the following information from Mr. Hart's book will be valuable to him:—

For the smaller shade plants, Corn (*Zea mays*), Pigeon or Gongo Pea (*Cajanus indicus*), Tannias, Eddoes, or Coccoes (*Colocasia esculenta*), Castor oil (*Ricinus communis*), Cassava (*Manihot utillissima*) and the Banana or Plantain (*Musa sapientum*), can be used. The Banana or Plantain used for shade is usually planted intermediate between the permanent rows of Cacao. If Cacao is at 15 feet, then Banana $7\frac{1}{2}$ and so on. A variety of Plantain commonly known as the "Moko," or "Jumbi Plantain," is preferred to other members of the family by Trinidad planters for the purpose of affording secondary shade. The fruit of this plant is however considered fit for little else but cattle food, though the green fruit when dried and pounded makes a wholesome, pleasant and nutritive meal, which is a most suitable food for invalids and children. Since the Banana trade has assumed such large proportions in the

West Indies, attention has been called to the value of the *Banana* as a shade plant for Cacao. The fruit shipped from Jamaica is known there as the "Martinique *Banana*," and in the various Colonies it appears under different names; in Trinidad being recognized only under the name of "Gros Michel," and the plant proves by those who have tried it to be very suitable for Cacao shade.

The distance at which the intermediate shade plants should be placed apart is a matter of the planter's convenience, the skilful will always take care that he has enough and not too much, but as they are removed after four or five years it matters little really what is the exact distance they are placed apart so long as the object is attained of giving the Cacao the necessary shade.

In this colony, where perfectly clean weeding is the rule, it is amusing to learn how different the system is where labour is so scarce and dear and the soil so rich as in Trinidad:—

The after cultivation, *i.e.* weeding or cutlassing of a Cacao estate is a work which is done on the average about twice in each year. It is done by task work as a rule and at the rate of 40c to 50c per task, or at a cost of about 6s per acre.

Mr. Hart holds the opinion that a "cacao or any other tree in good health needs no manure"! In defence of his theory he gives his idea of what a cacao tree in good health should be:—

It is a tree which from the seedling stage has annually made good periodic growth, producing leaves and branches which are healthy and strong, without disease, or blight, and which produces an average crop of fruit, without dropping it prematurely or losing it by the attacks of disease, and a tree which can withstand a maximum of either drought or rainfall without its general bearing being affected.

Such a tree I say needs no manure. It must not, however, be understood that I hold the opinion that no manure should ever be applied to Cacao, for such would be in direct opposition to the principles and practice of agricultural science and could not be upheld. The application of manure to trees planted in poor soil, to trees which are in weak health, or to trees which it is desirable should make a more than usually rapid growth to serve a purpose of the cultivator, would have good effect, and could not be deprecated, but the application of manures to trees in good health and in average bearing, would have the result of encouraging rank growth which would be non-productive and a loss of crop would be the result. A tree, like a horse, can do more work when in "condition" and with less exertion than it can if overfed or surfeited. Manure may, however, be advantageously applied to trees in average health, should it be found that the plant has set itself more work to do than it can efficiently carry out, *i.e.* by setting a larger crop of fruit than usual. In such a case the application of manure would certainly be beneficial and enable the tree to carry a crop which under ordinary circumstances and without manure, it would not be able to, but the application of manure to a tree before the fruit is formed, or at an early period of its growth, would probably result in inciting the tree to produce a large amount of branch growth, to the detriment of the fruit, which would probably fall.

It will be seen therefore that the application of manures to Cacao (having reference to chemical or artificial manures chiefly) requires great judgment and should only be done under the personal supervision of a skilful cultivator, or loss may result. Where, however, the plantation will evidently be the better as a whole for the stimulating action of manure owing to a poor soil, its application may be made general and not special from tree to tree.

Farm yard or stable manure can always be applied with much greater safety than chemical manures, it is not so quick in its action, but the effect lasts longer upon the tree.

He then warns cultivators against deep digging and cutting the feeding rootlets, while pointing

out that in natural forests a process allied to mulching goes on. We suppose the system in vogue in Ceylon of placing manure in holes dug between every four plants is as good for cacao as for coffee and tea. We must not omit the following paragraph:—

The plant or tree does not, however, obtain all its food from the soil, as the surrounding air provides it with a large proportion of its nourishment, taken up in a gaseous form by its leaves. It should be the aim of the cultivator therefore to maintain on his trees as large a proportion of healthy leaves as the tree can carry. Whether the food is taken up by the roots or by the leaves themselves, the leaves are the organs in which all the material necessary for the purposes of growth and reproduction is formed and distributed.

The system of pruning recommended is founded on this principle, and Mr. Hart states:—

Given a young tree in good health, and with a single stem, the pruning should commence by the regulation of the *primaries*, or first branches made by the tree. There should, as a general rule, be only three, or at most four primary branches left on the cacao tree. These should be encouraged to extend themselves laterally, as they have a natural tendency to do, and should be encouraged to develop at regular distances the secondary branches. The tertiary branches should also be encouraged to grow at regular intervals.

In these stages the operation should be performed before the wood is sufficiently hard to require the use of the knife, by the method called pinching which is carried out with the thumb and finger pinching off the young, succulent shoots that are not required. At all times it should be the endeavour of the pruner to maintain the tree well balanced, *i.e.* it should not have one branch growing more rapidly than another so as to make it appear lop-sided from any point of view. Many cultivators do not regard this point sufficiently in carrying out their pruning operations and many branches are left, owing to their being *bearing branches*, which for the permanent security of the tree, for its appearance and for its general bearing qualities, should be removed; for it is much better to check at once the tendency of a tree to assume an irregular and uncultivated form, than to allow a branch to grow for a time and finally be compelled to remove it when of a larger size.

The pruning of a tree should be conducted with a view to the production of fruit. Unless we have a plentiful supply of good healthy leaves, evenly distributed over the tree so as to obtain a maximum of the light and air they require, we cannot expect to secure large crops of fruit, in fact unless the machinery is in good working order and the supply of fuel abundant, we cannot expect a good output. The leaves and roots represent the machinery, and water, sunlight, air and manure, acting together, may well represent the fuel supplied.

The branches of a cacao tree therefore, should be evenly distributed, so that the leaves they carry may be maintained in good health, and just thinly enough distributed to admit sufficient sun and air to mature the fruit.

Then come directions to cut out all useless wood and "gormandizers," and the principle is quoted that:—

Every physiologist knows that unless branches are produced, roots cannot be, and the production of root is in exact ratio to the production of branch.

The author adds:—

If pruning is done by a saw the wounds should afterwards be smoothed over with a sharp knife, as they always heal over better if thus treated. In situations where the cacao beetle or beetles (for there are several species), are plentiful a mixture of coal tar and clay of the consistency of paint should be applied to all wounds.

Pruning with a blunt cutlass, knife, or cacao hook, should never be allowed. The instruments used should

be those only which are able to carry a keen edge; and pruners should always be supplied with the means of sharpening them without leaving the field. Mr. Hart is sceptical as to the popular notion of the influence of the moon on vegetation, pruning is, of course, best carried out at the close of crop time; and Mr. Hart advises the removal of prunings, lest they should breed beetles. The chapter on pruning closes thus:—

Good maxims for the cultivator are, "prune little, but prune often; prune carefully, but prune with decision. Prune for leaves and a crop must come." For Ceylon planters we need not quote what is said about roading and draining; but the following principle is worth noticing, viz. that "the richer the soil, the nearer the roads should be together." The temperature at which cacao can best be grown is indicated by that of the Trinidad Royal Botanic Gardens: mean of 4 years ending 1890, 78·6; mean minimum 69·4; mean maximum 86·8; mean annual humidity (almost important quality of climate, 79. The four years' mean rainfall was 71·55, for 35 years it was 65·49 inches only. Mr. Hart states:—

In my experience, humidity is a much more important feature in plant growth than temperature alone, and no plant suffers more than Cacao at periods when the air is deficient in moisture. Even in the driest weather in Trinidad the Hygrometer shows that during the later portion of the night and early morning the moisture in the air closely approaches to saturation and it is only the readings of the periods between 10 a.m. and 4 p.m. which reduced the record to the average of 78.

Cacao can stand a certain amount of severe drought for short intervals, but districts which are subject to continued drought, are certainly not suitable for the cultivation of the Cacao tree, as under such circumstances the Cacao tree MUST certainly die.

Under rainfall Mr. Hart states:—

Countries in which the mean annual rainfall is greater than in Trinidad may not possess the same humidity, and therefore are not as suitable for the cultivation of our plant, and countries on the other hand which exhibit a smaller annual rainfall may be more suitable for Cacao cultivation owing to the presence of the requisite amount of humidity; for in no country is the humidity fully determined by or coincident with the rainfall, as it is often influenced by many other outside conditions. On the south side of the Island of Jamaica for instance, although a similar temperature prevails as in Trinidad, the humidity shows a remarkable divergence from our record, and in that fact shows plainly that this district is utterly unsuited for the growth of Cacao. Though there are other situations in that Island where the requisite humidity can be obtained and where the tree thrives exceedingly well and produces large crops and fruit.

The planter must not take it for granted therefore, that because he is in the West Indies, Central or South America, etc., etc., in a climate exhibiting a temperature similar to Trinidad, that he can rely upon such a situation or climate as being suitable for Cacao, for he cannot do so, as he will find probably to his cost if he attempts the venture. Having thus learnt what the Cacao tree requires in the matter of moisture or humidity the planter must examine for himself and depend on his own judgment in selecting a spot for a Cacao plantation, especially if it happens to be in a country where the cultivation of that product has not proceeded him.

In the West Indies as in other countries the higher the elevation the cooler the temperature, and the greater the moisture during the hours of darkness, and in hilly situations in well sheltered positions Cacao has been found to thrive owing to the presence of sufficient humidity in places where the temperature is very much below the mean annual of the finest Cacao districts.

Here we close our notice of this valuable handbook on the culture and preparation of a

very interesting and valuable food product, which holds an important place in the estate culture of Ceylon. We have still to deal with the harvesting of the fruit and the treatment of the "beans" to prepare them for the market, on which subject the information is full and interesting. To the remaining subjects treated of by Mr. Hart we hope to address ourselves in a closing article on "Theobroma," the food of the gods, as Ambrosia (Ceylon tea) was doubtless (?) the favorite tippie of the members of the Greek Pantheon.

TEA EXPORTS FROM CHINA IN 1891.

Consul R. J. Forrest reports on the trade of Amoy for 1891 in the following terms:—

Lead, which is used for the lining of tea-boxes, declines in sympathy with the tea trade.

The main exports from Amoy are, in the order of their value, tea, sugar, paper, and tobacco. In roading the following figures in regard to Tea it must be borne in mind that they deal with the exports from January to December of each year, so that both new and old seasons' teas are included in the returns given:—

	1891.	1890.	1889.
Amoy teas lb	3,195,493	3,253,736	3,343,700
Formosa teas lb.	20,275,419	15,087,967	17,992,524
	lb, 23,470,212	18,346,703	21,336,224

These figures represent the total export of Amoy teas and of Formosa teas exported through Amoy to foreign countries and to Chinese ports. The latter took very small quantities, namely, 52,575 lb. in 1889, 92,325 lb. in 1890, and 44,116 lb. in 1891. With the exception of an insignificant quantity of Souchong these teas are Oolongs. For Amoy teas the export of 1891 is the lowest on record, while the Formosa export has not been surpassed. In my report on the tea trade of Amoy for 1890 I remarked that had it not been for the silver question and the speculation excitement created in the United States, 1890 would have been a most discouraging year, and that when trade resumed its normal course it would appear that Amoy's share in the tea trade is gradually and surely decreasing. My prophecy has been fulfilled: the export of Amoy Oolong to the United States has fallen from 1,710,139 lb. in 1890 to 1,163,656 lb. in 1891 and the end of the decline has not yet been reached.

The fact is, Formosa is gradually extinguishing the tea trade of Amoy, and the foreign merchant has to send his agent to Tamsui, where the question as to weight of dollars has not yet been raised. There the native dealers are prepared without cavil to accept as good dollars coins which defacement and chopping have rendered lighter than when issued from the mint. Here they are not.

Mr. T. L. Bullock reports to the Marquis of Salisbury on the trade of Kiukiang for the year 1891 as follows:—

Tea.—Knowing how China tea has been superseded in England by Ceylon and Indian, one at first sight can hardly believe the figures, which show how small has been the diminution in export from Kiukiang. The fact seems to be that, so far as Kiukiang tea is concerned, as the consumption in England declines, that in Russia grows almost *pari passu*.

As compared with 1890 *Black Tea* even shows a certain increase—namely, 25,684,012 lb. or 192,630 piculs, against 184,922 piculs in 1890. But as one can get a fairer idea from a number of seasons together, I have taken the average of the last three periods of five years. In 1876-80 the average export was about 190,000 piculs; in 1881-85, about 205,000 piculs; in 1886-90, about 198,000 piculs. Thus the figures for 1891, though lower than those for the last decade are above those from ten to fifteen years ago.

With *Green Tea*, a less important article, the case is very different. In 1891 the export was 4,615,656 lb.

or 34,617 piculs, almost exactly as much as in 1890 while for the three periods above-mentioned it averaged respectively 49,000 piculs, 48,000 piculs, and 40,000 piculs, so that in this branch of the trade a steady decline has set in. Taking black tea and green tea together, one may say roughly that the export is less than it was when it was at its highest a few years ago by something under 10 per cent.

Brick Tea for Russia, as in 1890, shows only about half the amount that it did two or three years back the figures for 1891 being 2,005,543 lb or 15,041 piculs. Want of tea dust is said to account for this.

Tablet tea appears for the first time in Kiukiang returns, machinery for its manufacture having recently been erected here. The quantity of it shipped was 493,392 lb. Tablet tea is made from the very best quality of tea dust. It is formed by pressure alone into small cakes, which are perfectly strong and solid and rather resemble chocolate in appearance. The material is not, like brick tea, moistened with steam before being compressed, and the flavour is not in any way impaired by the process of manufacture. Taking up little space, and being unlikely to get spoilt or damaged, it presents the best and most convenient form of tea that one can possibly imagine for travellers, backwoodsmen, or armies in the field.

The export of Congou commenced in May and was almost ended in July. That of green tea began in July and was nearly finished in October. Brick and tablet tea began to go away in October, and continued to do so till the end of the year. The export of tea in the three months of May, June and July was 18,600,328 lb., 3,588,843 lb. and 4,141,600 lb. respectively.

The following was furnished to this office by a very high authority, Mr. Alexander Campbell, of this port. Masters of Ningchows began to arrive on May 3, and of Keemungs on May 6. Extreme prices were asked for the former, and no business was practicable here, but the teas met with a good reception in Hankow, where Russian buyers competed for the finest parcels at prices far above the level of last year, the range being from Tls. 60 to Tls. 75 (one parcel at Tls. 75), against Tls. 50 to Tls. 60. The prices paid are accounted for by the fact that "first chops" were usually small. Keemungs, which hitherto have not been in demand for Russia, were more freely offered here, and the finest parcels were bought at Tls. 40 to Tls. 45, being Tls. 3 or Tls. 4 or over last year's rates. Kiukiang pack teas were of average quality, and realised good prices when pure. The first crop was about the same size as last year, or practically 21,000,000 lb. Second crops, Ningchow, began to arrive on June 13. Quality was very poor, and no business took place here.—*L. and C. Express.*

INDIAN PRESERVES.

The demand for Indian preserves and jams has greatly increased during the past few years. In India preserves and jellies are made of the pear, quince, mango, tamarind, date, banana, guava, and other fruits. In Singapore pineapples are preserved whole, and in the Bahamas the manufacture is also carried on on a large scale, to the extent of nearly 1,000,000 cans annually. Each can of fruit, before the syrup is added, weighs 2 lbs. From 12,000 to 14,000 can be filled in a day, and 25,000 pines are usually consumed daily during the season. In Singapore much enterprise has been shown in preserving tropical fruits. There are two or three firms who deal largely in them.

The Indian preserves were formerly much in request. Thus, in the 13th century the most renowned preserve was a paste made of candied ginger. Among other fruits, &c., preserved in their natural state in syrup, crystallised with sugar, or made into jelly, are the pineapple, bread-fruit, ginger, jack-fruit, the papaw, mangosteen, pomelo, guava, and nutmeg. Although in flavour and preparation these preserves may not equal those of Europe, they make an agreeable change.

Pineapple.—The Pineapple is one of the best of tropical fruits, although it is produced of a superior quality by European cultivators. Its sweet and acid flavour, and pleasant aroma, make it sought after by

consumers of all classes. One house in Singapore ships about 70,000 tins of this fruit. Pineapple marmalade (thought by some to be the most delicious preserve in the world) might also be sold at 5d. per pound in London.

Guava Jelly.—There are two species of guava fruit, the red guava, and the white, or Peruvian guava. Both make excellent sweetmeat paste or jelly, which is very pleasant and nutritious, from its superior power of assimilation with the gastric juice, and perfect development of saccharine.

It is said that a hundred different preserves could be made from a judicious blending of the fruits of the East and West Indies and South America.

The jamun (*Syzgium jambolanum*), a sort of long, dark, purple plum, the size of a large date, makes excellent preserves, and has exactly the flavour of black-currant jelly, to simulate which large quantities are sent from India to England. It is also used for flavouring other jams.

The fruits of *Inocarpus edulis* are preserved in the Indian Archipelago. A sweet conserve is made in India of the fruits of *Terminalia Chebula*. Another is made of the fruits of *Phyllanthus distichus*, at Birbhun in Bengal. The acid calyces of the rosella (*Hibiscus sabdariffa*) are converted into an excellent jelly, which would be highly appreciated in England, if once introduced. Jam and jelly are made in Canada from the fruit of *Shepherdia argentea*.

The fruit of *Spondias*, not unlike a cherry, is made into jelly. The scarlet fruit of the quandong (*Fusanus acuminatus*), the size of a small peach, make an excellent preserve for tarts in Australia.

The tamarind plum (*Dialium indum*) of Java has a pod filled with a delicate, agreeable pulp, much less acid than the tamarind. The golden drupes of *Spondias cytherea*, or *dulcis*, a native of the Society Islands, are compared, for flavour and fragrance, to the pineapple. The large acid fruits of the kai apple (*Aberia caffra*) of Natal can be converted into a good preserve of the red-currant jelly class. The fruit of *Cornea speciosa* is delicious; it is called "mangaba" by the Brazilians, and when ripe is brought in great quantities to Pernambuco for sale.

The fruit of the goumi, of Japan (*Elaegnus edulis*), makes excellent preserves, fruit syrups, and tarts. The berries of *Pyrus aucuparia*, and of *P. baccata* are made into comfits, conserves, and *compotes*. The fruits of *Astrocaryum ayri* of Brazil, are made into an excellent preserve, which is much esteemed in that country.

The fruit of the Chinese quince (*Diospyros amara*) is converted into sweetmeats, of which the Chinese are exceedingly fond.

The bread-fruit, in syrup or crystallised, may please native plates, but it is not likely to find favour in Europe, being flavourless, and more of a food substance than a fruit.

Preserved ginger is popular in England, but is not much esteemed on the Continent. The Spaniards eat raw ginger in the morning, to give them an appetite; and it is used at table fresh or candied. Among sailors it is considered antiscorbutic. The quantity of preserved ginger imported ranges annually from 1,500 to 2,500 cwt., value £3,500 to £4,300. It forms the bulk of the succades received from the Chinese Empire, 18,000 to 20,000 cwt. coming from Hong Kong. Some ginger is also received from India. The mode of preparing it in the East is as follows:—The racemes are steeped in vats of water for four days, changing the water once. After being taken out, spread on a table, and well picked or pierced with bodkins, they are boiled in a copper cauldron. They are then steeped for two days and nights in a vat with a mixture of water and rice flour. After this they are washed with a solution of shell lime in a trough, then boiled with an equal weight of sugar, and a little white of egg is added to clarify. The ginger, candied or dried in sugar, is shipped in small squares of zinc. That preserved in syrup, is sent out in jars of glazed porcelain of 6 and 3 lbs., and packed in cases of six jars. The quality called "mandarin" is put up in barrels.

The papaw (*Carica papaya*) is a fleshy, pulpy fruit, of an orange colour, sweet and refreshing, which is eaten as the melon is in Europe. This fruit, however, in syrup crystallised, has very much the taste of a turnip.

The mangosteen is a fruit about the size of a mandarin orange, of a sweet flavour, accompanied with a slight acidity, and an odour resembling the raspberry. It is the produce of *Garcinia mangostana*, and is one of the most delicious and famous of the fruits of the Indian Archipelago, ranking with the pineapple. Presents of baskets of it are sent from Singapore to India and China. It is a pleasant fruit, with a delicate but characteristic flavour, partaking of the strawberry, grape, pine-apple, and peach. The happy mixture of tart and sweet in the pulp renders it no less salutary than pleasant; and it is the only fruit which sick people are allowed to eat without scruple. In Cochinchina they sell at 4s. to 5s. the 100.

The pomelo (*Citrus decumana*) is a large fruit of the orange family, with an acid flavour, frequently bitter. The pulp and thick rind, crystallised with sugar, are eatable, but lose much of their natural flavour. It is better known as the shaddock; and the fruit will exceptionally attain a weight of 20 pounds.

The Mammea Apple (*Mammea Americana*) is abundant in the West Indies. The pulp is of a sweet, aromatic smell, and of a peculiar, yet delicious flavour. It is sometimes sliced and eaten with sugar or wine, and also makes a very good jam, by being preserved in sugar. Another tropical fruit, the *Mammea sapota*, is known as American marmalade, from the similarity of the flavour of the pulp to the marmalade made from quinces.

The succulent fruits of *Cicca disticha* have an acid sweet flavour, and are eaten cooked, or made into preserve.

The green, fleshy, gratefully acid fruits of *Averrhoa Bilimbi* and *A. Carambola* are preserved, and used for tarts, and for flavouring various dishes.

The Conquat, or Kumquat (*Citrus japonica*). An excellent preserve is made from the sweet peel and acid pulp of this curious, small nutmeg-shaped orange in China and Japan.

The red berries of *Carissa corandis* furnish a well-known substitute for red currant jelly, in India and China.

The Peruvian cherimoyer (*Anona cherimolia*) is a highly esteemed succulent fruit, of a most luscious flavour, containing a soft sweet mucilage, resembling strawberries and cream. It is often called the "Queen of Fruits."

The mango, the mangosteen, the custard-apple, and the durian, are known by repute only to the people of this country; but while they might easily be frozen and brought here in admirable condition—dishes fit for the gods—no attempt is made to utilise these luscious fruits of India in their fresh state, nor is very much done in preserving them.

The durian (*Duris zibethinus*), although it has a strong offensive smell, is eaten greedily by the Burmese, and as many as 40,000 are annually sent to Upper Burma.

The mango (*Mangifera indica*) is the best fruit in India, as highly-valued as the peach with us, and forms a considerable portion of the food of large classes of the native inhabitants. The varieties cultivated are about as numerous as are those of the apple. An Indian gentleman has made coloured illustrations of more than 200 varieties of this fruit. The quality is difficult to judge of from external appearance. There are large and small, elongated and abbreviated, bright orange-coloured and green. They vary much in taste, some being of the flavour of honey, some of pineapple, some of orange, while others have distinct flavours of their own. A good mango should be as little stringy, as possible, and should not have too much of the turpentine flavour towards where it is attached to the foot-stalk; a moderately aromatic savour there is by no means objectionable.

The young unripe fruit are largely consumed in India in tarts, &c., and mango-fool there takes the place of gooseberry-fool. The half-ripe fruits are also made into a marmalade which resembles much that of apples.

So large is the consumption of this fruit in India that waggon loads, bringing collectively twenty tons of the fruit, have entered the Island of Bombay in a single day. The fruit of the finest mangoes have a rich, sweet-perfumed flavour, accompanied by a grateful acidity.

The thick juice is by the natives of India squeezed out, spread on plates, and allowed to dry, in order to form the thin cakes known as *amsatta*. The green fruit is sliced and cooked in curry; is made into pickle with salt, mustard, oil, and chillies; and also into preserves and jams by being boiled and cooked in syrup. Some varieties of mango have fruits as big as an infant's head, ovate, with a golden skin, speckled with a carmine, and a greengage flavour.

The finest varieties of this almost unequalled fruit seem to thrive in Jamaica (where it was introduced about a century ago), as well as in Bombay. It is the popular fruit there with the negroes.

The Siam mango is a tolerable kind, which sometimes grows to one pound weight. The egg-mango is a small, yellow kind, with too much of the turpentine flavour, and too acidulous to be much prized. The horse-mango is a very coarse fruit of unpleasant odour, much eaten by the lower classes, and producing cholera, diarrhoea, and dysentery. The Bombay mango, termed "Parsee," is known for its lusciousness and delicacy of flavour, the absence of fibre, firmness of flesh, thinness of skin, and small size of the stone. It must, however, be admitted that on tasting this delicious fruit for the first time, a slight turpentine flavour is experienced.

A raw guava, or even a raw mango, may not be, to every Englishman's palate, a satisfactory exchange for a mellow pear or a juicy peach, but preserved mango and guava jelly are things by no means to be despised. Some of these preserved foreign fruits are delicacies only to be obtained at some of the best West-end houses, at prices too high for ordinary consumers; but if large quantities were sent into the market, and the prices consequently lowered, the demand would become greater, and the sale more profitable, and would probably lead to the introduction of new articles, to the mutual benefit both of ourselves and the growers and preservers of the fruits.

Mango jam is prepared by boiling the mango in syrup, after removing the skins and stones, and the sour juice squeezed out by the free use of forks, and soaking in fresh water. Two pounds of mango to one pound of sugar, is the proportion in which it is prepared.

Bilimbi jam is made by removing nearly three-fourths of the juice of the fruits of *Averrhoa bilimbi*, and soaking in water, squeezing the fruit and boiling them in syrup. Nelli jam, from the fruit of *Phyllanthus emblica*, is made in the same manner; proportion of fruit and sugar same as mango.

From Natal, there have been shown at the various exhibitions, Amatungula jam, the produce of the fruit of *Arduina grandiflora*, sometimes called the Natal plum. This jam is firm, nearly like that of the quince, and has a rough acid flavour; but is a curious and agreeable preserve.

The gooseberry jelly from there is the produce of *Physalis pubescens*. It is pleasantly sharp, without having the rough, metal like acid of the amatungula. The guava jelly has the full taste of the West Indian preserve. The pineapple jam has the rich, almost too-luscious, taste for which the Natal pines are famed. The loquat is a very sweet and fine preserve, slightly resembling quince marmalade, but with less pronounced individual flavour. The fruit is very delicious in its unpreserved ripe state, having the flavour of an apple grafted upon the flesh of the melting peach, with large apple pips taking the place of the stone, and ripening in massive bunches. Like the peach, the fruit is almost too delicate for a preserve. Its most refined and exquisite qualities do not survive the bath of boiling sugar. The rosella is the preserved fruits or calyces of the *Hibiscus sabdariffa*, which makes a most estimable substitute for red currant jelly, particularly relished in hot climates. The grenadilla, the purple fruit of a passion-flower (*Passiflora edulis*), is almost without a rival for delicate fragrance and perfume, has a sweetish acid taste, and makes excellent preserve. The St. Helena peach resembles, in the preserved state, a very excellent yellow plum. The shaddock marmalade might also be spoken of as a worthy substitute for the Seville orange marmalade.—*Journal of the Society of Arts.*

PLANTING NOTES FROM BRITISH NORTH BORNEO.

Mr. J. L. Shand, a Ceylon planter, has been visiting North Borneo. The insight thus obtained of its soil and climate impressed Mr. Shand favourably and of the cultivation at Kudat by the Chinese Mr. Shand speaks with enthusiasm. He considers the future of British North Borneo to lie in the development of coffee, cocoa and coconut plantations; and with regard to the crop on the coffee trees at Kudat he says he never saw blossoms set better nor young coffee looking more promising, and he looks upon Kudat as the future Kandy of British North Borneo. We hear that the Chinese at Kudat meditate the formation of a small Company to grow sugarcane and to erect a sugar mill.

The Segaliud river is well worth a visit at present from those interested in the agricultural prospects of the country. The Liberian coffee on the Trading and Planting Company's estate at Loongmangis is in excellent condition, the rows of handsome plants with their large dark glossy leaves, and the branches weighed down with masses of fruit in every stage of development are very impressive. Alongside these is a plantation *Musa textilis*, the Manila hemp plant from which samples recently taken have been valued at a high price in Hongkong. A few pepper, cocoa, tea and other plants are doing extremely well, the former, growing on poles like hops do in England, are smothered with bunches of pepper; one tea plant was over seven feet high, and very bushy. A good many cotton plants of true Sea Island seed were scattered about the place; these also are in very good condition and in heavy bearing, and are suggestive of a large export in the future.

To encourage cultivation in these provinces over 110,000 coffee seedlings have been issued. As no person was sent there to instruct in mode of selection of seedlings and of seeds, it is regrettable that so many young plants should have been grown from seeds taken from inferior trees. It will probably discourage coffee growers.—*British North Borneo Herald*, May 1st.

SEMI-TROPICAL FRUIT CULTURE.

The census bulletin on tropic and semi-tropic fruits and nuts contains a large amount of more or less valuable information. It appears that there were in the census year of 1890 the following areas devoted to the cultivation of this class of products: Almonds 13,515 acres; bananas, 677 acres; citrons, 169 acres; coconuts, 9,364 acres; figs, 4,477 acres; guavas, 550; kaki (Japanese persimmons), 1,362; lemons, 7,256; limes, 495; Madeira, nuts (English walnuts), 12,180; olives, 7,097; oranges, 184,003; pineapples, 2,189; pomelos, 171, and pecans, 27,419. The average of non-bearing trees is about twice that of the bearing, so that only about a third of the acreage given is at present producing crops. The product of this acreage at the time the returns were made was valued at a total of \$14,116,226, divided as follows: Almonds, \$1,525,109; bananas, \$280,653; coconuts, \$251,217; figs, \$307,271; lemons, \$988,099; limes, \$62,496; English walnuts, \$1,256,958; olives, \$586,368; oranges, \$6,602,099; pineapples, \$312,159; pomelos, \$27,216, and pecans, \$1,616,576. On the basis of present prices, with all the non-bearing trees in fruitage, the next census ought to show a product worth over \$50,000,000.

The production of the fruits and nuts under consideration is confined largely to the states of California and Florida, but figs, oranges, kaki and pecans were found growing to a considerable extent in all states bordering on the Gulf of Mexico. While Louisiana and Arizona have each a considerable acreage in oranges the trees of Arizona are nearly all young and of recent planting.

In all these investigations it has been found that the great march of progress moving in other lines of industry has not left these behind; in fact, so rapid is now the increase in citrus fruit planting and so favorable are the conditions, especially in California, that there are many well informed in the business who

believe that within another decade the United States will not only produce its full supply of citrus fruit, but also export them quite largely.

The acreage, of oranges, as a matter of course, exceeds that of all the other products, yet the possibilities of pineapple culture on the southeast coast of Florida and for 100 miles north of Key West, on the gulf coast, are such as to give promise of a very great and profitable extension of the culture of this delicious fruit.

Pecan culture in northwest Florida and all the gulf states has apparently just begun to develop some of its wonderful possibilities as a reliable and profitable crop, while there is every reason to believe that within a few years the figs, olives, Madeira nuts and lemons of California will rival in value of her wondrous crops of oranges, and yet a comparison of the tables of bearing and nonbearing trees will show three times as many nonbearing as bearing orange trees in the census year, and as planting has been going on more rapidly than ever since the census was taken the number of orange trees now growing in California must be nearly double that of eighteen months ago, all of which means an output of at least 10,000,000 boxes of oranges from California before the end of the present century.—*Bradstreets*, April 9.

INDIAN TEA AND THE CHICAGO EXHIBITION.

We have more than once recently urged upon all connected with the Indian tea industry the immense importance of making a good fight for the American market on the occasion of the Chicago Exhibition. It is gratifying, therefore, to learn that the leaders of the tea interest in Calcutta are alive to the nature of the opportunity, and are resolved to make the most of it. The Indian Tea Association is publishing a paper written by a well-known Indian planter, and read before a meeting of the Committee of the Indian Tea Districts Association, London. It contains practical suggestions with regard to the financial side of the question, and should give an impulse to the movement. Already, it seems, Ceylon has secured a large central space at the Chicago Exhibition, and has deputed two gentlemen to proceed there at once to superintend the necessary preparations. A fund of \$2,000,000 is to be raised, of which the Government has given \$500,000, the Chamber of Commerce \$350,000, and individuals \$200,000, the planters being expected to raise \$650,000. A Ceylon Company in America with a capital of a million dollars, and with agencies in all the large towns, advertising in fifty newspapers, is to aid in the work of pushing Ceylon tea, so that their efforts will not be confined to Chicago but will extend all over the United States. For years past Ceylon has shown what can be done by pushing and advertising, and in the present instance she is setting an example that will not be lost upon India.

Already the General Committee of the Indian Tea Association has appointed a sub-Committee to collect subscriptions, which, added to money collected in England should amount to a respectable sum. All gardens are invited to subscribe two annas per acre, which should bring in about \$25,000, and subscription lists will be circulated in all districts among agents, managers, etc. A good beginning has been made in Calcutta, the following firms having put down their names for \$1,000 each:—Messrs. Williamson, Magor & Co., Jardine, Skinner and Co., Balmer, Lawrie and Co., J. Thomas and Co., Begg, Dunlop and Co., Octavius Steel and Co., Finlay, Muir and Co., Gillanders, Arbuthnot and Co., Kilburn and Co., and Shaw, Wallace and Co. The subscriptions of these firms make a substantial total of \$10,000 which is a good guarantee for the collection of the full amount that may be counted necessary. On former occasions when combined action in the interest of the Indian tea industry has been called for, the matter has generally been left to the Calcutta agents and brokers. But now it is hoped that the whole industry will be fully represented and that all connected with it will combine to ensure

the success of the Chicago project. When the question of out-bidding Ceylon at Chicago was first raised in these columns, it was pointed out that India can produce finer tea than our southerly neighbour. Unfortunately it must be admitted that the tea produced in recent years has not always been of a quality that would bear comparison with the finer samples of Ceylon. As our correspondent "Enterprise" wrote on the 29th ultimo:—"Your article on the quality of Ceylon tea will be read with interest by all concerned in the welfare of Indian tea. That India can produce finer teas than Ceylon there is no doubt, but managers of late years have been sacrificing quality for quantity, which has proved a fatal and ruinous mistake. There is no doubt, moreover, that Ceylon owes much to advertising and push; and India, it may be hoped, has learnt a lesson which should make her put forth all her energies. The forthcoming Exhibition at Chicago should be a favourable opportunity for retrieving lost ground." It is true that India has lost ground in the competition with Ceylon, and that with half the courage and energy displayed by Ceylon, we should by this time have secured a very different place in the markets of the world.

There is something absurd in the spectacle of India engaging in a struggle for supremacy with Ceylon. Had we bestirred ourselves at the proper time, the necessity for such a contest would never have arisen. But while we chose to rely upon our natural advantages, and were content to wait till China tea had lost its hold of the market in the mere lapse of time, our aggressive rival in the South adopted a much more rational policy. Striking out vigorously and letting all the world hear of its virtues, Ceylon rapidly secured a front place in the trade, and it is somewhat humiliating to have to confess that India has benefitted in no small degree by the extensive advertising of her rival. The superior qualities of Ceylon tea being constantly and loudly trumpeted to people who had hitherto believed in nothing but China, it is obvious that the popular taste by an easy step in progression would extend to the tea of Assam. To the near-sighted and economical there was even something pleasant in the idea that we were gaining by a side-wind from the advertisements for which our rival had to pay. It was not observed that we were losing a great deal more than we were gaining, or that Ceylon was taking the lead in the display of all the qualities which contribute to the success of a large enterprise. Our conversion has only come with the consciousness that we are being beaten in the race. We have much to learn from Ceylon, especially in the arts by which she has advanced her fortunes, and in the methods of powerful combination which alone rendered complete and rapid success possible in such an undertaking. In one respect Ceylon is to be envied. The local Government is evidently proud of the spirit which has signalled the new departure, and is prepared to encourage the trade by a liberal measure of assistance. The contribution of the Government to the fund in connection with the Chicago Exhibition is on a generous scale, and will enable Ceylon to offer a formidable opposition to all comers in the contest for the great American market. And the object is certainly well worth a struggle. It has long been a reproach to India that her exports of tea to America have been so insignificant. The inhabitants of the United States, while they abhor the Chinese, are somewhat behind the time in their preference for the tea of the Flowery Land. In this respect their education has been sadly neglected, and it is high time that the deficiency was being looked to by Indian emissaries. The conquest of a Continent is a notable ambition, and the United States with its population of sixty-three millions offers an inviting field for Indian enterprise.—*Englishman.*

NEW SEASON FOR CHINA TEAS.

The news that the market at Kinkiang is on the eve of being opened, as reported by special telegram, reminds us that the period for the commencement

of another season for China teas is drawing near, and that before they have advanced far into the present month the trade will be calculating the time when the first vessel with the new season's Monings will probably arrive in the "Thames." But although it is formally announced, according to old-established usage, that the market for Chinese teas is opened so early this month for the year 1892-93, it does not follow that business will immediately begin, for, from what we hear, the Russians are nothing like so eager to operate as they were in 1891 or most previous years, having, on the contrary determined to adopt very different tactics with the traders of the Flowery Land from what they did last year. Then the Russian houses made a grand demonstration in favour of the new teas, and paid as much as 2s 2d to 2s 6d and even upon to 3s per lb. for what they required—prices almost as high as the Chinese in their "hongs" were pleased to ask. This hold not to say rash, action of theirs entirely spoiled the market for English purchasers, whose instructions as to buying did not admit of their giving more than 1s 6d to 2s per lb. at the outside for the finest chops, and the greater part of the first crop teas, as may be imagined, passed into the hands of the Moscowite merchants, who in the excitement of the hour, no doubt fondly imagined that they had secured most, if not all, of the best bargains in new teas.

These fierce Russian operators, however, not long afterwards found out the mistake they had committed in buying hand-over-head at such extravagant figures as the above, and as the season 1891-92 progressed they discovered to their dismay that when the teas arrived at Moscow and other principal cities, and sales had to be pressed, the highest bids that could be extracted from local buyers were 1s. to 1s. 6d. per lb., or 50 per cent. below what the black and red leaf had cost in China some months back. It was generally remarked by those who held aloof that the opening rates for China tea last year were quite unwarranted, for, besides giving a deal more money themselves for the earliest shipments, the Russians not only "burnt their own fingers," as the saying is, in making their contracts, but also caused their rivals or competitors to do the same by sanctioning a range of prices which was injurious to all parties; and many London firms, wholesale dealers as well as import merchants, have had to rue the day when they rashly gave for choice Moning and Kaisow sorts quite 1s. per lb. more than they were really worth. In fact, the whole season may be said to have been wasted, so far as the European trade were concerned, by fruitless attempts to realise the 1891-92 teas at anything like remunerative rates, and a serious contraction of operations has been experienced accordingly. Instead of confidence prevailing, nothing but mistrust has been bred, and the new season for 1892-93 opens with a determination on the part of Western buyers not to purchase an ounce of tea except on pretty much their own terms. Nearly all bidders for the new teas at Hankow will now be seen playing a waiting game, as the English have already let it be clearly understood that they will not be the first to go in and buy, whilst the deplorable state of commercial affairs at home, through the ravages and distress occasioned by the rye famine last year, will prevent the Russians from taking the lead in clearing off the tea as it arrives from up the country to the shipping ports. When it is remembered that most of the China tea in London has been sold during the season now closing at marvellously cheap rates 10d. to 1s. per lb., and several pence under,—it is not the least surprising to hear that the merchants this year intend adopting a strictly cautious policy, and will be careful not to plunge too deeply into engagements until other persons have satisfied their most pressing wants. This may not be until the second-crop teas come down for sale at such rates as would accord with the value here, which, at the utmost stretch of the merchants' limits, is not above 1s. 6d. to 1s. 7d. per lb. for the finest qualities; and offers on this basis will no doubt act as a great shock to the ideas of

the "native Chinese," accustomed has been to receiving relatively fancy prices for his produce.

London statistics of China tea are favourable only as regards the quantity on hand, which is exceedingly light, and of Congou only 14,934,050 lb., in contrast with 25,404,400 lb. last year, and 38,433,750 lb. at the end of April in 1890. Reckoning that eleven months of the 1891-92 season have elapsed, the landings of all kinds of China tea since the beginning of June last have not been more than 60,000,000 lb., in comparison with 69,497,550 lb. in 1890-91, and 39,771,100 lb. in the same period of 1889-90. The falling-off in the supply within two years is thus shown to have been no less than 29,771,100 lb., which no amount of reasoning can prove to be otherwise than serious, especially as a great part of this deficiency is reflected in the deliveries. These in the past eleven months have shrunk more alarmingly than in the previous season, having been only 63,426,550 lb. against 75,219,500 lb., whereas the difference between that total and the corresponding one in 1889-90—when the delivery was 76,073,150 lb.—was not more than 858,650 lb. It is therefore to be hoped that the coming season will witness a recovery in the trade for China tea.—*Grocer*.

THE MICA MINES OF NELLORE.

Dr. Warth, Officiating Superintendent of the Central Museum, has just written a most interesting Report upon Mr. E. H. Sargent's mica mine near Inikurti, a place 19 miles from Nellore. Mica is the talc of commerce, although scientifically speaking the latter is quite a distinct mineral. In elastic and generally transparent plates mica is used for a variety of purposes, chiefly as a substitute for glass, as it bears sudden changes of temperature better and is not so liable to be broken. Some idea of its value may be gathered from the following approximate rule for calculating the price of ready-cut selected rectangular pieces in London. One pound weight costs as many times twopence as each single piece has square inches surface. This equation holds good between 10 and 100 square inches. Below these limits the prices are smaller and become finally *nil*! above these limits they are higher and would end in fancy prices. Although Mr. Sargent's mine has only reached a depth of 80 feet, no less than 20 tons of pure ready-cut mica have been extracted during the past two years. In fact, Mr. Sargent's enterprise has been highly successful. It appears that the first indication for this deposit was a ridge of quartz which stood eight feet above the surface of the plain. Then Mr. Sargent found old excavations on the west side of the ridge, which he followed up. It is very likely, Dr. Warth thinks, that similar deposits exist in the neighbourhood, but such facts could only be proved by trial excavations, aided by the existence of quartz ridges and traces of broken mica. At a distance of about 10 miles to the south Dr. Warth found quite a group of more or less successful mica mines in similar rocks near the village of Utkur. The mica was associated with the same white quartz and whitish felspar. There were also the same accessory minerals, garnet and tourmaline. One mine, called Sukhagini (black stained mine), produces mica which is stained black and brown through the spread of manganese ore and iron between the planes of cleavage. Some slabs of very clean surface without any cracks whatever, 27 inches by 32 inches, were in store. The price of these would have been fabulous if they had not been black. We further learn from Dr. Warth's Report that the sorting of the mica is very important for the trade. A large quantity of the mica is thrown away at the pit, where the waste heaps glisten in the sun. Of the mica brought to Mr. Sargent's stores at Inikurti only about 23 per cent is finally selected for the trade. Everything else is thrown away, being either cracked, not sufficiently transparent, ripple-marked, or too small. The smallest limit of rectangular size is 2 inches by 2 inches, but such small sizes are at present very cheap, as Bengal exports too much of it. The pieces are all cut according to

rectangular standard patterns. Pieces of the same pattern are then tied in bundles and so sent to London. Dr. Warth thinks that such successful mining should be continued and extended by granting favourable concessions to trustworthy Companies applying to take up the industry. Government, in its Order on his Report, concurs in this, and we may therefore expect to see a further development of the mineral in the near future. The corundum deposits of Salem and Coimbatore also deserve attention, and we should like to see Dr. Warth deputed on special duty to report upon them.—*M. Mail*, May 19.

MACHINERY FOR THE PREPARATION OF TEA.

It is now between thirty and forty years since the systematic planting of the tea bush commenced in the northern provinces of India, and from the date of such commencement there started that competition which has now almost succeeded in ousting the teas of China from the home market. The progress made with such suppression was, however, for many years extremely slow. It was not until Ceylon, as the result of the failure of coffee cultivation there, began to grow tea some eighteen years back and joined in the competition, that the trade in the China growth began perceptibly to fall off. The decadence of that trade is now so great, that in course of but a few more years it may be expected to cease altogether. The losses incurred with respect to it during last year have amounted to no less than £750,000, teas, the cost price of which in China had been two shillings per pound, having fetched rates in the London market varying between 1s 4d and 1s 6d per pound only.

Having thus briefly sketched results to the competition exercised by British growers of tea, we may turn to the express subject of this article, the means which have mainly contributed to render that competition so successful. We have on several occasions described and illustrated some of the machines which have been designed for the preparation of tea, but these have been but as a drop in the ocean compared with the enormous number of patents taken out both in India and Ceylon for inventions having that process for their object. It would of course be invidious in an article like this to specify any particular invention of this nature, and it is apart from our intention to do so. We shall content ourselves with a description of the needs which these many and various devices have been designed to supply, for to the success of some of them has doubtless been largely due the astonishing rapidity with which the imports of China teas into the London market have dwindled. To effect this object it is necessary just to glance at the methods used by the Chinese from time immemorial for the preparation of the tea leaf. It must be premised that the system of growth by that people has ever been entirely different from that which has answered so well both in India and Ceylon. Nothing like the large plantations of those two British dependencies is, or has ever been known in China. The crop of this latter country is derived from myriads—so to speak—of small gardens, every peasant cultivating a few bushes around his hut. The gathering, and all the subsequent manipulation of the leaf, is performed by him, and he has to retain the trifling outcome of his individual industry until the buyer—the middleman—calls for it at intervals of a few weeks or months. As the consequence of this waiting, the tea falls off both in strength and aroma, a depreciation unknown to the estates of India and Ceylon, where the leaf may be plucked, withered, rolled, dried, packed, and shipped, within the course of a few days only.

But it is with the manipulation by the Chinese peasant that we have first chiefly to deal. He spreads the green leaf when plucked upon the soil surrounding his cottage. This is often done without the protection of matting; and in that case the leaf often

becomes contaminated during the process of withering from the unsavoury conditions of the soil in the neighbourhood of a peasant residence. The succeeding operation is the rolling of the leaf between the palms of the hands, and it is certainly during this somewhat disagreeable process that Chinese prepared tea acquires most of the deteriorating qualities which experts assert it to possess. The tea is next dried on pans over a charcoal fire, and is, of course, often exposed to the obnoxious fumes of that fuel. With the further operations of packing we need not here concern ourselves. It is with the three operations described that we have to deal. As to the first of these, the withering, modern mechanical design has but little to do beyond ingenuity shown in providing withering rooms, the temperature of which is equably maintained, the air being at the same time kept free from moisture by suitably designed screens for its inlet. Several of the inventions to which we have referred have been made with this latter object—no unimportant one to the final quality of the tea. The machines for treating the leaf in this withered state, by rolling it into the form to which we are all accustomed, form perhaps the most important of all those in use. At the same time the difficulties as to effectually superseding the use of the human hand, with its delicacy of touch and movement acquired by long practice, have been great, for it is an absolute requirement that the leaf should be rolled only just so tightly that it will not break by after-handling when submitted to the final drying process. A great number of comparative failures had to be faced before this requirement was attended to. Anyone who reflects upon the diversity of movement which can be accomplished by one palm superimposed upon the other will realise how difficult it must have been to select that one among that infinite variety which would yield the most-to-be-desired result. Differential speed movements between the revolving surfaces employed in, we believe, all the inventions patented with this object were tried, *ad infinitum* almost; but even when the best relative speeds were apparently settled upon, these were found not to be equally suited to all conditions of the withered leaf. It is said that the method now largely and the most successfully employed was, as has so often been the case, the result of an accident. The top plate or cover of a certain machine became loose, and owed its propulsion mainly to the dragging effect of the mass of leaf moved by the under-revolving plate. The speed so given seemed to accommodate itself naturally to the requirements of the charge under treatment, and the system so determined seems to be almost incapable of improvement.

The final operation, that of drying, is performed by a wholly different class of machines; some of which we have on previous occasions illustrated. The number of these protected by patents is very great, and the Law Courts of India and Ceylon witness many disputations over their infringement. The general principle of all of them is the same almost invariably; the tea is exposed to a current of heated air, of such a temperature that it is necessary to keep the leaves moving to prevent them from becoming burned, or what is technically known as "over-fired." The diversity of the methods employed to secure this immunity, and to guarantee the equal drying of the mass of leaf, is great, and we do not here pretend to assert that one patent has in any respect advantages over another; for the planters both of India and Ceylon exhibit a preference for machines of very diverse design, each one of them selecting that which his experience suggests to him at best. It will readily be conceived from what we have written that the machinery outfit of a large tea factory of modern character is by no means inexpensive. The engine power required to give it movement is also considerable, and in one way and another the introduction of preparing tea by mechanical agency has done much to support the engineering establishments of this country. From this point of view alone, we should recognise the benefit this new form of an old industry has conferred upon many classes among our

own countrymen. But to these this has not been the sole gain. Practically, it has by its purifying methods largely added to the healthy qualities of the decoction, the consumption of which enters so largely into our national bill of fare, while in combination with a more extended system of culture, it has enabled all of us to now obtain thoroughly good tea at from 1s. 6d. to 2s. 6d. per pound, for which not more than twenty years ago we should have had to pay from 4s. to 6s. a pound. The difference thus made to this form of "national drink bill" can well be realised, while to the same cause we mainly owe it that instead of having to send many millions sterling to China annually, our remittance is made to our own fellow subjects of the Queen, a healthy stimulus being afforded thereby to the success in life of many hundreds of our sons, to find an opening career for whom is now one of the greatest among the many social difficulties of the day.—*Engineer.*

LIBERIAN COFFEE IN JAVA.—In West Java, Liberian coffee is coming into greater favour for cultivation than the Java article, owing to climatic conditions giving the African berry the advantage, provided the ground be not too high lying. Liberian coffee now readily finds buyers at Amsterdam, and also in America. Fair Java, it is said, brings at the utmost 54 to 54½ guilder cents per picul, while Liberia fetches 56 cents a picul.—*Pinang Gazette.*

ERYTHROXYLON COCA.—As there is still some demand for this plant among correspondents in tropical countries, attention may be called to the fact that fresh seeds of it may be sent long distances without losing the power to germinate. A quantity of seeds of the typical plant, with broad-pointed leaves, received at Kew from Ceylon on January 29th, and sown at once in a tropical house, have germinated feely. They were packed in a small tin box in slightly moist soil and sent from Ceylon by post. Plants of *Erythroxylon* do not travel well in Wardian cases.—*Kew Bulletin.*

PRONUNCIATION OF PLANT NAMES.—Many estimable persons, and well-educated to boot, yet show themselves capable on occasions of perpetrating shocking atrocities. Take, for instance, that very popular plant—the Dahlia. It was called Dahlia to perpetuate the memory of a Swedish botanist and doctor by the name of Dahl, a pupil of the illustrious Linnaeus; yet in spite of this, in spite of the spelling, in spite, indeed, of every good reason, many good people will persist in miscalling a Dahlia a Dalea. Now there happens to be a plant rightly called, as it is also spelled, Dalea. This, however, is something very different to the popular garden flower, the Dahlia. Dalea was so called after Dr. Samuel Dale, an English botanist of the last century, and it belongs to the natural order Leguminosæ, while the Dahlia is one of the Compositæ. In miscalling Dahlia Dalea, not only is a gross error in pronunciation made, but a slight is offered to the memory of a Swedish botanist, and a wrong done to that of an English one. [A foreigner would pronounce Dalea as Dablia, so that the balance is redressed.—Ed.] There may be excuse for miscalling *Olémais* *Olemátis* and *Wistaria* *Wisteria*, but none for making *Camellia* *Camilla*. Will not the horticultural press make another effort to establish a pronunciation of at least these few popular plant names? *J. E. Ewing.*—*Gardeners' Chronicle*, May 7th. [The writer might have also instanced the fuchsia, named after Fuchsia, a German botanist, but invariably pronounced fushia, and often misspelt fuschia.—Ed. T. A.]

FROM THE METROPOLIS.

May 13th, 1892.

THE TEA TRADE AND PROSPECTS OF CEYLON [TEA.

Important news has reached me from the City in reference to the China trade which, in respect of tea and silk, is said to be in a very bad way. Apart from the disturbing political and social outlook in that Far Eastern land—which some regard as importing the near approach of the Revolution of far-extending influence—London bankers and financiers had such an unhappy experience last year that they are reported to have refused advances to a very considerable degree during the present season. The chances therefore are that the import of China tea into the United Kingdom this year will show a large falling-off even on the diminished supply of 1891. I need scarcely say how such an experience is calculated to benefit the Ceylon planters, but it is impossible to make quite sure as yet of the diminished importation; because the persistent cry that Ceylon Tea Exports for 1892 have been “largely” overestimated has undoubtedly encouraged a spirit of speculation in “Chinas” for which a certain amount of capital will no doubt be found. Probably, a good deal will depend on the ratio of the exports from Ceylon during May and perhaps even June. Should they show no special increase, we may see further orders passing by wire to the China ports. Meantime, the China tea producers and middle-men are likely to have fewer orders from Russia owing to the “famine” and the consequent discouragement to trade and scarcity of money. This may perhaps lead to such a fall in prices even for fine teas at Shanghai and Foochow, as would further encourage the speculative export of such to England. We shall see.

NEW MARKETS FOR INDIAN AND CEYLON TEA.

Messrs. Gow, Wilson & Stanton have issued one of their interesting coloured-diagram circulars at this juncture on the above subject. A supply of these will, I believe, reach you by this mail and the circular and diagrams are certain to excite very general and great interest; for the object is to draw such attention to foreign markets as may aid in showing how they can absorb all the Indian and Ceylon tea not required in the United Kingdom in 1892. In the first place, they estimate the crop of Indian and Ceylon tea at about 210 million lb. This must be made up in round numbers of

Indian Tea	..	130,000,000 lb.
Ceylon „	..	80,000,000 „

210,000,000 lb.

And of this they do not estimate that the United Kingdom will consume more than 170,000,000 lb.—leaving 40 millions for all markets outside Great Britain. Seeing that in 1890 countries outside only took 14 millions and in 1891 but 20 millions, double the latter is a big order to deal with for export in 1892. Nevertheless, good reasons are adduced why all concerned should aim at, work for, and expect such a result. There is no need here to go into the interesting details supplied in the circular; but certainly in respect of Australasia which consumes altogether 30 millions per annum, and last year only took 4½ of Indian and 3¼ of Ceylon teas, there is ample room for a special increase. Then again America and Canada are undoubtedly beginning to respond and they ought very shortly to take far more than 3 or 4 per cent of their teas from India and Ceylon. The Chicago Exposition is, of course, expected to exercise a favourable influence; but it is a matter of regret that India and the Indian tea planters especially do not at all take up this “Exposition” business

with the heartiness of Ceylon. This was the complaint to me this week of Mr. S. Digby—who has been nominated Secretary to the Indian section of the Exhibition Committee—though he is hopeful that at least the Government will do its duty. If it votes as much as Ceylon in proportion to revenue, there should be a goodly sum. Persia, Russia and Holland are favourably referred to; and in regard to the latter especially, I am surprised to see so much made of the activity of the Dutch tea-consuming market; for, in my opinion, Holland should take off every pound of Java tea, in place of consuming only 563,000 lb. of tea last year and allowing some millions to be thrown on the London market.

THE CEYLON TEA INDUSTRY AND ITS STABILITY.

Such is the subject of a very interesting discussion in the *Financial News* of this past week, to which my attention has been kindly called by Mr. William Gow who sent me the cuttings I forward for insertion, namely a leading article (perhaps more or less inspired by Mr. Hawes), a letter of correction from the leading Brokers, Messrs. W. J. and Henry Thompson, and a rejoinder from Mr. F. Sutton Hawes, also a buyer and seller of teas. I must leave to speak for themselves in the meantime: they reached me just as I was starting for Bedford, and a suggestion made that I should notice the discussion perhaps by a letter to the editor in further correction of Mr. Hawes, may perhaps take effect before next mail, when, of course, you will hear about it. For the present here is what has reached me:—

CEYLON TEA.

To the Editor of the *Financial News*.

SIR,—In reading your interesting article about tea, we were somewhat surprised to find it suggested that Ceylon is not likely to remain a good tea-producing country, as the climate or soil exhaust the good qualities of the plants, and that the gardens year by year decline into producing only common and medium teas. In some few instances, where an unsuitable site was chosen for the plantation, this may possibly be the case; but there is ample evidence that the Ceylon tea industry, as a whole, has the elements of stability, and has no special reason to fear deterioration of the plant.

As we sold, and are still selling, the produce of the estates which were the first to send tea to market ten and twelve years ago, and have constantly before us samples from an immense number of estates which have been producing tea for six or eight years and more, we have reason to know that old Ceylon gardens can produce tea of the finest quality when it answers the purpose of the proprietors to make it.

The real reason why the bulk of the crops sent home of late are marked by what appears to be deterioration of quality is that the position of the tea market some time ago induced the great majority of planters to cease making fine tea, and to produce, instead, as large a quantity as they could—which has, of course, been done at the expense of quality for the time being.

Many of the Indian planters have adopted a similar policy with a like result: but no one would argue therefrom that the tea plants in India are deteriorating, which would be contrary to all experience.—We are, sir, yours, &c., WM. JAS. AND HENRY THOMPSON, Brokers.

38, Mincing-lane, May 6.

THE CEYLON TEA TRADE.

To the Editor of the *Financial News*.

Sir,—In answer to the letter in your issue of today from Messrs. W. J. and Henry Thompson, I beg to state that I have been also largely interested, as a seller and buyer of Ceylon teas, ever since they were first imported to this market, and follow the trade closely. My experience has been distinctly opposite to what they express to have been theirs, and I could

name very many gardens that formerly were conspicuous for the excellence of the teas which now never produce any but good medium, medium, or common qualities. I believe the statement in your article is generally accepted by those most largely interested in Ceylon teas here to be a correct one. I was talking to one of the leading Ceylon tea brokers and to one of the largest buyers of Ceylon teas on this market today on this subject, and they both expressed their opinions as distinctly opposite to those of Messrs. Thompson. It is certainly extraordinary, when for the last six or nine months choice Indian, Ceylon, and China teas have been exceptionally scarce, and on all sides the want of better teas has been acknowledged—particularly that of Ceylon tea—and in various brokers' circles the hope has been constantly expressed that Ceylon planters should make more good and less common teas, that they should not have done so if they could.

As Messrs. Thompson state, "there is ample evidence that the Ceylon tea industry, as a whole, has the elements of stability"—it may have stability; but still may, and I venture to say has every fear of deterioration of the plant, if the present wholesale plucking is continued. Unfortunately, a good profit can be made by growers out of medium and common as well as of fine teas, if the supply does not overrun the demand, and so reduce ordinary to extraordinary low rates here.

The humid atmosphere and fertile soil of Ceylon cause the plants to grow fast and yield abundantly, and the greed of the average planter makes him take from the plants all they will yield, not giving them the proper time to rest. The tea plant is in the position of a human being, or any animal: overwork them, without sufficient rest and nourishment, and in due time their systems become enfeebled, and they break down. Regarding what Indian as against what Ceylon planters may do, I think Messrs. Thompson's comparison is a mistaken one, as the climate, soil, and various other conditions are different. Again when Indian and Ceylon teas were first imported, and were from newly-planted gardens, and mostly from virgin soils, there was, in comparison, much less common and much more fine teas than there are now. Of course, many estates, both in India and Ceylon, in exceptionally favoured positions, and under good management, may for a more lengthened period produce a finer class of tea than their less favoured neighbours; but I am speaking of the majority, not the exceptions. The immense quantity of common teas we have had from India the last two seasons, which we know have not generally realised profitable rates to the growers, when fine teas would have been remunerative, does not give one the idea that they are so easily made as Messrs. Thompson would have us believe.—I am, sir, yours, &c., F. SUTTON HAWES.

14, Mincing-lane, E.C., May 9th.

FEMALE ENTERPRIZE IN THE TEA TRADE.

It is undoubtedly the case that the weaker sex have in times past—namely those of the days which followed the collapse of the coffee industry in this island—been among the chief sufferers from the reduction of means caused by that failure. There can scarcely be one among us who has not heard of the straits to which many ladies well known and esteemed among us were reduced during those sad times. The husbands or fathers in very many instances had succumbed to the intense strain which then had to be endured; and many ladies of high culture found themselves cast with their children upon the world, and face to face with embarrassments and difficulties which they were but ill-fitted by their training to endure and overcome. We could narrate, were it now our object to do so, many such sad instances known to us; but the almost universal knowledge as to these, and the reflection that they are now happily things of the past,

render it unnecessary that we should do this. But apparently time is bringing about its revenges, and those to whom we have above referred as having suffered so greatly during our former experience are, we are told, at length participating in the happier state of things produced by the success of our tea cultivation. We do not know which amount of dependence may be placed upon the statements of the paragraph appearing in the *Daily Telegraph*, which has found quotation in the last letter of our London Correspondent. These may possibly, and not impossibly, be wholly correct; and it may be that among our numerous readers there will be those able to fully verify them. There can be nothing extraordinary in the fact of seven ladies combining together to become the proprietors of a Ceylon tea estate, or in their further efforts to dispose of its produce by their own direct agency and labour. The openings for female employment at home are, as is well-known, exceedingly few; and we shall be glad indeed if this recorded effort to open up a new one should result in the fullest success. There seems to be something sentimentally appropriate in the handling of such a delicate article as tea by the dainty hands of English ladies. The packing of it in packets, and the many other ways in which it may be manipulated for the retail trade, is a work not necessitating any heavy amount of manual labour. Indeed we may regard such work as being specially adapted for females; and we should be pleased to hear that the example now said to have been set had found a wide circle of imitators. But although, as we have above admitted, we are in no position to vouch for the accuracy of the information given by the *Daily Telegraph*, it is a thing well-known to us that in a less direct way hundreds of English ladies have for a good many years past been adding to their income by acting as the agents of friends or relatives resident here concerned with tea production. The sad pinch of necessity that, as has been pointed out, told so sadly upon the means of many ladies formerly resident in Ceylon compelled these to lay aside all scruples which the prejudices of a lost position had engendered; and among the many who have taken an active part in aiding towards securing for our teas the popularity that they now enjoy few have contributed more largely than former friends of ours of the opposite sex who have tempted by skillful infusion and dainty accompaniments their numerous friends and acquaintances into a thorough appreciation of the flavour and qualities of Ceylon teas. We can scarcely imagine a male creature so sternly moulded as to be able to resist the pleadings of a fair hostess, who, after supplying the most efficient proof of the qualities of her "brew," pleaded on behalf either of herself or her relatives that her guest should in future supply himself with tea furnished by herself. We all know how efficacious is female pleading; and if reserve were not too far maintained, a hint that its own necessities actuated the pleader could not fail of insuring a willing and satisfied.

COFFEE CULTIVATION ON THE KAREN HILLS.
—In his report on cultivation during 1891-92 at the Nanco Estate, Karen Hill Tracts, Mr. Pelley says:—

The outturn of this year's crop of coffee, the gathering and clearing of which has just been completed, has been very disappointing; there is only half of what was at first anticipated, from the following causes:—

1. At the blossoming of the trees in April heavy

squalls of wind scattered the flowers before the fruit set to a much greater extent than was supposed.

2. During the season the meagre state of the rains much retarded the development of the berry, while afterwards the late and unusual rain at the time of ripening (November and December) damaged the fruit, or "cherry," seriously splitting and causing a large proportion to dry up.

3. Much loss was no doubt suffered owing to the weeds not being kept down, nor the trees properly attended to, from want of sufficient labour. It is clear, however, that the land of these hills is favourable to the production of good coffee, as shown by its well known excellent quality, the disastrous small outturn being due to the abovenamed causes.

4. The young plants sets out on the newly prepared ground of five acres (*vide* last year's report) have come on well thus far with scarcely a single failure, and further clearance of 5 or 6 acres has been made. The total area of coffee under cultivation is about 60 acres, namely, 40 acres of mature trees and 20 acres of immature trees.

Tea has not been fully worked.

Cinchona is not worked owing to the unfavourable state of the market; there are about 25 acres of land under cultivation.

The pear continues to flourish and can be increased from shoots rapidly; one apricot and one plum tree have blossomed, there are about four or five more that exist, but do not bid fair to come to anything; it is, however, expected to be able now to increase the stock by means of shoots from the two acclimated trees.

It becomes more and more apparent that the shiftless inhabitants of this part of the Karen Hill tracts cannot be brought under training to regular work for a very long time; and that to increase the cultivation, even on this small plantation, it is manifest, labour will have to be imported from some more industrious and less apathetic tribes. I am striving to bring in the Padaungers from beyond the frontier, who are very much better at digging, weeding, and such like, than any of the local tribes; and as I have had a good batch of them to work lately and got the whole cultivated part of the plantation well cleared of weeds by them, and they have promised to return to the work, I hope for better success this coming season, especially as the coffee has blossomed well all over.

QUININE AS A PROTECTION AGAINST CHOLERA.

—Two or three years ago it was announced in the columns of the now defunct *Deccan Times* that Dr. Laurie "staked his professional reputation" on the efficacy of quinine as a prophylactic against cholera. A five-grain dose of this drug every morning while the disease is about is, he holds, a sure preventive. Dr. Hehir, if we remember aright, did not then concur with his chief, but according to his latest writings on the subject he would appear to have changed his opinion. During the epidemic of cholera last year, Dr. Hehir made certain investigations which resulted in the discovery of the presence in the blood, &c., of cholera patients, of a peculiar parasitic protozoon or microbe—whether the cause or the result of the disease has yet to be determined. He found that this organism could not live in strong solutions of quinine, and he further found that the protective virus of quinine were amply demonstrated during the epidemic. He now gives effect to his conversion by recommending the use of quinine as a prophylactic in addition to his own pet drug—sulphurous acid. It has been his practice for years to administer drachm doses of this acid every three hours to all the inmates of a house in which the disease breaks out during the time the patient is in the house. He has given it in about 7,000 instances, and for the last three years he has not seen cholera occur in any case in which it was used. The above facts are obtained from Dr. Hehir's latest report as Health Officer of the Chudderghat Municipality, and they are of such vital importance we think they ought to be made known as widely as possible. If quinine is really the effective prophylactic against cholera that Dr. Laurie claims it to be, and which Dr. Hehir now believes it to be, he has this fell disease lost all its terrors, for no-

thing is easier, less harmful,—nay, positively beneficial for other reasons,—than taking a five-grain dose of the drug during epidemics of the disease. We know of many who, since the publication above referred to, observe the practice. If it came into more general use, we would soon be in a position to judge what we have to fear from that hitherto deadly scourge of the East.—*Deccan Budget*.

AUSTRALIAN MANGOSTEENS.—The *Queenslander* of the 12th March gives particulars of two new species of mangosteen just discovered on the Bellenden Ker mountains in N. E. Australia. One of them is the *Garcinia Mestoni*, which was found growing between 2,600 ft. and 4000 ft. It is said to be larger than the Java mangosteen, *Garcinia mangostana*, and possesses an additional quality. Only the inside of the Java variety is eaten, but the whole fruit of this new species is available. It contains from five to seven seeds embedded in a soft thick white pulp, and pulp, rind, and skin can all be eaten. The fruit never changes colour, being always of a bright green, though a slight shade of golden yellow is sometimes observed on one side of a ripe fruit. It is acidulous, and the acidity actually increases as it ripens. It refreshes and invigorates the system in a surprising manner on a hot day. The tree bears at an early age, as fruit were found on bushes not more than 7ft. high. The tallest trees were about 25ft. but very few of these were bearing. It is a graceful and elegant tree, pyramidal in shape, and the fruit hangs by a long stem from a cluster of leaves. Apparently it is not eaten by either birds or insects, as there were none found in a damaged condition. Among the fruits brought down from the mountains is another new mangosteen, a handsome fruit about the size of an apple. It differs internally from the first but is also pleasant to eat. Only one tree was discovered about 30ft. high and 9 in. in diameter.—*Straits Times*.

On some of the Java cinchona plantations the prolonged period of cold, accompanied by night-frosts, which occurred in July last, made possible to ascertain the effect of a low temperature upon the alkaloids in the bark. Mr. Van Leersum, who has investigated the matter, reports that the freezing of the bark of *C. Ledgeriana* is accompanied by a considerable decrease in its alkaloidal richness. In one sample analysed by him the total proportion of alkaloid declined from 8.26 to 4.12 per cent, while the quinine alone decreased by over 1 per cent. In cases where the frost-bitten parts die not off at once, the proportion of cinchonidine increased considerably at the expense of quinine—an effect similar to that observed in certain forms of cinchona disease. The following are the results of Mr. Van Leersum's analyses of various samples of bark (presumably taken from the same tree):—

	Quinine.	Cinchonidine.	Quinidine.	Cinchonin & amorph. alk.	Total.
1. Frozen bark, twenty four hours after the frost	3.09	0.65	—	0.38	4.12
2. Partially-frozen bark, twenty-four hours after the frost	4.40	2.01	—	2.25	8.26
3. Sound bark, eighteen months old	4.49	—	0.02	1.90	6.41
4. Frozen bark, peeled three months after frost	0.97	0.70	—	1.17	2.84
5. Frozen bark, analysed after fourteen days	1.96	0.79	—	1.21	3.96
6. Frozen bark, analysed after fourteen days	1.50	1.20	—	1.19	3.89

—*Madras Times*, May 7th.

USES OF CINNAMON.—*Modern Society* of 23rd April says:—

By the way, the latest craze in Parisian Society is for cinnamon. Everything is cinnamon, not so much the colour as the spice itself, which flavours everything, and has been introduced into *ragoûts* within the last few days by one of the leading *chefs* of the French Metropolis. The reason of this may seem a mystery to our readers, but we can explain it. One of the leading French scientists has discovered that no microbe can long resist a strong infusion of cinnamon, or, in other words, that cinnamon is, in its essence, hostile and deadly to disease germs. This discovery is, of course, if it be a really *bond fide* one, of the utmost importance, for hitherto we have been taught to believe that nothing but dynamite would remove his or your crobes from the system; but the scientist in question has tested the power of cinnamon on every known living germ of disease, and in no instance found it to fail; and he asserts, moreover, that it does not—unlike antiseptics extracted from coal tar—injurious affect the human organism. Our ancestors were fond of spices, and what quantities of cinnamon did they not use in mulled wine and beer? Hitherto, we confess that we believed that these liquids were drunk for their own sake, and perhaps, indeed, for their intoxicating properties; but now we find we were mistaken, and that these spiced drinks were only ingurgitated for hygienic reasons. The Dutch, who live in a low ague-haunted country and drink the polluted water of their canals, used formerly to have a passion for this spice, which, somehow or other, would seem of late years to have gone out of fashion. Now it is in again with a vengeance; so if you want to be *dans le mouvement*, dear reader, you must devour cinnamon. We have already quoted paragraphs to the same effect; and we should be only too glad to be assured that the germ-destroying powers attributed to cinnamon are true. In former days, we believe, the workers in quicksilver mines chewed cinnamon as a prophylactic against the deadly fumes of the mineral.

SPENT TEA LEAVES IN TOBACCO.—In the *Illustrated London News* of 14th May Mr. James Payn writes:—

The combination of many useful things in one, though ingenious, seldom very successful. A knife with half-a-dozen blades, which also comprehends a corkscrew, a tooth-pick, and an instrument for extracting stones from a horse's shoe, is seldom of much practical utility. The chest of drawers that is "a bed by night, a chest of drawers by day," deceives no one by its duplicity, and is never a comfortable bed. But an article which, having been used for one purpose, can be used for another entirely different, and then be done with, stands on another footing. It has just been found that black tea-leaves, after use, and "when dried and sprinkled with oil of cloves and spirits of wine," make excellent tobacco. If this be so, we may now all smoke without incurring the anathemas of the anti-tobacco societies, unless, indeed (as some say,) their antagonism is not to the weed but to the fact of their fellow-creatures enjoying themselves. There can be no injury to our moral nature in smoking the herb that cheers and does not inebriate. Moreover, the discovery utilises waste, for hitherto spent tea-leaves have been only used by the housemaid to lay the dust. This novel mixture is said to be "very quieting to the nerves," and it is too possible that after the excitement of a five o'clock tea, when the one or two males who have been inveigled to join it have escaped, there may be a cry for cloves and spirits of wine, and the ladies may proceed to put their tea to its latest use. The habit of taking tea in their own rooms will also become open to suspicion; "It isn't drink," the scandal-mongers will say, "it's smoking they are after." Where there is smoke, we are told, there is fire, but whether when tea-leaves are smoked there is smell, we are not told. This will, however make a great difference as regards the popularity of the new discovery with fair sex.

A CINCHONA BARK SYNDICATE, to buy up the produce of the whole world and control the market is the subject of an article on another page. The project reads very finely on paper; but the whole scheme rests admittedly on the willingness of cinchona growers to accede to the terms of the promoters, and this we very much doubt their doing.

TEA IN FOOSHOW.—April 30th.—A total of \$1,400,000 has been sent into the country for the purchase of the new season's tea. As compared with last year it is less than half the amount. May 7th.—Since our last issue a further amount of \$300,000 has been sent up country for the purchase of new season's teas. By the last two coast steamers several well known 'Chaazees' have arrived from various quarters of the globe, Australia, England and America, each rendering its tribute. These gentlemen are no doubt well provided with 'orders,' and the latest ideas from central markets. Let us hope that for once common sense may hold sway, and the mad competition and high prices of recent years may be replaced by calm judgment, and a basis more in conformity with the demands of the age.—*Echo*.

THE DURIAN (*Durio Zebthimus*), the tree producing the celebrated Durian fruit of the Indian Archipelago, is now, we learn, bearing fruit for the first time in South India in the Government Gardens at Burliar. The plants were imported from Singapore by Mr. Jamieson in 1879, and one of them has now attained a height of nearly 40 feet. Mr. Russell Wallace, in his *Malay Archipelago*, remarks on the various fruit met with in Borneo, and says—"But most abundant and most esteemed is the Durian." The old traveller Linschott, writing in 1599, says:—"It is of such an excellent taste that it surpasses in flavor all the other fruits of the world, according to those who have tasted it!" and Doctor Paludarus adds:—"This fruit is of a hot and humid nature. To those not used to it, it seems at first to smell like rotten onions, but immediately they have tasted it they prefer it to all other food. The Natives give it honourable titles, exalt it, and make verses on it! When brought into a house, the smell is often so offensive that some persons can never bear to taste it. This was my own case when I tried it in Malacca, but in Borneo I found a ripe fruit on the ground, and eating it out of doors, I at once became a confirmed Durian eater. . . . The fruit is round or slightly oval, about the size of a large coconut. . . . From the base to the apex, five very faint lines may be traced, over which the spines arch a little; these are the sutures of the carpels, and show where the fruit may be divided with a heavy knife and a strong hand. The fine cells are satiny white within and are each filled with an oval mass of cream-colored pulp, imbedded in which are two or three seeds about the size of chestnuts. This pulp is the eatable part, and its consistence and flavor are indescribable. A rich butter-like custard highly flavored with almond gives the best general idea of it, but intermingled with it come wafts of flavor that call to mind cream-cheese, onion-sauce, brown sherry and other incongruities. . . . in fact to eat Durian is a new sensation, worth a journey to the East to experience." Durians seems to have come early into season this year, for they have been on sale some weeks in our bazaars and streets. Those sold in Rangoon just now come principally from Moulmein although there are bearing trees in increased numbers in Kemindine and the Prom Road. The fruit here, however, seldom ripens until the middle of May.—*Rangoon Times*, April 29.

NEW MARKET FOR CEYLON TEA :
THE COUNTRIES TO WHICH IT WAS
EXPORTED IN 1891.

Mr. John Ferguson, in his letter "From the Metropolis," has already noticed the main features of the very interesting and valuable circular which, by arrangement with Messrs. Gow, Wilson & Stanter, we are able to give as a Supplement. But there are some points to which attention can still with advantage be drawn. And first as to the comparatively good show of the yellow colour which represents Ceylon tea in the first diagram. In the large, increasing and promising markets of the Australian colonies, especially, the position of Ceylon tea, considering the recentness of our island enterprise, compares exceedingly well with that of our Indian competitor. But we ought not to be contented until a far larger proportion than 10 per cent of the 30 millions of pounds of tea consumed in the colonists of the south consist of Ceylon tea. In the other great British colony of Canada we also compare favourably with India, but the proportion of either is as nothing to what it ought to be. Of 20 million pounds consumption Ceylon furnishes only the fraction of 410,000 lb. The truth seems to be that in the matter of preference for tea, as in many other respects, Canada assimilates to the United States, and the mission to Chicago must be regarded as directed to the capture of the combined markets of the United States and Canada with their aggregate annual consumption of 80 millions of pounds, such markets as South and Central America present being also favourably affected. In the United States we run Indian tea very close; but our position is still most unsatisfactory considering all the efforts which have been made. Indian tea seems to have nearly a monopoly of the Persian markets; but it is possible that some of the shipments of Ceylon tea to India may find their way to Persia, and also to Turkey, where, in the diagram, our yellow does not show at all. In Germany we show considerably better than India, but our readers will notice that the Brokers believe that much of the tea exported to Germany is ultimately destined for Russia. In that great tea-drinking country as well as in the countries of the European Continent generally there is much room for enterprise on the part of our planters and merchants. Austria curiously enough is all yellow, showing that she takes no Indian tea, while in immediate contact and contrast Arabia is all red. This reminds us, that when we wrote recently of Indian-grown coffee being exported to Egypt and Arabia to be sold as Mocha, the compositors changed Arabia into Australia, in which form, if allowed, they would generally print Austria, Russia and Mauritius are both yellow, showing that neither takes any Indian tea at yet. In South America, South Africa and Holland, Ceylon tea shows in fair proportion to Indian, but there is great room for expansion. Natal will no doubt try her "level best" to supply the South African markets but it seems doubtful if labour, even Tamil labour, is not too dear for continued success. There would be more to fear from the Central African

settlements, if the natives could be got to settle down to the steady continuous work necessary for the successful culture of the tea plant. We take it for granted that the figures in the circular represent exports from the colony as well as from London. That taken for granted, it seems that 20 millions of pounds of British-grown tea were exported to other than the London market in 1891, and that the surplus over British consumption (200,000,000 lb) will be 40 millions of pounds in 1892, which it is hoped may be advantageously exported. The proportions of Indian and Ceylon tea exported last year were 13 millions Indian and seven Ceylon. If the same proportions prevail in 1892, the figures will be 26 millions for Indian and 14 for Ceylon; but it is probable the proportion of Ceylon may increase. The Brokers calculate that Britain's consumption of 200 millions of pounds per annum is within 50 millions of the aggregate consumption of all other non-producing countries! The consumption in India is, unhappily, insignificant; so with Ceylon, although better in proportion. What the consumption in China may be, can only be guessed. But the calculations have been generally extravagant, for there are millions upon millions in China too poor to taste even the watery tea in general use by the masses. The consumption in non-producing countries being close on 500,000,000 lb, we should say that a couple more millions at the utmost, added to this, would represent the consumption of true tea in the whole world. We say true tea, because *mate* and other substitutes are in use. If peace could be preserved, the demand for tea must increase with advancing civilization. Remembering the history of the Ceylon coffee enterprise, we feel inclined to agree with the authors of the circular, that recent low prices of our product, calculated as they are to extend its use, and thus create a taste which *must* subsequently be gratified, may turn out to have been "a blessing in disguise." Of course prudence as well as energy is requisite in the cultivation of new markets. Messrs Gow, Wilson & Stanton, it will be seen, wrote before the Indian planters had really bestirred themselves and determined that they also and their product should be represented at Chicago. Let us hope that the brokers are right, and that the depression which has prevailed is but the harbinger of renewed and increased prosperity, in the shape of extended markets and prices rising in proportion to increased demand.

It seems fitting that to Messrs. Gow, Wilson and Stanton's generalizations we should add the details of the history of Ceylon tea in 1891 as embodied in the customs report recently issued.

The increase in the production of our staple and the corresponding decrease in customs valuations have for the past three years been as follows:—

1889	34,345,000 lb.	rate per lb.	52 cents	R17,859,000
1890	45,799,000 "	"	50 "	" 22,889,000
1891	67,718,000 "	"	45 "	" 30,473,000

Notwithstanding the great fall in rated value tea figures for nearly 30½ millions of rupees in our export commerce, out of a total value of Ceylon productions of 56 millions. We must copy in full the extraordinary list of countries, no fewer than thirty-eight, to which we sent more or less tea in 1891:—

Tea.—There is a large increase both in quantity and value, the increase in quantity amounting to 33,372,519 lb., as compared with the year 1889, and 21,918,853 lb. with last year, and in value to R12,613,424 and R7,573,508 respectively. The value would have been greater had not the average price

valuable forest land but an excellent site for factory, with ample and exclusive water power. Works at the factory are progressing rapidly.

The Company's total acreage consists of:—

Tea in full bearing	...	1,498	acres.
„ in partial bearing and young clearings	...	62	„
Coffee and other products	...	14	„
Forest and waste land	...	374	„
		1,948	acres.

and the yield of Sea from the Company's Estates for 1891 amounted to 574,481 lb., and in addition 120 cwt. 1 qr. 5 lb of Coffee were secured, and 13,925 lb. of Cinchona Bark.

It is not the intention of the Directors at present to create fresh capital to provide the money to pay for their recent purchases, but should it be thought necessary or expedient to do so later on, an Extraordinary General Meeting of the Company will be called for the purpose.

The Board are deeply sensible of their obligation to their Manager in Ceylon, Mr. D. Kerr, for his untiring and efficient conduct of the Company's affairs, and desire also to express their appreciation of the cordial affective cooperation of the staff, who have throughout the past year acted as one in their efforts to promote the Company's interests.

In accordance with the Articles of Association, Mr. R. W. Forbes retires from the Board, and, being eligible, offers himself for re-election.

The Shareholders will be called upon to fix the remuneration of the Directors.

The Shareholders will be called upon to elect an Auditor for the ensuing year, and Mr. J. B. Laurie offers himself for election.

3rd May 1892. H. L. FORBES, Chairman.

THE "JAM CROP" OF 1891.

Interesting and profitable as are the tables annually published in these pages in connection with the fruit crops of Great Britain and Ireland, they would probably be of still greater value could they be supplemented by such returns as that noted above, the "jam crop;" but, to obtain these, manufacturers would have to be consulted, and we are very well aware that most of them object to the publication of that, which, as they put it, "the benefit of which to themselves they do not see." Perhaps they are right—possibly they are wrong; at any rate, what we have termed the jam crop of the present year must be a very large one, and in humble life will run marginally very closely in the race for economic food supply. The taste is a growing one, and extends with the population. London adds 60,000 souls to its great total every year: given four in a family, then 60,000 ÷ 4 = 15,000 families. Suppose these consume 1 lb. of jam per week, then the consumption for the twelve-months is represented by 735,000 lb. = (say) 350 tons per annum. The consumption per week for each family is admittedly low—but even at this figure what an enormous mass of wholesome sweetness must enter into the food bill of 5,000,000 men, women, and children—a million and a quarter one pound jars per week, or, roughly 625,000 tons a year! You can do much with figures. Quite an enormous sale of "bread and jam" made in all the busy quarters of London—in the immediate neighbourhood of factories and workshops. The keeper of one little "general" shop informed the writer the other day that she sold over 500 slices of jam every day—there were plenty of margarine slices as well, but the "jam" was preferred. It would appear then that the supply can hardly be overdone—as yet, and the amount of labour called into use in the manufacture and marketing is very great. There are the regular field and orchard workers, those concerned in harvesting and manufacturing, in the manufacture of glass and earthenware bottles and jars, in fancy printing and packing-cases, and in a lot of other industries. Here is a little item worth nothing, as giving point to our remarks all

round. The Britannia Fruit Preserving Company at the world-renowned Tiptree, in Essex, have this year harvested over 200 tons of fruit—have made 100 tons of jam, in which they have used 50 tons of sugar; in producing all this have employed 400 persons, young and old, for various terms; and have used nearly 58,000 glass bottles and jars in getting this jam ready for market. How the genial countenance of the once-famous tenant of Tiptree Hall, "Alderman and Sheriff" Mechi, would brighten at such an enumeration as this, and how he would have lectured his brother agriculturists on jam as his theme! But not only this "sweetness" is manufactured by this young and enterprising company; as with nearly all other fruit preservers, some dozen other commodities are put upon the market—not all the eggs being put in one basket. But it would be waste of space to occupy attention further with this matter at present; the reader, landowner, grower, manufacturer, speculator, vendor—whichever he may be—can readily read for himself the lesson sought to be inculcated by us in thus noting the "jam crop" of the present year.—*Gardeners' Chronicle.*

SERMO SINENSIS.

"Come up to my house for a chat this afternoon if you have nothing better to do. It's raining, business has gone to sleep, and I don't fancy that there is much doing in your line," said the great teaman to me a few days ago.

"O.K.," I replied, and later in the day found myself in Awai's hospitable mansion reclining in the easiest of morocco-covered arm chairs, my feet the while sinking into the thick pile of a luxurious carpet. The furniture of the room was nearly all of European manufacture, and the best of its kind. The walls were covered with the "silken pictures" so loved of the wealthy native, and there was withal a general sense of those solid comforts which money alone can supply.

And the dismal iteration of the rain drops in the courtyard only tended to make more sensible the serenity which reigned within.

Napoleon was not long in making his appearance, and as is his wont plunged at once into the discussion of that great subject about which he is universally admitted to know so much. "But before we go any further," said he, "try one of these smokes. They were given to me as a kind of thank-offering by a *chaasze* who got a cheap chop of Ningchow out of me last season.

"Yes, did the tea pay?"

"Not exactly," he replied. "It only lost 9d per lb. and that is saying a great deal. You don't often come across such a sincere case of gratitude."

"Well, Awai, your former delivery on tea prospects did not evoke much discussion in the paper, as you had hoped."

"No," said he, "still I was amused at what did appear.

First, there came a letter signed *Chaasze* who commenced by congratulating me on my vigour, and wound up by telling me that I was quite wrong in my figures as to the average cost of last season's crop. I confess I was wrong. I always am. Then a *Tea Merchant* informs me that he had read my remarks with pleasure and that it has set people talking over what will soon be the *business of the hour*. And that's all. Finally appears a letter signed A. J. L. He doesn't agree with me at all, and with unanswerable logic points out that if the production of India and Ceylon is this year 200,000,000 lb. it will only make more patent the *steadily dwindling* consumption of China tea. But I still maintain that China tea can hold its own in the competition if the crop is large and cheap and good. But I dare say that here again I am wrong as usual. Further, speaking of the heavy export A. J. L. adds, 'For merchants to Pursue their trade under its weight is but to go on from year to year "flogging a dead horse" until nothing of the carcass is left.' For the life of me I cannot see the object of flogging a dead horse at any time, but especially from year to year."

"Good old horse," I exclaimed.
 "High old horse," he added.

"And by the way," he continued, "a practical planter tells me in his letter how he arrives at the cost of the Ceylon crop. But I don't place much reliance on his figures, for he omits the serious and all important item of interest on the cost of his estate."

"I see the Russian contingent has arrived. Did you get any information from them?"

"Not very much, though I gave them a capital dinner and a fine entertainment at our local Rotherhithe. No, they are rather close; but one indiscreet member admitted to me, after his thirtieth cup of hot *samsu*, that things weren't quite so bad in Russia as they were represented to be, and personally that he took a cheerful view. And here he became lost to my cheerful view beneath the table."

"Well, now that we are within a measurable distance of practical politics, have your ideas changed at all during the month?"

"I can't say that they have. I hold to the figures I before gave you as to the extent of the crop and the prices foreigners should not exceed. One would have thought that in common with many other crops tea would have been backward this season. But I'm to'd musters can be in Hankow by the 5th of May, if wanted. There is one pull buyers will have this year and that is in exchange. Merchants' bills have already been sold forward at 4s 0½d per tael, which is 16 per cent lower than last May's average rate. I hope they won't throw away the advantage. But surely there can't be any desire to rush things this year? I know what losses are and I have just closed my 1891 shipment account by the payment of Tls. 2,500 loss on 200 half-chests tea. Here are some losses, all authentic, which will make your hair stand:—

	s	d	sold at	s	d
Cost	2	4	1	0	
"	2	2½	"	0	9½
"	1	10	"	0	9½
"	2	1	"	1	0½
refused	2	0	"	0	9½
"	1	9	"	0	10½

These are Kiukiang teas. It's not worth while troubling you with the sales of the Hankow district teas. The loss was very uniform, 30%. Try a cup of tea. And from dainty porcelain I sipped something like water tewitched.

"What's this?" I asked.

"Oh, that's a new country tea: look at the infusion, how thick and bright and red it is. What do you think of the flavour?"

"Well, Awai, as the Americans say 'it ain't got no flavour'."

"Ah, you have hit it: that is just what the Russians like, pure tea."

"Pure hot water," I muttered, as I put down the scalding liquid.

"I see you don't care for the new article. Try some champagne out of earthenware."

Perhaps it was fancy, but I certainly liked the novelty and thought it increased both the flavour and the bouquet.

"Have you seen the China Association's circular on the tea question?" I asked as I rose to leave.

"Oh, yes." It was headed "private and confidential;" hence, perhaps, the reason why it so soon became public property. It didn't contain much that was new. Amongst other suggestions it urged that immediate steps should be taken to get tea-men to fire the leaf in such a way as to prevent the recurrence of the tar trouble this season. Just as if a matter like that could be settled within a fortnight of the commencement of a new season. It was not huilt in a day, and the Chinese move slowly. There is one thing, however, that I should advise, and that is as soon as the Hankow season is over the Chaasze committee meet, draw up a plan of campaign, secure the good offices of the present Commissioner of Customs here, a *persona gratissima* with the authorities, and then try through the Tea Guild to obtain the co-operation of the Taotai. No

effective steps in this matter can be taken unless the sympathy of the Taotai is enlisted. Of course, I will do the little that is in my power to attain this end."

"Well, Awai, I hope that you will have a good season."

"I hope that it will be good for all of us. Meantime I don't think that you will find that I shall be much cut either in my facts or figures. Ohinchin."

H. T. W.

[The above initials should have been signed to the previous *Sermo*.—ED.]—*N. C. Herald*.

THE CHINA TEA TRADE.

TO THE EDITOR OF THE NORTH-CHINA DAILY NEWS.

SIR,—I have read with much interest the very able and amusing articles, which have appeared in your column recently, on the Tea Trade, under the title of *Sermo Sinensis* as also the various letters which followed on the same subject, and in all these letters I find the same refrain—"The Tea Trade of China is doomed unless the Export Duty be taken off."

Now it is easy enough for your correspondents to sit at their desks and write these "fateful" words, but why stop there? How about the Chinese Government? Is it likely that Sir Robert Hart will recommend, or the Tsungli Yamen sanction, the abolition of a duty which brings in a revenue of from 3,000,000 to 4,000,000 Hk. Tls. per annum, unless it can be shown that the abolition of this tax is expedient and some other source of revenue be proposed in its place. * * *

In 1887, owing to the representations made to Sir Robert Hart on the decadence of the Tea Trade, a despatch was addressed by him to the Tsungli Yamen on the subject; the Commissioners of Customs at Hankow, Kiukiang, Wuhu, Shaoghai, Ningpo, Foochow, Tamsui, Amoy and Canton, were requested by the Inspector General to investigate the matter fully, and their exhaustive Reports will be found in No. 11 of the special series of the Customs publications. I do not propose to trespass on your valuable space with extracts from these Reports, suffice it to say that no reduction of the duty was then, or has since been made.

Let us examine the pulse of this "moribund" Trade, (so I have heard it called for the past 20 years) and try to diagnose "its case." The Customs Reports give the following figures under the heading of total Export of Tea to Foreign countries:—

	1887.	1887.	1890.	1891.
	Piculs.	Piculs.	Piculs.	Piculs.
Blaek	1,611,920	1,629,880	1,149,310	1,201,880
Green	178,840	184,680	129,500	206,760
Brick & Tablet	219,030	331,280	307,440	336,100
Dust, Leaf, &c.	7,360	7,200	9,150	5,300

2,017,150 2,153,040 1,665,400 1,750,040

These statistics are instructive, and if the falling off in the next four years, be as large as it has been in the past four, some prompt and decisive steps will have to be taken: though the total for 1891 shows a slight improvement on 1890, and from this it might be inferred that the decline has been arrested, I fear the seeming improvement is due to the export in 1890 having been retarded by the advance in exchange, and that if the Customs figures were made up to the 31st March, instead of the 31st December, the totals for 1890 and 1891 would be reversed.

It will be seen then from the above table that the decrease since 1887 has been entirely in Blaek (under which heading the Customs include Congon and Sou-chong, Oolong and P. wchong, Flowery Pekoe, Sc. Orange Pekoe and Sc. Caper); both Green and Brick show a slight increase, the former being due mainly to the increased shipments to India, which amounted to 4,000,000 lb. in 1891 as against 2,000,000 lb. in 1887. The following is a rough estimate, (open to correction,) of how this falling off in the export, of 428,000 piculs or 57,000,000 lb. as compared with 1887, may be accounted for

Decrease to Great Britain	{	from Hankow and S'hai	25,600,000 lb.	All Cougho
		" Foochow	24,000,000 "	Mostly "
		" Canton	6,300,000 "	" "
		" Amoy	500,000 "	Oolcug
			56,400,000 lb.	
Decrease to	Colonies (from Foochow)	7,600,000	„	„nearly all „
" "	Continent of Europe excluding Russia)	2,000,000	„	„ „ „
" "	Russia (over-land)	4,000,000	„	„ all „
			70,000,100 lb.	
Increase to Russia (By sea via Odessa)			13,000,000	„ „ „ „
Total decrease			57,000,000	

As was to be expected, it is to England and her colonies that the falling off is mainly confined; fortunately for China the Russians have not yet learnt to appreciate the pungent produce of India and Ceylon and may be relied on to keep to their "old friend" for some time to come. Fashion and taste are proverbially fickle, but India and Ceylon teas have gained such a hold on the British public, as those who have recently been in England testify, that it will be difficult, I had almost said impossible, for China to regain her former position; if Mr. Awai thinks he has solved the problem and can outbid his rivals by flooding the London market with cheap and good (Query, How cheap? How good?) China tea, by all means let him try the experiment, methinks it will prove in verity to be "a game he did not understand."

"The instability of industries is well known; any industry may be killed, as it was by enchantment, in an old country, by the discovery of new means of cheaper production in another part of the world;" as a proof of this, it was stated by some Ceylon tea planters who recently visited Shanghai, that their gardens could produce tea to sell in London at an average price of 6s. per lb., and give a fair return at that, a result attained, partly by personal superintendence, partly by the use of machinery, partly because the teas went from the gardens "direct" to London. Few merchants doing business in China have any true idea of the number of hands produce of all kinds passes through before it reaches them ready for export; these middlemen all take their little "squeeze" and when in addition likin has to be paid, as well as export duty, no wonder China teas cannot compete with Ceylon. Furthermore it is evident that China Coughos have been deteriorating in quality, he it from exhaustion of the soil, or indifferent preparation, or both these causes combined, I know not, the fact remains that though last season at Hankow a few chops showed improvement, the bulk of the teas have no longer any keeping power and in a few months loose both their flavour and strength. The opinion expressed by Sir Robert Hart in 1887, "that when consumption decreases at one point it will be found to increase at another," proves unfortunately for China, as the figures I have given show, not to have been correct; whether any reduction of the duties levied would now revive the trade can only be ascertained by experiment; it is doubtful, and knowing the procrastinating proclivities of the Chinese and their dislike of change, I scarcely expect to see anything done by the authorities.

Heaven helps those who help themselves is an old saying; greater care in the cultivation, less haste in the preparation, the erection of weather-proof godowns for storing the leaf, and the use of machinery, would be steps in the right direction. Advertising is a great aid now-a-days to success in business, of this the Indian and Ceylon planters have largely and wisely availed, hence their present strong foothold in England. They are pushing their teas into notice in every country and will be well represented at the coming Chicago Exhibition. Is China to be conspicuous by her absence?

One word in conclusion of this already lengthy letter; buyers, in my opinion, are partially to blame for the present unsatisfactory state of the China tea trade, there has always been keen competition, occasionally reckless haste in the buying, and shipments, aggregating three or four months' consumption, have been forced on the home market in about as many weeks, with the inevitable result. It is to be hoped that the severe lesson of last season's losses will induce a more prudent course of action this season, though we shall doubtless hear later on that the wily Awai has again successfully planted on his friends, at Hankow, several of his "cheap chops."—I am, &c., SCOLOPAX VERNALIS: 29th April.

—N.-C. Herald.

ENGLISH-GROWN TEA.

The *St. James's Budget* of 20th May says:—

We understand that during their visit to Exeter Hall on Monday, Princes Louise and the Marquess of Lorne were regaled with tea made from leaf grown in this country and prepared by Mr. John Roger, who was formerly a tea planter in Ceylon. The plants from which the leaf was obtained were reared in Mr. W. Icton's Palm Nurseries at Putney. Mr. Roger had some of the plants on view at the hall, and also a quantity of the prepared tea. He believes that this is the first occasion on which a cup of tea has been made from English-grown leaf.

Mr. Roger's letter on this subject is as follows:—

SIR,—With reference to your paragraph under the above heading in today's issue, will you favour me with a little of your valuable space to say that I am—not unnaturally, I think—rather curious to know whether I may justly claim to be the first who has made any quantity of drinkable tea in this country from leaf plucked from plants or bushes grown from seed imported from Ceylon or India?

There are some details in connection with the making of this tea which would, I think, interest some of your readers. For example, to the practical tea-planter or tea-maker it will seem rather a curious fact that I plucked the green leaf in the morning, and it was withered, rolled, fermented, and fired before night, or converted into drinkable tea within the limits of a working day of eight hours. The plants are, I am informed, not yet quite twelve months old; this, and the forcing treatment they have lately undergone, may account for a lack of the true Ceylon or Indian flavour in the tea made; which, however, did not appear to be noticed by H. R. H. the Princess Louise and the distinguished party at Exeter Hall who were kind enough to try it in cup, and who seemed much interested in its history and in the plants which were shown to them.—I am, sir, your obedient servant,

JOHN ROGER.

20, Guilford-street, Russell-square, W.C., May 17.

SCOTTISH CEYLON TEA COMPANY, LIMITED.

The third annual ordinary meeting of the Scottish Ceylon Tea Company, Limited, was held at the Company's office, 16, Philpot Lane, E.C., on Monday, Mr. H. L. Forbes in the chair.

The Secretary read the notice convening the meeting, and the report and accounts were taken as read.

The Chairman said: I have again a very pleasing report to lay before the meeting, which leaves little for me to say by way of supplement or explanation, except to congratulate the shareholders on the highly satisfactory results of the past year's working. I trust that the report may not be considered a monotonous one; but it is a monotony which I hope may be long

continued. The profits for the year amount to £8,799 14s 11d, which, with the balance of £387 5s 7d carried forward from 1890, leaves the sum of £6,187 0s 6d to be dealt with. It is proposed now to pay a further dividend of 13 per cent, making a distribution of 18 per cent for the year, to place £1,000 to reserve, bringing this fund up to £2,000, and to carry forward the balance of £807 0s 6d to 1892. The company's estates are in excellent condition. Lonach, the purchase of which I arranged when in Ceylon last year, is proving a success, and when the factory is completed—and it will be, I hope, during 1892—it must prove of immense benefit to us. The company's acreage, with its analysis, is before you in the report, and the yield of tea during 1891, although fair, has, in my opinion, far from reached its limit. The prices obtained for our teas are above the Ceylon average for the year. As to coffee, I fear you will have lit le more of it; but the company possesses some fine cinchona waiting for a profitable market. The shareholders may notice the absence of any debit for depreciation on factories and machinery, and, in explanation, I would remind them that the entire expenditure on these during 1889—amounting to £4,315—was written off profit and loss. Fresh capital to meet the cost of recent purchases we do not require at present, and it is to the interest of the shareholders to delay the issue of this as long as possible; but it may be that before another annual general meeting takes place I may have to ask you to consider the question. Our proposed vote of thanks to Mr. Kerr and his staff has been again thoroughly earned, and also by our worthy secretaries and their staff. With your permission, I will read you a few sentences from Mr. Kerr's letter closing the season for 1891: "In conclusion, I would congratulate our directors on the fact of all their estates being thoroughly healthy and in good heart, while the improvement noted by Mr. Forbes on his last visit has been more than maintained; and I would also take this opportunity to thank them for the very cordial support and kindly consideration which I have received at their hands during the year that has gone—relations which I shall endeavour to maintain. For the measure of success which has attended the management here I am indebted to the willing and harmonious way in which the various superintendents have carried on the company's work." Before reading the resolution I will be glad to answer any question that any shareholder may desire to put.

After a few observations by Mr. Cooper, the Chairman moved: "That the report and accounts be adopted, and that a dividend of 13 per cent. (free of income-tax) be paid on and after this date."

Mr. John Anderson seconded the resolution, which was carried unanimously.

On the motion of the Chairman seconded by Mr. Cooper, Mr. Robert William Forbes was re-elected a director of the company; and, on the proposition of Mr. Andrew, seconded by Mr. Arbuthnot, Mr. J. B. Lamie was re-appointed auditor for the ensuing year at the remuneration of fifteen guineas. It was also resolved that the remuneration of the directors should remain on the same scale as before until further notice.

A vote of thanks to Mr. Kerr and his staff in Ceylon and to the London secretaries and their staff was carried *nem. con.* on the motion of the Chairman seconded by Mr. Ferguson.

The Chairman stated that that was all the business they had before them; but, before they separated, he desired to call attention to the severe loss the Ceylon Tea Plantations Company and the Planting interests in Ceylon had sustained by the death of the chairman of that company, Mr. David Reid, and he proposed the following resolution, which was cordially received and passed: "That this meeting begs to express its sympathy with the Ceylon Tea Plantations Company Limited, for the loss they and Ceylon generally, have sustained by the death of their chairman, Mr. David Reid."

A vote of thanks to the chairman, and directors, proposed by Mr. Cooper, seconded by Mr. Todd, and carried by acclamation, brought the proceedings to a close.—*Financial News*, May 20th.

NOTES ON PRODUCE AND FINANCE.

THE MAKUM ASSAM TEA COMPANY, LIM.—The applications for shares in this company were, we understand, considerably in excess of the amount which was offered for subscription.

THE CEYLON TEA INDUSTRY.—In a long letter to the *Financial News* Mr. J. Ferguson, of the *Ceylon Observer*, gives a review of the position and prospects of Ceylon tea, from the planter's point of view. The gist of his letter, which may be taken as a reply to that of Mr. F. S. Hawes, is that "there is nothing in the tea industry of Ceylon at present, or the mode of cultivation, &c., which justifies the statement that it is not likely to be as stable as any other industry."

SCOTTISH CEYLON TEA COMPANY.—The directors and shareholders of the above company have good reason to feel gratified at the dividend of 18 per cent, which this company pays during the third year of its existence.

THE TEA TRADE OF JAVA.—In the report on the trade of Java during 1891 the acting British Consul, Mr. S. R. Lankester, referring to the tea industry of the island, mentions that the tea crop last year suffered, in sympathy with all others, from the drought; but this has had a not altogether unfavourable result for the trees have had an apparently required rest, the result being that after the rains set in they grew vigorously, and the increase this year will, it is expected, more than compensate planters for the small quantity they could pluck during the spell of dry weather. The production shows a marked falling off, being about 1,000,000 lb. less than in 1890. One or two new gardens have, however, been opened; but against these have to put those chiefly on low lands, which have been, or are being abandoned in favour of Liberian coffee. The exports were 5,939,011 lb., against 7,788,484 lb. in 1890 and 7,716,225 lb. in 1889. The quality of the crop proved satisfactory, and some estates realised good prices.

THE POSITION OF COFFEE.—It is extremely risky to attempt to foreshadow the course of any market, but it is useful to look at facts and endeavour to deduce conclusions therefrom. The quantity of coffee in hands of the dealers is below the average, and the market is in an uncertain state, with probabilities in favour of higher prices. The fall of from 5s. to 10s. per cwt. established during the first five months of the year has had its effect, and if the earlier shipments of the new season go readily into consumption the chances are strongly in favour of better prices. The main sources of supply of late have been the East Indies, Costa Rica, and Guatemala. The decline in the receipts of coffee from Brazil and Ceylon has been considerable.

THE ADULTERATION OF PEPPER.—Messrs. Joseph Travers and Son, Limited, call attention to the adulteration of pepper. They say "the commoner qualities of ground white pepper are being at present extensively coloured with turmeric, in order to give them a yellow hue. A properly ground sample of the commoner qualities of Penang, Siam, and Singapore white pepper does not possess this yellow tinge, which is only to be found in the finer grades of decorated pepper. This adulteration makes pepper which is really worth 6d or 7d per lb. bring very much more, and it appears to us to be a distinct fraud, and one which the public authorities should put a stop to. So far as we can gather, a very little turmeric is added, and we think it must be in the grinding, in order to make the colour uniform. It is to the interest of the grocers, in our belief, to use the utmost vigilance in such matters, which in no way benefit them, while they enable the wholesale grinder to palm off inferior qualities upon them at a highly remunerative profit. The dyeing of the pepper also can answer no purpose whatever. The public do not see it in bulk, as they do in the case of sugar upon their tables, so that the yellow look can be no attraction to the purchaser. It is thus simply a bait held out to the retail buyer, in order to induce him to buy very common pepper at a

price, perhaps, of a halfpenny per pond beyond what he ought to pay for it if it had not been dyed. The addition of turmeric to pepper appears to be a distinct adulteration, for, although only a very small quantity is added, turmeric is an absolutely different substance from pepper, and has no flavour. In fact it is a drug, the main value of which is its colouring property. The adulteration of white pepper with ground rice also goes on almost unchecked, and there is surely room for the public analysts to put a stop to these malpractices, which are so degrading to the trade and so vexatious to honest traders."

COFFEE AND CHICORY.—A grocer in Bedfordshire was recently fined for selling a mixture of coffee and chicory, in which there was only 90 per cent. of chicory. As the price of this stuff was 1s 4d. per lb., no wonder the magistrate remarked "that it was a proper case for the police to take up, and it was very hard that poor people who could ill afford to be misled in this way should be supplied with a mixture containing 90 per cent. of chicory." It is hard on coffee growers also.—*H. & C. Mail*, May 20th.

PLANTING NOTES FROM COORG.

COORG, 27th May.—Owing to adverse circumstances, such as the lateness of the rains, rain falling on open blossom, &c., there has been a partial failure in the setting of this season's crop, which has caused reductions, by several tons in each case, of all estimates formed on the blossom. "A Recent Traveller," in his letter in your issue of the 12th instant arrives, I think, at a fairly correct calculation of what the crop, taking the country all round, is likely to turn out. He gives it as an 8 to 10 anna one, assuming 16 annas to represent a full crop. The reasons he gives to account for the shrinkage are, however, not in accordance with the actual state of affairs. He says that the heavy rains, which followed the opening of the blossom, will make the trees throw out a flush of wood, thus diverting the sap from the fruit germs, which will in consequence "pale off." Ad danger of this description is, I think, obviated once the set has taken place—the berries that are likely to come off being the abortive ones that have not set. The rains do not appear to have operated in the way here indicated; on the contrary a profusion of shoots is only noticeable on trees on which last season's crop has not told so severely as to prevent them making growth, although it has probably incapacitated them for cropping. It is necessary to make this specification as there are trees so impoverished through overbearing that they remain in a precarious condition a long time before they recover sufficiently, even under the most favourable conditions, to begin to sprout. There is also considerable growth on lightly laden trees. The true explanation would therefore appear to be that the dropping of ill set berries releases that amount of nutrient matter which would have gone for their support to be utilized by the trees in making growth. A pardonable confusion of cause and effect in this connection would inevitably lead up to the conclusion that the sap was being diverted from the young berries, thus causing them to drop. Botany teaches "that the growing parts of plants do not necessarily depend upon nutrient matter simultaneously absorbed from without, but take their required supply of plastic material from the older and permanent portions which have ceased growing." Unformed berries are growing parts of trees and once their growth has been started, which is probably after they have set, it is inconceivable how an addition by absorption of nutrient matter from without can effect a diversion of it from them. It is believed that flushes following the pruning before the blossom has been started is detrimental to the formation of the latter; but this is "another story." Light showers insufficient to move the spike or just enough to do so partially are instrumental in bringing about these flushes; also, heavy continuous rain between the start and the finish of the blossom. Some

places have, I believe suffered in this way this season but it must be only in cases where heavy bearing last season has rendered the trees unequal to cropping again this year. Considering the heavy crops that have just been gathered off South Coorg estates, results will I think be highly gratifying if half crops be obtained this year. On the Santikoppa side of the country men expected to do very well, but circumstances were not entirely favourable. On the whole the crops ought to turn out 10 to 12 anna ones. A 14 anna crop will be exceptional, and only in isolated cases will they drop as low as 6 and 8 anna crops.

Attention is now being paid to centering, removing borers, looking after last year's supplies and supply pitting. Unfortunately estates are usually short handed at this time of year. This being the case, some of us are merely contenting ourselves by removing suckers and creepers off the trees, as this carries us rapidly over the ground and it is the suckers that principally take it out of the trees, centering being left till a more convenient season, when supplies of labour become more abundant. The slow progress made by small gangs removing borers is very trying. The more borers that are removed now the better, as it enables us to put supplies into their places. The position of some estates hereabouts in respect of labour is envious. Work is getting on in them by leaps and bounds, while in others it is as bad as being at a standstill.

The recent heavy rains are making the weeds grow apace and they will soon be overtopping the trees. They are less advanced, however, than they were at this time last year. If they are allowed to remain long it will be to the detriment of the trees, as when land is crowded with vegetation suffocation is induced to some extent, which perhaps is only second to an attack of leaf disease in its ill effects. I do not, however, advocate anything beyond keeping down the weeds by grass-knifing during the early part of the year, leaving the forking to do the rest in cleaning the place. Weeds are not an unmixed evil. They serve to keep the soil together during heavy rains and only become injurious when allowed to grow to such an extent as to choke the coffee. As they draw nourishment from the atmosphere they eventually return more to the soil than they took from it. This naturally brings me to the subject of green manuring, as this is one of the strongest points in its favour. Green manures have a mechanical action on the soil rendering it more open. Plants of the leguminous order would be especially beneficial in supplying the soil with nitrogen. There is too much sourness in the green manure obtained by the burying in of weeds. A change would therefore be advantageous. There would, I think, be no difficulty in growing crops of green manures if the seed were put down after the pruning, as the thinning out of the trees would admit enough light for their healthy growth, and as the ground is at this time free of weeds they would spring up with the first showers. Now it is quite out of the question. The next best time to grow them would probably be in September and October next, after the handling has been finished and shade trees have been lopped up, as growth then, owing to alternate sunshine and rain, is vigorous.

The sweet plaintive melody of that harbinger of the monsoon, the monsoon bird, known as the "Lonely Ploughboy" I think, on the Nilgiris, strikes pleasantly on the ear during the day. The bird selects the most secluded leafy spots where, undisturbed it pours out its song. The coolies call it the *Guntay hakki*, or hour bird, as they say that it whistles regularly every hour throughout the day. The wind has veered round to the south-west and clouds since Sunday last have been drifting up from that quarter. Altogether it looks as if the monsoon forecast for this year will be verified in its bursting at an early date.

I had progressed thus far with these notes when I was told about an estate hereabouts which is expected to give 50 tons off about 180 acres! The rain had been entirely favourable, and excellent blossoming weather was experienced after it.—*M. Mail*, May 30th.

THE PRODUCTION OF LATAKIA TOBACCO.

The *Journal de la Chambre de Commerce de Constantinople* says that the district of Latakia, which gives its name to the famous tobacco, is situated in the north of Syria, and occupies the site of the ancient Laodicea, in the neighbourhood of Tripoli; but the port, formerly so renowned, has been blocked up with sand, so that only small, lightly-laden vessels can now enter. Behind the town extends a vast plain to the south beyond Jibleh, as far as the range of hills inhabited by the Nocairis or Ansariel. This tribe is specially engaged in the cultivation of Latakia tobacco, and obtain considerable profit from it. The Nahr-el-Kebir, which runs through the plain, affords the necessary irrigation. The following is the method adopted in the cultivation of the tobacco:—Towards the end of December the ground is broken up and the sowing takes place in January, ten or twelve seeds being placed in holes from four to five feet in depth. As soon as the sprouts appear above the ground they are covered with mats which are taken off when the sun shines. Women and children are employed to frighten away the birds and see that they commit no injury to the sprouts. In February the plants are transplanted to another field, and earth is plentifully piled up around them, while in March they are kept well watered, and in April the harvest commences. The first leaves are placed to dry in the sun or by the fire; these constitute what is called the new tobacco, and is particularly appreciated by the fellahs themselves as it is considered stronger than that obtained subsequently. From April until the month of August the plants are watered according to the state of the weather, the yellow leaves are lopped off, and the buds are removed in order to strengthen the general growth of the plants. The full harvest takes place in the commencement of August, and, towards the south, in September. The entire plant is cut, the leaves removed, tied up in bundles, and placed in the sun to dry, care being taken to frequently turn them over. In November, the tobacco is sufficiently dry; it is placed in horse-hair sacks, and put upon the market. The merchants, however, subject the leaves to a new drying, and then sort them according to colour, perfume, and general quality. The different varieties placed upon the markets are the *Abou-Richa* or *Djebeli*, which is the finest quality, and is only obtained in the high plantations of the Nocairis, and which is much in favour in Europe as well as in Egypt. The *Djidar* is a little rougher in quality but burns well, and is much appreciated by great smokers. The *Schick el Bent* very closely resembles the *Djebeli*, with which it is frequently mixed by the retail dealers. The plain of Koura, which extends from the foot of Lebanon to Nahr-el-Kelb between Tripoli and the mountains, also furnishes excellent Syrian tobacco, the best products being those of the villages of Sebail and Serai. The district of Gabail, and particularly Kesrasan, furnishes the finest variety, and also the most expensive. This tobacco leaves a white ash, while Oriental tobaccos as a rule leave a black or dark grey ash. The southern districts of Lebanon, and particularly the region of Tripoli, only supplies very ordinary varieties of tobacco. In the districts of Aleppo and Damascus, a little tobacco is also grown, but of an inferior quality.—*Journal of the Society of Arts.*

TEA IN JAPAN.—The *Japan Weekly Mail* of 14th May says:—Tea is bought as fast as it comes to market, but the trade cannot be said to be in full swing even at this late date. Less than 1,000 piculs of leaf was the total business last week, but the qualities taken were all "fine" to "choicest." This week, however, much more has been done, the total settlements on the 12th inst. having amounted to 15,577 piculs. Prices from the opening to the present time have been fully \$2 per picul higher than last year, but the first week's continuous warm and dry weather will produce such heavy arrivals of leaf on this market as to make a considerable drop in prices a certainty.

SEEDS AND PLANT DISEASES.

REPORT OF CONSULTING ENTOMOLOGIST.

During the late winter and spring months much attention has been directed in the Western fruit growing counties to ascertaining what reliable measures could be adopted in order to destroy the hordes of caterpillars which now appear almost as a regular, yearly recurring, cause of serious loss to fruit growers.

It has become more and more plain each year that although sticky banding is so far of service, that in many cases the foliage of orchard-trees would have been totally destroyed if the banding had not been done, yet still that it is only a partial protection against wingless months gaining access to the trees for egg-laying, and is no protection at all from the many kinds of attack originated by winged infestations: also it is expensive, needs renewing at intervals, and, without special arrangements to insure safety to bark, is detrimental to the health of the trees.

In my own suggestions as to applications I limited myself to advising trials of "Paris green" spray as with this application we had clear information from the U. S. A. and Canadian Government reports of the exact proportions in which it was to be used and of every detail concerned and also of its success and warnings as to requisite caution in use, it being a poison; for those who did not care to try it (by advice of the Dominion entomologist) I suggested the use of washes of soft soap and mineral oil.

The experiment Committee has wisely made a trial and recorded results of many applications, and of these after the committee meeting at Toddington on the 1st of the present month, the committee decided that they would recommend the following for spraying on infested trees:—Paris green paste, in the proportion of one ounce to eight or ten gallons of water for plums; and one ounce to twenty gallons of water for apples; London fluid (that is, a mixture of a preparation sold as "London purple") one part to twenty parts. Both of these the committee recommended as effective in destroying the caterpillar while they did no material harm to the foliage.

I am favoured by reports of the meeting (with full details) being placed in my hands both by Mr. Masters, and from Toddington, but as these important points are too long to be entered on here, I just mention that I will (as matter of course) give all information in my power to any applicant, or so long as they last, forward copies of the separate impression of the orchard fruit paper from my early report. In this I give exact proportion of Paris green found serviceable in American horticulture, which I am thankful to find has now been confirmed as a safe and serviceable preparation by the above well-skilled horticultural authorities.

It will be observed that the term Paris green "paste" is used. In order to avoid risk to health from careless workers inhaling the powder, one of our chief supply firms arranged to send out small orders damped, which saves all danger from inhalation in mixing. Besides the above experiments which are considered to be progressing satisfactorily, I have had information of the successful use of the Paris green, or arsenite of copper, from private correspondents, and am in much communication on the subject, and also it is being a new application here and a poison. I invariably warn that it is not to be left about, nor the powder inhaled.

At present the main point under consideration is, I believe, date of application. Mr. Masters added to the observations on the part of the committee that they considered the syringing should be done when the leaf bud was first developed, before the blossoming period, and then again after the blossoms had disappeared and the fruit was forming. So far the work is considered to be progressing satisfactorily, and if, as there appears to me reason to hope, our operations succeed as well as they have long done in America, the hard and skilled work of the Evesham Committee will be a benefit throughout the country.

ELEANOR A. ORMEROD.

—*Indian Agriculturist.*

THE ALLEGED OVER-PLUCKING OF OUR TEA BUSHES.

The following remarks have been made on the statements contained in our London Correspondent's recent letter as to criticisms at home in support of Mr. J. L. Shand's accusations that our tea planters are exhausting their plants by plucking of an inordinate and exhausting nature:—

"It is impossible to attempt to disguise the fact that the remarks reported to have been made by Mr. J. L. Shand during his recent visit to this island in deprecation of the exhaustive plucking of our tea bushes awakened a great deal of angry feeling. Letters addressed to the *Observer* and appearing in its columns but too fully evidenced the existence of such a feeling and the bitterness of denial they contained may have been but the 'froth upon the wave' which shows the strength of the tide. But the opinion expressed by a gentleman of long experience which is reported in the London Letter coincides very strongly with that which has brought down so much of animadversion upon Mr. Shand's head, and although we can have no desire to pose as alarmists, we think we shall scarcely be fully performing our duty if we should altogether abstain from asking our planting friends if there may not be a stratum of truthfulness in the allegations made, and whether, in that case, it may not be to their interest to modify their present practice so far as to set aside a small acreage on each estate over which present practice might be varied and the results to doing so be recorded. It is acknowledged by high expert testimony that the soil and climate of Ceylon are far better suited to the growth of leaf than to the production of fruit, exemplars of both kinds being found in tea and coffee trees. It is argued upon this that tea has a far greater chance of enduring vitality here than had our now almost wholly lost cultivation, and with the strength of that argument we fully concur. But it is one thing to produce, it must be another to maintain; and if, as is asserted in several quarters, our tea bushes are being overplucked to an extent which must in the long run overtask their powers, it will be hopeless to rely upon the qualities of soil and climate as an assurance of perpetuity. We are aware that ominous prophesying has been made by men of India and China experience, with respect to the results which must follow our perennial plucking. These critics—interested and hostile, doubtless—are said to base much hope for the ultimate results to their competition with ourselves upon the issue which they state they can rely upon to the course while our estate proprietors still hold themselves to be justified in following; and we do not think it to be altogether wise to ignore the views which seem to afford to these so much of anticipative satisfaction. We therefore think that experiment might well be tried over, as we have said, a restricted acreage on each estate, with the view of determining whether certain periods of rest from plucking for the purpose of admitting occasional full development of leaf, might not be not only beneficial to the tree but economical as tending to foster a higher quality of production where the ordinary course of plucking is re-sorted to. It certainly does not seem likely that a vegetable growth never allowed to attain the full development nature has assigned, for it should remain wholly healthy. We believe we have read that the dwarfed plants of China, Holland, and some other countries, curiosities and monstrosities only, are produced by checking at an early stage

their natural development. If such be the case, this treatment would seem to be allied to that we are now pursuing with respect to our tea bushes. If such an experiment as we have suggested were made, a year or two would suffice to enable comparison to be made between the condition of the acreage so treated and that left to the results of existing practice. We therefore think that on all the considerations mentioned such an experiment might usefully be made by all our planters."

On the above we have to remark that experiments in the direction indicated might well be made. But it must be remembered that in the case of tea, as in that of coffee and many other products, profitable cultivation includes and must ever involve interference more or less considerable with "natural habits" and spontaneous growth. The tea plant, if left to grow at its own sweet will, would shoot up into a tree of from thirty to forty feet in height, and following the instinct common to all vegetation would produce leaf only of a quantity and of a character best calculated to enable it to mature a crop of fruit for the perpetuation of its kind. The instinct of the coffee and cacao plants in this direction is furthered and assisted by the planters who grow them, by all possible means. The object of the tea planter, on the other hand, is to compel the tree to put its whole strength into the production of leaf; and one of his greatest troubles is the development, at certain stages of growth and in certain seasons, of blossom and the formation of seeds. This is the natural tendency of the plant,—a desperate effort to propagate its species but for the planter to encourage or permit this natural tendency would be not only injurious to his immediate interests, but more injurious to and exhaustive of the strength of the tea bush than many pluckings of leaf would be. If, therefore, the time for pruning has not come (an operation, in the case of the tea bush, performed largely to prevent the formation of fruit and procure abundance of leaf in the form of "flush"), the coolies on the estate (generally the boys and girls) are turned on to deprive the bushes of every blossom developed and every fruit formed or commencing to form. Then as to allowing the trees to rest, by allowing a luxuriant crop of flush suited for manufacture into marketable tea, to harden into ordinary leaves, we suppose the orthodox planter would protest against such a course as depriving him not only of the crop of flush thus hardened but of several others; because the tree relieved from the incitement of supplying the flush removed, would put out buds and young leaves but sparingly, unless the knife was used. The process of "perennial plucking" is, no doubt, exhausting to the bush, but so is the gathering of fruit from coffee and cacao trees. Our bushes in Ceylon, grown within 7° of the equator, have not the rest which a real winter affords between November and March to the tea grown in Assam and Northern India. But it would be a mistake to suppose that our Ceylon tea plants do not enjoy occasional rests, more or less protracted, according to the amount of wind driven rain which strikes on them during the height of the monsoons. There are also the dry winds, the heat during the day and the lowered temperature during the night,—with real frostiness at high altitudes,—in the clear weather of January to April. But what is the specially exhaustive plucking complained of? On every hand Ceylon planters are warned and intreated to pluck "fine"; and yet experts tell us that the finer the plucking,—that of the buds and the just developed minute flush,—the more exhausting it is to the tree. Anyhow, the processes of periodical pruning and frequent, though not incessant, plucking are and must be more or less exhaust-

ing, according to the nature of the climate in which plantations are situated. In large portions of the island the climate—warm but moist—is of a recuperative as well as a forcing nature, the atmosphere supplying much of the constituents needed for the formation of leaf; and when signs of exhaustion begin to appear, or even beforehand, fertilizing substances ought to be applied to the soil. If justice is done to the culture in this way the period of exhaustion of the tea bushes, frequently plucked as they are, can be indefinitely postponed to forty, fifty, sixty, or more years, instead of the twelve, which we find in Fortune's book was the period of exhaustion and replanting in the tea regions of China some forty years ago. We believe we represent the general opinion of the most experienced and intelligent Ceylon tea planters, when we say that the evils of over-plucking have been greatly exaggerated; that the planter's wisdom is to pluck crops of flush as they attain the proper size; and that medium and not fine plucking is not only most profitable to the planter but the least injurious to the health, vigour and life of the tea plant.

FROM THE METROPOLIS.

May 20th, 1892.

ANOTHER CEYLON TEA ESTATES COMPANY.

"The cry is still they come," and is it any wonder in the face of satisfactory reports of the working of existing Companies and the fact that money is now, once again, so abundant and so "idle" in the London market. "THE CALEDONIAN (CEYLON) TEA PLANTATIONS COMPANY" is the title of an Association with a capital of £30,000, formed to take over, work and develop certain tea estates belonging to Mr. Alex. Ross in Maskeliya and Dikoya, including Venture, New Caledonia, Merria Cotta, &c. I am not sure if a copy of the prospectus will reach me in time for this mail or be sent to you direct; but meantime it may suffice to say that Messrs. A. Sinclair, W. Gow and A. Ross are among the Directors.

THE SCOTTISH CEYLON TEA COMPANY, LIMITED,

had, as you may imagine from the Director's Report sent you by last mail, a satisfactory gathering at the offices of the esteemed, popular Secretaries, Messrs. Anderson Brothers, in Philpot Lane, on Monday afternoon last. Mr. H. L. Forbes looked quite the veteran Ceylon planter as he presided in his double capacity of Chairman and Managing Director. He was supported by Mr. John Anderson and Mr. R. W. Forbes (and I suggested afterwards that they should have been photographed as a model Board only equalled, perhaps, by that of the famous Yatiyantota Company, leaving out of view of course, so big a concern as the Ceylon Tea Plantations Company). Mr. Forbes proved an admirable Chairman for clearness and precision in his several business statements, and no less so in his sympathetic and well-expressed reference to the sudden and much-regretted death of the Chairman of another and perhaps leading Ceylon Tea Company, Mr. David Reid. This very becoming testimony to the worth of Mr. Reid and of regret at the loss to his family, friends and the colony, is to be embodied in a letter by the Secretaries and sent on to the sister Company's Directors. After a little discussion in which the Chairman, Mr. Wm. Cooper and some others took part, the usual resolutions and votes were proposed and carried. It was intimated that the new Factory now being erected on Lonach in Upper Ambagamuwa or rather Lower Dikoya, will cost between £2,500 and

£3,000. It was pleasant seeing Major Forbes, the father of the Chairman, bearing his years so well.

THE RISE IN TEA—

—such succeeding sale now indicating a firmer market —is putting everybody interested in Ceylon and its staple industry in good humour.

ALTERATION OF RAILWAY GAUGE.

A great deal of attention has been attracted this week to the work of the Great Western Railway Company in converting their very broad, into the English standard, gauge. It is said that even now the conversion of 200 miles will cost the Company quite a million-and-a-half sterling: the conversion of the stock alone absorbing £370,000. Now what is to be thought of this operation and of the original cause? Very diverse opinions are entertained and it is well before the ordinary cry of "See the mistake made in taking up with too broad a gauge even in England," should be re-echoed in Ceylon, that there is a very strong view entertained even here that Brunel was right in his very wide gauge, and the other Engineers were wrong in choosing a narrow one, so far as Great Britain is concerned. A Railway Director remarked to a Press correspondent the other day that Brunel had demonstrated it was possible to build both a ship and a railway too big. But this is scarcely correct. Brunel was simply before his time. Our ships are now following close on the size of the "Great Eastern," and leading Railway Engineers are very free in expressing the wish that Brunel's seven-foot gauge had been adopted as the standard for English railways. It is only now, when too late, that he has been acknowledged to have been right. Meantime there is every reason for congratulation—especially on the score of safety and power—that our Ceylon lines (up the mountains especially) are on so good and wide a gauge as they are.

THE STABILITY OF THE CEYLON TEA INDUSTRY: FROM THE PLANTER'S POINT OF VIEW.

Just as I am closing this long contribution there comes in *The Financial News* of today with my reply on the discussion raised by the Editor and continued by Messrs. W. J. & Henry Thompson and Mr. F. S. Hawes. I think I mentioned in my last how I was specially requested in "the Lanes" and by Ceylon men to deal with the matter and put forward the case for the stability of our staple industry. I hope the Planters' Association and the Planting community generally will consider I have done fairly by them in the limited time at my disposal. Perhaps some of them, or at any rate some members of the Chamber of Commerce, may think I ran wild in anticipating that 150 million lb. of tea could ever be produced in Ceylon; but who can tell, if China is shut up, how far planting may go in the lowcountry? At any rate no harm is done if such figures discourage planting in India and Java, and the development of tea trade in China. My letter is as follows:—

THE CEYLON TEA INDUSTRY.

ITS POSITION AND PROSPECTS FROM THE PLANTER'S POINT OF VIEW.

To the Editor of THE FINANCIAL NEWS.
SIR,—My attention has been called by a friend interested in tea to your recent editorial deliverance on the tea trade, the comments on some points affecting Ceylon tea offered by Messrs. W. J. and Henry Thompson, and the rejoinder of Mr. F. S. Hawes, in which he specially questions the stability of the Ceylon tea-planting industry. It is on this

last topic that I should like, with your permission, to occupy some portion of your space.

Though tea had been planted in the hill country of Ceylon about thirty years ago, yet so recently as 1875 the total area cultivated was only about 1,000 acres, and the rush into planting did not commence until after 1880, the area planted exceeding 100,000 acres in 1885, while now I estimate, from the returns compiled by me for the latest "Ceylon Handbook and Directory," that not less than 255,000 acres are covered by the tea plant. In the same way, our tea exports continued small up to 1886, when they reached nearly 8,000,000 lb., the increase being very rapid every year thereafter, so that, in round figures, the annual totals have reached 14,000,000 lb., 24,000,000 lb., 34,500,000 lb., and 46,000,000 lb. respectively; while last year we sent away more than 68,000,000 lb., and this may be exceeded by 10,000,000 lb. to 12,000,000 lb. in the present year. Personally, I have had thirty years' experience as a resident in Ceylon; I have constantly watched its planting industries, and have paid more attention than anyone else to its agricultural statistics. The wonder to us all now is that we did not find out twenty or thirty years earlier how admirably adapted Ceylon was to become a great tea-growing county, how much better, for instance, the Ceylon climate and soil are for the growth of tea than coffee, which continued to be our staple for forty years, and how much hardier and more adaptable to varying conditions of altitude and soil the tea plant is than almost any other tropical or sub-tropical plant that can be named. The moist south-western zone of Ceylon, with its comparatively high range of temperature, affords an almost perfect home for the tea plant, with its leaf-yielding crops—a habitat almost as suitable as its original one between Assam and China, and one in which, so far as we in Ceylon can judge, it is likely to continue to grow and flourish, as long as even our several cultivated palms.*

Tea grows with wonderful vigour in Ceylon, from the south-west coast districts up to plantations 6,500 ft. above sea level. As a rule, the higher we go the finer and more delicate are the teas produced, but the less crop per acre; the lower we go the stronger, and perhaps coarser, the product, but the heavier the crop return. There are frequent exceptions to this, as to most generalising rules, the heavy crops of fine teas yielded in plantations above 4,000 ft. or 4,500 ft. having of recent years astonished all concerned.

So much I have ventured to put down by way of introduction towards an understanding of the conditions attending our tea planting enterprise. Now, the cry raised by Mr. Hawes about instability at this time is by no means a new one; it was one of the earliest advanced by Indian planting critics when Ceylon tea began to come into notice. I have had Indian planting visitors in my Colombo office so far back as 1886-87 who, after an inspection of our planting districts, declared, very much in the words now used, that Ceylon planters were over-plucking and forcing their tea bushes, and that they (the visitors) were convinced there was no stability about the enterprise. This reminds me of a Canton merchant who would scarcely allow me to mention Ceylon tea when I visited him in 1884, en route to Japan and America, but who, three years afterwards, wrote apologising, because he had realised that Ceylon tea was to be the great tea of the future, and he felt bound to turn his attention to it more than any other. We had not much to say in reply to our critics, save that our instructors, our "guides, philosophers and friends," in the arts of plucking and pruning tea were experienced Indian planters, and that Ceylon planters,

* Our Sinhalese agriculturists (many of them shrewd, observant men) at an early date in the tea era expressed themselves astonished at the hardness of the tea shrub as compared with the coffee bush—the latter chiefly a surface feeder, while tea sends its roots far down, like "a regular jungle plant," as they called it. Of course, cheaper labour and transport are indispensable conditions to success in the cultivation of tea.

above any in the world, were ready to profit by good advice, example, and experiment. But since that time we have been able to turn the tables on our critics, and to call their attention to facts which may well make them pause. It is, however, not so much the experience of an additional six or seven years—though that may count for a good deal—but we have altogether enough of typical plantation fields in regular cultivation and cropping for nearly twenty-five years to point to as constituting an object lesson from which much may be learned. There is, for instance, the oldest field in Loolecondura plantation, some 20 acres cleared and planted by Mr. Taylor in 1867, and which has been plucked regularly ever since it came into bearing, with the usual intervals for pruning, &c.

Now, I have for some years back applied to Mr. Taylor for an annual report on the condition of the tea in this field, as one of the oldest in Ceylon. In 1888, for instance, Mr. Taylor reported the twenty-year-old bushes to be very vigorous, and last year (1891), when I made the latest inquiry, Mr. Taylor wrote to me: "The field is as good as ever, giving about the same crops: it was manured once only with castor cake in the beginning of 1885." I may be told "one swallow does not make a summer," and that Mr. Taylor is probably more careful in his cultivation and plucking than most Ceylon planters; but, though there is, perhaps, no other case in the island so old and so reliable in its information, yet there is abundant evidence to show that there is nothing in the appearance of our tea fields generally, or in the yield of crop—I shall come to quality—to justify doubts as to the stability of the Ceylon tea-planting industry. As to heavy yields of crop, I may give the case of the Mariawatte plantation (of the Ceylon Tea Plantations Company), situated lower down than Loolecondura. Here the original 104 acres were planted in 1879, and the returns of crop in made tea, as recorded by me in the "Planting Directory" from the manager's reports, run as follows:—

		Per acre.		Maunds
		lb.		(about).
1884	Tea 5 years old	1,042	...	13
1885	" 6 "	1,178	...	14½
1886	" 7 "	1,059	...	13
1887	" 8 "	1,126	...	14
1888	" 9 "	1,035	...	13
1889	" 10 "	1,106	...	13½
1890	" 11 "	1,347	...	16½
1891	" 12 "	(Not got figures by me, but fully up to average).*		

In 1891 I was told no manure had been applied to the above tea for two years. This particular field affords an admirable lay of land—comparatively flat for tea; but over the whole plantation of over 400 acres the average crop in 1890 was 757 lb. per acre in bearing. Of course, such returns are far above the average for all the Ceylon plantations; indeed, if, over the whole 255,000 acres now planted, we only get half this return per acre average, it will mean a crop, when all is in bearing, not far short of 100,000,000 lb. One reliable planting report, written at the beginning of this year, described Ceylon plantations as "everywhere looking in good health."

But now as to quality. It is quite true that many plantations in their early years send home better teas than they do later on; but I think Mr. Hawes will find, on more careful inquiry and study of the question, that the explanation has nothing to do with "the stability of the industry," or with the soil, or even the mode of planting. There may be a little allowance made for aroma for the first few crops off virgin soil; but far more is due, in the case of fine teas coming from plantations in their younger years, to the great and deliberate attention which the planter and his staff can give to the comparatively trifling crops of the first few seasons. It is when the rush of "flush" commences from big healthy, vigorous bushes, and all the resources of the

* Since received from Mr. Rutherford:—In 1891 Tea 12 years old gave 1,157 lb per acre, about 14½ maunds. The whole estate gave an average of 866 lb per acre.

factory, it may be, are taxed, that it is impossible to prepare with the same deliberate care. No doubt, in some cases "coarser plucking" also explains a difference; indeed, there are not a few plantations where, in view of lower prices, even for fine teas, it has been found more profitable to give up fine plucking and the very careful preparation of a limited quantity of superior teas in favour of the harvesting and preparation of a larger quantity of more ordinary cheaper teas. This fact accounts for the falling off in the average quantity of certain marks, rather than any deterioration in the tea bushes, the soil, or any other circumstances affecting the stability of the Ceylon tea-planting industry. I may be told by Mr. Hawes and other London tea authorities how much better it would be for the Ceylon planter to aim, above all things, at keeping up the quality of his teas; and, *prima facie*, it may be argued that such a course as taking less leaf off the bush, and so less out of the soil, must be conducive to the permanency of the industry. But London authorities do not know everything about the tea bushes; nor, for that matter, does the Ceylon planter as yet profess to know all. And, among the rest, there is the experience, under certain weather conditions, of the flush becoming so abundant—of the flush running away—that it is only by plucking very freely that the planter is able to keep his bush in proper order, and he is, perhaps, forced by the circumstances of the case to make as much tea in one month as, ordinarily, he would do in two or three months. In this connection it must not be overlooked how greatly our tropical rains in Ceylon, rich as they are in nitrogenous properties (in ammonia), contribute to the production of leaf crops. But, again, let me notice how perplexing sometimes to the practical planter is the advice he gets from London in regard to the advantage of only preparing superior fine teas. This was a doctrine taught free from the metropolis during 1890, and, as a journalist (dreading more particularly production in quantity outstripping consumption), I preached it in season and out of season towards the beginning of that year in Ceylon. I remember, too, how much my opinion was strengthened by the visit of the late lamented chairman (Mr. David Reid) of the Ceylon Tea Plantations Company. His theory then was that the ordinary Ceylon teas (chiefly from the low districts) would henceforward come into competition with the average Indian teas; whereas the finer and high-grown Ceylon teas could always have a profitable market of their own, with scarcely any competition from India and China. How much better and more profitable, then, for the planter to do all he could to turn out fine teas! Such was the advice given, and in many cases acted on, in 1890. But what happened in the London markets? I need only ask you to recall the anomalous condition of affairs during the latter half of 1890 and first half of last year in Mincing-lane to understand the discredit that temporarily overcame the "fine tea" theory. Without much warning, the prices for the contemned common Ceylon teas rose almost to the level of those paid for fine high-grown, and continued so for months; the planter who had taken our advice and perhaps reduced his cropping from a ratio of 500 lb. to 600 lb., to say 300 lb. to 400 lb. an acre, in order to secure fine, delicate teas, found that while he got, perhaps, an increased average, his neighbour, who went on his old course, and gathered the equivalent of crops 30 per cent to 50 per cent more per acre, got prices averaging nearly as high, and was, in fact, making far more profits through disregarding the advice of London tea men—(I learned two days ago, in Mincing-lane, of a case where the same quality teas from the same plantation realised nearly double the price, within a few months after the strong demand for common teas set in),—and the consequence was that early in 1891 a large number of Ceylon planters made up their minds that their policy lay in the direction of quantity rather than quality. I merely give this as an illustration of the difficulty of laying down hard-and-fast rules.

I have said above that the Ceylon tea planter does

not profess yet to know "all about his tea bush"—what may be the very best mode of cultivation, of harvesting and of manipulation of the leaf. There is no such school in the world for the tropical agriculturist as Ceylon. Our planters vie with each other in observation, experiment, and interchange of ideas. Many of them are practical engineers, some are well read in scientific agriculture, while there are local working engineers giving full attention to the requirements and the improvement of the tea factory. Already in Ceylon much advance has been made on the old Indian system; but there is room, I am convinced, for a great deal of improvement still. The whole question of "manuring" with reference to quantity and quality of leaf has yet to be experimentally dealt with. The best mode and time for "pruning," the style of "plucking" best suited for different altitudes, and, above all, means to ensure more complete withering, the proper degree of time and temperature for drying the leaf, and the due amount of fermentation, will all form, in the course of the next few years, the subjects of careful inquiry and experiments. I know even now of very important experiments being made in these directions. The aid of the analytical chemist as well as of the practical engineer, will be freely availed of by the Ceylon planters, and whatever men in their position can do will be done to ensure further success in turning out good teas with profitable results, and in ensuring the stability of their industry. In this respect, the hardy tea bush, with its deep roots,* offers great advantages over the more delicate coffee shrubs. If necessary, it would be possible, in the case of an epidemic of insect or fungus pest on tea, to deal with it in a far more radical way than could ever have been tried with coffee; but there is no need to go into details.

Already, I fear, my letter is too long, although I have said so much in order to indicate grounds for our belief that there is nothing in the tea industry of Ceylon at present, or the mode of cultivation, &c., which justified the statement that it is not likely to be as stable as any other tropical industry. No one can tell, of course, what the next twenty or thirty years may show—even five or ten years are a long spell in tropical experience; but certainly, I see no good reason (if prices keep up within a decent reach of present averages) why Ceylon tea, for ten years to come, at least—or, indeed, for twenty or thirty—should not continue to show as prosperous and stable an industry as at present. Let me, in conclusion, recapitulate briefly some of the special advantages appertaining to tea cultivation in Ceylon:—

(1) Easy access to the planting districts, which are served by railways or roads, or both, affording ready, certain, and economical means of transport to and from the shipping port, whence there is always freight available at moderate rates to London, Australia or America.

(2) A good supply of free and fairly cheap labour, the labourers being among the most docile and steady working in the world.

(3) The comparatively healthful character of nearly all the island's planting districts, the larger portion of the hill country having one of the finest climates in the world.

(4) A climate and soil admirably adapted to the tea plant, with an abundant rainfall, rich in ammonia, well calculated to develop leaf.

(5) A large body of good artificers, and even skilled artisans, among the Sinhalese and Tamils, ready, not only to do duty in the workshops, but to aid planters in their factories with the machinery and various processes of tea preparation.

(6) A community of planters, many of whom have passed through the fires of adversity, and are ready to do their utmost in devising means of economising expenditure compatible with doing justice to

* A planter, with prolonged Assam experience before he came to Ceylon, assures me that he has found the tap root of the tea plant in our tropical island running down to a much greater depth than he ever saw in Assam.

cultivation and preparation, and all keenly alive to the advantage of profiting by every improvement resulting from observation or experiment.

Hitherto, however, nearly every Ceylon tea planter has been kept busy with the formation and furnishing of his plantation, if I may so say. Every season nearly, there has been some additional field to be planted, machinery to be got, or factory extended. Indeed, it is a question if more than a minority of our plantations can even now be said to be thoroughly equipped for work, with requisite withering space in factories, sufficient motive power for rolling and drying, a proper number of machines, and, in wet districts with means (by fans, &c.) for supplementing the ordinary withering arrangement in continuously wet weather. All this may read as petty technical detail, but what I aim at pointing out is that in a few years, when Ceylon may, perhaps—at 100,000,000 lb. to 120,000,000 lb. (or perhaps 150,000,000)* of tea—attain its maximum annual crop, there will be a vastly increased amount of attention and experiment directed to the improvement, in every detail, of the modes of culture, harvesting, and preparation of tea. Even now the process is going on. Perhaps London tea experts will better understand my position and opinion if I allege, as I do with confidence, that there is not a plantation in Ceylon whose teas have, as supplied to the London market, fallen off in quality of recent years, but which could resume sending teas as good as ever, if only it were made worth the while of the manager and proprietor to do so. It is not a question of tea bush, or soil, or even climate—though an unusually wet season in 1891 increased the quantity of common teas—but one of market and prices. In one well-known case, where an average close on 2s a lb. used to be got some years ago, the plucking was so kept down that the crop per acre was not equal to one-half what it is now, and the latter, of course, pays the proprietor better at a far lower price, while many planters hold that “free” or, at any rate, “medium” plucking is much better for the health and vigour of the tea bush than fine plucking.

I must apologise for running on at so much length; but I venture to think that information in regard to the great tea-planting industry will be of interest to your City readers, as it should be, indeed, in every British household. For this reason, I should be glad if you would permit me, in a second and briefer letter, to notice certain erroneous ideas which prevail in England about Indian and Ceylon, as contrasted with China, teas. Meantime, I am, sir, yours, &c.,

J. FERGUSON, of the

Ceylon Observer and Tropical Agriculturist.

Royal Colonial Institute; Northumberland-street, W.C., May 19th.

TEA PLANTING IN PERAK.

Among the passengers who joined the homeward-bound mail at Colombo is Mr. Fred. Watson on his way from Perak, where he has been engaged in tea planting. He has been a year and a half in Perak, which he describes as a splendid tea-growing country. The leaf compares very favourably indeed with that of Darjeeling, where he had four years' experience; and he hopes to secure a good place for it in the English market, that being the object of his trip home. Regarding the price of labour in Perak he says that it is just what the planters make it, and that he has obtained coolies from the hill estates of China for four dollars a month.

* This would, of course, mean a great extension of planting in the lowcountry.

THE CEYLON PLANTERS' TEA CO.

The following are the cuttings referred to by our London correspondent recently as having been handed to him by Mr. Elwood May:—

SECRETS ABOUT TEA.

INTERESTING FACTS AND SUGGESTIONS TO LOVERS OF GOOD TEA—AMERICANS DRINK THE WORST AND CHEAPEST—PAYING \$1,000 FOR FIVE POUNDS OF CEYLON TEA.

Tea drinkers will be interested in an interview a Mail and Expressman recently held with Mr. S. Elwood May, president of the great Ceylon Planters' Tea Company, at No. 110 Fifth avenue, in this city. He is a tea expert, and said:

THE PERFECT TEA.

“The perfect tea does not please at first, for two or three reasons. Too strong; or, rather, you use too much of it. Excellent fault, when you find it out and adapt your making of it. Too strong in another sense; that is, you steep it too long and get the tannin. You want the tea without the tannin. Stop, then, between tea and tannin. This applies to all sorts of tea. Hotel and restaurant tea is steeped by the hour, and nobody wants a second cup of it. Tea at home, as a rule, is steeped too long; it is tea and tannin; puckery; wrong in strength; it is too strong, not of tea, but of tannin.

THE FAMOUS CEYLON TEA.

“The tea of Ceylon has two strengths: that of tea, which is delicate, fine, inspiring, and that of tannin, puckery, harsh, unpleasing, bitter. One is a beautiful amber; the other is dark and forbidding. All tea has these two strengths. A proper steeping extracts the better and leaves the worse. Japan and China teas, at their best, are coarse compared with that of Ceylon, which is new to your taste. This newness is ‘herby.’ Why not? Is not tea an herb? Would you have it metallic? Excuse the herby taste for a week; you will find it outgrowing excuse. Your taste is righting itself.

AMERICANS DRINK THE WORST TEA.

“The worst teas in the world are sold to this country. English Breakfast tea is a name invented to humbug with; there is no such tea. American teas are weighted and colored; some of them steeped and the leaves ‘manufactured’ over again. It is useless to say they are poisonous—people do not die of them. Taste is perverted. Give it time to recover. Drink the herby tea for a week, but be sure that you follow directions in making it.”

This is a fair introduction of tea—pure, clean, fine tea—an attempt to get it made right, steeped right and judged deliberately, with some allowance for taste, misled by long habit.

CULTIVATE A TASTE FOR FINE TEA.

Is it worth your while to reform your taste in the trifle of tea? In a week you will know. Let us send you a sample. A primer goes with it with clear and full instructions for steeping. As often happens, they need it most who least suspect it. You shall say you never knew the comfort, the cheer, the power of tea. And the tea would be cheap if the price were double.

\$1,000 FOR FIVE POUNDS OF TEA.

Mr. May related this interesting incident: “As I was sitting in my private office one morning, not long ago, I heard a well-bred woman's voice in the outer office asking our native Ceylon servant if the company could furnish her with Golden Tip Ceylon tea, worth \$200 a pound. I was not long in presenting myself, and informed her that the last sale of Golden Tip Ceylon tea brought at public auction \$183 in London and was bought by an English lord, that it would be impossible to say when the next parcel would be offered, and that only five to eight pounds came to the London market at a time, and that only occasionally. There must have been some of the curiosity I felt as to what she could want with such costly tea depicted on my countenance, for after a short pause she said: ‘I would gladly purchase five pounds at \$200 a pound, as I am going to give a tea. I am constantly going abroad, and always proclaim, when provoked to do so, that we Americans

have the best of everything. I should like to feel that we had entertained our friends in America with tea at \$200 a pound, for I recently read of the sale of tea you speak of in London at \$183.' I was so carried away with her national pride, that I forthwith offered, if she would permit me, to send her some of our best Bhud tea, with my compliments. After her departure my mind turned to other whims that rich Americans had indulged in, and I concluded that nowhere are there so many people willing to spend fabulous sums for the gratification of their pride and fancies."

HOW THE PRINCESS OF WALES MAKES TEA.

The Hamburg correspondent of the London Item relates some interesting gossip concerning the Princess of Wales and her recent visit to that famous watering place. She invariably breakfasted in a private dining room of the principal restaurant, the door of which was always left open. It was noticed that the Princess made her own tea. The hot water was served at the table. She carried with her a little parcel of Ceylon tea, and with her fingers took up and placed in the tea urn a very small quantity, apparently insufficient for a single cup, though usually she prepared enough for several cups for herself and some for her daughters; most of them, however, drank coffee. The Ceylon tea is made of the blossoms or buds of the tea plant and not of the leaves themselves. It is only necessary, therefore, to use a very small quantity as compared with the amount ordinary required. The fragrance of the tea was such, says the writer in the Item, that it filled the outer dining room. One of the inquisitive guests made inquiries in reference to its cost, and was told that it was called BHUD tea, and was imported expressly for the use of the Princess. More than this she could not learn. Ceylon tea since its use by the Princess has become known, has been greatly favored by English tea drinkers, and the importations of it during the last few years have marvellously increased. So successful has the business become that a branch of the London house has been established in New York, with its offices in the Judge building, No. 110 Fifth Avenue. The Ceylon teas imported by this company have within a few months achieved a wonderful reputation in the United States. It was BHUD CEYLON tea that was served at the banquet to President Harrison while he was visiting Mount McGregor. The cost of the tea served at this banquet was \$23 a pound.

One of the difficult things to do in any country is to get a woman to change her way of doing housework.

She will change her dress; she is used to that. Let her way of steeping tea?

She will come to it. Now is the time.

WARNING

If you steep this tea American fashion, that is, boil it and let it stand with the leaves in it ten or fifteen minutes, you spoil it. That is not the way to make good tea.

Not one in a thousand American families ever tasted good tea; you do not know what it is.

Good tea is the proper leaf prepared as it ought to be. It is cheering, refreshing, agreeable, gentle, and harmless; not pungent, bitter, puckery, stomach-disturbing, and nerve undoing.

The goodness of tea is drawn from the leaf by steeping it in boiling fresh water, the instant it boils, from two to seven minutes off the stove. After that what is got from the leaf is color and bitterness; strength, but not tea strength; a strength to tan leather—steep it a little longer and you can tan leather with it.

But tea is not all alike, and water differs. Tea grown on the higher mountain-levels requires the longer steeping. Hard water takes more time than soft.

The flavor depends on the tea itself in the first place and then on the steeping. Too short or too long, too cold or too hot, and the flavour is either not got or spoiled.

With these hints a careful taste may be left to find

out the time required to develop the finest flavor your tea is capable of.

This tea is the natural leaf of Ceylon, prepared in Ceylon by modern British appliances; nothing but tea; and not touched by the hand except in plucking the leaf from the plant. It is natural, pure and clean.

It is two or three times as strong as Japan or China tea. Use therefore only half or a third as much of it, and steep it at table.

Strange as it may seem to you, there is no economy in boiling tea. Economy steeps it at table, and pours it off the leaves in from two to seven minutes.

This tea is new; it has a strength and flavour unknown before. If you want its utmost value, lay aside your old ways and follow the new one.

It isn't new. The English always make their tea at table; it would be hard to get them to change, for they know that the proper flavour of tea is got by steeping it right—Americans do not distinguish that flavour. You will find it out; it is delicate, fine, aromatic—indescribably delicate, fresh and fine. When you get it right you will say you would never tested tea before; you will miss what you never quite liked in tea.

Our Brands of Tea are

Bhud (tea leaf buds) ...	at \$1 25
Tiffin (small leaves) ...	at .90
Bungalow (large leaves) ...	at .65

Our Brand of Coffee is

Lanka (roasted) ...	at .50
---------------------	--------

Ask your grocer for our brands and take no others. You thereby secure absolute purity and uniformity of quality.

To preserve the full strength and flavour of the tea keep it in an air-tight jar.

You may as well begin right—
Make this tea at the table.

CULTIVATION IN MALABAR.

A Coorg planter who has lately been travelling in Malabar writes to us:—"To a stranger it seems a mystery what becomes of the enormous quantities of pepper annually shipped from the ports on the Western Coast, mostly to the Continent of Europe. Production is outstripping consumption, and the local prices have fallen almost one-fourth this season. But the high prices that have ruled of late years have greatly stimulated the cultivation of pepper, as we shall learn probably from Messrs. Alston Low and Co.'s annual table of statistics issued at the end of the season.

Any tree that will hold the pepper vine in Malabar will be found covered. Poles are planted for the purpose and the favourites seem to be of the leguminose order, *Erythrina indica* and *E. stricta*, the first named smooth barked, the other prickly, called in Coorg *palvan* and *mul palvan*, in Madras *dalap*. I believe. The *Erythrina indica* is used freely in the early stages of coffee planting for shading, until more enduring kinds can be raised. It produces soft corky wood, and is short-lived. Plantations of considerable extent of these trees are to be seen from all the roads, in every direction, in Malabar, covered with pepper. The vines climb 10 to 12 feet in height, and the stems run to an inch thick and over. The cultivation is carefully managed, and it occurred to me that coffee planters might take a lesson from the pepper cultivators, in one respect, and that is in terracing. Whatever the slope of the land in Malabar, easy or steep, it will be found terraced for pepper and even for coconuts. The rainfall is no lighter in Malabar than in that of the favourite coffee districts of Coorg. Fields of coffee, in good districts that have been exhausted and abandoned, might be very well renewed by a scientific system of terracing, planting in manured holes, and carefully shaded and cultivated. I was told, too, by the late Sir Oliver St. John that terracing is the general system of cultivation practised in Northern India. If this careful preparation of the land will pay the pepper grower, whose produce is worth today £20 a cwt., care-

ful terracing and re-planting of old places is an idea deserving of the consideration of coffee growers, whose produce is worth R60 a cwt. Levels might be taken up the face of a hill and level pegs put down, at distances to suit the slope, the last one being 12 to 15 feet from the top. The terraces might be cut to the level of the pegs, sloping inwards, at 1 in 30 or 40, to prevent the loss of soil by wash. They should be of width to suit the land, wide enough to take two or three rows of trees. In this way a good deal of valuable ground now lying idle can be recovered probably. Moreover, if shade trees are present, a planter would like to preserve some, for a while at least, which would be another reason against wide terraces. I think this is an idea that it is worth the while of others to turn over in their minds, and an experiment made where practicable. I have found it successful and remunerative, though costly, I admit. The system of rice cultivation in Malabar appeared to me advanced, and about Tellicherry as near perfection as possible, not a yard of ground lying idle, separated from the coconut and arecanut orchards by trim mud or laterite walls with artistic steps and entrances. Everything bespoke careful and intelligent cultivation, and however primitive may be their ploughs and implements of tilth, it struck me they were not in need of a Dr. Voelcker or of any other scientist to teach them how to take most out of the soil. The Malabar ryot takes 3 crops a year! The occupiers of the soil are not needy in these regions, there is nothing to indicate indigence, and they would not stick at extra expenditure *that would pay*. The areas one could take in with the eye, while diving about, led me to form a high opinion of the growing powers of Malabar, and of the intelligence and enterprise of its cultivators. I saw it at its best, however, as rain had been falling daily, the total since 1st Jan., having reached over 12 inches."—*Madras Mail*, May 23rd.

COFFEE.

A circular recently issued by four of the largest coffee brokers in Continental Europe estimates the production of coffee in 1891-92 at 11,342,000 bags, against 9,297,000 bags in 1890-91; 8,658,200 in 1889-90; 10,598,200, in 1888-89; 7,077,000 in 1887-88; 10,312,500 in 1886-87; 9,488,000 in 1885-86; 11,440,000 in 1884-85; 9,767,000 in 1883-84; 11,080,000 in 1882-83; 10,391,000 in 1881-82. Messrs. W. Schoffer & Co. take exception to the estimate for 1891-92, placing the total export of coffee from all countries during the season of 1891-92, 10,100,000 bags or 648,000,000 kilos, equivalent to 1,425,600,000 pounds.

It appears from the first group of figures that the last ten crops gave 99,060,900 bags or an average yearly supply for ten years of 9,906,090 bags.

The author of the first estimate places the arrivals in Europe and America during ten years, 1882-91, at 102,994,900 bags; total deliveries at 104,915,300 bags. Messrs. Schoffer & Co. regard these figures as unreliable, or in their words, "of no value," because no account is made of direct shipments to Spain, Portugal, Italy, Mediterranean, Canada, Pacific coast, Australia, etc.

Messrs. Schoffer & Co. note a steadily increasing consumption, and on the basis of Custom House figures for Europe and deliveries for the United States furnish the following estimate showing the consumption in Germany, France, Austria Hungary, England, Belgium, Switzerland and the United States).

	Centner. (100 lb.)		Centner. (100 lb.)
1881	8,665,888	1887	8,382,000
1882	9,105,950	1888	9,607,990
1883	9,215,920	1889	9,415,760
1884	9,410,080	1890	9,462,760
1885	10,202,000	1891	10,214,120
1886	10,304,220		

In order to fix the total approximate consumption of coffee at the present time, Schoffer & Co. take

the Custom House figures of 1891, of course only of those countries which are officially controlled.

For Germany	2,509,480
France	1,402,000
Austria Hungary	706,740
England	261,100
Belgium	510,480
Switzerland	162,160
Further United States of America deliveries			4,661,060
Do Canada and Pacific (at least), the result of former investigation			381,740
Do Cap. Laplata, Australia (at least)			400,000
Do Holland			550,000
Do Sweden and Norway (consumption 1890, 15,121,541 kilos)			302,490
Do Denmark (consumption 1891, 5,700,000 kilos)			114,000
Do Russia and Poland (former estimate)			300,000
Do Italy (Custom House figures 1891, 13,814,700 kilos)			276,294
Do Spain (former estimate)			140,000
Do Portugal (former estimate)			37,000
Do Turkey, Levant, and Balkan States			400,000
Northwest of Africa			150,000
Total...			13,265,544

Or 11,054,620 bags, against a production of 1891-92, which the four Rotterdam brokers estimate to be 11,343,000 bags while Schoffer & Co are of the opinion that during this period only 10,800,000 bags are at hand to be exported and that the excess must be taken from the visible and invisible supply.

These figures indicate, in our opinion, a fluctuating consumption, difficult to estimate. When prices rule very high consumption decreases and rises as prices decrease. Messrs. Schoffer & Co., referring to the first estimate given, say:—

We will drop our estimate of 10,800,000 bags for the year 1891-92, and assume the one of the four brokers, in which Brazil figures with 7,425,000 bags. Then a production of 11,342,000 bags stands against a consumption of 11,054,620 bags, and at the end of the campaign the visible supply would have increased 289,000 bags on the smallest ever known figure.

For the year 1892-93 the proportion would be as follows:—

The production of Brazil taken as 6,500,000 bags would be 925,000 bags less than 1891-92.

Java may be 250,000 bags more than 1891-92, and consequently the total production of 1892-93 would be 675,000 bags smaller than 1891-92.

For the other coffee-growing countries we adopt the same figures as this year, which, no doubt, are much too high.

Without taking the increase of consumption into consideration, the latter (*i.e.* the consumption) would surmount in 1892-93 the production for about 450,000 bags.

How, however, would be the lookout if 1891-92 instead of 11,343,000 bags would yield 10,800,000 bags?

In that case one would have to reckon:

Production 1891-92	...	10,800,000
Production 1892-93
Brazil's 6,500,000 bags, against 7,000,000 our estimate, 1891-92.
<i>i.e.</i> 500,000 bags less than 1891-92.		
250,000 bags Java more.		
Difference.....	250,000 bags less than 1891-92.	10,550,000

Production during these two years	...	21,350,000
Consumption during these two years at 11,054,620 bags each year	...	22,109,240

Besides prices of the principal description, Brazil coffees are about 15 to 20 per cent, lower than those at which the consumption bought with confidence during almost two years, and the invisible supply must be the smallest ever known.—*American Grocer*.

CACAO: ITS NATURAL HISTORY, CULTURE, AND PREPARATION.

We now proceed to notice the remaining portion^s of Mr. Hart's valuable Handbook of the Culture and Preparation of Cacao. From the chapter which describes the operation of picking the fruits from the trees, we have already quoted the description of the instrument used in Trinidad, of which a figure is given. The pods ought not to be harvested until fully ripe, and they ought not to be left on the trees beyond this stage, so that only experienced and trustworthy labourers should be employed in this important work. Mr. Hart also advises that the pods should be sorted before being "shelled," should they vary in size and quality. The different varieties grown in Trinidad require different treatment, and there is a difference of practice as to leaving the pods in heaps for a few days or opening them at once, which latter course is deemed the better. The seeds from any over-ripe pods which may be found ought to be separately dealt with. The shelling can be done in the field or in the curing-house as is found most convenient. The process, as conducted in Trinidad, is thus described:—

The operation of shelling or breaking is done with a cutlass or large knife. A cut is made round the middle of the pod, taking care not to allow the tool to go through the shell so to injure the beans. The pod is then broken in the middle by a sharp jerk, and the beans are taken out and separated from the fibrous tissue of which the *placenta* is composed. If superior samples of cacao are intended to be made, it is very important that the breakers should be instructed to carry out strictly a sorting process which will separate the ripe from the unripe beans, and the different varieties from one another, for it is possible to make a more even sample by giving due attention at this stage than by any other means, for from the appearance of the sweet pulp surrounding it, the condition of the interior of the bean can be correctly estimated.

And Mr. Hart adds:—

It is here I am persuaded that the Ceylon planter obtains a most decided advantage over his Trinidad *confère*. In the majority of cases, and on the greater number of estates in Trinidad, the breaking is left to those who are not able, through the want of technical education, to understand the value of pursuing at this point any particular system, and they are besides so wedded to the use of a system of their own on which they are unable or uninclined to improve, that it becomes almost useless to attempt to introduce any measure of reform.

There are men among the planters of Trinidad however, who are well alive to the importance of making improvements in their manufacture, but as they are met at every turn by the prejudices in favour of the ordinary rule-of-thumb methods, and often ridiculed by those who ought to know better, it is a hard uphill and an expensive fight to get these required reforms into working order.

To make a first class article in any trade or business, is well known to pay much better than to make ordinary produce, and this is where the Ceylon planter has shewn himself to great advantage of late years, and his Trinidad *confère* loses *per contra* by inattention to such details.

The important process of "fermentation," (real fermentation in this case and not oxygenation, as in the case of tea) is then described, and reference is made to the three prize essays by Trinidad planters, which will be found reprinted in the *Tropical Agriculturist* with very valuable remarks by Mr. Jardine embodying the experience obtained in Ceylon and the principles of treatment founded thereon. The essays, with all their diversity of opinion, are printed as appendices to Mr. Hart's Handbook. A variety of methods may lead to equally good results, but Mr. Hart states:—

In writing upon the Fermentation of Cacao it is

necessary however to consider—

- 1st. The necessity for the operation;
- 2nd. The change that is brought about;
- 3rd. What causes the change, and
- 4th. Why dissimilar methods produce similar results.

Unfermented cacao is inferior in quality and realizes proportionately lower prices than that which is fermented. In all processes of fermentation, there is one underlying principle:—

It is necessary first of all to remove the pulp surrounding the berry, so as to allow the bean to dry—how we do this is a matter of little moment so that we do it effectually—but if in removing it, we can at the same time effect improvement in the substance of the kernel itself, we shall be carrying out at one operation what we should find very difficult to do if carried out separately. For instance, if we first removed the pulp, we should not afterwards be able to change the substance of the kernel. Fermentation is considered by all operators as the easiest way of effectually getting rid of the pulp, and it is also probably the only reliable way of changing the character of the interior of the seed.

It may be held that little or no fermentation is necessary for some markets, and that the bitter flavour and the purplish colour of the bean do not require alteration; but those who hold these views in Trinidad are greatly in the minority at present. It is plain therefore that fermentation is a necessity for the removal of the pulp, it is a necessity to allow of the bean being quickly dried, and it is a necessity for the purpose of altering and improving the character of the substance of the bean, and to improve the colour and keeping qualities of the produce.

All the saccharine pulp ought to be got rid of and the colour of the beans changed from a purple to a rich chocolate or cinnamon colour. The hardening of the shell is also of importance with reference to obviating damage in carriage or in keeping. What causes the change in the bean is a question for chemical science to decide: what is certain is that a material and beneficial change is effected. Analyses have differed, but the following table and the information which follows is interesting:—

Professor Church's analysis is as follows:—

	In 100 parts.	In 1 lb.	
Water	...	5.0	0.350 grs.
Albuminoids	...	17.0	2.315 "
Fat	...	51.0	8.070 "
Theobromine	...	1.5	0.105 "
Cacao Red	...	3.0	0.210 "
Gum, &c.	...	10.9	1.326 "
Cellulose and lignose	...	8.0	1.122 "
Mineral matter	...	3.6	0.252 "

In his analysis Professor McCarthy found 18 and 28 per cent. of fatty matter in two samples of fresh cacao—but this apparently might represent an amount of 50 per cent. in the cured bean in consequence of the removal of moisture and the pulp and mucilage from the outside of the bean, which material goes to make up a large porportion of weight, and would reduce the percentage of fat in proportion to the total weight of fresh bean.

An examination of beans fresh from the pod showed the following:—

Total weight from inside pod—No. 1	==3.75	ozs.
Weight of pulp and testa or skin of seed removed	...	==1.65
Kernel (clean)	...	==1.75
Loss during operation	3.40
		.35
		ozs.
Total weight from inside pod—No. 2	==5.40	
Weight of pulp and testa or skin of seed removed	==2.40
Kernel (clean)	==2.40
Loss during operation80
		60

The pods were ripe pods, the entire contents were removed from the shell after it was opened, and then carefully weighed. After weighing the pulp, the *testa* or skin of the seed was removed and the waste and cleaned bean again weighed as above. It will be seen that the pulp surrounding the bean, with the *placenta*, weighs nearly the same as the cleaned kernel, and therefore if Mr. McCarthy's analysis was taken from the fresh bean, pulp included, it is no wonder that he did not get a higher percentage of fat than 18 and 28 per cent. Taking the average between these and allowing the difference of 100 per cent for the weight of waste on the fresh beans, we have 46 per cent of fat in the fresh bean according to that analysis—which approaches that of an average sample of cured cacao.

To know by the appearance of the beans when fermentation has effected its object, is, of course, a matter of experience:—

The prime object of sweating or fermentation appears to be, to change the inside portion of the bean, by absorbing into it products obtained from the fermenting and decomposing pulp, and where this is not accomplished by any of the methods, the bean is classed as unfermented and the product is of lower value.

The experienced planter knows at once that *Criollo* beans do not require nearly as much time to "stew in their own juice" as *Forastero*, or *Calabacillo*, and he knows when each has reached the proper stage of preparation needed previous to the final drying, but the why and the wherefore of the variation of time in reaching this stage is, I believe, as yet a matter of doubt even among the most able. That the difference in the membranous texture of the outer covering of the bean bears a material part in influencing the time necessary for fermentation cannot however be doubted.

Heat, of course, is essential to the process of fermentation, some using sun heat and others heat artificially produced. Full scientific examination is desiderated, but one conclusion seems obvious, and it is thus indicated by Mr. Hart:—

Malt differs from barley inasmuch as it contains more dextrin and soluble substances, but rather less starch, cellular matter, and insoluble albumenoids and a smaller proportion of inorganic constituents; and I should certainly expect to find that there is a similar difference between the *unfermented* Cacao bean and the *fermented* one.

The fermenting process in the case of the cacao beans may be described as "maling without germination." Have any observations been made in Ceylon on the best degree of heat for fermentation? Mr. Hart states:—

Mr. Morris in his pamphlet mentions that the heat of fermentation generally used is about 140 deg. Fah. Our second prize essayist gives the temperature most suitable as 110 deg. Fah. in the first stage, raising it by 8 deg. in the second stage. Dr. Chittenden gives 115 deg. to 120 deg. as the requisite temperature, but it is doubtful on what basis or on what experiments these temperatures have been determined, for it is certain that the Thermometer is an instrument not in use on many of the best estates in Trinidad.

A thorough set of experiments or even hourly readings of the temperature which obtains in the sweating-house of a first-class estate would be a valuable record, and would considerably add to our present knowledge of the subject.

We have now to deal with a chapter describing the processes of washing, drying, polishing, colouring and dancing (!) Mr. Hart states:—

Washing comes next, because if the planter wishes to wash his cacao, it must be done immediately after fermentation, or not at all. The pulp cannot be removed by washing before fermentation, and even after the decomposition caused by fermentation it is somewhat hard to remove.

The Ceylon planter has of late years adopted the washing process of preparing cacao as a cleaner and better method than the one which generally obtains in Trinidad, and the high prices obtained by the Ceylon produce is a guarantee that their cacao

is of first-class quality, and market reports show their prices to range higher than the average of Trinidad. However, brokers in London advise Trinidad growers not to wash their cacao, the argument being that what Ceylon gains in price it loses in weight, and *vice versa* with the Trinidad grower: Anyway for the present, washing does not find favour with the Trinidad planter, although a few growers who have tried the process have not been wholly unsuccessful.

Mr. Eugene Lanke, junr., in his article in the *Agricultural Record* for March, 1891, clearly proved that, as carried out by him, the extra trouble was not compensated for by the price obtained; still, however, from the tenor of his article he appears to be in favour of the washed product.

Mr. Lange states in his letter that—"Messrs. Wilson Smithett & Co. advised him that it was not advisable to imitate Ceylon cacao because the principal value of that class of cacao resided in its pale cinnamon break, which, whether due to the soil or a different variety of cacao, Trinidad planters could not imitate."

Mr. Morris of Kew appears to favour the view that the kind of cacao mostly grown in Ceylon is of the *Criollo* variety. Dr. Trimen in his report for 1890 gives the remarks made "by a large grower who has great opportunities for observation, that the *Forastero* varieties which he chiefly cultivates, appear to be gradually changing their characters and becoming more like the 'old Ceylon Red,' the seeds losing their dark colour on section and becoming pale or nearly white."

With regard to this supposition, I quite agree that such a change is both possible and probable. In Grenada I believe such a change to be common, and fairly apparent—*i.e.* the character of the *Forastero* imported from Trinidad soon disappears.

If the superiority of Ceylon cacao is really due to a difference in the variety of plant producing it—it will certainly be useless to insist upon the method of washing as an improvement in the ordinary Trinidad practice. If, however, (as has been asserted in the Ceylon papers) the Ceylon planter can prepare *Forastero* cacao to equal that produced by *Criollo* we should know as soon as possible the method he employs to obtain that result.

Washed cacao, however, dries much quicker than unwashed cacao, and this fact, together with artificial drying during a wet season, means money saved to the planter, and is certainly a point not to be lost sight of.

In Trinidad drying is effected on large sliding trays, which can be run into the curing-house should rain occur. The employment of artificial heat being deemed better and more economical, a prize of \$200 was offered for the best apparatus at an Exhibition in 1890. The full prize was not awarded but an honorarium of \$40 each was awarded to each of three designs:—

The first was simply the adoption of the method of heating by hot water, to the ordinary cacao house. The second was a telescopic drying apparatus adapted for either dry or wet weather, and the third was a dryer having the means of keeping the beans constantly stirred, which was very promising.

A full sized apparatus on the first principle has been affixed to a cacao house at *San Salvador* estate, and has been found to work very easily and satisfactorily, but I have not learnt that anything has been done in the way of advancing the usefulness of the second design. The third design is said to have been much improved and is to be erected on a scale which will allow of its chief points being fully demonstrated.

Sir William Robinson in his pamphlet on cacao, previously referred to, gave an account of the Ceylon drying house as furnished by Dr. Trimeu, Director of Botanic Gardens in that Colony, it is as follows:—

"The house is about twice as long as broad, built of brick, and is provided with double doors, but with the exception of the openings for the ingress and egress of the hot air, is hermetically sealed. The interior is fitted with a number of up-

right frames into which slide, one above the other, the trays upon which the beans are spread; these should be made of narrow pieces of split bamboo, not of wire or coirnetting. The heating apparatus is outside in contact with one end of the building, and consist of a large stove standing in a short tunnel which opens into the house. At the other end of the building, also outside, is a powerful fan, fitted in another short tunnel; this is worked by hand (three or four coolies needed), and by its rapid revolutions draws the air through the house. By passing over and round the stove the air is dried and heated; that which passes out is hot and damp. The flue of the stove passes under the floor of the house and contributes to warm it. A drying house of this sort is very simple and its cost only about 120 rupees; it does its work perfectly, and nothing more elaborate or costly is required.

It is found desirable here to dry Cacao as slowly as possible provided the risk of mould be avoided. This appears in the interior of the beans in twelve hours and on their outside in about twenty-four in wet weather if they are left cold, but by passing them rapidly through the hot air house, so as to have them hot when taken out, it is found that they will remain for a night or so in the store without injury.

As the annual average number of rainy days in Ceylon is from 80 in dry districts, to 328 in the wet, and Cocoa is grown only in the moist regions of the Island we may assume that at least four-fifths of the Cocoa exported from that Colony is dried artificially. The rainfall in the best Cocoa Districts of Trinidad appears to average between 80 and 100 inches. The total yield as before stated is 125,000 cwt. representing an enormous crop and an immense number of people dependent upon it. *Yet there are not half a dozen artificial drying houses, if as many, in the whole Island.*

The method appears to be a very simple one, but the amount of labour needed ("three or four coolies") appears to be large when compared with that required for the ordinary Trinidad methods.

It will be observed that the Ceylon planter has found it desirable to dry cacao as "slowly as possible, provided the risk of mould be avoided." This is an experience which has been known and recognized for years by the Trinidad planter, and on the strength of this fact alone it is doubtful whether any drying apparatus which will shorten the time of the operation in any great degree will secure general adoption, as it is to be feared that the quality of the cacao will suffer if quickly dried; however, if it can be proved that the quality of the produce does not suffer by a quick method of drying, the method will undoubtedly be of the greatest service to the cacao planter, and experiments in this direction are fully justified.

During the drying process Cacao has to be frequently turned, but it appears to dry much better if kept in 3 or 4 inch layers than if spread more thinly over the surface of the drying floors, as it does not allow of so rapid an evaporation of the watery particles.

There is then a notice of the use of red earth to get rid of the mucilage of the bean as practised not only in Venezuela but by some planters in Trinidad. No such process has been or will be adopted in Ceylon, we should say. Dr. Hart states:—

It appears that in Venezuela the practise of using dry-earth is, first, for the absorption of the mucilaginous portions of the covering of the beans, and secondly, to give the bean "colour and gloss."

In Trinidad various mixtures are used for colouring purposes and for bringing out the polished appearance of the cacao; among them may be mentioned starch, red ochre, *roucou* or annatto, and red earth or clay. The red clay of San Antonio estate, Trinidad, is described by J. J. Bowrey, Esq., F.I.C., F.C.S. Analyst to the Jamaica Government, as "a very fine, ferruginous clay free from organic matter," and is said to answer the purpose admirably. Dressing or colouring of cacao is however more practised by the mer-

chants who purchase from the small growers than by the well-to-do planter; and cacao of finest quality, and appearance can be made *without the addition of any single particle of extraneous matter.*

We should think so, but if any colouring matter should ever be resorted to, preference should be given to anatto which grows so plentifully in Ceylon. It is used to colour butter and cheese and is stated to be perfectly innocuous. The concluding paragraphs of this chapter explain the process described by the curious term "dancing:—

In damp weather the partially dried bean is extremely liable to be attacked by numerous microscopic fungi or moulds, and if these are allowed to continue their growth undisturbed the coating of the bean will be pierced and its contents spoiled. Various measures are adopted in bad weather to disturb the growth of the mildew, and of these none is more familiar than the process called "Dancing." The cacao is collected in heaps and the labourers are employed to tread the heap with their naked feet. The friction caused by the treading removes the mildew from the outside of the beans and polishes them at the same time. Red earth is also used to "minimise the risk of mildew," and where "dancing" is not convenient "hand rubbing" is resorted to for the same purpose.

The process of drying is continued until the cacao is thoroughly dry, and only an experienced hand can tell when this point is reached.

Quoting Mr. Morris—"If well cured it should have the outer skin hard, crisp and separating easily from the bean below. The latter should be firm, bright, and breaking easily on pressure."

It may be added that a plump bean of a light chocolate, or what is known as a "cinnamon" colour, is a mark of the highest quality of cacao, when combined with what is known as "a good break."

It would appear to be held by some that heat is especially necessary to harden the interior of the bean, and that to obtain this it is found necessary to heap the beans, so as to make them undergo a second and third fermentation at intervals during the drying process, and it is contended that without this the bean will often refuse to assume that plump appearance which is held in such high estimation by buyers. Having already dealt with the chapter on the botany and nomenclature of cacao, we now proceed to notice the chapter on diseases &c., insect pests, fungi, vegetable parasites, epiphytes and other enemies. The diseases are stated to be fortunately few and we observe that helopeltis is not named amongst the insect pests. Canker in the trees is referred to unsuitable soil and drainage; and black rot in pods to a long continuance of dry weather. Pods also drop in very wet weather. The greatest enemies of the Trinidad cacao planter are:—

The Parasol or Umbrella Ant (*Ecodoma Cephalotes*) and the Cacao beetle *Steirastoma histrionica*, White—which latter has been determined by R. McLachlan, Esq., F.R.S., from specimens forwarded to us by John Guilbert, Esq., of La Gloria Estate. Another species of this genus *Steirastoma depressa*, L., has been determined as seriously affecting the trees cultivated in Grenada, and it is quite possible there are several other species of *Longicornia*, a section of Coleoptera, or beetles which do damage to the trees.

The beetles do not seem to be difficult to deal with, but the parasol ant is a very formidable insect. Mr. Hart states:—

The Parasol Ant is truly the *bête noir* of the Cacao planter and generally of the Agri-Horticultural community. Until one becomes fully acquainted with the persistent depredations of this creature, it is hard to realize what an immense amount of damage is effected by it alone. So much is this the case that the Legislative Council of Trinidad lately passed an Ordinance which enables the Governor to declare certain districts infested, and to enable planters to take means for their destruction.

The destruction of this pest is extremely simple, but from the persistence with which impregnated females seek the spots that contained former nests, an equal persistence and careful watching is needed to keep the ground clear. Where cultivation is conducted in proximity to a large area of forest lands the matter becomes a very difficult one indeed, for not only have the local nests to be destroyed but also those in the distant woodlands, and especially the large nests, a raid from which will frequently do irreparable damage to a plantation in a single night. There are many methods in use for compassing their destruction, the most common being that of digging out and puddling with water. Some forms of destruction are suitable for one locality and some for another. Where a constant watch for new nests is regularly kept, as at the Royal Botanic Gardens, they do not become of any great size before they are discovered, and a dose of coal tar poured into their nest effectually disposes of them, once and for all at that particular spot, as they never again return where coal tar has once been applied. Other nests can be best attacked by using the fumes of sulphur driven in by bellows or fan. A handy machine lately introduced, known as the "Asphyxiator," can be used with sulphur or any other chemical producing deadly fumes. These ants will, when on raid from a large nest, make a track 10 or 12 inches wide (from which every portion of herbage is carefully cut away) for the purpose of carrying home to the nest the leaves they cut from the trees, and several large trees are often completely cleared of leaves and flowers in the space of a single night. Each ant is able to carry a piece of leaf half an inch in diameter, and hold it in its mandibles above its head, resembling when on the march the sails of a fleet of lilliputian schooners dipping and swaying to the wind. Belt, in the Naturalist in Nicaragua, studied these insects and came to the conclusion that the leaf is not used primarily for food, but is chewed up, and placed in a position where the mycelium of certain fungi at once attack it, and form food for the ants and their larvæ. Certain it is, that a peculiar mycelium is found permeating the inside of every nest, and gives to it a peculiar odour of its own, which once recognized, is again easily distinguished.

Plant lice and wood ants are mentioned, and what ought surely never to be allowed to infest cultivated trees, *Ioranthaceæ*, *cuscuta* or dodder, and orchids! But,—

The squirrel is a great enemy to the Cacao planter, and it is always found that he selects the best class of pods, not alone on account of the thinness of their pods, but also owing to the greater amount of sweetness that the pulp of the *Criollo* varieties possess. It is for this reason that in some instances the *Forastero* or thick podded varieties are planted instead of the finer sorts, and the same argument applies to the damages done by rats and mice, which are plentiful in some districts. The ratlike *opossum*, known locally as "Manicou Gros Yeux," is similarly credited with doing much damage to Cacao, and is invariably destroyed when found, on that account. There is a chapter on export of cacao, value of estates, buildings required, labour &c. We have already noticed that Trinidad exports about 22 millions of pounds of cacao per annum, valued at about £600,000. As an incentive to Trinidad planters to improve their culture, Mr. Hart again reverts to the example set by Ceylon, but curiously contradicts his own previous utterance—

The Ceylon planter has succeeded wonderfully well in obtaining the highest price in the market, but it is questionable whether his Trinidad *compère* does not obtain from his *Forastero* trees, a better return per acre, than his Ceylon brother does. From Dr. Trimen's Report it appears almost certain that the quality of the bean as imported from Trinidad is improved by Ceylon tending. Now with us the better the bean the more tender the tree, and the less the crop we obtain, and it is possible that the decrease in yield and vitality of the tree, will also follow the improvement of the bean in Ceylon.

Cacao estates are deemed permanent investments, the trees coming into bearing in their ninth year and continuing to bear for periods up to a century:—

The yield per tree will be seen to depend entirely upon the quality of the land, the size of the trees and various other attendant circumstances, but is generally considered that a yield of 1.6 lb. per tree which will be 10 bags of 165 lb. each to 1,000 trees, is a first-class yield, 5 bags per 1,000 trees or 0.8 lb. per tree would be considered a poor yield.

Taking our trees to be planted at 15 feet apart, there will be 193 trees per acre nominally (of course it is never possible to maintain this regularity, on account of roads, drains, &c., but for the sake of method in the estimate we accept this number) and the yield per acre will be $193 \times 1.6 \text{ lb.} = 308.8 \text{ lb.}$ which, valued at 80/ per cwt., will produce the sum of £11 per acre. Calculating the trees at 12 feet apart we get 302 to the acre, and these at 1.5 lb. per tree, the value per acre would be £16 3s.

Into the question of "buildings required" we need not enter, as we suppose Ceylon planters have little or nothing to learn from Trinidad in that respect, while the conditions of labour are essentially different, wages in Trinidad varying from 25 to 60 cents of a dollar per diem or over 50 to 150 cents of our currency. The chapter on chemical composition and manufacture of chocolate are not possessed of much popular interest. We therefore make only one quotation:—

From the fact that clean fats have a remarkable affinity for the volatile or essential oils, it appears probable that a large proportion of the aroma of chocolate is lost by the removal of the Cacao-butter, and this fact would alone account for the superiority of the flavour of that Cacao in which the natural fat is all present, over that from which it has been removed. Which way the manufacturer must make it, the public must say, but the less the manufacturer adulterates a pure article the better as a rule will he please the public and the better are his prospects for the future of his business.

Here our notice of a very valuable work descriptive of the culture and preparation of an important, agreeable and nutritious food product must close; and we feel sure our readers will agree with us that Mr. Hart has performed his task of preparing a Handbook of Cacao with great ability and discrimination, and so as to render planters in Ceylon as well as in Trinidad, the West Indies generally and South America largely his debtors.

THE SAPPHIRE AND RUBY MINING COMPANY OF MONTANA.

It was but natural that with the evidence of failure present among our own community with respect to associated gemming enterprizes we should take an interest in similar undertakings started to work in quarters outside of our own island. When that bearing the title quoted above was started strong doubts had arisen as to the issue to our own local speculation of the same character, and we can now realize that the doubts we then expressed as to the amount of success which would attend upon the application by its direction for public subscription towards its capital seems to have been fully justified by the result which we learn from the report of a legal case cited in our London Letter. It is very evident that with the examples of the Burma Ruby Mining Company and our own multifarious companies of a like description before it, the British public had become exceedingly shy of investing in matters of the kind. From this case we can realize the shift to which the promoters of Montana Company were driven in the attempt to raise, in the face

of the deterrent influences we have mentioned, the capital necessary to enable it to start. Those shifts, as recorded in the report of the case mentioned, will be found to be particularly instructive and cautioning to those who have a tendency to invest in speculative companies. We can only say that we do not believe similar expedients had to be resorted to in the case of any of the gemming enterprises formed to develop the mining capacities of our own island. These, we believe, stood upon their own merits, and their promoters had not to seek to bolster up their concerns by any such questionable measures as had to be descended to in the case of the Montana Company. It is reported that an honorarium of £2,000 (let us give it a consolatory name) was offered to certain individuals if these secured responsible people to underwrite £75,000 worth of shares in the Company at a charge of 15 per cent! Now this means that £13,250 was to be sacrificed in order to obtain a guaranteed balance of capital of £62,750 wherewith to float the undertaking. The total nominal capital of the Company was £450,000, and if the whole of this was eventually subscribed, it was no doubt largely due to the incentive afforded by the outlay of the above mentioned sum of £13,250. We have no disposition to wish anything but good to undertakings of this character, wherever the scene of their operation may lie. In Ceylon, at all events as yet, success cannot be said to have attended efforts made in the same direction, although, as we have above pointed out, the capital for these was raised without having recourse to expedients which we believe must be injurious to the reputation of any enterprise. We are quite aware that it has been long the practice to give a fillip, so to speak, to the investing public by obtaining the underwriting at a considerable monetary sacrifice of a large amount of capital. Such a course is not regarded among financial men as at all dishonourable; though we suspect every effort is made to insure that the fact that a proportion of subscribed capital is largely "bogus" is withheld from the general investor. It is plainly to be seen that, if collapse follows with respect to undertakings, a considerable amount of the capital of which has been underwritten at heavy rates of discount, the private investor must suffer heavily in proportion. We are thankful, therefore, that in the case of those gemming companies which commenced work in Ceylon such a method of stimulating public subscription has not had to be resorted to. Whether the Montana Company has better prospects before it than those which have resulted in failure in Ceylon, we do not pretend to say; but if not, the lightness of loss which has followed in our own cases cannot be anticipated for shareholders in the Montana scheme.

THE CHINA TEA TRADE.

The *N. C. Daily News'* Hankow correspondent writing on the 12th inst., mentions the opening of the market on the 7th by Russian buyers and gives the following comparative figures for the same number of days from the opening:—

	Season 1892-93.	Season 1891-92.
Arrivals	52,412	112,785
Settlements	11,209	56,934
Stock	41,203	55,851

Quality of the teas hitherto shown is decidedly disappointing, generally being very dull and showing great want of character. Of the Kinkiang teas, Ningchows are the only description yet to hand, and these on the whole seem very badly made, being in many cases very choppy and dusty and in liquor decidedly flat. Hankow has scarcely arrived in sufficient quantity to judge

of their quality with the exception of Towyuens and Oanfas, the first packs of these having all been offered and with one or two exceptions been purchased for Russia. The remainder seem likely to be settled for the same market during the course of the next few days. These kinds though of very good leaf show great want of point in liquor, being for the most part thin and dull. Of Kokews some 30 chops have been on offer and seem very much out of favour, the majority being very rough in leaf and tarry in cup. Shantams.—The first packs of these seem inferior in quality to last year. Quantity is very difficult to estimate as yet, though natives are trying to raise the market on the usual rumours of a very short crop.

In a postscript, dated the 13th, he adds:—“This afternoon we have had some 200 musters on the market, including the first arrivals of Keemun. These also are somewhat disappointing showing in many cases great want of strength. A few offers are being made of from Tls. 32 to Tls. 36, but nothing has yet been settled.”—*China Mail*, May 26th.

NOTES FROM PEERMAAD.

May 1892,

In the early part of March, we had, after months of drought, one day's—and most unfortunately only one day's—heavy rain. This brought out a very promising spike, but I regret to say that during the very hot weather that followed, a large proportion got burnt. This burst of hot weather was followed by a hurricane that, in violence though fortunately it only lasted a few hours, has seldom if ever been exceeded, at any rate within the memory of the proverbial oldest inhabitant. Fortunately no damage was done to buildings, though more than one felt some anxiety for the safety of their three-ried factories which, by the way, are by no means uncommon now-a-days owing to the ever-increasing yield of tea.

Early in April, and more or less ever since we have been favoured with delightful rains, never heavy, and all the coffee in the districts—alas! that it should now be such an insignificant item—has blossomed, and set (fairly) well; crops will, on the whole, be well above the average. Of course it is yet early to prophesy, as there is always the off-chance that July and August will develop a “go” of leaf disease; so far there are, however, no signs of it, and as all the coffee is in particularly good heart, even if we should have a touch of it, the trees have strength and vigour enough to resist it and ripen the crop. One estate at the Periar is reported to have a magnificent crop on, and a friend has gone so far as to prophesy that the crop will nearly reach the number (*in tons*) of the joint ages of the two proprietors!

Tea is doing as well as ever, if not better. In my last notes, I alluded briefly to the Kudawa Karnu Factory; I am glad to report that the outturn of made tea for March and April just exceeded 40,000lbs.; at this rate, we shall soon be estimating the outturn from this district in millions. Fresh clearings are being opened up, tea nurseries are to be seen all over the districts, and if prices improve a bit—by the way the averages of Fairfield and Arnkel, both Peermaad, 10½, at the auctions of the last week in April are not bad—and exchange keeps more or less *in statu quo*, the Tea Planter—on Peermaad at any rate—has little to fear.—*M. Times*, June 1st.

BARK AND DRUG REPORT.

(From the *Chemist and Druggist*.)

London, May 19.

CINCHONA.—At the cinchona auctions on Tuesday a moderate quantity of bark was offered for sale, the catalogues comprising:—

	Packages.	Packages.
Ceylon cinchona..	617 of which	552 were sold
East India cinchona	885	789
Java cinchona	30	30
South American cinchona	246	207
West African cinchona	451	454
	2,232	2,032

The assortment of the bark was a fairly good one, and included an unusually large proportion of druggists' kinds. The greater part of the East Indian cinchona consisted of Nilgiri bark, recently imported from Madras part of which realised fairly satisfactory prices with good competition. The general tone at the auctions was good, and nearly the whole of the supply offered sold, with fair animation, at prices fully on a par with those of the last sales, with an occasional slight advance. The unit runs from 1 lb. to 1 1/2 lbs. d. for poor to 1 1/2 lb. for good bark.

The following are the approximate quantities purchased by the principal buyers:—

	Lb.
Agents for the Mannheim and Amsterdam works...	80,755
Agents for the Auerbach factory ...	69,705
Agents for the Brunswick works ...	61,333
Agents for the French factory ...	29,005
Agents for the American and Italian works ...	27,670
Messrs. Howards & Sons ...	16,543
Agents for the Frankfort O/M and Stuttgart works	24,729
Sundry druggists..	61,504

Total quantity of bark sold ...	381,304
Bought in or withdrawn...	35,704

Total quantity offered ... 417,008
 CINNAMON CHIPS are lower, 233 bags ordinary coarse cylon having been sold at auction at 1 1/2d to 2d per lb.

CONSULAR REPORTS.

KIUNGCHOW.

Consul E. H. Parker addressed the following report to the Marquis of Salisbury on the trade of Kiungchow:—

GRASS CLOTH.—Further inquiry made at the request of the Kew authorities elicits the information that the so-called grass-cloth alluded to in my last trade report is not made from the "Pandanus," or screw-pine, but from the "Ananas sativa," or ordinary pineapple of commerce. The specimens of both which were sent home enable the Kew authorities to establish this fact beyond doubt. Dr. Bretschneider, of the Russian Legation, several years ago, drew attention to the fact that cloth made from the pineapple fibre was mentioned in the maritime customs "Port Catalogues," published in 1873, and that a similar cloth, called "piña," is manufactured in the Philippine Islands.

WILD SILK.—I enclose with this report, for transmission to Kew, a specimen of the very tough "wild silk" of my last report, locally used for fish lines. The trade of Hainan informs me that, according to popular report, the insect is produced upon the "feng" tree, or liquidambar formosana" (Hance). In Hoibow it is called "hang-ti" (ch'ung-tz), or "insect silk," and it is said to cost £60 the 133 1/2 lb. or £1,000 the ton. * * *

BATAVIA.

On the trade of Java for 1891, Acting-Consul Lankester thus reports:—

Last year's trade has, on the whole, been satisfactory for the island, and both exports and imports show an increase. The results to merchants and planters have been generally profitable.

Preliminary steps have been taken with a view to holding, in the spring of 1893, an agricultural and industrial exhibition, and it is hoped that the general trade of the island may be benefited thereby.

The trade with Great Britain, especially as regards imports, continues undiminished.

Of exports, the United States, the Australian colonies and China have each had a considerable share.

The British flag has again more than held its own as carriers of imports and exports. * * *

COFFEE.—The estimate of the year's production, Government and private lands together, has been slightly exceeded, the former having amounted to 23,254 tons, and the latter 21,250 tons, while the quality has given general satisfaction. The value of the article having been well maintained in the consuming markets of the world, further stimulus has been given to the promotion of new plantations, and in the eastward of the island several large estates have been started, the future of which promise well.

The cultivation of the Liberia plant has this year again attracted considerable attention, and if the planting of this description continues at the present rate, the production in a few years will be a very important one. Owing to the high prices which consignments of Liberia have commanded, and the low rates which have ruled for tea, some planters are gradually abandoning the cultivation of the latter in favour of the former. The dreaded leaf disease has not been so prevalent as in previous years.

The coming crop would, under the circumstances, be a very large one, but on account of the drought the estimates have had to be considerably reduced, but the return is still expected to show a not inconsiderable increase upon 1891, viz., about 28,233 tons Government, and 24,286 tons private coffee. * * *

RICE suffered severely from the long spell of dry weather, and the production proved less than sufficient for the wants of export and consumption, and consequently supplies had again to be imported from Saigon, Rangoon, &c. Exports were as follows: 27,282 tons, against 30,407 tons in 1889, and 26,555 tons in 1890.

COCOA.—The few estates as yet producing this article have given a good yield, and prices have been well maintained. The cultivation is now almost exclusively restricted to Mid Java and West Java, but there is little doubt the cultivation will spread. Shipments to London have been tried with success.

INDIGO.—The crop was a fair one, but owing to prices having gradually receded the results to most plantations have been considerably worse than was anticipated.

CINCHONA.—In spite of the low value of this article there has been but a small alteration in the production, the output only showing a deficiency of about 9 per cent on the estimates, viz., 7,000,000 lb. against 7,700,000 lb. In the event of a permanent improvement in prices, next year's crop is expected to be a little over this year's output, but should the present low value remain unaltered there may be a not unimportant decrease.

TEA.—The crop suffered from the drought, but this has had a not altogether unfavourable result, for the trees have had an apparently required rest, the result being that after the rains set in they grew vigorously and the expected increase in the next few months will, it is expected, more than compensate planters. The production shows a marked falling-off, being about 1,000,000 lb. less than last year; one or two new gardens have, however, been opened, but against these have to be put those chiefly on low lands, which have been or are being abandoned in favour of Liberia coffee. The exports were 5,939,011 lb. against 7,788,484 lb. in 1890, and 7,716,225 lb. in 1889. The quality of the crop proved satisfactory, and some estates realised good prices.

RAILWAY COMMUNICATION.—The completion of the Government railway to connect Tjilatjap with East Java, Middle Java, and West Java, is progressing satisfactorily, and the line will probably be opened for traffic towards the end of 1893. A considerable extension of the Government railway net is under consideration, and already surveying for a new line from Probolingto to Stoehondo, via Loemadjang and Djember, has commenced; it is intended to connect this line with Banjoewangie (the most eastern part of Java) by a secondary line. A line from Batavia through Bantam is also proposed.

TRAMWAYS.—The line from Sonrabaya to Sepandjang has been opened, and permission has been granted to the Samarang-Java Line to increase its length by thirty miles.

SHIPPING.—Steam communication with Europe has been increased by two new lines running to Java from Holland, via Singapore, the German Sunda Line, and the Dutch Stoomvaart Maatschappij Oceaan, the latter being an offshoot of the well-known Hols China Line. For the last few years the two Dutch lines, de Nederland and the Rotterdamsche Lloyds, had practically enjoyed the monopoly of the trade.

GENERAL.—In November the Tandjoeng Priok Drydock Company commenced business; they possess extensive workshops, where repairs of all descriptions can be carried out, besides having a 3,000 ton floating

iron dock, which is worked under the patronage of the Government.

The total absence of rain, for the extended period already alluded to, could not but have a deleterious effect on the health of the colony, and it is a matter of congratulation that the results were not more alarming. During the month of July, August, and September cholera was very rife but not epidemic, and mortality among Europeans from the disease was comparatively small.

CATTLE PLAGUE only appeared in some of the districts of the Batavia residency, but was not of a severe nature.

At Batavia the number of British residents is 68, at Samarang 24, and at Sourabaya 53, while in the interior the number is extremely limited.

Annexed statistics show that from July of the one year to June of the following year the export of sugar was for 1890-91 412,780 tons, against 1889-90 329,878 tons; and 1888-89, 338,451 tons.

Government Java coffee sales during 1891 totalled 100,000 piculs, and sold at an average of fl.56.86.

The Government Padaug coffee sales during 1891 were on May 19th, first quality 30,166 piculs, at fl.66.88; second quality 275 piculs, at fl.45.25; on July 17th, first quality 6,610 piculs, at fl.68.15; second quality 40 piculs, fl.40.30; on September 22nd, first quality 12,219 piculs, at fl.61.94; second quality 115 piculs, at fl.34.96; on December 29th, first quality 8,980 piculs, at fl.69.02; second quality 120 piculs, at fl.40.15.

Exports from Java (including Madura) during 1890-91:—

NOTES.—These figures are merely approximate and are based on the average values of the various articles during the year, no reliable statistics being published.—*L. & C. Express.*

THE TRADE OF JAVA IN 1891.

Mr. N. P. van den Berg, the well-known political economist, President of the Netherlands Bank, and formerly President of the Java Bank, writes the following in our Amsterdam contemporary, *De Indische Mercur*, on the above subject:—

Java's commercial traffic last year shows favourably against that of the preceding few years. As for the import trade, this was already shown by the trustworthy declarations of import dues collected in 1891, from which source the treasury received an amount of f.6,978,000, against f. 6,255,000 in 1890, f. 6,292,000 in 1889, f. 5,917,000 in 1888, f. 5,780,000 in 1887, and f. 5,916,000 in 1886, in which year, from July 1st, the normal import duty, as it is called in the Colonial reports, was increased from 6 per cent. to 10 per cent *ad valorem*, an increase which was, however, not applied to the principal articles of import, the cotton and woollen manufactures.

Under effect of the unchanged tariff* the yield of the duties has recently risen considerably above the figures of the last few years.

In almost all articles of import, progress can be shown in 1891 against the average of the four preceding years; but in general the differences are too small to have any importance on the commercial traffic of Java. The import figures testify undoubtedly to an increased power of consumption by the population of Java, and legitimate in this respect the deduction that a change for the good has come over the depressed condition which reigned for so many years, a condition which was led to the fact that, notwithstanding the steady increase of the population, there was no trace of a proportionate increase of the commerce.

I do not know if Java still contemplates the possibility of creating a native cotton industry, which has become a source of prosperity in British India. In the recently published report of the *Soekaboemische Landbouvereeniging* not a word is spoken therein, but having talked with an individual recently returned from Java, I continue to hope that attention remains fixed on this subject. Many persons estimate that the quality of the rough material at Java is not inferior to the cotton of British India.

ARTICLES OF FOOD.—Against about 21,000,000 kilos or 340,000 piculs of rice per year in the four preceding years, it was necessary to import in 1891, 54,800,000 kilos or 887,000 piculs, in order to provide for the wants of the population. In general the rice crop was less favourable last year, and the import of rice is always dependent of the yield of the crop. An increasing import is thus in itself a less favourable event; but what the population has been obliged to spend in buying foreign rice has been no detriment to providing other articles of food, for of dried fish, the popular accompaniment of the daily rice dish, there was imported $\frac{1}{4}$ million kilos more than in the average of preceding years. The greater part of the other articles ranged under this heading, such as butter, hams, and cheese, are more particularly destined for the non-native population. The import of butter again shows a diminution, but from this it does not follow that the consumption of butter decreases. More and more the use of Dutch butter is put aside by the better Danish products, which being tinned is ranged among the "victuals not noted separately," as well as the tinned butter sent from the Netherlands or elsewhere.

Respecting the "victuals not noted separately," to use the official designation, it is probable that the imports in 1891 from Europe, to a value of about f.1,100,000, consists mostly of provisions destined for the consumption of the European population, and that the commodities imported from Singapore, Obina, and elsewhere are mostly destined for the native population, and that assimilated therewith. In both respects an increased consumption is shown.

FUEL, &c.—The want of coal regularly increases, for in 1891 the imported quantity amounted to 16,000 tons more than the average figure of the

* With the exception only that the import tax on petroleum from March 1, 1887, was decreased from 70 to 25 cents, per hectoliter, in connection with the levy of excises from that date, which yielded in 1891 for Java and Madras aloof f.1,674,622.99, whereas before 1887 the import tax on petroleum did not produce above f.400,000, or f.500,000 for the whole of Netherlands India.

years 1887-90, must still be supplied by importation from elsewhere, as long as the Ombilien coal-fields are not worked and the coal company "Oost-Borneo" does not bring larger quantities on the market than is now the case. Formerly, I hoped that the product of the Taniwari mine in the Preanger-Regentschap might provide for the want of coal, but it seems this will remain an illusion, as the coals obtained from thence are found nearly useless. In this respect a better future seems to be reserved to the building petroleum industry on the east coast of Sumatra. Undoubtedly, coarse petroleum is available in large quantities there in the soil, and the original reports on the quality of the refined product are in every respect favourable. Soon this Sumatra will be able to provide for the constantly-increasing want of petroleum of the surrounding regions, and particularly in Java, where in the course of 1891 not less than 93,610,000 litres were imported for consumption, against an average 81,231,000 litres per year in the four preceding years.

EXPORTS.

The following table gives a review of the export trade during the past year against the average figures of export of the four preceding years:—

Taxed Temporarily Free Articles.
Average 1887-1890.

	1891. kilos.	1890. kilos.
Sugar	361,521,000	423,547,000

Pepper (cubeb)	80,000	100,000
" (white)	50,000	44,000
" (black)	1,944,000	3,135,000
Jungle Products.		
Gum damar	1,081,000 kilos.	1,017,000 kilos
Gum elastic	24,000 "	22,000 "
Gutta percha	28,000 "	50,000 "
Sundries		
Rice 2 3/4	5,549,000 kilos.	27,505,000 kilos.
Tea	7,324,000 "	2,673,000 "
China	4,953,000 "	3,090,000 "
Arac	4,165,000 litres.	1,611,000 litres.
Kapok	1,388,000 kilos.	1,937,000 kilos.
Rotan	1,449,000 "	844,000 "
Cocoa	102,000 "	376,000 "

SUGAR.—The most remarkable of the above figures is the very notable increase of sugar exported. The export given for 1891 of 463,547,000 kilos, is 7,505,000 piculs, a figure thus far unknown, but which is, in the meantime, still 100,000 piculs below the export figure in statistics of the Bataviasche Handelsvereeniging, according to which in the course of 1891 not less than 7,610,000 piculs were exported. According to the reviews of the brokers, Dunlop and Kolff, at Batavia and Soerabaya, lying before me, the sugar crop should have amounted to:—

1886	5,864,000 piculs
1887	6,189,000 "
1888	5,852,000 "
1889	5,443,000 "
1890	6,447,000 "
1891	6,564,000 "

among with quantities, however, bag sugar is not included. The Government figures, which are published much later, show:—

1886	6,338,000 piculs
1887	6,569,000 "
1888	6,258,000 "
1889	5,916,000 "
1890	6,867,000 "

Between both statements there exists a constant difference in the average of 430,000 piculs per year

and when the estimated figure of production of Messrs. Dunlop and Kolff over 1891 is augmented by this quantity, one obtains a figure of 6,985,000 piculs, as the probable result of the official crop figures.

COFFEE.—As in former years, the Government statistics show separately as hulled or unhulled, and adding both quantities one obtains an export of 28,872,000 kgs. or 467,000 piculs, which figure again differs very little from that of the statistics of the Handelsvereeniging, according to which the export of coffee in 1891 amounted to about 478,000 piculs against 276,900 piculs in 1890; 433,100 piculs in 1889; 475,200 piculs in 1888; 319,200 piculs in 1887. Under these figures is included every year a quantity of 100,000 piculs Government coffee sold in Java, besides the coffee from other parts of the Archipelago, and that mostly from Palembang, Bali, and Celebes. The production figures collected and published by Government have, unhappily, no value at all, because a number of planters sent no declaration of their crops, so that the quantity of 61,389 piculs noted for that year (against 317,115 piculs in '89, and 298,338 piculs in '88) is no gauge of the real production of the private coffee estates. As formerly, the unhulled coffee was sent almost exclusively to the Netherlands, viz., 553,000 kilos, or 90,000 piculs out of the 5,755,000 kilos, or 93,000 piculs, whereas the hulled coffee was shipped as follows:—

To	'89. piculs.	'90. piculs.	'91. piculs.
Netherlands	224,200	172,000	239,000
England	5,200	2,600	500
France	17,600	10,200	14,000
Austria (Trieste)	7,600	2,200	11,000
Port Said, f.o	41,900	13,200	27,000
America	9,300	12,700	15,000
Singapore	23,400	16,600	14,000
Hong Kong	2,500	1,500	1,700
Australia	2,300	800	900
Elsewhere	800	1,000	1,500

PEPPER.—The export of cubeb (staarpeper) increased to 100,000 kilos or 20,000 piculs above the average of the four preceding years, in connection with the extension of the culture in Bantam, the Preanger, Banjoemaas, and Bagelen. The black pepper comes chiefly from the Lampung districts. The crop there, which in 1890, because of too much rain, had remained far beneath the average, seems to have been particularly favourable in 1891, but exact figures are not yet available. The export from Java increased to 3,135,000 kilos or circa 51,000 piculs, whereas according to the statistics of the Handelsvereeniging the exports were, in 1890 35,000 piculs; '89 41,000 piculs; '88 28,000 piculs; '87 20,000 piculs.

RICE.—The export of rice remained at 27,500,000 kilos or 445,000 piculs, the same as in 1890, when the officials statistics showed a figure of 26,954,000 kilos or 436,000 piculs. The rice crop (according to the official estimates of products) of the Government's lands in Java and the import and export amounted (in piculs):—

	Crop.	Import.	Export.
1887.....	34,940,000	7,000	1,164,000
'88.....	33,120,000	152,000	1,001,000
'89.....	32,763,000	451,000	405,000
'90.....	30,446,000	742,000	436,000
'91.....	?	887,000	445,000

From these figures it appears that the yield of the rice crops influences the import more than the export. Only with large crops and low prices the ordinary Java rice comes into consideration as an export. With high prices this export stops; but quite independently of the so-called table-rice, the products of the private estates in West Java, always finds its way to Europe, and the export of 1891 for the greater part is thus explained. For of the 445,000 piculs exported, about 330,000 piculs were shipped to Europe. The endeavours to improve the culture referred to in the colonial reports, deserve more than ordinary attention, for the culture of rice is one of the principal elements of prosperity of the Javanese population.

TEA.—Whereas the export was for several years almost stationary, and amounted in the four last preceding years to an average of 3,824,000 kilos., it decreased in 1891 to 2,673,000 kilos. as a result of the continual and severe drought which reigned in 1891. The export of tea was

To	1889. kilos.	1880. kilos.	1891. kilos.
Netherland ...	1,885,000	1,368,000	1,033,000
Englands ...	1,467,000	1,036,000	1,558,000
Singapore ...	67,000	805,000	72,000
Elsewhere ...	73,000	1,000	9,000
Total ...	3,492,000	3,210,000	2,672,000

Interesting are the widely differing figures of the export to Singapore, but a well-informed firm states that in 1891 important quantities of tea were shipped on through bills of lading, via Singapore, to London, as the Dutch mail boats and the Queensland Line had increased the freights to London. Under these circumstances, shipment via Singapore, was more profitable.

CACAO.—The export of cacao begins slowly to assume more important proportions, for it amounted in 1886 to 20,300 kilos., in 1887 to 23,300 ditto, in 1888 to 69,700 ditto, in 1889 to 86,700 ditto, in 1890 to 227,900 ditto, in 1891 to 375,700 ditto, which figures are probably more exact than those of the statistics of the Handelsvereniging, for according to these the export of cacao should have amounted in 1888 to 423 piculs (26,000 kilos.), in 1889 to 1,420 piculs (88,000 kilos.) in 1890 to 8,245 piculs (511,000 kilos.), in 1891 to 5,751 piculs (357,000 kilos.). At first only little cacao went to the Netherlands, but in the last years, on the contrary, the greatest export goes hence. In respect of the other articles of export not mentioned here, nothing in particular is to be remarked.—*L. and C. Express.*

LIBERIA.

The usual estimate of the extent of the Republic is about 35,000 square miles, with a population of 18,000 to 20,000 civilized negroes and over 100,000 African natives. The climate is esteemed to be the hottest in the world, but is tempered by constantly alternating breezes from the land and from the sea. The year is divided into dry and rainy seasons, of which the dry season begins in November and lasts until June, when heavy rains begin. From the coast the land rises rapidly towards the interior, and the temperature diminishes in the proportion of one degree to every 750ft. of latitude. The country is disposed in two main terraces, which run parallel with the coast. In the first and lower of the two a number of the small streams take their rise, and in the rainy season become flooded and rush to the sea carrying with them enormous masses of vegetable and mineral detritus that being deposited, form almost impassable bars and help to render them unfit for navigation. The second terrace, of much greater height than the first, is known by the name of the Kong Mountains. Their gold mines of considerable value are believed to exist, and here also a number of streams take their rise, and, descending by cataracts to the lower parallel, form fine rivers on their way to the sea. The country is at all points penetrable by these water-courses. The opportunities which they offer for navigation rendered this part of the coast a hotbed of human exportation in the days of West African slave trade, and it is hoped that under the happier auspices of its present Government the same advantages may serve to stimulate the development of legitimate commerce. The native products consists chiefly of palm oil, camwood, ivory, and gold dust. Rice, sugar,

coffee, cocoa, indigo, cotton, ginger, cassava, and potatoes are all indigenous to the soil, and many kinds of grain flourish amazingly. What resources the back country may offer in the way of a native market and how much truth there is in the reports of mineral wealth existing in the Kong Mountains remain to be demonstrated by experience. Liberian influence is said to extend for many hundred miles into the interior, where English is generally understood enough to serve as a means of communication, but there is a wide zone of country in which the chiefs do not own allegiance to any civilized Power. In this tract there is opportunity for the extension of British commercial enterprise, under countenance which the Government is powerless to extend to it when it takes the direction of the territories lying within the sphere assigned by the treaty of 1890 to French influence.—*Times Weekly Edition, May 20.*

TOBACCO CULTURE IN THE CONGO.—Colonel North is now devoting his attention to the Congo, where he and several other speculators propose going in largely for tobacco culture. The Colonel and his fellow-directors of the concern which has been organised to carry out the projected enterprise had an interview the other day with the King of the Belgians, and everything is now reported to have been satisfactorily arranged. The company will send out experienced tobacco planters to the Congo, and the work will be taken up promptly and vigorously.—*Colonies and India.*

POSITION AND PROSPECTS OF CHINA TEA.—We take over from the *North China Herald* a second "Sermo Sinensis" (see page 35) in which the position and prospects of the China tea trade are discussed in an amusing but very suggestive manner. The list of losses on sales of tea is simply terrible, and a most striking contrast to statements contained in Fortune's book, of the handsome profits made in 1848-50, under the influence of which so much new lands cultivated with the tea plant on the grand Bohea mountains. It will be noticed that Awai's remedy for the depression in China tea most curiously coincides with Mr. Roberts's theory that the more tea Ceylon sends into the London market, the sooner will she be able to oust the rival product from China. Our readers will not fail to notice that in order to meet the Russian taste for mild-flavoured teas an absolutely flavourless leaf has been prepared—that is it seemed flavourless to a gentleman who appears especially to enjoy the flavour of Awai's champagne. The suggestion to engage the help of the Commissioner of Customs is natural enough; but happily for India and Ceylon, though unfortunately for China, Sir Robert Hart, when previously appealed to, refused to recommend the removal of the export duty on tea, which, with "squeezes" of all kinds, constitutes a burden on China tea, before it can leave the country of more than 2d per lb. To this fact must be added the cost of carriage, largely by coolies, for enormous distances from the tea districts to the ports of final preparation, packing and shipment. The consumption of China tea in China is very large, qualified by the fact that as a general rule, the infused leaf is treated repeatedly with boiling water until water unflavoured by tea is the final result. But it was the foreign tea trade which yielded such large profits to middleman and merchants and gave remunerative employment to farmers, labourers and mechanics, the waning of which cannot but lead to much distress amongst the masses who are chronically poor, subsisting on the very minimum of food.

USEFUL PLANTS AND VEGETABLES IN NEW ORLEANS.

The British Consul at New Orleans has recently furnished to the Foreign Office a report on the cultivation of useful plants and vegetables. In the matter of fibrous plants it seems that the Ramie or China grass plant (*Boehmeria nivea*) has been grown with good promise of success. The plants were raised, not from seeds but from roots, which were obtained with considerable difficulty, so much so that only 85 acres were put under cultivation. The method pursued was to plough and prepare the land, taking care that the earth was well pulverised. Three ridges were formed in the way usual for sowing cotton. The ridges were 4 feet apart, and each root or piece of root from three to four inches long, and less than one inch broad, was placed in the furrow previously prepared, of about 5 inches to 6 inches deep, and 12 inches to 18 inches apart. The ridges or rows were slightly enriched with stable manure, and before a week the sprouting was distinctly seen, and before 48 hours the lines were well marked. Four months afterwards, when the growth had become rapid and the crop was 7 feet to 9 feet high and well matured for cutting, there was a severe drought of several weeks, followed by hail-storms and heavy rain, all of which the plants withstood with little or no injury. Roots planted in June were ready for cropping in October. The crop, although a first yield, was abundant, and was cut and gathered in less than 24 hours. As three crops a year in a tropical climate is a certainty, it is considered reasonable to expect two profitable crops in Louisiana. It is intended to plant at once 250 acres of the plant. With reference to the idea that Ramie would grow well in wet and undrained lands, it is stated that in Louisiana the plants perished if water remained sluggishly on the ground between the roots. The crop was taken off with difficulty in consequence of the planting having been made in ridges. It has been decided in future to plant on a dead level in rows only two feet apart, and in beds of 20, 40, or 60 feet wide, and as long as the field allows each bed to be sufficiently wide apart to allow a moving machine with mules attached to work between them. It is confidently expected that Ramie culture will prove a profitable industry.

Jute (*Corchorus capsularis* and *C. olitorius*). The cultivation of these plants, which has been known in India for centuries, has only recently attracted the attention of the planters of the Southern States of America. In the cultivation of jute, a warm humid climate is essential to success. It will grow upon comparatively dry lands or in flooded valleys. The land intended for a jute crop must be thoroughly broken up. The time for sowing the seed varies with the condition of soil and climate; March and April are the best months for sowing, which is done broadcast from 15 lb. to 20 lb. to the acre. It matures in twelve weeks, and grows to the height of from 12 to 18 feet. The yield is from 3,000 to 4,000 lbs. of fibre to the acre. The plant should be cut while it is in flower, as the fibre is then more glossy. In about five weeks after flowering the plant fully ripens and the fibre then becomes woody and loses much of its commercial value.

Okra, or Ochro (*Hibiscus esculentus*). This is a well-known tropical plant belonging to the Malvaceæ, valued alike for the fibre of its inner bark and for the fresh green fruits. It is easily cultivated and will grow on almost any soil, requires but very little attention, and when the stems are passed through a similar process as that adopted in the preparation of jute, produces a long, silky glossy fibre. The okra is said to yield about the same amount of fibre as jute, and it is much easier to work. The fibre is useful for cordage twine, bagging, matting, upholstery work, mattresses, &c. The fruit is a highly esteemed vegetable, and is used particularly in thickening soups. Boiled okras, served with proper dressing, are said to be very palatable. The fruit forms the chief component part in the dish called "Gumbo," a name which is sometimes

applied to the fruit itself. This dish is described as a highly-flavoured stew, made principally of fowl, fish, or oysters. The okra grows extensively in the West Indies. In Florida, the seed is sown late in spring in rich soil. It is said that the fruits may be preserved for winter use by cutting them in halves and hanging them up to dry. The ripened seeds, when roasted, make a good substitute for coffee.

On the subject of the sweet potato (*Ipomœa Batatas*). It is described as a leading article of food in the British West Indies, especially amongst the negroes. The tuber can be easily desiccated in the same way that peas and other fruits are dried, by slicing and exhausting it of its moisture. Like dried fruit, it will retain its saccharine, as well as its nutritious properties. It is expected that the business of drying sweet potatoes for the export trade will in due time become a profitable industry. It would probably find a market in many parts of Europe, as well as in South America. The plant may be grown so easily, cheaply, and abundantly in the southern parts of the United States, more so than in any other part of the globe, that the ramifications of an export trade in the article might be extended to embrace the uttermost parts of the earth, it being one of the cheapest of cheap and good food products.

Amongst other root crops the beet may be specially mentioned, as being specially cultivated in and around Pensacola, where it grows to a very large size, and of excellent quality.—*Journal of the Society of Arts.*

PEPPER PLANTING IN PENANG NINETY YEARS AGO.

(FROM THE PERAK GOVERNMENT GAZETTE.)

The following account of how pepper was planted in Pinang some 90 years ago will be of interest to District Officers in those parts of the State where the natives are vigorously taking up the cultivation of the vine:—

"The Manner of Cultivating the Pepper Vine. The Result of Personal Experience of a Cultivator, being an Appendix to 'A Short Account of the Settlements &c., of Prince of Wales's Island, in the Straits of Malacca,' Sir George Leith, Bart, Major 17th Foot, and late Lieutenant Governor. London: 1804."

The vines are propagated from either slips or cuttings, and planted in rows at the distance of 6 or 8 feet, varying in this respect according to the judgment of the cultivator. The supporter to the line is usually planted at the same time, or very shortly after, the vine. There are several sorts of supporters—the *dedap* and **mongkudu* trees, are, however, generally preferred; the former, which is propagated from cuttings, is esteemed the best, its spreading branches and thick foliage affording more shelter and support to the vine than the latter, but the uncertainty attending the rearing of it in many soils causes the *mongkudu*, which is raised from the seed without difficulty, to be more commonly used, particularly since the improvement introduced in training it with three or four perpendicular branches instead of one, which was the usual mode; this is done by cutting off the leader when the plant is between four and five months old; this causes it to throw outside shoots, three or four of which only are suffered to remain and trained in a perpendicular manner. When the vine is first planted it is covered with the branch of a tree called *piah*, something like the *nipah*, to protect it against the effects of the sun, until it has taken root, and is fit to be brought to the stick; this happens usually about six weeks after planting, when a stick of about three inches in circumference, and seven or eight feet long, is planted near it, to which it soon adheres (being first slightly attached to it by a string), and creeps up towards the top. In eleven or twelve months the vine generally begins to show

* *Mongkudu*.—A common jungle tree. The Malays make a medicine from its fruit.

blossoms, at which period it may have attained the height of six feet; it is then fit for training down; this is done by loosening the vine from the stick and removing that entirely; the leaves are slipped off the stem, leaving only a small tuft at the top; a pit is then dug close to the roots, about twenty inches in diameter, and nearly the same depth, at the bottom of which the stem of the vine is coiled horizontally, bringing the top or tuft before mentioned to the supporter already planted for that purpose, to which it is fastened by a string; the pit is then filled, covering the stem in that position. The increasing size of the vine in a short time after the above operation has been performed shows that roots are springing abundantly from the stem; the whole skill of the cultivator is now shown by the manner in which he trains the vine, as this naturally takes a perpendicular direction; his care is to prevent its ascending too rapidly, which, if not checked, it will certainly do. This was an error the majority of pepper planters fell into at the first settlement of the island, when the cultivation of this valuable plant was not so well understood as at present. The top of the vine, therefore, and a length of some feet below it, is consequently not allowed to adhere to the supporter, but being pendant and inclining to the ground, throws outside shoots, by which it increases in bulk proportionably to its height. Although the blossom on the vine thus turned down comes to maturity, the produce even of the third year is trifling, averaging perhaps, in a large plantation, about an eighth of a catty; from the third to the fourth year half a catty; increasing half a catty a year, until it will average two or two and a-half catties, at which time the vine may be considered to be in full vigour. As there are not many plantations on the island much above ten years old, we can only judge from information how long the vine will continue bearing. From intelligent Chinese, who have lived at Tringano and other places on the eastern side of the Malay Peninsula, we learn that it continues in full vigour to the age of fifteen years, and then gradually declines, still, however, yielding fruit, if properly attended to, to the age of twenty-five or thirty years. This opinion differs very materially from that entertained by the original cultivators on the island, who supposed the vine would cease bearing at sixteen years; there is, however, every reason to suppose the mean of the two opinions will prove nearly correct: a garden eleven years old, situated at Songhy Chuan, containing 3,000 plants only, has lately been let for three years for seventy piculs of pepper per annum, which makes each plant average $2\frac{1}{2}$ catties, a strong argument in favour of the vines bearing longer than sixteen years, as did it than cease giving fruit entirely, the gradual decrease would certainly have commenced at eleven years; but it has been before observed that the vine in full vigour will not average more than $2\frac{1}{2}$ catties per plant. The renter of this garden is thought by his countrymen, the Chinese, to have made a very good bargain. There are few soils on this island unfavourable to the vine: the dark mould mixed with gravel is generally preferred: it thrives in high and low situations—best in the latter, if sufficiently raised to prevent the water in the heavy rains from settling, if the roots were to be covered with water for six or eight days the vine would infallibly be killed. A plantation, if properly taken care of, should be kept perfectly free from weeds and grass, and for the first five or six years the earth should be regularly turned, twice a year; after that period once turning will be sufficient. Four coolies will take care of a laxa (10,000) of plants, if properly attended to; they must, however, be allowed a cook but they will require additional hands when the crop is gathered; the number will, of course, depend on the fertility of the vines. The vine blossoms twice a year—after the commencement of the rains in the setting in of the south-west monsoon in April and May, and when they cease in December; the former crop is gathered the latter end of December, January, and February: the latter in May, June and July. The quality of the pepper depends in

a great measure upon the care taken in the gathering and drying. The pepper when plucked before it is fully ripe diminishes both in size and weight, so much as frequently to occasion a difference of upwards of 30 per cent between what is gathered in this state and that which attains its full maturity. The Chinese planters fall frequently into this error from want of funds and the necessity they are often reduced to of realising cash at a fixed period in order to satisfy those who have made them advances at most extortionate interest, and also from a wish to save expense in collecting the pepper gradually as it ripens (which is when the fruit becomes a reddish colour) they pluck the whole or the greatest part of the pepper at once from the vine, instead of those bunches only which are perfectly ripe. This mode of course is more laborious and expensive. When gathered it is exposed to the sun on mats, and in the course of the day begins to turn black; it is then put into a large wicker basket in the shape of a tray, and trod upon to separate the pepper from the stem on which the bunch is formed: in favourable weather it will be perfectly dry in the course of four days, when it is packed in gunnies and ready for the market. A picul of green pepper if allowed to remain on the vines till perfectly ripe will yield from 35 to 36 catties when dry. The vines seldom fail of showing much blossom in gardens which are properly taken care of; but it is subject to be blighted even after the fruit has attained some size when the season proves either unusually hot or dry: when this happens considerable quantities of pepper will drop off: a few hours rain soon puts a stop to it. The pepper of this island when gathered in a proper state, and carefully dried, is esteemed equal in taste, weight, and size to that of any place whatever, and superior to most. European cultivators make their plantations by contract; the usual price is \$525 per thousand: this includes every expense of tools, houses, digging wells, and clearing the ground, and every other item, the price of the young plant excepted. The pepper plant was first introduced into the island from Acheen, by the then Captain China Che Kay, under the patronage of Mr. Light, who advanced him money for that purpose; this was about the year 1790, 100 years ago.—*British North Borneo Herald.*

COCOA AND CHOCOLATE.

Mr. Richard Bannister, F.I.C., F.S.C.I., Deputy Principal of the Inland Revenue Laboratory, Somerset House, recently delivered the third and last of the interesting series of Cantor Lectures at the Society of Arts, his subject being cocoa. He said that Linnæus was so pleased with the nourishing drink, derived from the seeds of the plant, that he named it *Theobroma*, or food of the gods. The native name was cacao, and the plant was therefore known as the *Theobroma cacao*. The name had now been corrupted into cocoa, but it was impossible to trace the steps of the change. The use of the word certainly led to confusion with the coco-nut, and it was now becoming customary to spell the latter "coker,"* for distinction's sake. Both cacao and chocolate were words of Mexican origin, and it had been surmised that the latter expressed the endeavour of the natives to render into language the sound made by the pestle and mortar in mixing the cacao with sugar and species for the production of that substance. Europe was indebted to Spain for the discovery of cacao, which was indigenous to Mexico, and especially Hernando Cortez, who conquered that country in 1521. Peter Martyr remarked that the natives used the seeds as coins, and he thus named them *amgdalæ pecuniariæ*. The natives also used it as food, and much esteemed the beverage made by in-

* Horrible! In Ceylon we have simply dropped the superfluous *a* and write the name of the palm coconut.—*Ed. T. A.*

fusing the seeds, one writer saying that "it was held in religious veneration." Cortez, when settled in Mexico, sent the products of the newly conquered country to his master, Charles V., and in this consignment cocoa occupied a very important position. It was minutely described, and the medical men of the day, who became acquainted with its virtues, recommended it to such of their patients as possessed sufficient wealth to purchase it. Hoffman pointed out that it had cured Cardinal Richelieu of a dangerous disease, and that proved so good an advertisement that it quickly became popular. It was thus known and used in Europe before the introduction of tea or coffee, and for many years the Spaniards secretly manufactured it for the supply of the rest of Europe. In 1533 Peru was conquered by the Spaniards, and cocoa was found to be of as good repute in that country as in Mexico. On the authority of Barnal Diaz, it was stated that the Mexican Emperor had fifty large jars filled with the drink prepared for his exclusive use every day. It was paid as tribute by many of the towns of the Empire, and Torquemada gave the amount annually consumed in the palace at Mexico, on the authority of a royal account-book which came into his possession, as about 2,744,000 cwt. Humboldt estimated that the consumption in Spain in 1806 was from 6,000,000 to 9,000,000 lb., and in the rest of Europe from 14,000,000 to 17,000,000 lb. From this it will be gathered that the quantity said to have been consumed in Mexico was thirteen times what was used in Europe 250 years afterwards—an evident exaggeration. It would appear that the natives had to surmount the same difficulties as the modern manufacturers in covering the strong taste of the seeds and the large quantity of oil or fat present in them. This they did by an admixture of maize flour and sugar, as well as vanilla and other species, and it was so prepared as to be "reduced to a froth of the consistency of honey, which dissolved in the mouth and was taken cold." In Rees' Cyclopædia (1819), it was stated that the South American Indians prepared the chocolate or chocolate by mixing it with maize and raw sugar as expressed from the cane. It was then made into a kind of bread, which was either eaten as it was, or dipped into hot water for a drink. The proportion given was a pound of the roasted nuts with half a pound of sugar dissolved in rose-water and half a pound of flour or maize.

In 1657 cocoa was publicly sold in London under the name of chocolate, and an advertisement appeared in the *Public Advertiser* of Tuesday, June 16, and six following days, that "In Bishopsgate Street, in Queen's Head-alley, at a Frenchman's house, is an excellent West Indian drink called chocolate to be sold, where you may have it ready at any time, and also unmade, at reasonable rates." A few years later other houses were opened, and it soon became a favourite with the rich and fashionable, together with tea and coffee. Chocolate paste was sold in 1660 at 10s to 15s. per lb. Imitations of the best qualities were sold cheaper, and in 1662 "at the coffee-house in Exchange-alley" chocolatta was sold by retail at 2s. per lb. in the ordinary pound boxes. The habits and fashions of life at the Restoration led the people to think less of home and more of club-life, and any such institutions as cocoa or coffee-houses became very popular. From these the present large clubs developed. Many of the houses became identified with the political parties and Defoe wrote: "A Whig will no more go to the Coffee Tree or Ozenda's than a Tory will be seen at the coffee-house at St. James." A famous club, of which Byron was a member, was the "Tory Cocoa Tree Club." At this period gambling became associated with the clubs, and Horace Walpole recorded in 1789 that one man had lost 180,000l. in one throw, and regained it again the next night. Gradually these clubs became more and more exclusive, and drinks, which were not non-intoxicating, took the place of the harmless coffee, tea, and cocoa.

In course of time these drinks were looked upon as necessities of life, and their sale got into the hands of the grocer, and they were thoroughly di-

forced from their improper alliance with the club and fashionable life of the last century. The result had been that every politician of the last generation had made it a part of his financial policy to tax spirits to the utmost, but to reduce the duty on non-intoxicants to the lowest possible point. The effect of this policy had been a reduction in the price of these articles, and a rise in the price of intoxicants, with a consequent rise and fall in the consumption of the two classes of drinks. In 1793 cocoa was charged with a duty of twelve guineas per cwt., and a further customs duty of 11s 11½d. Such a tax was prohibitive, and had the result that the trees were allowed to die out in those English colonies where it would grow, and sugar was made the staple crop. When the fiscal changes in Europe almost ruined the sugar planters, the cocoa plantations had disappeared through neglect, and with the exception of Trinidad and Grenada the West India Islands did not now practically produce cocoa as an article of commerce, although it was still being carried on experimentally.

Cocoa was found by analysis to be very nourishing, although many of the soluble substances were practically locked up in the large quantity of fat present. It would appear that our manufacturers of to-day were working on the same lines as the natives of Mexico did 300 years ago, and though good machinery and manipulative skill gave them great advantage, yet the addition of sugar and starch, and the flavouring with vanilla and other spices were only imitations of what was done in early times to make the cocoa more serviceable as a food, better suited to human requirements as an ordinary beverage, and adapted for consumption as a condiment or sweetmeat by the young and old. The plant was an evergreen, indigenous to tropical America, although now grown in Asia and Africa. Its height was fifteen to forty feet, but in plantations it was kept down to seventeen to eighteen feet. Its limits of cultivation were 25° N. or S., and the range of altitude 2,000 feet. It belonged to the natural order *Butriaceæ*, genus *Theobroma*, and was quite distinct from the cocoa nut (*Cocos nucifera*) and the coca (*Erythroxylon coca*). Its mode of growth was peculiar, as the leaves which were from eight to nine inches long and two to two and-a-half broad, were all at the ends of the branches, and the small saffron or pink odourless flowers were often thickly clustered on the old wood of the branches and trunk. The major part of the flowers fall, and usually only one pod was produced from each cluster. The pod, which was often seen ripe on the same bough as flowers, was of an elongated pear shape, rather blunt at the base, and tapering towards the end, and five to ten inches in length. The outside was usually marked by ten shallow furrows with blunt sometimes warty edges. The colour, when ripe, was, according to variety, greenish yellow, golden, dark purple, or bright red. The shell contained five cells, the outer walls of which were of a tough fleshy substance, about half to three-quarters of an inch in thickness. The seeds ranged from twenty-five to forty, closely packed in tiers, about the size of almonds, but more irregular in form. The seed were immersed in a copious acidulous sweetish pulp, and had two coats, the inner portion yielding the "nib" of commerce. There were many varieties, but the two best were the Creole or "Criofo" and the Caracas. An average of ten to twelve Creole fruits would yield rather more than one pound of cocoa. The pods were yellow, and the seeds short, thick, and almost globular, of slightly bitter but very agreeable flavour. The Caracas was much planted, and was preferred by many persons. The beans were more spongy than in the other variety, and it took fourteen to sixteen fruits to yield a pound of cocoa. The seeds were planted in low moist ground, from which the plants were transplanted, when from twelve to eighteen inches high, to a field, preferably on a gently sloping sheltered hill-side. In order to give the necessary shade to the plants the field was planted with coral beans, manioc, and plantains. In the second year all flowers were removed, and in the third all undergrowth was removed and the plants carefully pruned. The aver-

age was 900 trees per acre, and the produce was four to six pounds per mature plant. The tree bore in its fourth or fifth year, and would continue fifty years.

The tree bore fruit all the year round, but the chief seasons for harvesting were May and June and October and November, known as the St. John's crop and the Christmas crop. Great care was taken that only the ripe pods should be gathered, and that in removing the pods no damage was done to the tree. The colour was generally sufficient indication of the degree of ripeness, but those pods within reach were generally gently tapped to ascertain whether the seeds had shrunk from the pulp surrounding them. The stalk of the pod was then cut with a sharp knife, and the part remaining shrunk up and fell off, leaving the tree sound. The pods grew on soft places which had been the axil of a leaf, and if the pod were torn away it would take the soft part with it, leaving the tree sterile at that spot. The pods were placed in a heap, and, soon as convenient, they were cut open and the seeds separated from the pulp surrounding them, great care being taken to remove all black or unripe ones. They were then taken to the "sweating" or curing-house, the operations in which were of great importance, as the commercial value of the bean depended upon the care with which they were performed. The beans were first allowed to ferment, which loosened the adherent pulp, and also modified the bitter character of the seeds. This process lasted from two to seven days, according to the weather, when the seeds were easily removed from the now slimy pulp, and were found to have changed from their bright reddish colour to a deep brown. They were, after having been freed from the pulp, covered for a day with red earth or sand for further fermentation. The next step was to dust them with earth, which dried the mucilage still adhering, and by careful and systematic rubbing put on a nice appearance, which was therefore not quite natural. The seeds were then exposed to the sun until dry, when they were fit for shipment. Unfermented seeds were also to be had, but they were poor in flavour and bitter, and were often used for the cheap cocoas with which a large proportion of starch and sugar was mixed.

The cocoa industry in this country was one of great importance, and one which was growing. The manufacturers were no longer content to make cocoa only, leaving the French and Swiss to import various kinds of chocolate, creams, and sweetmeats, as this was having its effect on the comparative imports of raw and manufactured cocoa. Those engaged in the trade bought in the best markets, and as they combined the best materials and the best skill in their manufactures, they were able not only to hold their own, but to increase their trade. The chocolate was put up in fancy boxes in a great variety of forms, and it was therefore not surprising that the industry should have increased by leaps and bounds, and should have become one of the first importance as a home industry.

Cocoa, as imported, was not in a fit condition for consumption without further treatment. The first process was that of roasting which caused the husk to become loose and fit for removing, it developed a distinct aroma, and caused the seed to become friable. This was a process requiring great skill, and the men employed had to be men of great experience and capable of acting on their own judgment. The beans were passed over sieves to obtain uniformity of size, and were then placed in rotating cylinders. After the roasting, which was done at from 500° to 600° Fahr., they were cooled and the husks separated from the nib, which was then ground in a mill, which, if the cocoa was to be made into a paste, was warmed, for the purpose of melting the fat, which could then be squeezed out by pressure. As cocoa fat did not become rancid, the melted mixture was generally run into blocks and so kept for subsequent treatment or for sale. Cocoa had been for long manufactured at the Admiralty victualling yards for use in the navy. In 1825 it was introduced as a substitute for gruel for breakfast. Then,

and for seventeen years after, the husks and nibs were all ground up together, as was often done in commerce still, but as it had a bad effect on those who habitually used it, in 1842-44 a change was made, and the husk excluded. The husks were now sold at 11l. per ton, and as they lent themselves readily to the purpose of adulteration, few ground cocoas were now made which did not contain some of it. The navy cocoa consisted of 80 per cent. of cocoa and 20 per cent. of Demerara sugar, and was called ordinary, or of 20 per cent. of refined sugar and the same of arrowroot, when it was called soluble cocoa.

The aim of the manufacturers was to obtain a soluble cocoa, and the success with which their efforts had been attended had undoubtedly done much to increase its consumption. The manufacturer, who first presented to the public cocoa mixed with starch and sugar, had undoubtedly done much to popularise its use. The quantity of fat which cocoa contained rendered it unsuitable for dyspeptic persons, and thus the homœopathic cocoas were introduced, in which the cocoa was diluted with starch, Iceland moss, &c., and sugar. The sugar sweetened the liquor while the starch granules, by bursting on the addition of hot water, formed a gelatinous menstruum in which the finely ground cocoa was held in suspension. The prices paid for these mixtures showed that the public had to pay a very high price indeed for the starch and sugar present in them. The series of analyses conducted at the Inland Revenue Laboratory had shown that there was small chance of anyone being injured by reason of the proportion of fat present.

The admixture of starch did not long please, and manufacturers still sought to produce a really soluble cocoa. By expressing all the fat possible, and by adding an alkali, or by further heating the powder, they at last succeeded in making it more soluble, and the enormous sale of these extracts made it apparent that they supplied a public want. Each maker had his own speciality, and the following table will give the analysis of the various makes:—

Kind.	Percentage of			Ratio of Fat to non-fatty cocoa.	Starch (added)	Sugar (added)
	Moisture.	Fat.	Non-fatty cocoa.			
Finest Trin. nibs	2.60	51.77	45.63	1 to .8	None	None
Cocoa extract	3.52	23.98	72.50	3.0	"	"
Chocolatine	4.40	29.60	66.00	2.2	"	"
Cocoa extract	5.76	29.50	64.74	2.1	"	"
Flake	5.49	28.24	66.27	2.3	"	"
Rock	2.58	22.76	24.90	1.09	17.56	32.20
Prepared	4.95	24.94	27.89	1.1	19.19	23.03
Iceland Moss	5.47	16.86	23.74	1.4	24.70	29.23
Chocolate de Sante	1.44	22.08	13.27	.6	2.00	61.21

Name.	Percentage of		Amount of ash soluble in cold water.
	Ash.	Cocoa soluble in cold water.	
Trinidad nibs	2.86	10.58	2.44
Cocoa extract	6.81	18.00	3.95
Chocolatine	6.14	18.50	4.50
Cocoa extract	5.64	16.72	4.36
Flake	5.39	18.10	4.00
Rock	1.56	36.70	0.90
Prepared	1.52	30.66	1.17
Iceland Moss	1.83	40.80	1.06
Chocolate de Sante	1.76	65.60	1.26

It was only right for him to add that cocoa, which had been prepared by the extraction of the fat, was the very best form for general use, as the percentage of nitrogen had been increased, and it was thus richer as a flesh-former than when in its natural state. Cocoa did not suit every constitution, but

to those who could take it and preferred it to tea or coffee, there was no doubt that the modern preparation of it now under consideration was of very great value. It had none of the objections of so-called soluble cocoas, and yet was very soluble and nutritious, being strongly recommended by the medical profession in cases of debility as a partial substitute for tea and coffee. The average quantity of ash of raw cocoa was from 2.5 to 3.2 per cent., of fat-reduced cocoa from 4 to 5 per cent., and of cocoa treated with alkali 8 per cent., the bulk of the latter being potash and phosphoric acid.

As compared with tea and coffee, cocoa was deficient in aromatic principles, and the alkaloids were not the same in amount, and did not exert a similar stimulating effect upon the central nervous system. On the other hand, however, it was far richer in nutritious properties—fat, albumen, starch, and mineral salts. When deprived of the fat, which was liable to be irritating in the stomach—as fat was not digested until it had passed on, and met with the secretions of the liver and pancreas,—cocoa yielded a bland, easily digested, and slightly stimulating beverage, generally free from any subsequent unpleasant effects. It must not be forgotten that cocoa was not only used as a drink. As a sweetmeat for young and old it was perfectly safe to state that it was an improvement on the use of an inordinate quantity of sugar, and the use of cocoa as a sweet in the form of chocolate or creams was to be encouraged rather than condemned. It nourished rather than fattened, and as an article of diet, although expensive, it was wholesome. Mr. Bannister then proceeded to deal with the various forms chocolate took as a sweetmeat, saying that it was found necessary to add fat to it in order to accommodate it to the manufacture of creams. The fat used was the cocoa fat or butter obtained from the cocoa used for other purposes. The creams were composed of sugar melted up with glucose and flavoured. From the trade lists he had studied, he had found that one manufacturer enumerated 221 assortments of chocolate sweetmeats, another 244, and yet another 253. The increase in consumption during the past few years had been considerable, and, without taking too sanguine a view, they might expect the increase to steadily progress on account of the attractive and pleasant forms in which cocoa could be obtained, either as a drink or a food.—*Grocer*.

OIL PALM FIBRE.

(*Elæis guineensis*, Jacq.)

The African oil palm is probably the most valuable of the indigenous plants of West Africa. From the pericarp of the fruits of the well-known palm oil is prepared, while from the kernel of the nuts another kind of oil is extracted, scarcely less extensively used. According to Sir Alfred Moloney (*Forestry of West Africa*, p. 57), "although the palm oil industry has existed since 1790, if not before, the valuable palm kernels on the Gold Coast did not attract attention until 1842 or 1843, when also the ground-nut industry, at least in the Gambia, had its birth." The palm oil received in this country during the year 1885 amounted to 872,342 cwt., of the value of 1,172,862*l*. The palm kernels received during the same period amounted to 34,507 tons, of the value of 406,856*l*. We have therefore two important products from the African oil palm, the value of the quantity reaching the United Kingdom amounting to about one million and a half sterling yearly. To these we have now to add a third industry connected with the production of fibre from the leaves. It may, however, be mentioned that the immediate prospects of this new industry are not very hopeful. The fibre is extracted in a laborious manner by the natives, and it is not, as yet, produced in commercial quantities.

Its extensive use locally for fishing lines and other purposes requiring great strength shows that it is one of the most valuable and lasting of tropical fibres. Very little, if anything, has hitherto been

published respecting this fibre. Kew is indebted for the first specimens received for the Museums of Economic Botany to Mr. George Arbuthnot Moore, Managing Director of the Palma Trading Company, Liverpool. These were received in June 1891. Since that time a very complete series of specimens illustrating the method of extracting the fibre with samples of twine and fishing lines have been received from the Government of Lagos. A small specimen was received from Mr. Scott-Elliot from Sierra Leone, January 1892.—*Kew Bulletin*.

CULTIVATION OF RAMIE IN MEXICO.

In a recent report by the United States Secretary of Legation at Mexico, it is stated that Mexico offers special advantages for the successful cultivation of the ramie plant. The states of Vera Cruz is admirably adapted—from its frequent rains and facilities of irrigation in the zone which extends from Jalapa to Tuxtepec, passing through Cordoba—to the cultivation of ramie; and, in addition, the railways penetrating these districts offer ready means of transportation to market. After its second year the plant can, as it does in Venezuela, yield four, five, and even six cuttings a year. Both white and green ramie can be cultivated in Mexico, but the white is generally preferred, as it is very robust, and yields a superior fibre to the green ramie. White ramie comes from China. The leaf underneath is white, veined with green, and the leaves and stems are very hardy. Owing to this hardness the plant will grow in almost any climate, but, nevertheless, has a predilection for a sandy, light soil, with a well-drained under-soil, as the roots rot in swampy ground. Soil impregnated with saltpetre is also prejudicial to its development. In order that the stems may grow straight and narrow, without lateral branches, it is necessary that the plants should be crowded together, having a space of not more than half-a-yard between each; the stems will then give a much superior fibre. After the second year weeding is no longer necessary, as the multiplicity of roots does not allow the growth of any parasite. Once started, the plants will last for years without being renewed. It is stated that the plants will live for more than fifty years, but to obtain this result an annual manuring is indispensable. In spite of the assertion of some cultivators that the fallen leaves suffice to manure the land, experience shows that the best results are obtained by using manure. Again, the leaves may be used for making paper, as is done in China. The cultivation of ramie requires but a small outlay and very slight labour, and, as the harvests are numerous when once the plants are fairly started, the return is prompt. It is expected that weaving and spinning mills will be established in Mexico for making use of the fibre, but it is thought that the richness of the soil will prove such that the production of raw material will far exceed their capacity of consumption, and that Europe will take any such superfluity, in preference even to hennequin. Mr. Whitehouse states that none of the machines at present in use for decortication give satisfactory results; all are too expensive, and none do sufficient work.—*Journal of the Society of Arts*.

SOURCES OF RUBBER SUPPLY.

Para rubber is the produce of *Hevea brasiliensis*, Muell. Arg., a tree belonging to the natural order *Euphorbiaceæ*. The rubber is obtained from incisions cut through the bark, from whence the sap trickles into small bowls and is finally cured by being laddled on to a paddle-shaped implement and held over a stove in which Urucury Nuts (*Maximiliana regia*) are burnt as the fuel. In Museum No. 1, Case 94, will be found a fine series of articles used in collecting and preparing this rubber for export, and also numerous samples of the rubber. In 1891 the estimated export of Para rubber amounted to 17,700 tons, of which 6000 tons were imported into this country.

A sample of rubber from *H. brasiliensis*, grown at Mergui, India, was reported upon in this country in 1889 as worth 1s. 11d. per lb.

Ceara rubber or "Ceara Scrap" is afforded by *Manihot Glaziovii*, Muell. Arg., a tree native of South America and belonging to the natural order *Euphorbiaceae*. The imports of this rubber into this country amounted to 180 tons in 1891. In Case 96, Museum No. 1, will be found samples from Brazil, and also from plants introduced into Ceylon, Zanzibar, and Natal.

Mangabeira or Pernambuco rubber is extracted from a small tree (*Hanconia speciosa*, Gomez.) of the natural order *apocynaceae*. Specimens of this rubber are shown in Case 72, Museum No. 1.

The principal source of Central American rubber is *Castilloa elastica*, a large forest tree of the tribe *Artocarpeae* of the natural order *Urticaceae*. It affords the Ule of British Honduras as well as Nicaragua, Guatemala, Mexico, and Guayaquil rubbers. The total imports of Central America, West India, Columbian, Carthagena, and Guayaquil rubbers during the year 1891 amounted to 100 tons. See Case 100, Museum No. 1.

Esmeralda of Guiana may perhaps be afforded by *Hevea* sp. or *Sapium* sp. of the natural order *Euphorbiaceae*.

Columbian india-rubber and "Carthagena" are one and the same thing, as is pointed out in the *Kew Bulletin*, 1890, p. 149. The tree yielding this rubber, is *Sapium biglandulosum* of the natural order *Euphorbiaceae*, a widely spread and variable species; it is also the source of Touckpong or Cumakaballi rubber of British Guiana. Case 96, Museum No. 1. contains specimens of these rubbers.

Assam rubber is the produce of *Ficus elastica*, a large tree of the *Artocarpeae* tribe of *Urticaceae*. The imports of Assam and Rangoon rubber (also from *F. elastica*) amounted to 350 tons in 1891. Specimens may be seen in Case 99, Museum No. 1.

Borneo rubber is afforded by species of *Willughbeia* and *Leuconotis*, allied general of the order *Apocynaceae* (see *Kew Report* 1880, p. 43); 200 tons of this rubber were imported into this country during the year 1891. Samples will be found in Case 71, Museum No. 1.

African rubber is furnished by several species of the genus *Landolphia*, woody climbers of the natural order *Apocynaceae*. The best quality from the Zanzibar coast is derived from *L. Kirkii*; two other species, viz., *L. florida* (the chief source of Mozambique rubber), and *L. petersiana* are also sources of the East African supply.

On the West coast *L. owariensis*, which has a very wide distribution, is the principal species furnishing Congo and Sierra Leone rubbers. *L. florida*, which occurs on the east coast, and *L. Mannii* also afford part of the West African supply. Liberian rubber is perhaps in part afforded by the "Abba" tree (*Ficus Vogelii*), of the *Artocarpeae* tribe of *Urticaceae*, and has already been fully discussed in the *Kew Bulletin* for November 1888 and May 1890.

Messrs. Hecht, Levis, and Kahn give the following statistics concerning these rubbers for 1891, viz.:—African imports, 4,350 tons; Mozambique, 380 tons; Madagascar, 300 tons. Case 71, Museum No. 1, contains samples of these rubbers.

The following review of the sources of rubber supply from the commercial side has appeared in *The Indianrubber and Gutta Percha and Electrical Trades Journal*, January 8, 1892:—

There are merchantable in New York between 30 and 40 different sorts of indianrubber, the variations determining the selection by manufacturers in the purchase of stocks, says I. A. Sherman in the *Indianrubber World*. Of course, rubber in all its variations is essentially the same, differing somewhat in the same degree as the pumpkin in South Dakota from that in New England—one large and another small, one with little flavour and the other richer in food qualities. The difference between sorts of rubber, however, is due in large measure to the methods employed in gathering the sap. It happens that the natives of the Amazon Valley have always

taken pains in the curing of rubber. While climatic conditions in that country may have had their influence upon the character of "Para," the condition in which this rubber is exported has become a prime factor in making it a favourite with manufacturers. On the other hand, some of the African sorts are so full of bark and stones as to make them almost unfit for use. At one time "Assams" were almost unmarketable in New York, the price sinking as low as 10 cents per pound, and not wanted at that. One firm, after long experimenting, discovered a chemical solution in which the rubber was washed, the process being that the bark and other impurities absorbed the chemicals, making them so heavy that they separated from the gum and fell to the bottom and away. This company made a fortune in a moderate space of time: but they put up gradually the price of Assams, from the fact of their creating a demand for that sort of rubber, until the profits became comparatively small, when they disposed of the privilege of washing to some leading rubbermen, who use the process at the present day.

Para rubber is more largely consumed in the United States than any other. It may be noted, also, that the larger share of the rubber exported from Para comes to this country. There are three grades—fine, medium, and coarse. Fine Para is the standard by which all other grades are measured; it brings the best price, and probably is more used than any other. Should it become irregular in quality in the operation of curing over the smoke of palm nuts—as when little strips of virgin gum occur in the grain—it is called "medium," and its price is lessened by a cent or two per pound.

The "coarse" is imperfect, being composed of the scrapings and refuse of the fine sorts, and sell for about two thirds of the price of the better grade. It shrinks considerably, having much water in it, and the importer generally is in a hurry to turn it over to the manufacturer. There are again many variations in Para rubber coming from different localities on the Amazon. This subject is involved in some obscurity; but the best rubber is supposed to be found on the River Purus, a tributary of the Amazon, having its source in the Andes. Brazilians, however, are apt to believe that the locality of the best sorts is unknown to Americans, and possibly the Purus may not be the locality.

There comes from Peru, at the sources of the Amazon and its tributaries, a rubber resembling the Nicaragua sheet, and called Caucho. This rubber is very wet, and consequently shrinks very much, which is a serious drawback. It is considered a good strong rubber, and it is utilised to a considerable extent by the boot and shoe manufacturers.

Of Ceara rubber, there are three grades, numbered one, two, and three respectively. It is called a "mule gum," the significance being that it is neither one thing nor the other, it being so deficient in elasticity as to cause some to argue that it is not rubber. It is a very dry rubber, its gathering being peculiar. The tree is incised at the beginning of the dry season, and as the gum oozes from the want it forms on the outside of the bark, to be pulled off at the end of the season. The gathering of this rubber seems to be on the wane, for every year there is an extensive migration of Ceara people to Para, bound for the forests of the Amazon.

From Bahia and Pernambuco, in Brazil, comes a rubber of a different grade from that of Para. It is cured with alum and salt water. The Pernambuco comes in sheets, and is of a yellow-white tinge. That from Bahia is not so good, and comes in round balls. The principal objection to it is that it is very damp, entailing a large loss to the importer from shrinkage.

Of Mangabeira rubber, there are three grades, very similar to the Bahia and Pernambuco sorts. A grade that has a red look is considered superior, and sells for 5 or 10 cents per pound higher than the others.

From Central America comes a variety of rubbers, distinctive in name theoretically, but owing to the lines of transportation centering at Greytown, and the transshipment at that point to New York, there is much confusion, one sort often getting sub-

stituted for another. The Pacific mail steamers gather also different varieties at Panama with the same confusion. That which comes from Nicaragua is called Nicaragua "sheet" and "scrap." The latter comes in pieces about 2½ feet long, weighing from 10 to 40 pounds. In the gathering of rubber in the forest, around the cuts in the tree a residuum is left, which is given to the man as a perquisite, and this forms "scrap." As in the peculiar mode of gathering, it is very dry, there is little loss in shrinkage, and this quality makes it a favourite with manufacturers. It contains some bark, but not so much as the "sheet." The sheet, after it is milled and washed, is the same rubber as the "scrap." Both are cured by the use of a vine from which a soapy [? alkaline] substance is formed.

There is another grade which comes from Central America, containing a considerable amount of ashes, due to its being smoked over the latter. It comes in thin sheets ½ to ¾ inch thick. It is a dry rubber, there not being so much loss in shrinkage; but it is not so firm as the other grades, and it is difficult to work. There also comes from Central American ports a rubber which is chiefly grown in New Granada, and is called "Carthagena strip." It is from 1½ to 2 inches thick, and there is a great deal of sand and dirt in it. It is a black, tough rubber.

Honduras furnishes a great deal of rubber of the Tumo sort, which is found in many other sections of Central America. Guatemala ranks low in the American varieties, containing a resinous substance which gives it a tarry appearance. It comes in sheets pressed together. There is a rubber which comes from Angostura as good as Para. When cut it is found to contain little spots of white as large as a pea. Tuxpan, Mexico, once sent a fine grade of strip rubber; but as the trees have been destroyed by cutting them down instead of tapping for rubber, the imports from there are now very small. The rubber is gathered by scraping from the bark.

Guayaquil comes in large flakes or lumps of a whitish colour in the best sorts, the inferior sorts being porous, and exuding a black liquid which stains the knife and hands. As in a great many "Centrals" the name is often confounded with the sorts.

Esmeralda comes from Guiana, is a strip rubber, and is also made into "sausages." Some brokers are of the opinion that very little of the real Esmeralda finds its way to America, it being almost indistinguishable from other grades. It brings a high price. Certainly little of it finds its way to Europe, brokers not quoting it there. A great deal of the rubber gathered in Columbia finds its way to the Amazon and Para.

In rubber from Asia the Assams probably take the lead, and are rated above coarse Para in price. There are three or four grades, the lower ones being very dirty and all of them requiring much washing.

There are two grades of rubber coming from Borneo. The rubber from that source was first called a gutta, on account of its geographical location, but this error was a palpable one, and soon corrected. It is a white, soft, porous or spongy rubber, the pores being filled with salt water or whey. The better grade is a fair rubber, but the second grade is often when cut almost as soft as putty and practically worthless.

Of Africans there are many varieties. The favourite sorts come from Madagascar. The pinky sort comes in the shape of round balls, weighing 1½ to 4 pounds. It is not so strong as fine Para. There is always a good demand for it, and it is rarely found in store, being sold "to arrive." This sort comes from Tamatave. There are two or three variations in quality of Madagascars, but the grade called "black" comes from Majunga, is exported in small balls, and has a dark colour when cut.

From the West Coast of Africa there are many varieties, the best coming in the shape called "thimbles," which are square pieces one inch each way. The rubber is very dry, and is in good demand by mechanical goods manufacturers. It is very strong rubber, and naturally has little shrinkage. Tongues are shaped as their names indicate. There is con-

siderable shrinkage, but it is a very good rubber. There is also a small ball rubber about 1½ inches in diameter. It cuts white, and is fairly firm.

Congo ball is made from small strips of rubber and rolled into balls, from 1 to 2½ inches in diameter. It is a firm and very elastic rubber, but there is more or less bark in it, and as manufacturers do not always have proper machinery to exclude it, they do not buy readily.

Sierra Leone comes in balls 3 to 4 inches in diameter, and is a very fair grade of rubber. It has a considerable demand from boot and shoe and mechanical goods men. Like all West Coast rubbers it reaches us by way of Hamburg or Liverpool.

The finer grade of Mozambique is called "white ball." It resembles Congo ball in appearance, and comes in about the same shape. The "red ball" is mixed with a reddish bark, and gets its name for that reason. Oftentimes both varieties of "ball" will be found filled in the centre with bark. The rubber is then called "unripe Mozambique," and sells for 10 cents less per pound.

From Liberia comes a lump rubber. There are three rivers in Liberia from which rubber is gathered, but it is all assembled at the common mouth and the grades are not kept separately, making a class of rubber which is very variable, and therefore disliked by manufacturers.

There is, on the whole, a growing tendency toward the use of Africans, and in this is a true check on the price of Para. In Centrals there seems to be a falling off in the production consequent upon a scarcity of labour, which has been from time to time drawn into internal enterprises. In Europe the stocks of Africans are always larger than of Para, and a steady growth is very noticeable.—*Kew Bulletin*.

SCIENCE NOTES.

It is generally known that in prehistoric days Egypt was a wooded country, visited by great deluges of rain, which made the Lower Nile Valley a broad estuary, fed by streams which thundered over cliffs now dry and solitary amid the desert sands. The sequences of these changes—which resulted in the Nile being, except at the period of the annual rise, when it covers its old bed, now the only tillable part of the country, confined to the comparatively narrow channel it has worn for itself—have now been worked out by Mr. Flinders Petrie, who has done so much for the archaeology of Egypt. By means of the gravels, river mud, and other remains he has traced these slow revolutions, which the remains of man in places where man could no longer live prove, in some cases at least, to have been effected since man inhabited the country, though, as the weapons found are rudely chipped flints, this age must have been incalculably remote.

All through the historic period complete desiccation has prevailed. The roads marked out with stones on the plains at Tel-el-Amara in 1400 B.C. are only destroyed in the very lowest lines of the water-courses. The ancient Egyptian buildings only show the effect of rare storms and not of continued rain, while the mud deposits throughout this age are at an average rate of four inches per century. What has caused this desiccation is not known. There has evidently been some elevation of the country. But this alone will not account for the absence of rain. As Egypt lives by the Nile, any similar desiccation in the mountains of Abyssinia or in Central Africa would mean absolute ruin to the Delta and desertion of the up-river country.

The growth of the trees was largely dependent on the rainfall; but, at the same time, the rainfall was greatly affected by the trees. By aiding, as we know they do, passing clouds to discharge their load, and by protecting springs, they kept up a supply, and, moreover, prevented the showers sweeping off instead of sinking into the soil. Wherever the timber has been recklessly destroyed desiccation and other mischief have followed in its train. When the Arab conquerors came to North Africa they

marched from Tunis to Tangier under the shade of trees and among thickly-peopled villages, where nowadays there is nothing but desert and jackals. The United States is the latest country to get alarmed over the mischief caused by the clearing of great tracts without any kind of intelligent supervision. Rivers—the Schuylkill, for example—are getting too feeble to carry off the ever-increasing impurities which pour into them, and the water-supply of whole districts is in such danger that tree cultivation is now a serious subject for the new world.—*Daily Chronicle*.

AGRICULTURAL NOTES.

The ill wind that has seriously wrecked the trade in nitrate of soda has much cheapened this fertiliser in a dry, harsh season, when the farmer badly wants the article to top-dress his land. The market has been quite in a panic state for the last three months, and in Lille, Dunkirk, and other French ports the losses of merchants have been frightful, and the principal of a great firm, M. Morel, has lately committed suicide. Large accumulations of stocks and lowness of freights are regarded as the causes of ruinous depreciation—nearly 40s. a ton.

Sunflower bread seems one of the food varieties of Russia. The seeds yield much oil, the leaves are used for fodder, the stalks for fuel. An experiment made in recent years in Norfolk gave a good return to the farmer, but was not repeated. The crop was insured luckily, for English weather partly ruined it in a thunder-storm.

Austria-Hungary, Switzerland, and the Mid-Rhine districts send lamentations that the "splendid blossoms" that were out on the fruit trees, have been severely blighted by such frosts and snowfall at the end of April as had not been known in the present generation.

A hot and dry summer is expected by some naturalists, who have observed many lady-birds in Kent, where these "birds" clear the hops of insect pests.

What are those farmers about who are suffering a loss of over a million pounds a year through buying adulterated and inefficient chemical manures? They can get value for their money if they will go to firms of established reputation. Legislation for infants is becoming quite an election cry.—*Daily Graphic*.

NOTES ON POPULAR SCIENCE.

By DR. J. E. TAYLOR, F.L.S., F.G.S., &C.,

EDITOR OF "SCIENCE GOSSIP."

We Britishers shall have to look after our cotton trade. Hitherto we have practically had the monopoly of it. Then America stepped in as a competitor—afterwards Germany. The latter country, we are told, has increased its cotton-spinning industry within the last decade by ten per cent. The Japanese do not intend to depend on England or any other part of the world for their woollen fabrics. There has already been started in that lively country a woollen mill, and the company owning it is a purely Japanese one. Every member is a native, and they are so alive to the situation that they have sent representatives to our English woollen manufacturing centres, such as Bradford and Huddersfield, to pick up the necessary tips.

A good deal has been said and argued about by botanists concerning the origin and reasons for the existence of poisons in plants. Formerly, the devil and the "fall of man" (or rather of woman) was deemed a quite sufficient explanation. People thought they put all sorts of plants in a respectable position when they condescended to eat them, raw or cooked. What the plants thought, I cannot say—although I have always been sorry for the poor plants. To live for the sake of being eaten cannot be cheerful, even for a low-minded cabbage or potato. The fact is, the so-called poisonous secretions, (perhaps excretions) in plants, which animals do not like, are all more or less protective. But animals must live, and if vegetarian creatures cannot get exactly what they want, they must take what they can get. So, the poisonous plants

have gone on secreting all sorts of poison in leaves, stems, and roots, and the slugs, &c., have acquired (like opium-eaters) the power of not only eating the poisoned leaves, but of enjoying them. Of course, millions of their kind have died off in the process of this evolution. The game is a well-understood one. It is simply that between the most penetrating naval guns and the least penetrative armour-clad ships.

I refer to this most interesting matter now, because I see, in a very recent number of a scientific journal, a query concerning the "uses" of poisons in plants. It is useless to go to the devil for an explanation, as our devout forefathers generally did. If poisonous plants have not won in the long-continued game of vegetable "Nap" they must pay up. The so-called "animal and vegetable kingdoms" have been playing "Nap" for a hundred millions of years at least. Plants do not want to be eaten any more than Christians, except under special circumstances, and then they are honest enough to advertise the fact in some way or another. Plants like to live and enjoy themselves (in a quiet vegetable way) like some of us old fogies do. So you cannot blame them if they do their level best to secrete poisons in their leaves, roots, seeds, or fruits; if so be this secretion protects them and their kind.

Yet in spite of their poison some plants are eaten. A few species of slugs feed upon the foxglove, which yields digitaline (a decided poison) and although the laburnum tree is undoubtedly poisonous, rabbits will gnaw it. You Australian people know by this time that they will gnaw anything, except a county-court summons. The oleander is one of the most poisonous plants in the world, as every student and lover of the delightful *Anabasis* of Xenophon is well aware, yet the caterpillar of the oleander hawk moth has defeated the "sagacity" of the poisonous plant. One of our most powerfully poisonous native English plants is the deadly nightshade. It has such a botanical tradition of terrors, a veritable and vegetable Madame Tussaud's "Chamber of Horrors," that for hundreds of years this plant has been regarded by all our country people as a kind of incarnated vegetable devil. The ladies, however, with their usual adroitness, turned the devil to account (as they usually do), so although its generic name was that of one of the three Fates, the specific name revealed the fact that women who wanted to be good-looking used this plant (or rather its decoction)—hence its name of *bella-donna*. There can be not the slightest doubt that the "*bella-donna*" is a most poisonous plant. It belongs to the same natural order as the potatoes—but, in England, I have never found this suggestively poisonous plant except near ruined nunneries. It is seldom collected near ruined monasteries, although I have discovered it lingering there. There is in our old country at least, and I prognosticate in Australia, a possible botanical archaeology. Plants linger round ruins longer than the ruins linger.

According to the estimate of Mr. B. E. Fernow, chief of the Forestry Division of the United States Department of Agriculture, the existing American railroads annually require 73,000,000 ties, equal to 365,000,000 cubic feet of lumber, which latter could only be produced by 1,000,000 acres of natural forest land. Timber is advancing in value every year, for it is getting scarcer, not more abundant. The world will find this out before long. It is much easier to cut down a big tree than to grow one, and takes a shorter time. The Yankees, therefore, are going in for metal ties for their railroads.—*Australasian*.

BONES AND SHELLS.—A reader wishes to know if the hens can get lime from bones as easily as from other materials, and writes:—"Is it necessary to give shells, limestone or lime in any form if I feed bones to my fowls?" The bones are more soluble, are digestible and contain, also, both carbonaceous and nitrogenous matter. A shell is of the same composition as limestone, marble and chalk. A bone contains both mineral and animal matter, and is food. It is phosphate of lime, being the best form of lime known for poultry.—*Florida Agriculturist*.

Correspondence.

To the Editor.

THE STABILITY OF THE CEYLON TEA INDUSTRY.

38, Mincing Lane, E. C., London, 13th May.

DEAR SIR,—We hand herewith an article on tea which appeared in the London *Financial News* of May 6th.

As we deemed the statements respecting Ceylon misleading, and unfair to those interested in tea plantations, we at once wrote the enclosed letter, which appeared in print on the 9th and we hope may correct the wrong impressions produced by the article.

A letter which has since been printed, signed by Mr. Hawes, does not weaken the position we have taken up, nor, in our opinion, need reply.—Yours faithfully,

W. JAS. & HY. THOMPSON,

[The letters referred to are quoted by Mr. John Ferguson in his letter on page 42.—Ed. T. A.]

PROPOSED CINCHONA SYNDICATE.

London, May 13th.

DEAR SIR,—By today's registered book post I am sending you two copies of the papers connected with the proposed Cinchona Association, which is at the present moment engaging the serious attention of all sections of the trade.

It is not however, intended to form the Association until the bark unit shall have fallen below one penny and until planters shall have proved that they really desire higher prices by showing their willingness to join.—Yours faithfully,

RIVERS HICKS.

CINCHONA ASSOCIATION, LIMITED.

Capital £1,000,000 (£100,000 to be called up). Office London and Amsterdam.

It is proposed to associate all persons interested in the cultivation or in the sale of Cinchona with a view to raising its price.

The Association, when formed, will at once contract for the World's crops or shipments of Bark during 3 years, at a price a little over that ruling in the market immediately before the formation of the Company, and will resell them as required at an advance in price of 1d or 2d a unit.

The net profits thus made will be divided equally between those who shall have provided the bark and those who shall have found the money, with which to finance it thus:—

A planter who shall sell to the Association £1,000 worth of Bark will receive his £1,000 cash against deliveries, and in addition, even if he take no shares in the Association, will get one-half of the net profits which the Association shall make on the resale of £1,000 worth of its purchases. If however the planter shall also subscribe for £1,000 share in the Association he will receive beside his £1,000 cash against deliveries the whole of the net profits resulting from the sale by the Association of £1,000 worth of its purchases.

The profits of the Association will be subject to no deduction in respect of the cost of its formation until the price of Barks shall have advanced to 2d per unit, after which 10% of its profits will be paid to the Founders and this payment will constitute the sole remuneration of the founders.

Planters are requested to apply for, fill up and sign "Planters offer and contract" forms and then to return them to their own European representatives, for by so doing they will express their con-

sent to the formation of the Association which will not take definite shape until practically all the cinchona planters of the whole world shall have expressed their willingness to join.

The Association will be managed by a Committee of 12 (6 in London and 6 in Amsterdam) chosen from among the leading members of the Bark trade in its two chief centres and these gentlemen will both direct the affairs of the Association and also safeguard the interests of all those who are now in any way interested either in the cultivation or in the sale of cinchona.—Signed for the Trading Founders,

RIVERS HICKS.

TEA IN INDIA AND CEYLON.

Upcountry, June 4th.

DEAR SIR,—The note of warning to the planters in your London Letter of May 13th has not come a day too soon. India has resources, both in soil and climate (the latter giving the tea a rest), that we have not; they have also an unlimited reserve of new land to fall back upon, that we also have not—the struggle between the two is only now beginning, and, it is a case of who has got the greatest amount of mineral matter in the soil, available for tea. Allowing other conditions to be equal, this will decide who is going to take the cake.—Yours truly,

AN OLD COFFEE STUMP.

[This letter has been largely answered by anticipation in the article which appears on page 41. But we are glad of the reference to our soil, so as to be able to say that its quality, especially for the growth of tea, has been very unduly under-rated. Of course we speak of soil which has not been exhausted by many years of coffee culture. Even in such cases much may be done to bring the soil into good condition by the application of fertilizing substances, which also can be used indefinitely to postpone the exhaustion of virgin soil or soil only slightly exhausted, planted with tea. We have dealt with the question of "rest;" and as regards reserve of soil to fall back upon, we must, of course, admit that we cannot compete with India, although there is still considerable room for expansion, if lands at high altitude were sold subject to conditions of tree culture in good proportion. Meantime our wisdom is to concentrate culture including manure, on our planted area, which, if limited, is well supplied with means of communication, and everywhere much nearer the seaport than any Indian tea district is.—Ed. T. A.]

VEGETABLE PRODUCTION.

DEAR SIR,—In your issue of the 30th May I noticed an article evidently from yourself—under the above heading, quoting Surgeon-Major Kirtikar's observations on reproduction by means of fruit-eating birds, I think it fair to your readers to tell them, and you, what I have all my life observed. We all know that many species of birds, particularly the pigeon tribe, eat fruit voraciously, the smaller birds eating smaller fruit, the larger the large-sized kinds, according to throat or swallowing capacity. That while the painted pigeon (*Sin. battagoya*, *Tam tti praa*) swallows hundreds of *pala* or ironwood fruit and that of the *Ficus religiosa*, the great fruit pigeon, the *occasinca*, bolts a large number of the fruit of the wild nutmeg, known locally as the "pal-manicum," not to be distinguished from the true nutmeg by a stranger to Ceylon, by reason of the exact similarity, between the two, both possessing in common the yellow stiff rind, the mace and the lovely shiny-dark brown nut; but one difference there is and that is, that while the nutmeg of the "Moluccas" grows on a moderate sized tree more a large bush, the wild nutmeg grows to the height of

30 to 40, and even 50 feet! These pigeons also live on the fruit of the "Teta," which rubbed on the side of a new chatty clarifies water—and on that of the *Nux vomica*—found in all our lowland jungles. These large pigeons are properly inhabitants of the great forests on the hill sides and mountain speers of the interior, but make their appearance in the low-country on the regular fruit of the season in the middle of the year. The Wild Nutmeg is very common in the forests and jungles of the sea coast, but is not met with inland, or further west from us, than 10 or 14 miles away, but the seeds of the wild nutmeg they swallow—in their later feasts—are dropped by them far far inland, and grow rapidly in the deep rich vegetable loam of the mountain zone, but they die off in the cold! and wet for though the tree lives and luxuriates in a moist soil, they perish under too much rain! These pigeons are gregarious, for at certain seasons of the year you cannot find one in Ceylon jungles, but are widely distributed. David Stuart* a brother officer of mine saw them in Madagascar. I have seen them by hundreds on the slopes of the Neilgherries. A friend of mine ate plenty of them in Assam, and in the Straits Settlements they are very common, while Naturalists of all countries have noticed them all over the islands of the Pacific sea. We call them the *Mada Prua*, and the Sinhalese, the 'Milagoya'!!—Yours very truly, R. A.

[Very interesting, but it does not follow that wild pigeons conveyed nutmeg seeds all the way from Ceylon to the Moluccas.—Ed. T. A.]

THE "EARTH MULCH."—Few farmers fully realize the importance of keeping the land as level as possible during a drouth and an inch or two of the surface stirred frequently. When the earth is thrown up into ridges, the heated atmosphere penetrates it more readily than it would a flat surface and carries off its moisture. But a light and loose layer of earth, if level, is an advantage by reason of what is called broken capillarity. Where a soil is packed and dense, the particles of earth lie close together, and the moisture from below readily passes along from one to other until it reaches the surface and is evaporated into the atmosphere and lost. But when, by frequent shallow stirring, the particles are made to lie as far apart as possible, the capillarity is broken and the passage of moisture from the subsoil upward is impeded. Kick such a soil with the toe of the boot and the line of constant moisture will be found an inch or two down, while in a hard soil not stirred no moisture will be found for several inches. Now, every rainfall, even the slightest, will make a thin crust of packed soil, and as soon as this dries out it will begin to convey the moisture up from below faster than a broken surface would.—*Florida Dispatch*, May 5.

GAMBIER (*Uncaria Gambier*, Roxb.) was fully discussed in the *Kew Bulletin*, 1889, p. 247. The interest in this valuable tanning plant appears to be maintained, and efforts are being made to establish its cultivation in other countries. The following interesting report from Mr. Henry Walker, Commissioner of Lands, Sandahan, has been communicated, to Kew by Mr. William M. Crocker, the manager of the British North Borneo Company, 15, Leadenhall Street, E. C.:—

"I am pleased to report that the Gambier plantation on the Crocker Road of which I took charge in September appears likely to be a great success. Up to the end of September, 100 pepper cuttings and a few Gambier plants had been planted, and have since been increased to 587 pepper cuttings and 3,020 Gambier plants; of the latter there has not been a single failure and all are growing remark-

ably strong and well, generally with more than one shoot. The Gambier Hill has just been cleaned up and the plants appear about 16 inches to two feet above the ground. The Chinese gardeners speak enthusiastically of the growth of the Gambier, and say it beats anything they ever saw in Singapore, and they expect to take a cutting at 10 months old.

The troubles we have had in getting pepper cuttings from Singapore have prevented any extensive plantings, but I have just received 1,155 pepper cuttings through Mr. Joseph Wheatley by one of the Chinese gardeners whom I sent to collect cuttings at Bunda. These have arrived in very good order.

Since my return I have taken in hand the distribution of economic plants, and as I found a large number of coffee seedlings under the trees in the Silam gardens, I arranged to have some boxes sent up by each trip of the "Normanhurst." The Ceylon coffee seeds brought by me are not yet all to hand. Mr. Dunlop writes me from Penangah (acknowledging some seeds) to say he has found three coffee trees planted up Senanghal two years old and bearing well. They were planted by Hadii-Moussa at my request.

I have laid down a large quantity of Gambier seed, but it takes a few month's time before it is available for planting, and I am taking two Chinese to Labuan who will collect pepper cuttings and return as soon as possible. We shall then be able to carry out the object with which the garden was started, viz., the distribution of pepper cuttings and Gambier plants, and later on we shall be able to collect our own Gambier seed, which will be a boon as it suffers from the transport from Singapore. I gave some Gambier seed to one of the estates in Marudu Bay to make a trial planting and to ensure a supply of seed for that district. I am taking some to the west coast to give to the pepper planters.—*Kew Bulletin*.

INDIAN TEA AND CHICAGO.—The *Calcutta Englishman* says:—Chicago promises to be a memorable name in the history of the Indian tea trade. It is evident that the industry is thoroughly roused to the importance of the occasion, and means to push its interests at the World's Fair as it has never done before. Ceylon has already secured two lakhs to cover expenses; and whatever advertisement in large capital letters can do for her will be done. In a popular Exhibition, however, it may be as well to remember that the most effective advertising is not always done in capital letters. The amount of space occupied, the amount of placarding indulged in, the amount of money spent in any way that is merely lavish, is as nothing compared with a little picturesqueness and novelty in the disposition of the exhibit. The popular fancy must be caught, and this can be done by introducing the element of originality. Something in the nature of an Indian pagoda, as attractive as possible, may hold the exhibit. A constant supply of fresh tea, offered gratis may be the fragrant means of conversion, and real Kitmutgars, the most impressive that can be found, should play an important part in the scheme. Much will depend upon the energy, skill, and taste of the gentleman deputed by the Association to look after their interests. In fact, the success of the exhibit lies in this nutshell. It should be remembered that the Americans are not addicted to tea to anything like the same extent as the English. Coffee appeals more soothingly to the national temperament, and coffee is the national breakfast beverage. The institution of "afternoon tea" is practically confined to the few among them who take it not because they like it, but because it is the English and therefore the proper thing to do. Americans who drink tea do so largely because it is more economical than coffee. An important point to bring out will, therefore, be the economy, as well as the superiority in flavour of Indian tea. The luxurious aromatic quality of Kangra Valley Orange Pekoe may be quite thrown away upon an American housewife who would be impressed for the rest of her days if she were convinced that one tea spoonful of Indian tea makes as strong a brew as two or three of Chinese. And in the end, the appeal is to the American housewife.

* Died as Col. Stuart; married a daughter of Gen. Fraser.—Ed. T. A.

PLANTING NOTES FROM THE NILGIRIS.

COONOOR, June 1.—The season of 1891-92 is well nigh over on the Nilgiris, except on a few high estates, where the crop has been slow in ripening and where picking is still going on; and we are now just entering on the season of 1892-93. As far as one can judge at present, prospects are good on nearly all the estates which have been under proper cultivation. Blossom on some low-lying estates came out as early as February, which, contrary to expectations, set well. During March and April all the estates were under blossom, and as the weather then was on the whole favourable, there was nothing to prevent it from setting. No one expects bumper crops next season, but a good average yield is confidently looked forward to. The largest returns will probably be from the Adderly Estate, situated within a few miles of Coonoor, which has a young crop of about 80 tons on it. This estate is one of the oldest on this side of the Nilgiris, the first portion of it having been opened out early in the fifties; it is most favourably situated in a fine rich valley, and easy of access both from Coonoor and Mettappolium, and used to be one of the best paying properties on these hills, having often yielded over 100 tons. Some years ago, however, when leaf disease broke out in a virulent form those who owned the estate lost faith in coffee and cut down the expenditure on the estate at the very time the trees required the greatest amount of care and cultivation, with the result that the yield fell to about a quarter of what it used to be. About two years ago it was sold to two of the most enthusiastic planters in Coonoor, who rightly consider that proper cultivation alone is necessary to make coffee a paying speculation. These gentlemen, having perfect faith in coffee, cultivated the estate, both in a practical and liberal manner, with the result that they have now the satisfaction of seeing a splendid crop on the trees, and with every prospect of large yields in the future. During the late dispute between planters and Government, with respect to the value of portions of the estates taken up by the Nilgiri Railway, one of the arguments brought forward by the Government Solicitor in support of the very low valuations put on the portions required for the railway, was that as the trees were over 30 years of age they were old, passed bearing fair crops, and liable to die out; and although the evidence of several well-known and experienced planters went to show the contrary, yet the hypothesis adduced by the Government Solicitor tended to lower the value of the estates in the eyes of the Judge. The present crop on Adderly should be a conclusive proof that an estate between 30 and 40 years of age is still valuable property and capable, with proper cultivation, of yielding large crops.

The weather during the past ten or twelve days has been very unpleasant and unsettled. A nasty wind, accompanied with slight showers, blows all day and night. Whether this is the burst of the South-West monsoon or not, it is hard to tell as yet; if it is the monsoon it is a very mild one; but let us hope that we will get our full share of rain later on. The quality of the crop greatly depends on the quantity of rain we get during the South-West Monsoon. Although the rainfall on the Nilgiris is always great during the North-East than during the South-West Monsoon, yet crop prospects depend to a great extent on the latter, and any failure in the rains during this month, and July, has a most deteriorating effect on the quality of the bean. During the last two or three years, the quality of Nilgiri coffee has been rather below the average in consequence of the failure of the South-West Monsoons. This year a good monsoon is predicted and let us hope we shall not be disappointed. Leaf disease has, I am glad to say, been on the wane during the last 12 months. I had occasion to go over several estates lately, and I was rejoiced at not being able to find signs of the disease on any of them. We may, however, not be quite out of the wood yet for the worst months for the pest are July and August, and until those months are passed it is best not to be

too sanguine. Estates are this year looking better and freer of diseases of all sorts than they have done for years past, their present state making one hope that good days for coffee are returning.

All estates are at present short of labour, but in another week or two most of the coolies will return when the first thing to be done will be to weed estates and get them cleaned up. This work invariably occupies all hands for the best part of a month, and about the middle of July handling should commence. It is not advisable to handle out trees laden with crop before July, as the berries which have just set are liable to wither when exposed, before they are a month or two old. Handling, like pruning, is a most important work on all estates and one which should be very carefully done and constantly supervised by competent men, as the succeeding year's crop will to a great extent depend on the manner in which the trees are handled. I have heard planters say that although it is difficult to get good pruners yet any cooly can handle. No doubt any cooly can certainly pull out young wood, but merely taking out wood is not, what is commonly understood as handling. This work, to be properly done requires a great deal of care and forethought. If too much of the wood is pulled off now it will be a bad lookout for next season's crop as very little fresh wood comes out after the end of July, and such wood as the tree may about throw out late in the year will not be ripe enough for blossoming next March and April. On the other hand, if too much wood is left it becomes too great a drain on the trees, and although such trees often throw out a good blossom, yet, except under very favourable circumstances, the blossom invariably fails to set; and even when, under very favourable circumstances, the blossom on trees was laden with wood does set, the trees deteriorate and the crop turns out light and inferior in quality. A coffee tree should be handled with discretion, and according to its vigor. Trees which are strong enough to bear a heavy crop should have more wood left on them than weakly ones. Very few coolies have discretionary powers; or if they have they are much too apathetic to exercise them. Hence it is very necessary that handling, to be profitably done, should be conducted under proper supervision. I almost forgot to mention that while handling all gormandizers should be removed. Gormandizers are generally the results of too heavy pruning, and they will soon kill the tree if allowed to remain. Some little time ago I was very much amused to hear a planter, who said he had 26 years' experience, say that gormandizers always yield the heaviest crops. It was a great comfort to me that this planter hadn't the working of any estate I was interested in. Handling should be completed by the end of September, or at the very latest by the middle of October. On no account should trees be interfered with after October as they should be left alone to ripen the crop. If from any cause this work is not completed by October, it is best to leave it until the beginning of February, when the superfluous wood may be removed while pruning. I by no means advocate such a method, but I merely choose between two evils, as it is better to remove the surplus wood in February than to handle in November, December and January.

Mr. L. Keilly, who for the last 30 years or so, was connected with the Hillgrove Estate, first as Superintendent and then as part owner, severed his connection by selling his share to his partners about a month or two ago. The estate is a valuable property of about 300 acres under coffee cultivation.—*Madras Mail*, June 4th.

ASSAM AND CEYLON AS TEA DISTRICTS.

At a recent meeting of the Indian Tea Association, Mr. Playfair thus showed how unfavourably the great Brahmaputra tea region compares with Ceylon in facilities of communication and labour supply:—The province of Assam, most appropriately called by the Lord Napier of Magdala the Eden of India, is a conspicuous example of the strange indifference with

which the Government of this Empire at times administers to the wants of its best supporters. Left to find a means of communication through the jungle as best he can, and hampered by well-meaning but burdensome restrictions regarding the engagement of labour, history will yet have to extol the indomitable force of character that was displayed by the British planters who engaged in the early cultivation of tea in Assam, and Government will not be accused of having been an indulgent father to the industry. The manner in which large factories have been established and equipped with heavy machinery, transported through jungles and across roadless tracts, is nothing short of a marvel. With this in evidence, it is strange to have to add that even now, in the year of Grace 1892, the province, at all events on the Surma Valley side, continues to be roadless. How different to the experience of the Western world, where a commercial Government leads the van with railroad and telegraph wire. The district of Cachar, in area as large as one-sixth of Scotland, cannot boast of one good road of a mile in length. How can it when the Provincial grant for road construction is about R1,600 per annum, or probably less than the sum expended in putting soorkey round Government House before his Excellency returns from the Hills? I do not complain, sir, of the latter expenditure, but of the inadequacy of the former contribution. When riding during the rains of 1890 from Silchar station towards Luckipur I was advised to make a detour through rice lands rather than continue on the Government road, although the horse was thereby plunged to the girths in mud and water. There is surely reason to complain of such continued neglect. The projected railway will doubtless materially assist through communication, but to be thoroughly useful there must be auxiliary roadways leading to the line, and the age and importance of the industry has surely earned for it the right to press upon the administration the necessity for these communications. Not earth heaps but cart roads, made fit for traffic.

Our fine teas should no longer be subjected to risks of exposure while in transit. It can be no excuse that the Assam District is waterlaid during the rains. Bengal is equally submerged and the difficulty can be overcome. The staff and establishment of the Public Works Department stationed at Shillong should be capable of devising measures to overcome this drawback. And I would have introduced in parenthesis the remark, that while the Public Works Service is supported by many excellent and well-qualified native Engineers, Assam with its rough climate may not be the most appropriate province for their administration and employment. The European Engineer when on tour during the rains finds, through the hospitality of the residents, accommodation with which the native Engineer cannot suit himself equally well. And the European coming into closer contact with the planter ascertains the want of the district better. I don't think it is too much to say that had Government developed the province in the most energetic and enticing manner, welcoming the investment of British capital, being solicitous for a profitable return thereupon, it is probable that Ceylon would never have arisen as a powerful competitor in the production of tea for the resources of Assam and the Himalayas are capable of producing the world's consumption of tea as it is at present known, both as regards the quantity and the quality required. The latter consideration causes me to revert to the labour question with which administration is so closely identified. To cultivate tea, and especially to produce the fine quality now required, an adequate supply of labour is essential. To do so economically, a settled population is desirable, or, failing this, the employment of harvesters would be suitable. I hope the day is not far distant when the Emigration Act of 1882 may be repealed, to be supplanted by a simple Contract Act, and that the Protector of Inland Emigrants may be promoted to be Census Adviser to the Government of India. Since we last met the census of India has been published, showing that Assam has only 112 persons to the square mile as compared with 734

in Bengal, 413 in the North-West Provinces, and 513 persons in Oudh. Those engaged in the tea industry are too painfully aware that under the present system it costs R125 per adult to pass coolies from Bengal to Assam, and this too while Government is perplexed regarding the welfare of the surplus population in the provinces just named. This Association might approach his Excellency the Viceroy on the labour requirements of the tea districts and their value as a field for emigration. It is well-known that immigrants emerge from poverty to competency when they pass Dhubri. Is it not, therefore, a mystery that a paternal Government makes no attempt to populate Assam? In addition to employment to be derived from the tea industry, there are large tracts of lands and churs on the Brahmaputra most suitable for the cultivation of jute, rice, wheat, and seeds; valuable mineral deposits, and vegetable products, abound. This additional produce our Docks are waiting to receive, and, I might almost add, require. Droughts are unknown, and if the lands of Assam were brought under cultivation famines in Eastern India would in all probability be no longer formidable. Railway and road communication with Bengal would facilitate immigration, and although the tea industry has survived existing difficulties I hope this Association will not succumb through long delay to Indian lethargy, but press for their removal. For it looks as if it has become necessary to export our teas at a cost not exceeding 3d. per lb. to uphold profits.

The opening of the Chittagong-Assam Railway must herald a new era for the province, and let us hope this may be only a foretaste of the good things Government intends to provide. The Chamber of Commerce has been favoured with an interview with the agent of this railway, and I am pleased to be able to state that Mr. Buyers has expressed himself fully alive to the interests of the tea industry. He has determined, as far as it lies in his power, to protect planters against annoyance and loss in having their labour enticed away by contractors to construct embankments. He proposes to insert a clause that the engagement of such labour will cancel the contract. At the same time, Mr. Buyers will be happy to offer contracts of earthwork to planters, or hire their surplus labour during the cold weather months. I feel sure that this announcement will be received with much favour and appreciation by both planters and by Calcutta Agents. Mr. Buyers further stated that he proposes to commence work simultaneously all along the Chittagong-Comilla-Silchar section, to endeavour to complete it within two or at most three years. This he stated in reply to an appeal made by the Chamber for the construction, first, of the section to connect Fenchuganj with Silchar station, and admit of easy communication between Calcutta and Silchar throughout the year. Mr. Buyers does not at present consider that the latter portion could be constructed more rapidly were special endeavours to be devoted to this section. Another important consideration has been disclosed, *viz.*, that with the extension of the Central Bengal Railway beyond Jessore through Madanpur to a point opposite Chandpur, produce from Assam, Cachar and Sylhet might reach Calcutta without breaking bulk, the importance of which those present at this meeting will fully appreciate. The train would be ferried across from Chandpur. The Jute Manufacturers' Association has already considered the extension to Madanpur necessary in the interests of that trade, and this Association will doubtless now become interested in the matter.

NOTES FROM OUR LONDON LETTER. LONDON, May 27.

MR. ELWOOD MAY'S INTENDED DEPARTURE—PUSHING
CEYLON TEA IN AMERICA.

Very much to my astonishment it was told me a day or two back that Mr. Elwood May had secured his return passage to New York for the 6th June. It has not been possible for me to

ascertain with accuracy the causes which have led to this sudden determination upon the part of the American representative of the Ceylon tea interest. When last conversing with him he told me he expected to remain in England for at least several months further; and the knowledge that he was so quickly to depart therefore caused me much surprise. Although there has been no opportunity for me to personally see Mr. May since this determination was announced, I learn from those who have conversed with him that he is exceedingly reticent as to the reasons for his taking it. He says, however, that he has reasons to be well-satisfied with the result to his negotiations here in London, but that he fears Ceylon will not be so well-satisfied. We can only guess from the remark made by him that he had cabled to New York to discontinue all advertising of Ceylon tea until his return, that he has, failing support by the Ceylon interest, entered into some arrangement with parties here for pushing the sale in America of teas of good quality generally. We surmise that in such an adventure he has found parties willing to back him with pecuniary aid; and it is rumoured—though we believe without any adequate ground—that Mr. May has entered into some arrangement with Mr. Lipton's agent in London, it being well-known that that enterprising person has long had a hankering to work the States field. It is certain that Mr. May feels somewhat bitter with respect to the want of co-operation tendered him by Ceylon. I was conversing this week with one of the leading London tea brokers, who told me he felt sure that your Planters' Association had done unwisely in not giving Mr. May fuller representative powers and acknowledgment; and he told me that he thought much of Mr. May's feeling arose out of his having been ignored with reference to the representation of Ceylon tea at the Chicago Exhibition. He earnestly advised that Mr. May's efforts in America should form the subject of discussion at the forthcoming meeting of the Ceylon Association in London fixed for the 30th inst. Mr. May will be present at the meeting; and possibly, if he can be induced to speak, we may then learn the full reasons which have induced him, apparently, to throw Ceylon over. At the same time, although, if Mr. May has been forced to take this course, it will have to be much regretted, we most of us feel sure that Ceylon interests will not greatly suffer if he conducts for the future his American tea business on lines *à la* Lipton. The last mentioned does not profess to make a speciality of Ceylon tea as Mr. May has hitherto done. He advertises all sorts of tea, and works so successfully that the chances are he sells as much of Ceylon tea as if he had indeed made it his sole speciality. Mr. May is still going to work the Bhud, Bungalow, and Tiffin brands, but we judge that he will no longer advertise these as consisting of pure Ceylon only.

EXPORTS OF CEYLON TEA TO AMERICA.

But this matter is to be regretted, for the broker referred to—one of the most prominent in London—told me that during the past three months he had sold a largely increased quantity of Ceylon tea for America. He believes that Mr. May's efforts are at last beginning to tell, and he greatly regrets that, just as success is dawning, anything should have induced Mr. May to throw over Ceylon teas as his speciality and to discontinue advertising them as such. He said he believed that if Mr. May's efforts received due recognition at the meeting of the Ceylon Association, that gentleman might

be induced to reconsider his present decision, and it is to be hoped that something may be done to ensure this.

LONDON BROKERS AND SMALL BREAKS OF TEA.

We hear that the London tea brokers are endeavouring to make arrangements with the Custom authorities at this port by which may be sanctioned the bulking together of several small breaks of tea. You are aware how strong has been the complaint made here of the smallness of many parcels received from Ceylon. Each such parcel has to be separately sampled, and the time occupied in tasting the great number of these is declared to be a serious hindrance to the sales and to the conduct by the brokers of their business. Under the provisions of the Merchandise Marks Act it is incumbent that teas included under each individual mark shall be sold separately, and hitherto the Customs Department has been most strict in ensuring the observance of this rule. What the brokers seek to obtain permission to do is to group a lot of these small consignments together and offer them for sale as one. Speaking on this topic with a well-informed London merchant largely interested in the Ceylon tea trade, he remarked to me that he feared the course proposed, although one that he thought to be desirable in some respects, would scarcely be deemed as satisfactory by a large proportion of planters and tea shippers in Ceylon. These, he thought, could have no guarantee that the reputation of their particular brands would not be injuriously affected by being grouped with those of a less reputed description. At all events, in his opinion, it should be necessary for the owner's sanction to this course being followed to be obtained in all cases, and how this can be done in the instances of owners resident in Ceylon he wholly failed to see. The objections taken by my friend are very obvious ones, and it seems to us that, even if the tea brokers can persuade the Customs authorities to grant the permission they seek, it is not likely to be availed of in any large number of cases. But it is certain that these small breaks give rise to an immense amount of trouble and inconvenience, and I should think, save in very exceptional instances, there must arise out of that trouble and inconvenience a tendency to restrict the bidding for such breaks. Cannot your planters be induced to make some change in their present system of despatching such small parcels? I am myself too ignorant of the exigencies which may govern the system of forwarding practised on Ceylon estates to be able to say whether such a change would be practicable or not; but it seems to me that some effort should be made to effect it. If something be done on your side it is more than probable that the brokers will carry their point, and I believe this would not be for the welfare of your island interest. Repeated complaints have been made by all the leading London tea firms in their circulars with reference to these small breaks, but apparently without having had the effect of diminishing their number. A leading broker told me that large breaks always sold more freely and at better prices than small ones; so it would seem to be certain that the continuance of a system so opposed to all advice offered on this side must result in a positive cash loss to your planters.

MR. JOHN FERGUSON'S LETTERS ON THE CEYLON TEA INDUSTRY.

We have seen two very long and interesting letters addressed by Mr. John Ferguson to the editor of the *Financial News*, which appeared in the issues of that paper for Friday and Monday last,

That journal had, it appeared, contained some editorial remarks on the subject of the tea trade which had not been seen by me, and Mr. Ferguson has taken the opportunity of their appearance to submit to the British public a very complete account of the Ceylon tea industry, in a form and after a manner which we have no doubt will secure attentive reading by a very wide circle. No doubt you will receive from your absent co-editor copies of these letters, and will enable your readers to judge for themselves of the beneficial influence they are likely to have. We know them to be much appreciated here in London, and it is the general belief that no letters or articles heretofore published on the subject of Ceylon tea can surpass or even equal them in interest and possible usefulness.

ARABI PASHA'S RELATIONS WITH MR. LIPTON.

The *Western Morning News* of the 19th inst. refers to the report that Arabi has taken service under Mr. Lipton as superintendent of one of the tea estates belonging to the latter. The paragraph concludes:—"If this is so, they (Messrs. Lipton) no doubt count upon the words "Grown by Arabi Pasha" acting as an inducement to purchasers, and so recouping them for their outlay.

TEA GROWN IN ENGLAND.

The *Morning Advertiser* tells us that at a recent meeting at Exeter Hall the Princess Louise and some of her friends were presented with cups of tea brewed from tea leaf grown and prepared in England. It is said the bush was grown at Putney, of course being a forced plant. It was Mr. John Roger, a gentleman who has had experience of tea planting in Ceylon, who prepared the leaf, and he states that he gathered the leaves in the morning and that the whole process of fitting them for the teapot was accomplished within a working day of eight hours. The *Morning Advertiser* does not think that the success of this experiment would warrant the least hope that the tea plant could ever be acclimatized here for commercial purposes. Absence of intense sunshine rather than the frosts of winter must forbid this, and that paper remarks that of late years "we have had scarcely enough sunshine to ripen our native blackberry." With reference to this matter the following letter appeared in the *St. James's Gazette* of the 21st:—"Sir,—We shall be glad if you will allow us to state that the tea plants mentioned by Mr. Roger on our property, were forced on by Mr. Ietson at our request and expense, and that the tea made from them was made by Mr. Roger for us. We shall be pleased to answer any inquiries.—We are, sir, your obedient servants, the Ceylon Tea Agency, 71, Eastcheap."

THE INDIAN AGRI-HORTICULTURAL SOCIETY.

The following extracts are from the Proceedings of the Agricultural and Horticultural Society of India:—

KREAT. (*Andrographis paniculata*.)

The following letter was received from the President of the Société d'Acclimatation de Mauritiuis:—"I have read in the *Tropical Agriculturist*, Vol. X, No. 11, of May 1891, page 771, an extract entitled 'Remedy for Malaria, in which Mr. Yates Hunter, late Brigade Surgeon of the Bombay Army, stated that the plant named 'Indian KREAT is now admitted to be, in many respects, superior to quinine.' I beg you will be good enough to give me any information regarding that plant and also on its therapeutic value, and you would greatly oblige me were you kind enough to send me seeds of that plant.—Daruty de Grandpré."

The reply sent on the 5th January was as follows:—
SIR,—I am in receipt of your letter of the 21st November last, in which you enquire about *Kreat*, a reputed remedy for malarial fever. The name *Kreat*, or as it was formerly spelled *Creata* is one of the native synonyms for the *Andrographis paniculata* (Lees) a common weed in most parts of India. The plant is described in the *Flora of British India* (Vol. IV., p. 501). As regards its therapeutic value, it is official in the *Indian Pharmacopœia*, and I enclose the reference made to it in the *Pharmacopœia Indica* (Waring 1868). There are allusions to the drug in all the more recent writers on *Materia Medica*, and I give extracts showing the estimate in which it has been held. Dr. O'Shanghnessy in the *Bengal Dispensatory* and *Pharmacopœia* (Calcutta 1841) described the plant and says:—"Celebrated as stomachic bitter and used in cholera and dysentery. It is the basis of the celebrated *Droque amere*; this is a compound of mastic-frankincense, resin, myrrh, aloe, and Ceat root steeped in brandy for a month, and the tincture strained and bottled."

The *Pharmacopœia Indica* says:—"The drug is analogous to quassia in action, and is used in general debility and in convalescence after fevers, and in the advanced stages of dysentery it has been found serviceable." In the appendix to the same work, Fleming (*asiatic Researches*, Vol. XI), Ainslie (*Materia Medica*, Vol. I), Drury (*Useful Plants of India*) and Waring (*Annals of Med. Ser.*, Vol. V) as well as Roxburgh are referred to.

In the 'Indigenous Drugs of India' (Kannyall Dey Calcutta, 1867) it is stated the *Creata*, Calapnath, Kalmeg, Muhalita (these names being synonymous), is the basis of the well-known "domestic medicine, *Aloie*," and this is also mentioned in 'The *Materia Medica of the Hindus*' (Udhoy Chand Dutt, Calcutta, 1877). Dr. Dymock, in his 'Vegetable *Materia Medica of Western India*,' refers to Dutt and Forskahl, and to the latter's remark that *Kreat* is common in Arabia, and is there called *Wizr*. He also quotes Ainslie as stating that the plant was introduced to the southern parts of the Indian peninsula from the Isle of France, and Flückiger and Hanbury, "who point out that it has been wrongly supposed that the drug is a constituent of the famous bitter tincture called by the Portuguese of India *Droga Amara*." The same author quoting from the *Pharmacographia*, gives the *chemical compositions* as follows:—

"The aqueous infusion of the herb exhibits a slight acid reaction, and has an intensely bitter taste, which appears due to an indifferent non-basic principle, for the usual re-agents do not indicate the presence of an alkaloid. Tannic acid on the other hand produces an abundant precipitate, a compound of itself with the bitter principle. The infusion is but little altered by the salts of iron; it contains a considerable quantity of chloride of sodium."

Dr. Dymock says:—"In Bombay the herb is very common in shady situations, and is much used by the natives as a domestic remedy for fever, in combination with aromatics, especially lemon-grass."

In *Watts' Dictionary of the Economic Products of India* Vol. I., Calcutta 119) in addition to the authorities I have quoted, the opinions of several medical men in different parts of India are given. Dr. J. Lancaster mentions that "decoctions of all parts of the plant act as a mild antiperiodic." Dr. J. J. Ratton says it is a "febrifuge used in infusions," and Dr. Kinsley refers to its use by a gipsy tribe in Madras in the form of a pill mixed with tamarind pulp, as an antidote to cobra poison. The "*Pharmacographia Indica*," a work now in progress (Education Society's Press, Byculla, Bombay), and of which two volumes have been published, has unfortunately not touched on the *Acanthaceæ* yet, or more chemical details would be forthcoming. I will have the pleasure of sending you the seeds when they ripen but fancy the plant must be common in Mauritius.

TEA SOILS, PLANTS, AND MANURES.

The following is some correspondence in reference to the First Report on progress made in the inquiry relating to Tea Soils, Plants, and Manures:—

Mr. R. Blechynden, Secretary, Joint Tea Committee, writes as follows to the Secretary, Indian Tea Association, Calcutta.

Sir,—I am directed by the Joint Committee to forward a copy of the First Report on progress made in the inquiry relating to Tea-soils, Plants and Manures, and am to say that this Report marks a stage of the inquiry when it becomes necessary to consider the arrangements for the future. The original scheme included "the analysis of the Tea-plant, Soils and various Manures practically available; and also for a scientific enquiry into the chemical changes undergone by tea leaf in the process of manufacture." The subject, therefore, naturally falls into two divisions, and the Report accompanying this letter deals solely with the first portion. The important questions of the chemical composition of the soils, tea-bush, manures used, and rain-water have been dealt with fully, and suggestions based on these data made as to the cultivation, manures in use, manures recommended, and similar points. The season was too far advanced by the time the information was collected to make full practical test on the lines indicated, but when the results of some experiments with manures, which were initiated earlier in the season, are received, they will, it is hoped, tend to confirm some of the conclusions arrived at from the analytical data. These results will be dealt with in a Supplementary Report. The Committee consider that sufficient progress has been made to warrant a continuance of the investigation on the lines originally laid down, and they are desirous of ascertaining, as early as possible, whether the Association propose to continue their grant, as arrangements should now be made for entering upon the second portion of the enquiry. Mr. Bamber's agreement expires in April, 1892, and three months' notice has to be given to terminate it. Should the Association allow the grant for a further period of 18 months, by taking up the 2nd portion of the enquiry early in the year, two whole seasons would be secured for the investigations. The preliminary arrangements include the obtaining of certain chemical apparatus from Europe, and it is necessary for the Committee to know as soon as possible the intentions of the Association, so that no valuable time may be lost.

The original grant from the Association was R10,000, of which R6,392 have been expended. There is a balance in hand to meet the current expenses to the month of April next, and the Committee desire me to point out that unless arrangements are now made for the continuance of the investigations, that the balance of Mr. Bamber's time cannot be employed with much profit. The Committee estimate that a further grant of R11,000 would amply cover all expenses for a further term of 18 months, an approximate estimate of which is given. The Committee desire it to be understood, that the inquiry into the manufacture of Tea would necessitate Mr. Bamber's residing on a Tea Garden, so that all circumstances affecting the quality of the Tea manufactured could be closely observed and experimented upon.

At this stage it is not possible to do more than sketch in outline the course the investigations would probably take, but the following would be included:—

Withering.—(a) The rate of drying and loss of weight in property withering leaf. (b) Whether the chemical changes produced are noxious or beneficial to the Tea, and if they can be checked or increased.

Rolling.—(a) The effect of hard and rapid, or light and protracted rolling on the strength of the Tea, and the reason of any such effect.

Fermenting.—(a) The amount of Tannin destroyed, and whether any other chemical changes can be checked or increased accordingly as they are noxious or beneficial to the Tea. (b) The most suitable conditions of temperature and humidity of the atmosphere, and the temperature to which the fermenting leaf should rise to yield the best results. (c) Effect of fermentation under various conditions.

Firing.—(a) The effect of high and low temperatures on the product. (b) The amount of moisture lost during the process, and whether the amount of moist-

ure left in the Tea has any relation to the value. **Storing.**—(a) Increase or loss of moisture in the leaf by storage. (b) The chemical changes produced during the process which would influence the value of the Tea.

Refiring.—(a) The amount of moisture in the refined Tea and the chemical changes produced.

In the first instance experiments would be carried out on a laboratory scale to test the correctness of any ideas suggested by chemical analysis, and, in cases when these ideas are borne out, further experiments would have to be made on a manufacturing scale. Working on the system, it is not probable that the outturn of Tea manufactured on the garden selected for the operations would be materially effected.

COOKED MEAT AND BROTH.—Meat from the butcher is the best food that can be fed to the laying hens, as it is egg producing and does not make them fat, if the meat is lean. Ground meat may be mixed with the morning meal. To feed meat, cook it to a broth and thicken with ground oats, or chop the meat fine. A pound of meat to sixteen hens, three times a week, is about the proper quantity, which, however, depends on the kind of hen. If she is laying well she may be given meat every day with advantage.—*Florida Agriculturist*

MARKET RATES FOR OLD AND NEW PRODUCTS.

(From S. Figgis & Co.'s Fortnightly Price Current, London, June 2nd, 1892.)

Table with columns: EAST INDIA, QUALITY, QUOTATIONS, EAST INDIA Continued, QUALITY, QUOTATIONS. Rows include various commodities like ALOES, BARK, BEES' WAX, CARDAMOMS, CASTOR OIL, CHILLIES, CINNAMON, CLOVES, COCULUS INDICUS, COFFEE, COLOMBO ROOT, CROTON SEEDS, CUTCH, DRAGONS BLOOD, GALLS, GINGER, GUM AMMONIACUM, ARABIC E.I., ASSAFETIDA, KINO, MYRRH, OLIBANUM, INDIARUBBER, VANILLOES, etc.

THE MAGAZINE

OF

THE SCHOOL OF AGRICULTURE,

COLOMBO.

Added as a Supplement monthly to the "TROPICAL AGRICULTURIST."

The following pages include the contents of the *Magazine of the School of Agriculture* for July:—

OCCASIONAL NOTES.

WITH this number commences the fourth volume of the Magazine of the School of Agriculture. We take this opportunity of thanking our subscribers, contributors and daily contemporaries for their support and encouragement during the past year.

In connection with the appointment of the Veterinary Surgeon there are two points that suggest themselves to us as worthy the attention of Government: (1) That the Veterinary Surgeon should have at the very least two assistants, not necessary "qualified men," but such as have been instructed in methods of disinfection and administration of medicines, and the general care of diseased animals, so that these men may carry out the orders of the Veterinary Surgeon much in the same way as the Municipal Inspectors carry out the orders of the Sanitary Officer. To trust to native cattle-owners or even headmen at a distance from the Metropolis, observing rules and regulations as to treatment that is not "native," is the height of absurdity. (2) That a central hospital, consisting of thatched buildings should be erected not far from the office of the Veterinary Surgeon, for the housing and treatment of diseased animals in and about Colombo, that similar small hospitals should be run up as required in centres of cattle disease, and that these provincial hospitals be directly under the supervision of the Veterinary Surgeon's assistants, who should be instantly dispatched to such places where cattle disease is reported from. The proper accommodation of diseased animals is of course the main point in any method adopted for the prevention or cure of disease. Another matter which we would urge upon the Government is that some surveillance should be placed upon animals brought over from India. These animals should be quarantined for a

definite period before being taken into the town and kept for sale or milking purposes in cattle byres in the city. We have repeatedly traced outbreaks of disease of one kind or other to a well-known centre where cattle brought over from India are exposed for sale.

We hope before long to be in possession of an "Eclair" knapsack liquid insecticide distributor and a soufflet for powdered insecticides. The insecticides themselves are not difficult to prepare or purchase; but the apparatus for distributing them is what is required. As we have already explained it is essential that every part of a tree liable to insect attack should be covered over with a thin coating of the poison, and in the case of the sucking insects, it is further necessary that the substances distributed should strike the insect itself. We lately imported small quantities of those well-known insect poisons "Paris Green" and "London Purple," but though a fine growth of Bandakais were badly attacked by the "Cotton worm," we had no satisfactory means of distributing the liquids. A solution of "London Purple" of the proper strength was applied to a portion of this crop by means of a small watering can with a fine rose, but the process was very tedious and entailed much loss of the liquid owing to the spray not being fine enough.

From the programme of the Technical College. Finsbury, we learn that the operations of the Institute are divided into two portions: Day classes for those who are able to devote 1, 2, or 3 years to systematic technical education; Evening classes for those who are engaged in industrial or commercial pursuits in the day, and wish to receive supplementary instruction in the application of science and art to the trades and manufactures in which they are employed or concerned. The College embraces the following departments: Mechanical Engineering and Applied Physics, Industrial and Technical Chemistry, Applied Art, and Building Trades

The College is under the general direction of a Principal, and each Professor is assisted by demonstrators. Besides these, there are lecturers and teachers in special subjects. The instructors in the workshops are skilled craftsmen, and all the teachers of the trade classes are men who have worked at their industry as foremen. In the Trade classes instruction is given in metal platerwork, plumbing, carpentry and joinery, bricklaying, and builders' quantities. Under Applied Art, instruction is given in technical painting, modelling, repoussé metal work, and cabinet makers' drawing. The instruction given in mathematics, physics, mechanics and chemistry is as full as possible.

Mr. Manchanayake, late of this school, and now in the Straits Settlements, writes:—Pig breeding is a common occupation with the Chinese in the Peninsula, and is generally combined with market gardening, since such vegetables as are unsaleable go to feed the pig, who in turn supply manure for the garden. The animals are not allowed to wander about, but are kept in a railed enclosure, which is generally thatched overhead, the pigs resting on bars of wood put together so as to allow all the manure to drop into a hollow underneath. The pig breeders also go round the town with "pingoes" to collect all the refuse food from dwelling-houses, paying about 25 cents a month for being allowed to do this partial scavenging work. Of course all that is gathered goes to feed the pigs. The stems, leaves, and such tubers as can be spared of sweet potatoes are chopped up and given to the animals. The breeding is systematic and managed on well-regulated principles. Pork is of course better appreciated by the Chinese than any other kind of meat. In this town of Kuala Kumpar about 25 pigs are slaughtered daily. Here are the market rates of meat:—

A catty (about 18 oz.) of	pork	48 cts.	
"	"	mutton	40 cts.
"	"	buffalo meat	14 cts.
"	"	good ox meat	20 cts.

Mr. Manchanayake illustrates his letter with pen and ink sketches which we regret we cannot reproduce.

The last, though not the least of the 34 cases of exhibits for the Imperial Institute has been shipped. This contains a perfect model of the New Peradeniya Estate tea factory, the work of W. E. Fernando of Moratuwa, who till lately was the family carpenter of Lady de Soysa. W. E. Fernando was taken to London by the late Mr. C. H. de Soysa, and there exhibited some specimens of his work at the Indian and Colonial Exhibition. The Chicago Exhibition Committee would do well to secure his services in time to build for them a similar, and, if that be possible, a more highly-finished model of a tea factory.

Mr. C. D. de Silva, Muhandiram, Headmaster of the Training School, which is now being carried on together with the School of Agriculture, has taken over Mr. Jayawardene's dairy stock and is working the dairy in good style

Mr. de Silva contemplates increasing his stock owing to the large demand for good milk in the city.

The conditions of soil and climate in Zanzibar seem to be rather similar to those of Ceylon, and the chief vegetable products of the Islands of Zanzibar and Pemba, as given in the *Kew Bulletin*, are such as occur in our own Island. The following are those of commercial importance at present:—Cloves, coconuts, sugar-cane, chillies, rice, sorghum, cumbu, kurakkan, manioc, sweet potato, yams, dhall, groundnut, pumpkins, brinjal, bandakai, mango, pumelo, orange, mandarin, lime, citron, anonas, rambutan, guava, jambu, roseapple, durian, jak, breadfruit, mulberry, mangosteen, vine, date, papaw, pineapple, passion fruit, castor-oil plant, gingelly, cotton, coffee, arecanut, pepper, vanilla, cinnamon, cashew, nutmeg, anatto, and a few others. Of coconuts it is said that the ordinary kind take 8 years to come into bearing, but a dwarf variety bears in 5 years. The young palms are liable to the attack of a large rhinoceros beetle (*Oryctes insularis*). Coffee (Arabian) yields badly, and liable to be killed suddenly by a beetle that bores down the pith to the root; but Liberian Coffee yields freely and the produce is of excellent quality. For cocoa, the soil is generally too light and the air too dry. Tea does not thrive, and it is said will never be a product of Zanzibar.

A gentleman in the trade, writing from London in April, about prepared papaw milk, says:—"Having a fresh supply just coming in from your Island, I enclose sample sufficient to show what I am buying. I am taking this in large quantities, about 80 to 100 lbs. per month, and if you can match this, I must ask you to let me have your sample without delay. At present I pay about 22s. per lb. delivered in London.

In this number is begun a series of Zoological Notes for Agricultural students. Such student generally experience much difficulty in isolating from large and comprehensive text-books on the science, such matter for study as would give them a knowledge of animals, whether they belong to the highest or lowest orders of the Zoological kingdom, whose life-history is more or less of interest to the Agriculturist. Our object is therefore to supply the want of a convenient collection of Zoological Notes for Agricultural students. No claim to originality is made in this work, but the best authorities on the subject will be consulted and a reliable and it is hoped useful, compilation will be the result.

The following changes have lately been made by the Director of Public Instruction: Mr. Hoole of Happy Valley, Haputale, has been appointed Agricultural Instructor at Bandaragama, and is succeeded by Mr. Ayampillai from Batticaloa. Mr. J. Rodrigo of Bandaragama has been transferred to the School of Agriculture in place of Mr. W. A. de Silva at present in Bombay.

Mr. Alfred Driberg, late a student of this School, has secured a berth under the Talgaswell

Tea Company, and is working on Talgaswella Estate near Alutgama.

Term commenced at the School of Agriculture on the 1st July.

ACIDITY IN MILK.

The researches of Dr. Bond into this question throw a new light on the subject of milk which is at all times an important one. When it is considered, says Dr. Bond, that directly milk passes from the udder of the cow it exhibits traces of acidity, that this acidity goes not steadily increasing the longer the milk is kept, and that it exercises a most important influence both on the value of the milk itself as an element of food and on its conversion into butter and cheese, it will be evident how essential it must be to the proper conduct of dairying that those who have to handle milk should be able not only to recognise the presence of acidity in it, but also to estimate with some approach to accuracy the *degree* of acidity which a given sample of milk or its products may have reached.

To this end Dr. Bond has invented apparatus, and has impressed certain reagents into use: (1) The neutraliser, which consists of a solution of potassium hydrate (*caustic potash*) of such a strength that one unit volume (namely one drop) exactly neutralises one volume of a solution of 7.875 grammes of pure, dry, crystallised oxalic acid in one litre of water. The solution of oxalic acid is exactly one-eighth the strength of the normal solution as employed for ordinary laboratory purposes, and it has been adopted because it has been found by a good deal of practical experimentation to represent an alkaline solution of convenient strength for general dairy works. (2) A dropper, with an outlet of standard size, regulated to drop about one drop per second. With a view to providing a dropper which may be used by various persons so as to give comparable results, Dr. Bond has adopted a nickel-plated brass tube having an external diameter of 17 B. W. G. (Birmingham wire gauze) as being as convenient as any for the purpose. (3) A glass-well for fitting in an airtight manner in the neck of the bottle holding the neutraliser in such a way that the bottom of the tube nearly reaches to the bottom of the bottle, and is constricted to such an extent that the metallic tube of the dropper just fits into it and projects about half an inch below, when the dropper rests in the well-tube. By this device the neutraliser is exposed to the air to the minimum extent, and at the same time could be extracted so as to be measured in drops. (4) A suitable bottle for the neutraliser. (5) The Indicator consisting of phenolphthallein one of the numerous derivatives of coal-tar. This substance which, when in solution gives a full purple colour in the presence of a most minute quantity of any alkali loses that colour altogether when the alkali is neutralised by an acid; and while in the presence of an acid it gives no colour at all, when the acid is unneutralised by the addition of an alkali, the purple tint makes its appearance. By taking advantage

of the properties of this sensitive colour reagent, and adding a minute quantity of it to any acid solution, and then gradually adding to the mixture an alkaline solution until permanent purple colour is produced, we are enabled to recognise with ease the precise point when the acidity is perfectly neutralised. A few words will suffice to explain the proceeding involved in making the test itself. The end of the sampling tube is inserted into the liquid to be tested, say milk, and by pressing the rubber capsule the proper quantity is taken up and squeezed into a glass. In the same way a charge of the *neutraliser* (caustic potash) is taken by means of the dropping tube, and dropped into the milk, to which a minute quantity of the *Indicator* (phenolphthallein) has been added, until a permanent purple colour has been produced. The number of drops required for this purpose gives the number of *degrees of acidity* which the milk possesses.

No one who uses milk, says Dr. Bond, can do so with any certainty of its condition and behaviour unless he can estimate its acidity, and this it is claimed can now be done by the Acidometer with as much ease and certainty as its temperature can be gauged by the thermometer, or its weight determined by the balance.

INDIAN JOTTINGS.

The subject of fodder supply is one of such importance in India, that experiments are continually being made to test the value of different materials as cattle and horse food. The results of the latest experiments in this direction are embodied in a report, issued by the Government of Bombay, on the feeding of cattle with the prickly pear.

Prickly Pear (*Opuntia delenii*) is a cactus commonly known as Pathok in Ceylon. It is found growing wild abundantly in the dry regions of the Island, and I remember having seen a large number in the Hambantota District. In Colombo this is much a favourite as a hedge plant, and on account of the long thorns which cover the broad fleshy leaves and the succulent stems, it acts as a very affective preventative against the inroads of men and animals. It has to be borne in mind that this plant is not cultivated here as a fodder crop, but the experiments have been undertaken to see whether the weed which is abundant in some districts could be utilized for a useful purpose. As such the results are interesting.

The first great difficulty in dealing with this plant is that of getting rid of the thorns, for no animal will eat the leaves with the thorns on them. For the purpose of gathering the leaves a long stick with a bent knife attached to it is used, whilst the thorns are got rid of by scraping with two handled scrapers, which do not cost more than an anna each. A single man is said to be able to clean seventy pounds of leaves per day.

The prickly pear did not succeed with highly-fed animals, especially milch cows. The milch cows experimented on refused to take the pear leaves till they were literally starved, and after a day or two they began to lessen in weight and give very little milk. On the other hand three

calves which were fed with this leaf and given only four pounds of hay in addition thrived well and gained in weight.

At any rate prickly pear is not more than a famine fodder, but even as such it is worthy of attention, for in Ceylon cattle frequently run short of pasture during long droughts and often starve. In such a case the knowledge of the use of a fodder like this would be of great importance.

One is simply astonished at the number of cows allowed to roam about in the streets of Bombay. The streets are generally so crowded with tramcars, carriages and bullock gharries, that people find it difficult to move about. What would be said of cows roaming about at Kayman's Gate in Colombo? But one thing is observable in the animals here, they are unlike our country cattle or the coast cows, being quite tame and perfectly indifferent to persons who pass by them.

It seems that buffalo milk is more valued here than cows milk, for there is a great demand for the former, and the prices of the two are almost equal. In Colombo the milkman often carries about a mixture of buffalo milk and water, and he cannot be made to say that there is buffalo milk, whilst a milkman here would not hesitate to call cows milk buffalo milk, since the latter seems to be a favourite with the generality of people.

One could hardly give a reason why buffalo milk is preferred to cows milk unless it be custom. It must be confessed, however, that buffalo milk is the richer of the two. Why Colombo folks have such a dread of buffalo milk is a problem that remains to be solved!

It is a great pity that grass is never dried in Ceylon for after use. During the rainy seasons abundance of grass is found in the villages, but nobody thinks of laying any by. When the dry weather sets in the grass dries up, the meadows no longer flush, and cattle begin to suffer. If during the favourable season the over-abundance of grass could be dried and preserved, it would be better for both the animals and their owners. In Bombay large stacks of dry grass are seen evidently brought from the country, and horses and cattle are all fed on this. The grass itself is long and wiry, such as we meet with in the neglected paddy-fields of the interior villages.

I have not seen much of the vegetables and fruits here, but if I may judge from what are found in the market, fruit trees must thrive there a good deal better than they do in Ceylon. There is any quantity of a variety of Madan (*Sisyygium jambolanum*), taken about for sale, the berries of which are about five to six times the size of our Madan and taste better too. Whether this be on account of the superiority of the variety or a peculiarity of the soil and climate, I cannot yet say. Some of these seeds will be sent to the School.

Writing of fruits, I omitted to mention that the most striking are the mangoes. There are different varieties of these fruits to be seen here, the small round, large round, the long cylindrical, the sweet and delicate, and the coarse fibrous mango. But all these differ from our Ceylon mangoes, inasmuch as the Bombay mangoes possess a peculiar yellow and pink colour. The

trees here appear not to be so prolific as they are in Ceylon, and hence the fruits are very dear. In spite of all that may be said in praise of Bombay fruit, I prefer the Ceylon "Jaffna" to gaudy-coloured Bombay mango! costing four to eight annas. I shall not fail to procure seeds of as many varieties as possible for our School garden, where a good many Ceylon varieties flourish.

W. A. D. S.

A COOL DAIRY.

The following suggestions for building a cool dairy, so as to secure the lowest degree of temperature during the hot months, have been put forward by the Agricultural Department of Brisbane:—(1) The dairy room should be a wooden rectangular structure, say 12 feet by 8 feet by 10 feet high to the ceiling, having a door at one end and a window at the other, and simply covered over by a roof—the roof, excepting at the gable ends which must be boarded up, not touching the sides of the inner room. It should have a latticed verandah on three sides, and the roof should be of bark or shingle, another galvanised iron roof put over it giving still better results. The door and window should be opposite to each other, the door having a hole 12 inches by 6 inches cut out at the bottom of it, and covered with perforated zinc or wire gauze. The roof should not immediately join the walls, a space of 6 inches being left to permit of the free passage of air under the roof and over the ceiling of the room. The walls may be made double, the space between being filled up with charcoal or sawdust. It is not insisted that the walls should be of wood; any handy material may be used—the mere fact of the verandahs being latticed preventing the sun's rays from heating the walls. Over the window should be fixed a framework of wood to which strong calico or canvas must be nailed. The framework may be constructed of battens 2 inches by $\frac{1}{2}$ inch nailed together, the size being say a couple of inches longer and wider than that of the window. The window may be 3 to 4 feet long by 18 to 24 inches wide, and run up to within 3 inches of the ceiling, the object being to get the cool air to enter the room at as near the ceiling as possible. This window must be covered with perforated zinc or wire gauze. After the frame covered with cloth is fixed in position outside the window, strips of canvas or stout calico should be nailed over the front and two sides, and a gutter or piece of bent tin placed at the bottom of the frame. On the ground, at the lower end of the gutter, should be placed a bucket to catch the drippings. Fix a kerosine tin or any other vessel that will hold water above the window, and put one end of a piece of blanketting or flannel into this, carrying the lower end down on to the canvas blind, and stitch it up there. The kerosine tin is now filled with water which is gradually absorbed by the flannel and drips down on the outside and on to the front and sides of the canvas blind, keeping it saturated with water. The air entering the room first passes over and under the saturated blind, and

owing to the evaporation taking place on the blind is considerably cooled. The cool air forces the hot and heavier air through the hole in the door. The kerosine tin filled with water should not require attention for at least 48 hours, when the bucket that has caught the drippings is emptied into it. Round the building should be planted a thick grove of banana trees, 3 or 4 deep, and about 6 or 8 feet from the house. The owner of the dairy will derive profit from the fruit, and keep his dairy cool owing to the great evaporation from these trees. A dairy constructed on the above plan is said to preserve the atmosphere inside it fully 25 to 30 degrees cooler than the air outside.

THE KITUL PALM.

(Continued.)

It has been stated that the spathe has to be cut into by means of a chisel in order to introduce certain "medicines." Now this cutting into needs to be very carefully performed, for if the chisel through carelessness or ignorance is driven too deep, so as to reach the central portion of the flower, the latter becomes altogether useless. There are other "medicines" (Sin. "Lunumirisa, literally a compound of salt and chillies) besides the one I mentioned in my last contribution. Here is another: Heeraspatu (*Vitis quadrangularis*) and chillies are first well pounded together, and then fried in oil. Another very effective preparation is made as follows:—The leaves of Japala, the bark of the Murunga, salt, pepper, white onion, ginger and chillies are taken in certain proportions and pounded, the juice of the Caffre lime being applied at intervals to the mixture. After the "medicine" is inserted into the cavity prepared for it, the leaves of the orange, lime, Caffre lime, Nattaran, and Heen-naran (the latter two being varieties of oranges) are pounded together and placed over the first medicine. The apex of the inflorescence is sliced about 3 or 4 days after the introduction of the "medicine," by which time the latter will have produced the necessary effect, after being well exposed to the sun. When sweet toddy is heated and at the same time stirred, it turns into a thick syrup or treacle called "peni." When this operation is continued further it becomes "jaggery," which is generally sold in the form of cakes. If, however, the treacle be put into a vessel and hung over a fire-place, exposed to the actions of the smoke, it crystallises out, and becomes like sugar candy. Kandyans of the Jaggery-caste make excellent jaggery models of boxes, animals, birds, &c. Jaggery is generally dark brown in colour owing to the presence of impurities, to remove which the Kandyans use Heeraspatu (*Vitis quadrangularis*), beforementioned, which they put into the vessel of sweet toddy before heating. The jaggery then assumes a light colour. In India sugar is prepared from this palm. The following is a Sinhalese riddle alluding to the Kitul Palm:—

Sinhalese Verse.

1. Varadak netuwa bammak badinawa dutimi
2. Ladak netuwa batak kawanawa dutimi.

3. Dukak netuwa kadulak vetanawa dutimi.
4. Kalayak aran galayak banawa dutimi.

English Version.

I saw a tree being tied to another without any fault.
I saw a medicine being given without any disease.
I saw a tear being shed without any trace of sorrow.
I saw a pot being taken up and brought brimful.

ZOOLOGICAL NOTES FOR AGRICULTURAL STUDENTS.

The animal kingdom is divided by Zoologists into 6 sub-kingdoms, viz., Protozoa, Cœlenterata, Echinodermata, Annulosa, Mollusca, and Vertebrata; Protozoa being the lowest division of the animal kingdom, and Vertebrata the highest.

Protozoa.

(So called from Gr. *protos*, first; *zoon* animal.)

General characters.—Animal, simple or compound, generally very minute; the body composed of a jelly-like albuminoid substance called protoplasm or "sarcode," not divided into regular segments; no nervous system; no definite body-cavity (that is a cavity within the body).

Class 1.—Gregarinidæ (*L. gregarius*, living in flocks). These are Protozoans which live parasitically in the interior of animals; they are destitute of a mouth, and have no power of throwing out prolongations of the body (pseudopodia).

Under this class fall certain psorosperms which deserve some notice.

The coccidium oviformes are egg-shaped bodies .033 to .037 mm. long and .015 to .002 mm. broad, with thick smooth shells which have a micropyle-like opening at one end, usually the narrower. The granular contents are sometimes uniformly distributed throughout the whole interior space or sometimes collected into spherical masses. In this state the parasites pass from the liver and intestine which they inhabit, to the exterior, there to undergo further development in moist surroundings. The contents thereupon aggregate into four oval spores which become surrounded with a slighty firm coat, and form each a single C-shaped carved rod, the concavity of which is closely packed with granules. In their youth these parasites are naked inhabitants of epithelial cells, but afterwards envelope themselves into a firm shell at the close of their period of growth. In this condition, in which they present a puzzling resemblance to the eggs of certain entozoa, they quit their former resting place, and generally the former host also, and transform their substance into a larger or smaller number of spores, each having a granular ball and rod within. The spores themselves have rather a thin wall, and are of a round or elliptical shape. These organisms are found in many warm-blooded animals (including man), their habitat being mainly the intestines, liver and bileducts. A species of coccidia is also found in the various organs and parts of the body of the fowl. Leuckart quotes an instance of a case of epizootic occurring in Pisa in 1872, in which the lesions were located in the pharynx, larynx, nose, conjunctiva, intestines, and comb, and

which were attributed by eminent authorities to the action of Coccidia. Coccidian diseases occur most largely in the rabbit, and its lesions are most generally observed in the liver; they resemble in a marked degree the nodular lesions of tuberculosis, and their existence gives rise to emaciation and anæmia, the abdomen becoming enlarged owing to enlargements of the liver. 80 per cent. of the rabbits in Tasmania were found to be affected with Coccidian disease in 1884, and Coccidia were found abundantly in N. S. Wales in 1889. Prof. Brown considers it unwise to allow the organs and even the bodies of animals (poultry included) to be used for the purpose of human food.

Meischer's or Rainy's tubes were discovered by Meischer in 1843, and by Rainy in 1857. They were found in the muscular fibres of various animals, according to Leuckart in the pig, ox, sheep, and goat. The boundary walls of these bodies consist of a somewhat thick and firm cuticle, perforated by numerous pores: inside are found embedded in a tough and somewhat homogeneous matrix a number of kidney-shaped bodies. The presence of these psorosperms causes difficulty in breathing, and symptoms allied to paraplegia.

Class II.—Rhizopoda. (Gr. *rhiza* root, and *pous* foot) or "root-footed" animalcules, are Protozoans which are simple or compound, and have the power of throwing out and retracing temporary prolongations of the body substance; a month is generally if not always absent.

In the order foraminifera, the body is protected by a shell generally composed of carbonate of lime. At great depths in the Atlantic and Pacific exists a mud or "ooze" found almost entirely of the remains of foraminifer shells. This ooze is found to a depth of 3,000 fathoms and may be regarded as the modern analogue of the white chalk of the cretaceous period. Chalk itself is, in fact very largely composed of the tests or shells of foraminifera. Nummulitic limestone is to a large degree composed of the tests of the nummulite, a foraminifer. Carboniferous limestone is often wholly composed of the shells of a foraminifer known as Fusulina. In the order Radiolaria, the organisms have a siliceous test or siliceous spicules, and large areas of the sea floor, up to a depth of 4,500 fathoms are composed of their shells. The well-known "Barbadoes earth" consists almost entirely of the minute flinty shells of a Radiolarian known as Polycystina.

To the Foraminifera and Radiolaria, are thus traceable the origin of certain organic geological deposits. Apart from the possibility of both these deposits forming the constituents of agricultural soils, is the fact that lime, which is prepared from the carbonate, is a most important and useful agent in the art of Agriculture.

There is one other order of this class, viz., Spongida, which deserves a passing note. The sponges live in colonies supported by a common framework of horny, siliceous or calcareous spicules. The softer horny frameworks are the sponges of commerce and of economic value. The siliceous sponges are held by geologists to have been in most cases the origin of flint.

Class III.—Infusoria, or infusorian animalcules, so called because they are generated in organic

infusious. They possess a mouth and short gullet: are able to put forth pseudopodia: are furnished with vibrating hair-like processes (cilia); body composed of three distinct layers, Ex. bell-animalcule. What is known as "infusorial earth" or "Tripoli powder" is sometimes thought to have some connection with the Infusoria, but this is a mistake. These deposits, the finer varieties of which contain over 90 per cent. of silica, are composed of the siliceous frustules of diatoms, which are minute aquatic plants.

(To be continued.)

GENERAL ITEMS.

The Port-of-Spain *Gazette* of April 29th, contains an account of a cocoa-drying exhibition by means of the "Torrido Dryer," the invention of Mr. Hemans. In the words of the inventor "it enables one to save his crops independent of sun and in spite of rain, and at an almost incredible short period of 5 to 7 hours, according to the more or less efficacious mode of fermenting." The machine is said to be so simple in construction, that any ordinary intelligent unskilled labourer could work it, and no more than two persons are required to manipulate the article to be dried. Other advantages of using the "Torrido Dryer" are that the aroma and quality of the cocoa dried by it are far superior to those of cocoa dried in the sun, the value of the cocoa rising 5 to 7 per cent; the loss in weight is reduced from 50 to 37 per cent owing to the rapid evaporation, thus increasing the profits by 9s. per cwt., taking the mean price of cocoa at 65s. per cwt. The "Torrido Dryer" is also suitable for drying fruit, such as plantains and figs. The Director of the Botanical Gardens, Trinidad, himself recommends Mr. Hemans's machine, which is manufactured in different sizes, and costs from £125 to £300. The address of the inventor is: Henry Hemans, of Henry Hemans & Co., 38, Queen Victoria Street, London, E. C.

Creolin which is antiseptic, disinfectant, deodorant, parasiticide, and astringent is now being largely used in Veterinary Surgery and Medicine. It is a coal-tar product of complex composition, of an oily consistency and dark brown in colour, with a tarry odour and taste, and forming an emulsion when mixed with 40 parts of water. Bacteriological tests prove it to be more prompt and effective than carbolic acid in the destruction of the microbes of anthrax, fowl cholera, glanders, &c. A one per cent solution is stated by Esmarch and Fröhner to kill cholera bacteria in ten minutes, and arrest development of typhus bacilli in half an hour; while a one per cent solution of carbolic acid requires four days to kill cholera bacilli, and had no effect on typhus bacilli in twenty-one days. Kauffmann states that as a bactericide it is ten times as powerful as carbolic acid. Unlike carbolic acid and creosote, 10 per cent solutions do not irritate the skin, the mucous or abraded surfaces.

The *Horticultural Times* says that the edible and poisonous mushroom may be distinguished in the following ways:—1. The table mushroom,

or *Agaricus campestris*, is usually white on the outer surface, and has a skin which readily peels off. This is not true of the unwholesome mushroom. 2. The gills or under-radicals are of a beautiful pink in the *A. campestris*; but the gills as well as the whole plant, turn to a mahogany brown after it has been exposed to sun and air in the open for two or three days. 3. But this is the most definite test:—The inner ends of the gills are not joined to the stem in the wholesome mushroom, but they are joined in all that are not edible. The flesh of the *campestris* is solid, and the perfume sweet and nutty. There is another edible member of this family, known as the horse mushroom, which grows four or five times larger than the one described; but it is coarse, stringy, and almost devoid of flavour. The plant, however, above all others to be avoided is the *Agaricus fastibilites*; it looks almost exactly like the edible fungus, but the gills are joined to the stalk, though many of them are of a salmon or coral pink on the under side.

Laportea crenulata is the stinging tree about which so much has been written in the Indian papers. It is known as "Maossa-gass" in Ceylon, and is very common up to an elevation of 5,000 feet in damp forests. Sir Joseph Hooker says that he found the greatest difficulty in getting it cut down, owing to the dread in which it is held. He mentions having gathered many specimens without allowing any part to touch his skin, and yet the scentless effluvium was so powerful that mucous matter poured from his eyes and nose all the afternoon in such abundance that he had to hold his head over a basin for an hour. The French Botanist Leschenault de la Tour was stung on three fingers of his hand in the Calcutta Botanical Gardens, and suffered according to Hooker, from sneezing and running at the nose, followed by tetanic symptoms and two days' suffering, the effect only disappearing after nine days. It was thought by Endlicher that the causticity of the juice of the plant was due to bicarbonate of Ammonia, but this salt was not found by Dr. Thompson and Sir Joseph Hooker in the *Laportea*. Sir Joseph records it as a remarkable fact that its sting is only bad in the autumn. To those who can brave the disagreeable effects of preparing it, says the *Indian Agriculturist*, it would give a strong useful fibre. Another plant of this family,

L. terminalis, occurs in Ceylon, in the Central Province, at an elevation of 4,000 to 6,000 ft. These plants belong to the order Urticacea, to which order also belong the English nettles (*Urtica*) and the well-known stinging Kahambilliya of the Sinhalese (*Gerardinia Zeylanica*).

Mr. Thistelton Dyer speaking at a meeting of the Society of Arts stated it as his opinion that the real want of the Indian soil was nitrogen, and recommended that this want should be supplied by the growth of leguminous crops. He also recommended the improvement of the Indian plough, and stated that a former pupil of his at Bangalore obtained good results by stirring the soil deeper than the ordinary plough did. The plants were thus able even in dry seasons to get moisture by sending their roots deeper into the soil.

The twenty specimen collections of Economic products selected by the Indian Government as the first year's supply of exhibits for the Imperial Institute, include *Adhatoda Vasica*, brush-making fibres, caoutchouc, castor oil, coal, coconut, cotton, indigo, iron, jute, ipecacuanha, linseed, mica, morinda, podophyllin, emodi, resins and tars, sesamum, sida, silk and padunk timber. Each collection will be accompanied by a monograph in which the characteristics and objects of the collection are explained, and illustrated by maps and diagrams.

Chinese insect wax is an article of export where it is gathered. The female of the insect in question develops scales, pear-shaped, and brown in colour, and deposits eggs in them, while the males excrete the substance known as white wax which is supposed to serve as a protection for the scales. This goes on on the bark of the Chinese evergreen tree, and the wax is spread over the branches to a depth of quarter of an inch. When the deposit appears to be complete, the branches are cut off and the wax removed by the hand and by boiling.

The juice of the lacquer tree is the natural varnish upon which depends the famous lacquer work of the Japanese. The tree belongs to the Rhus family, other members of which produce "Sumach"—the powder got by grinding the dried twigs and leaves,—valuable as a dye, a tan material, and a mordant.

MR. JOHN FERGUSON'S LETTERS TO THE
"FINANCIAL NEWS."

We think it will be generally agreed that our absent brother-editor has rendered good service to this colony by the letters he has written to one of the leading London financial journals on the subject of our island-grown teas. The discussion which gave occasion for those letters being written arose in some degree out of Sir Andrew Clark's ill-considered and unjustifiable remarks with respect to the qualities of China and Indian teas respectively. We have before dealt with the topic of those remarks, and need not therefore here recapitulate our arguments previously expressed in refutation of the absurd calumny passed by Sir Andrew on the teas of India, with which he no doubt intended to class—although not specifically named by him—those of this island. Mr. John Ferguson, however, has taken the occasion of this discussion to place on record in the columns of the London press a series of facts with regard to our teas far more complete and important in their scope than any which have heretofore been submitted for the consideration of the home public. Space must prevent us from reviewing the letters at length; but we believe that after perusing them all of our readers will agree in the verdict we have passed upon them. A more efficient counterblast to Sir Andrew Clark's ill-advised strictures could hardly be imagined than is afforded by those letters. One would have thought, after the numerous contributions to the literature of Ceylon tea which have been made, that it would have been found impossible to find anything to write or say anything respecting it which could excite the interest of home readers, but Mr. John Ferguson has certainly proved such an apprehension to be an ill-founded one. We doubt exceedingly if the leading statistics of our tea industry and the history of its inception and growth have ever been put in a clearer or more intelligible form before the public at home than in these letters by our absent co-editor; and we should imagine that the figures quoted by him as to the successive annual yields upon the celebrated Mariawatte plantation will likely to cause the mouths of many of our

Indian fellow-planters to water exceedingly. We need not here notice the remarks in the letters dealing with the question of possible continuity to the tea planting industry in Ceylon; for we have but recently offered remarks upon the same subject. More important as affecting the judgment of tea dealers in England are Mr. John Ferguson's observations upon the multifariousness of the advice tendered to our planters by home critics of our procedure. With this subject the letters deal at some length, and they show how almost impossible it has been for our planters to be on all occasions guided by such advice, especially in the matter of coarse and fine plucking. No doubt the writer while at home has heard much said deprecatory of the stability of tea cultivation in Ceylon. In placing before the public the reasons why there is but little reason to dread a decadence of this stability Mr. John Ferguson has done yeoman's service to this colony, because, while reports inimical to that anticipation remain uncontradicted and in free circulation, they must tend to disincline investors from coming forward as freely as they otherwise would do to stimulate our local enterprize by liberally subsidizing towards the capital of the Companies which are almost daily started to carry on and extend the planting and cultivation of tea in this colony. No one has given fuller consideration to all the questions which affect this cultivation than has Mr. John Ferguson, and we feel sure that every reader of his letters will recognize this fact in every sentence of them.

FROM THE METROPOLIS.

27th May 1892.

THE CEYLON TEA DISCUSSION.

The long letter I addressed by request to the Editor of the *Financial News*—a paper, I am assured, with the largest circulation of its class—and which was forwarded to you by last mail, was followed by another in the issue of May 23rd. This you will also want to reproduce as under:—

THE TEA INDUSTRY.

CEYLON AND INDIAN V. CHINA TEAS FROM THE
PLANTER'S POINT OF VIEW.

To the Editor of *The Financial News*.

Sir,—Notwithstanding all the information circulated during the past seven years, very erroneous ideas appear to prevail still in certain quarters in England in reference to the quality and merits of Indian, and especially Ceylon, as contrasted with China, teas. There can be no doubt that Sir Andrew Clark's hasty, ill-considered remarks in his address to the London Hospital students in October last

have been regarded in some directions as a reason for avoiding British-grown teas, and drinking only those of China. These remarks have been very widely quoted, and specially reprinted by interested parties in circular form, for distribution in the Australasian colonies and America, as well as throughout the United Kingdom. Let me refer to the offending passage. After remarking sensibly enough, on the injury done by allowing tea to stand too long, and then drinking a black infusion of what had been, perhaps, half an hour in the pot, Sir Andrew Clark went on to say:—"Tea, to be useful, should be, first of all, black China tea. The Indian tea which is being cultivated has become so powerful in its effects upon the nervous system that a cup of it taken early in the morning, as many people do, so disorders the nervous system that those who take it actually get into a state of tea intoxication, and it produces a form of nerve disturbance which is most painful to witness. If you want to have, either for yourselves or for your patients, tea which will not injure and which will refresh, get black China tea, putting in the right measure—the old-fashioned teaspoonful for each person, and one for the blessed pot. Then pour on briskly boiling water, and within five minutes you must pour it off again, or it will become wicked instead of good." Now, in the above, Sir Andrew Clark seems quite unaware of the fact that some of the Indian teas are among the most delicate in the world, while, apparently, he has yet to learn of the medium position between the stronger Indian and the poor China taken up by Ceylon tea as a whole, though in our island (as in India) the higher the altitude above sea level at which tea is cultivated the finer and more delicate the leaf. In this way some of our Ceylon high-grown teas have been shown by analysis to have as low a percentage of tannin as any ever recorded.* Indeed, in ignoring Ceylon teas in his October address, Sir Andrew Clark had forgotten the eulogy he himself had passed some time ago when drinking a cup of Ceylon tea, as the most pleasant he had ever tasted.

But of far more importance is it to remind Sir Andrew Clark, and all others concerned, that, dealing with Indian and Ceylon teas as a whole, attention to the quantity used and the time of infusion will obviate any deleterious effects, such as those referred to, just as certainly as in the use of China teas. Sir Andrew is quite right about five minutes being ample for "infusion"; indeed, with strong tea, or for nervously-inclined tea-drinkers, rather less may suffice; but he has yet to learn that "the old-fashioned teaspoonful for each person, and one for the blessed pot," is too liberal in the case of Indian and Ceylon teas. Ceylon Pekoes, for instance, will generally go twice as far as China Congous, and very seldom need more than two-thirds of the quantity taken of China tea be used in the case of pure Ceylon tea to make an even better infusion. Here, then, may be the secret of Sir Andrew Clark's implied, if not express, condemnation of Indian and Ceylon teas—namely, that he has been making his comparison after using the same quantity of such teas as of China in his infusion. Fortunately, the economy attending the use of the former is becoming better understood and appreciated every year by English housewives.

Next, it would be well if Sir Andrew Clark and other home critics of British-grown teas understood the great difference in the cleanliness attending the preparation of Indian and Ceylon teas, machinery being used extensively in the factories, as contrasted with the manual (and sometimes pedal) system adopted in China. I believe, too, it is a fact that in certain districts "John Chinaman" considers anything good enough for "foreign devils," and so contrives to redry and manipulate for export, tea leaf from which he has already taken an infusion—a mild one, perhaps—for his own use. Adulteration with other leaves and the artificial colouring of certain classes of teas are also practised in China and Japan—more especially in the product shipped to the United States. It is very important that the purity,

cleanliness, and good value of British-grown teas should be generally understood. Only a few weeks back an important Liverpool paper (the *Courier*) had an article bewailing the falling off in teas, due, as the writer thought, partly, at least, to the super-session of China by Indian and Ceylon teas in the London market; and yet it is surely admitted by unprejudiced experts that China teas, as a whole now and in years gone by are, and were, inferior to the pure, strong, yet flavoured British-grown product.

In conclusion, I may, perhaps, be permitted to quote a brief summary of reasons why English-speaking people everywhere should drink Ceylon tea:—

(1) Because Ceylon tea is pure, and China too often adulterated or artificially faced.

(2) Ceylon tea is acknowledged to be about the best the world produces.

(3) It is grown and manufactured by their own countrymen.

(4) The Ceylon tea industry affords employment in increasing volume to thousands of English-speaking workmen in the manufacture of implements, machinery, steam-engines, and other factory requisites, materials for buildings, and packages.

(5) China uses only her own locally-made materials for the production and preparation of her teas, so that the consumption of China teas aids chiefly in the purchase of Indian opium instead of English manufactures.

(6) Machine inventors of all countries are welcome to use their skill in Ceylon, the most progressive of all tropical planting lands.

(7) If they saw the respective modes of preparation for themselves, tea consumers outside Asia who could get the pure, clean, machine-prepared leaf which is sent out from the planter's factory would never touch the article prepared by the hands and feet of the Mongolians.

What is here said of Ceylon is obviously to a great extent, true of Indian teas. Thanking you for giving me so much of your space in the interests of the British tea-planting industry.—I am, sir, yours, &c.,

J. FERGUSON, of the
Ceylon Observer and Tropical Agriculturist,
Royal Colonial Institute, May 20th, 1892.

THE DECLINE OF CHINA TEA.

Referring to our recent "instructive and suggestive" article on the tea trade, with "much of which" it "entirely agrees," the *Grocers' Chronicle* says:—"Our contemporary, THE FINANCIAL NEWS, occasionally enlightens its readers on topics which, whilst not exactly financial, are sufficiently germane thereto to make their discussion interesting to capitalists. In a recent issue the topic of tea came under review. . . . We cannot say that we attach much value to the prospect of the Chinese reforming their methods. We have all along steadily upheld the use of tea of British production, and our judgment has been endorsed year by year by increased trade. And whilst we are not so uncharitable as to wish the Chinese entirely 'out of it,' we very much fear that there is about as much prospect of their modernising their system of manufacture and introducing machinery as there is of them adopting female suffrage or representative Government."

In the *Financial News* of the 25th there comes the following skilfully-wordsd rejoinder from Mr. Hawes:—

THE CEYLON TEA INDUSTRY.

To the Editor of *The Financial News*.

Sir,—Everyone interested in the Ceylon tea industry must have read Mr. Ferguson's letter of the 20th inst. with great interest, but, at the same time, could not help feeling that it was written undoubtedly from a planter's point of view. Mr. Ferguson refers especially to the subject of stability of the Ceylon tea industry, and infers that in your leader, and in my letter, doubts were made as to the stability of the trade. If he reads my letter again more carefully he will find I do not doubt the general stability; but what I maintain, from present and past experience, is that the average fine quality of the teas from Ceylon is declining, and will

* See "Ceylon Tea Analyses," by Mr. John Hughes, Analytical Chemist, 79, Mark-lane.

further decline, and that planters cannot alter this natural course of events, whatever may be the cause. Mr. Ferguson's arguments do not, I think, alter what I wrote on this subject. I did not advocate that the planters should, at any special time, go by advice from London, and all set to work at once to make very fine or all common leaf at any given time, and, by so doing, by chance fall into the troubles, which he recalls, of 1890 and 1891. I am sure I am supported in my opinion by most large operators in Ceylon teas here, that the average good quality of Ceylon teas has gradually dropped off, and there are less fine and choice teas obtainable, although better teas have been and are wanted, and sell at good prices when they do come.

It does not do to name them, but there are many gardens, which used to be famous for the all-round fine quality of their teas, which now never show anything but medium or common qualities. To support his argument that Ceylon can grow whatever tea is required, and can maintain steady average crops of fine or common teas, Mr. Ferguson only names two of the older established gardens, covering only about 500 acres out of the 255,000 acres under tea cultivation; but the produce of these two estates does not rank, in market estimation here, amongst the fine tea group, and the Loocondera estate undoubtedly used to send much finer average quality than it does now. There are many more gardens the quality of the produce of which is declining, and which decline would be more marked but for the fact that there is some newly-planted land continually coming into bearing, the leaf from which is mixed with that of the older-grown trees, and keeps up the higher standard. I have now given you a broker's and buyer's view of the situation; let time prove whether the planter's or broker's views are correct. With the large supplies of common China Congous on hand and further heavy arrivals during the coming season, and a preponderance of common teas from India and a fair share from Ceylon, the fine and finest Ceylon teas, which are now wanted, will probably later be in very strong demand, and command high prices. We shall then see if they can be produced at will by the planters, as Mr. Ferguson would have us believe.—I am, sir, yours, &c.,

F. SUTTON HAWES.

14, Mincing-lane.

I felt bound to send a few (final) words correcting his reference to the two plantations "named," and accordingly, the same afternoon from the Colonial Institute, sent a short final note. But meantime there appeared yesterday morning the following clever letter from our friend, Mr. T. C. Owen:—

THE CEYLON TEA INDUSTRY.

To the Editor of *The Financial News*.

Sir,—As a Ceylon planter who was one of the first to cultivate tea in that island, and as the writer of several works on planting, I venture to make a few remarks in connection with the correspondence on Ceylon tea which has recently appeared in your columns. Mr. J. Ferguson's letter is a most exhaustive and able review of the subject, in attributing the falling off in the quality of the bulk of Ceylon teas to coarser plucking and to the impossibility of dealing as carefully with large as with small quantities of leaf, he undoubtedly adduces two very important factors in the case; on the other hand, the loss of certain qualities which leaf from new land possesses—a point he merely alludes to—is, in my opinion as a practical planter, a matter of great importance. For the first few years after land comes into bearing the tea is characterised by a delicacy of flavour which, as a general rule, cannot be obtained afterwards. How this occurs it is difficult to say; probably certain constituents in the soil on which this special flavour depends become quickly exhausted. When, however, Mr. Hawes, writing from a London office, speaks of "the greed of the average planter," of the deterioration of the plant" through "wholesale plucking," he ceases to deal with facts within his experience and theorises in matters of which he has no personal knowledge. I, and I fancy any other

practical planter, even after studying the question closely for years, would be very sorry to dogmatise on the subject as your correspondent has done.

The effect of giving the plant a rest—of ceasing to pluck it—is to induce an abundant growth of shoots, which turn "hangy," as it is called, and harden up to the tip. I need scarcely say that the very worst tea possible is made from a growth of this kind. The best teas are made from moderately-plucked bushes, excessively-close plucking and too easy treatment being equally avoided. Such a system is now being followed almost universally in Ceylon, and it is one which gives the planter the maximum profit from his estate consistently with a due regard to the welfare of the bush.—I am, sir, yours, &c.,

T. C. OWEN.

92, Gower-street.

I do not think it needful to notice further the point raised by Mr. Owen, unless indeed it is seized and made too much of by Mr. Hawes; for, assuredly, in saying that virgin soil *per se* gives a delicacy of flavour lasting over *some years*, which is afterwards lost, Mr. Owen seems to concede a very great deal to the critics. For, of course, a large proportion of over 250,000 acres is still within the "few years'" limit, and when it is past are we to understand that a flavour is lost never to be recovered in our teas? This I have been asking Mr. Owen in a private note to consider. For my own part, I have always been inclined to attribute much of the "first few years'" flavour and delicacy to the great care taken in preparing the necessarily small crops—a condition which affords good reason to hope for improved aroma when all factories are enabled to settle down to regular work and the utmost care is taken at every point. Of course, even as Mr. Owen puts it, we can find room for hope; because if the virgin flavour depend on certain "soil constituents" gradually abstracted, we must ere long begin to analyse and supply these used-up constituents. But is there not more than one plantation in Ceylon, which (through the proprietor consenting possibly to prefer name and fame to some additional profit) has managed, by plucking fine and preparing with extra care, to keep up the grade and quality of its teas? If so, then the fact should go far to show that very little weight, commercially speaking, should be placed on the "virgin aroma" theory. This is a point on which, no doubt, you will hear from some of your correspondents. The opinions of "Wanderer," and of such tea-planters as Messrs. Armstrong, Reeves, Megginson, Merison, A. L. Cross, Blackett, G. A. Dick, and the Chairman and leaders of the P. A. would be of interest. Meantime here is my letter from today's *Financial News* written, of course, before Mr. Owen's appeared:—

THE CEYLON TEA INDUSTRY.

To the Editor of *The Financial News*.

Sir,—I am quite content to leave time to decide the point at issue between the Ceylon tea planter and the London broker and buyer, so far as the latter may be represented by Mr. Hawes; but there is one misconception in his letter today which requires correction. The two estates—Loocondura and Mariawatte—named by me on the 20th were not brought forward to support my argument in regard to the quality of Ceylon tea, but to show the stability of the planting industry in respect of satisfactory, and even heavy, crops gathered over a series of years without any depreciation of the tea bushes or plantations.

My argument in reference to the ability of our planters to maintain quality was based on acquaintance with other estates, or gardens, not named (for obvious reasons), but some of them indicated, which had only given up sending to London the fine teas for which they were some years ago distinguished because their proprietors found it paid them better

to send a lower or medium grade, of which they got from 50 to 100 per cent. more crop. I stated further, that not a few planters have been led to think that apart from the bigger harvest compensating for lower quality and prices medium rather than fine plucking of leaf best suits the healthy development and vigour of their bushes.

Nevertheless, let the London buyers establish such a difference in price between fine and common or medium teas as will show to the planter a decided pecuniary advantage in supplying the former, and sure am I that there will be a response from Ceylon and that, too, from some of the gardens which used to be famous for fine quality teas.—I am, sir, yours, &c.,
May 25th. J. FERGUSON.

In the same paper the following sub-editorial paragraph has appeared:—

A Ceylon tea grower has been investigating Southern California in regard to its adaptability for tea culture, and is favourably impressed.

And this has provoked me to give the Editor a few facts of which I hope he will, with Captain Cuttle, "make a note on" to obviate such absurd intimations in the future:—

TEA CULTURE IN SOUTHERN CALIFORNIA.

To the Editor of *The Financial News*.

Sir,—Kindly note, once for all, that you ought, editorially, to meet proposals or suggestions about tea culture in new countries—America, S. Africa, Australasia, &c.—with the simple but indispensable question, "Can an abundance of field labour be commanded at from 6d to 9d a day for each adult man or woman?"

If not, there is scarcely any use trying to grow tea for market against India, Ceylon, Japan, Java and China, which already produce in excess of the demand for the world's present consumption.

I found the tea plant flourishing in the open air at Washington in 1884; but in California I could not get my boots blacked for less than 6d, and in Florida I found no Negro man or woman could be got to work in a garden for less than a dollar a day. This may do for the culture of the prolific orange tree; but it is of no use for tea plucking which can scarcely afford $\frac{1}{2}$ dollar per day's labour.—Yours truly,
J. F.

Among other comments provoked by my long letters, the following is from the letter of a City tea authority:—

"I have read both your articles on tea (Ceylon) in the *Financial News* with great interest. And certainly the planters in Ceylon owe you a deep debt of gratitude for championing their cause in the way you have done."

Mr. J. H. Barber—clever tea planter as well as lawyer and musician, "admirable Orichton" indeed—is also good enough to write:—

"I am very much obliged to you for the instructive communication by you in the *Financial* and I am glad that you have noticed again Sir Andrew Clark's rash assertion to give it your contradiction. His *ipse dixit* will do, I am sure, incalculable mischief to both tea growers and drinkers. That there should be one man in Great Britain to champion China against British grown teas, is only the exception which proves a good rule. But as even the devil can quote Scripture to suit his purposes, so the unscrupulous vendors of China muck will misquote Sir Andrew, for their own ends, in order to vilify our pure article."

'Tea' is indeed quite a stock subject for discussion in the home press now-a-days, and your attention will no doubt be called to an article in *The Statist* of 21st May, which, though dealing with facts already familiar to Ceylon readers, may as well be partly quoted here:—

THE CHANGE IN THE TEA TRADE.

Tea, in common with the depressed state of the market for Eastern produce, has in recent months fallen very severely, and some China descriptions have declined to unprecedentedly low quotations. From time to time in past years we have referred to remarkable variations in the source of supply; at one time it was the displacement of China teas with Indian that called

for comment, and later on it was the rapid development of the production of Ceylon tea that excited so much interest. Never before in the history of the trade has the proportion of China tea to the whole home consumption of tea been so low as it now is. Out of a total import of 231,500,000 lb. from June 1st last to end of April this year, India and Ceylon together have sent us 168,600,000 lb. or approximately 72 per cent., and the deliveries for home consumption and export have been on such a scale that the enormous production of tea grown in British possessions has been absorbed. Whereas the stock two years ago was equal to almost exactly six months' consumption, at the present time the supplies on hand but little exceed four months' requirements. It would consequently appear that large as the increase in supply has been, it is other reasons than the statistical position that have brought about the great fall in prices; indeed, on the statistical position alone a rise rather than a fall should have occurred.

The real causes that have brought about the fall in the price of tea, some qualities having since a year ago declined as much as 30 to 40 per cent., are firstly, the keen competition between British-grown tea and China; secondly, the Baring crisis, which stopped speculation all over the world, and restricted credit facilities; thirdly, the fall in silver, enabling exporters from the Far East to sell far more cheaply; and, fourthly, speculation for the fall encouraged by the foregoing reasons. In the twelve months there has been a fall in silver of about 5d. per ounce, or over 11 per cent. But the exporter of tea evidently could sell in London for 11 per cent. less than twelve months ago, and yet get precisely the same price in rupees or in dollars in India or China, as the case may be. From this it will be seen that the fall in silver only partially accounts for the state of the tea market, for the fall in tea to the extent mentioned has occurred at the same time that there has been a fall in silver from 44 $\frac{1}{2}$ d to 39 $\frac{1}{2}$ d per ounce, which is little more than 11 per cent. On the other hand, tea a year ago was considerably higher than twelve months previously, and the last few days there has been a decided turn for the better in the tea market.

It is worth glancing at the modification shown in the sources of supply; and, parenthetically, it may be noticed that the United Kingdom uses about 44 per cent of all the tea that is consumed in the world outside those countries which produce tea; the next countries that rank in importance as tea consumers being the United States and Russia; Australasia and Canada showing a fair consumption per head of population, very much larger, in fact, than either Russia or the United States. All these countries might be stimulated to greater consumption now that sound teas are produced in British possessions. The decadence of China tea is continuing, as late accounts by wire report the Hankow market to have been opened for the new season at prices 30 per cent below those current last year, and the teas show no improvement in quality.

The advent of India as a tea producer was about 30 years ago. In 1864 the consumption of Indian tea in this country was some 2,800,000 lb.; by 1874 the consumption had increased to 18,500,000 lb., and now we use about 100,000,000 lb. Ceylon, however, has literally raced ahead as a producer, and of the total tea we consume Ceylon contributes more than 25 per cent. The figures given below show how China tea has gone out of favour, and British grown tea has come into use:—

HOME CONSUMPTION OF TEA.

	China, &c. lb.	India. lb.	Ceylon. lb.	Total. lb.
1864...	85,799,000...	2,800,000...	—	88,599,000
1874...	118,751,000...	13,528,000...	—	132,279,000
1884...	110,843,000...	62,717,000...	1,500,000...	175,060,000
1885...	113,514,000...	65,678,000...	3,217,000...	182,409,000
1886...	104,226,000...	68,420,000...	6,245,000...	178,891,000
1887...	90,508,000...	83,112,000...	9,941,000...	183,561,000
1888...	80,653,000...	86,210,000...	18,553,000...	185,416,000
1889...	61,100,000...	96,000,000...	28,500,000...	185,600,000
1890...	57,530,000...	101,962,000...	34,516,000...	194,008,000
1891...	49,287,000...	98,942,000...	51,227,000...	202,456,000

In connection with tea, I have to offer an important correction in regard to the "CALEDONIAN Co.," the proposed formation of which I referred to in my last. The plantations to be named in the Prospectus do not include Venture estate, Dikoya, as I supposed. They are rather Mr. Ross's estates in Upper Maskeliya and some properties in Matale, both in the Valley on the flat and, like Selagama, higher up.

THE TEA GARDEN in the grounds of the International Horticultural Exhibition at Earls-court turns out to be a very poor affair. Having a business call to make in the neighbourhood, I turned in mainly to see "tea growing" and met at the entrance the veteran Mr. Charles Shand—looking wonderfully well in spite of his burden of years—and he gave me at once a very poor picture of the "tea-watte" which I afterwards verified for myself. It is nothing but a small plot—say 8 to 10 yards square—filled with nursery plants, placed about a foot apart and poor specimens both as to jāt and appearance they looked, either nipped by cold winds or red spider; and yet opposite this garden was posted a big placard,—“Manufacture of tea to commence May 31st”—as if the poor plants of less than a year or 18 months from seed were to yield “flush” or “leaf” for manufacture! Evidently Mr. John Rogers' experiment, as a good advertisement for one of the City Tea Companies, had provoked emulation.

CEYLON TEA FUND.

Minutes of proceedings of a meeting of the Standing Committee of the Ceylon Tea Fund held at Kandy on Thursday, the 9th day of June 1892, at 4 o'clock in the afternoon.

Present:—Messrs. Giles F. Walker, Kandy (Chairman, Planters' Association of Ceylon), R. W. Wickham (Chairman, Dimbula Association) A. Melville White, (Kellebokka and Kandy), W. D. Gibbon (Kandy), J. Anderson (Matale West and Kandy), W. S. Thomas (Dimbula), D. Kerr (Chairman, Ambagamuwa Association), W. J. Mason (Honorary Secretary, Ambagamuwa Association), W. Cross Buchanan (Dimbula and Kandy), and A. Philip, Kandy (Secretary Planters' Association of Ceylon).

The notice calling the meeting was read.

The minutes of proceedings of a meeting of the Standing Committee held at Kandy on Friday, the 8th day of April 1892, were read and were confirmed.

Read letter from Mr. R. S. Duff Tytler, Rakwana. Resolved:—“That in reply Mr. Tytler's attention be invited to the Reports of the Standing Committee of the Ceylon Tea Fund and to the statements by the Chairman of the Planters' Association to be found in the Books of Proceedings of the Association. (II) That copies be forwarded to him, as affording as full an answer to Mr. Tytler's questions as the Standing Committee is in a position to give.”

Read letter from Mr. H. B. Roberts.

Read letter from Mr. W. F. Dew.

Read letter from Messrs. J. M. Robertson & Co.

Read letter from Mr. Geo. Kent Deaker.

DEPOSIT OF CHICAGO EXHIBITION FUND SUBSCRIPTIONS IN THE COLONIAL TREASURY, AND THE QUESTION OF EXPENDITURE, AND NEED OF FURTHER SUPPORT.

Read letters from Mr. W. W. Mitchell enclosing memo. and telegraphic communication from Mr. Grinlinton.

Read letter from the Colonial Secretary acknowledging receipt of cheque for R5,000 to be credited to the Government Chicago Exhibition Fund. Resolved:—(I) “That Mr. W. W. Mitchell be requested to telegraph to Mr. Grinlinton on behalf of the Standing Committee of the Ceylon Tea Fund asking him to wire briefly the minimum sum be considered necessary for the requirements of Ceylon at the

Chicago Exhibition.” (II) “That subscriptions to the Ceylon Tea Fund be paid into the Bank of Madras; and that subscriptions to the Chicago Exhibition Fund be paid into the National Bank of India Colombo.”

CEYLON TEA AT THE WORLD'S EXPOSITION AT CHICAGO IN 1893.

Considered the question of exhibits and some connected details. Resolved:—“That it is advisable to defer definite plans to a later period.”

Read letter from the Chairman, Travancore Planters' Association, requesting to be allowed to join with the Planters' Association of Ceylon in the Chicago Exhibition. Resolved:—“That the Standing Committee of the Ceylon Tea Fund is unable to recommend compliance with the request made by the Chairman of the Travancore Planters' Association.”

CEYLON TEA IN GERMANY.

Read letter from Mr. E. Schrader acknowledging with best thanks the grant of 5,000 lb. of Ceylon tea in two instalments for free distribution in Germany on condition of his buying an equal quantity of Ceylon tea on his own account. Resolved:—“That the arrangements made in connection with this grant be approved and they are hereby confirmed.”

CEYLON TEA IN VIENNA, PRAGUE, KARLSBAD, &C.

Read letter from Mr. John Ferguson stating that he was much gratified to learn that the Standing Committee of the “Ceylon Tea Fund” had deemed his suggestions with reference to extending the use of Ceylon tea in Austria and Switzerland worthy of attention; (II) mentioning having forwarded a copy of the *Financial News* containing a letter he had written in defence of the stability of the Tea Planting Enterprise of Ceylon. Resolved:—“That the thanks of the Committee be conveyed to Mr. Ferguson for his letter.”

CEYLON TEA IN RUSSIA.

Read letters from Mr. M. Rogivue. Resolved:—“That consideration of Mr. Rogivue's request be deferred.”

CEYLON TEA IN SWITZERLAND AND AUSTRIA:

Read letter from Mr. Charles Oswald on the subject of the grant of 500 lb. Ceylon tea for free distribution by Mr. Weiner in Vienna and expressing his sincere thanks.

Read letter from Messrs. Whitall & Co. advising shipment of the Tea, as requested, and enclosing invoice amounting to R346.70.

CEYLON TEA IN HUNGARY, AND ROUMANIA, BULGARIA AND SERVIA.

Read letter from Mr. Hugo Graepel, Budapest, Hungary on the subject of the Ceylon Tea in $\frac{1}{2}$ lb. packets for free distribution in Hungary, Roumania, Bulgaria, and Servia. Resolved:—“That Mr. H. Graepel's letter be acknowledged and that he be informed that his letter has been handed over to the Ceylon Tea Company, Ltd. under the Patronage of the Planters' Association of Ceylon, who have been requested to communicate with him in regard to business operations; (II) that the Ceylon Tea Company Limited will be requested as soon as possible to purchase and ship 250 lb. Ceylon Tea in $\frac{1}{2}$ lb. packets to Mr. H. Graepel in terms of his letter for free distribution in Hungary, Roumania Bulgaria and Servia.”

CEYLON TEA IN SIERRA COUNTY, CALIFORNIA.

Read letter from Mr. Joseph C. Dunbar asking for a grant of Tea for free distribution in Sierra county, California. Resolved:—“That Mr. Dunbar's letter be acknowledged and that the Standing Committee would wish to know what quantity of Tea is desired and through what agency it is proposed to distribute it in Sierra County, California.”

CEYLON TEA IN TONQUIN.

Read letter from Mr. P. O. MacMahon enclosing letter from Mr. James Ryan applying on behalf of Mr. MacMahon for a grant of Ceylon Tea in packets for free distribution in Tonquin. Resolved:—“That

Mr. Ryan's letter he acknowledged, and that he informed that the Standing Committee of the Ceylon Tea Fund is not in a position to vote the large grant asked for at the present time, but will be glad to further consider the application if further details are received from Mr. MacMahon after his arrival at Tonquin."

CEYLON TEA IN NEW ZEALAND.

Read letter from Mr. Alex. Thom enquiring if a grant of 250 lb. of Ceylon Tea made available to him by resolution of the Standing Committee of the Ceylon Tea Fund on the 5th of July 1889 is still at his disposal. Resolved:—"That Mr. Thom be informed that the grant referred to cannot be given after this lapse of time, (11) that Mr. Thom be referred to the Ceylon Tea Company, Limited, under the patronage of the Planters' Association of Ceylon."

PURE CEYLON TEA AGENCY.

Read letter from Mr. W. A. Theobald. Resolved:—"That Mr. Theobald's letter be acknowledged, and that he be informed that the Standing Committee is unable to express any opinion for want of sufficient data on which to form one."

NEW MARKETS FOR BRITISH GROWN TEA.

Laid on the table Messrs. Gow, Wilson & Stanton's printed circular letter drawing attention to foreign markets in the hope that a great portion of the surplus crop of Indian and Ceylon Tea may be absorbed by them.

The Standing Committee of the Ceylon Tea Fund then adjourned.

A. PHILIP,

Secretary to the Planters' Association of Ceylon.

THE INDIAN TEA ASSOCIATION AND OCEAN FREIGHTS.

CALCUTTA, June 7.—An important meeting of the Indian Tea Association was held yesterday afternoon to consider the question of Ocean freight and the agreement with the Calcutta Steamship Conference. The Chairman stated the case as follows:—"The last agreement was made in April 1888 between nine lines of steamers and about eighteen firms and companies. The rate of freight was paid at 20s. above deadweight. This agreement contained a rebate clause, which is one of the most extraordinary clauses possible. It is one of those clauses which occasionally come into agreements drafted, one knows not how, and agreed to, one knows not why, and the full meaning of which is not appreciated until they come to be used by this clause. Shippers are precluded from shipping by other steamers for four months after the agreement is terminated, and indeed the penalty for shipping by outside steamers goes on for ever. It is this rebate clause which is the most objectionable part of the agreement and which is now causing us so much trouble. Last year an application was made to the Liners' Conference to reduce their rates as the freight from Ceylon was so much over in proportion, but they declined. Accordingly, in November last, the shippers who did sign the agreement gave notice to terminate it at the end of February of this year. Previous to this, however, the "Anchor Line" gave notice to withdraw, and on the 8th of January, 1892, the Conference was broken up by their withdrawing from it. Since then the Conference has offered to take 35s. less 5s rebate, and there the matter stood. It is now for us to consider whether a new agreement shall be made or not. I feel sure that all will agree that the objectionable rebate clause shall not be allowed to be stated in any future agreement. One source of weakness, to which I would draw your attention, is that the head offices of many of the tea companies are in London, and consequently, we can never be entirely unanimous, unless these companies give authority to their agents here to decide questions of this kind, of the tea industry, as a whole is interested. From what I have seen lately, I am of opinion that we have had enough of the Conference. Competition is healthy and will give us faster steamers and greater facilities

for monopoly gives no inducement to steamers to improve, and only bolsters up the worst steamers at the expense of the best. After several speakers had addressed the meeting the following resolution was carried:—"That this meeting protests against the manner in which the Liners have pressed the rebate clause after the termination of the agreement, and considers it is best in the interests of the Indian Tea Trade that no monopoly be given for carrying tea to any line or lines of steamers."—*Times of India.*

NOTES ON PRODUCE AND FINANCE.

THEY MEAN BUSINESS.—We are glad to learn from a cable message in *The Times* that the Indian planters are taking steps to have the industry properly represented at the Chicago Exhibition. It is a pity that the agreement to levy a cess of two annas per acre on all gardens to meet the expenses was not "fixed up" a little earlier, but better late than never. It is a good sign that the representatives of the Indian industry are waking up all round.

NEW MARKET'S TEA FUND.—Promises of support to the fund which is now being raised are coming in, and the majority of the leading companies here have expressed their willingness to support this laudable attempt at self-help tentatively for the next three years. We would urge that those who have not yet sent in their adhesion should do so with as little delay as possible, otherwise this well-directed effort may fall to the ground. Various proposals, we hear, are being made in different quarters to the members of the committee appointed to administer this fund in regard to operating in new markets, and much difference of opinion exists as to the lines this committee should follow. The natural course would be to aid persons already acquainted with the working of the tea trade in different countries, but it is felt that this would look like using the fund for the benefit of private traders and in consequence the more general desire is that the money should be devoted to sending commissioners with the object of furthering the propaganda in the different countries. This might undoubtedly succeed if the very best men were forthcoming, whose personal interests were bound up in tea planting. We confess, however, that we have grave doubts as to any scheme being successful which does not make use of and exploit the knowledge which is only to be found among traders whose personal interests could be associated with the enterprise, and to whom subvention would be given almost unconditionally to enable them to stand the heavy expenses which must be incurred in making a start in a new country and with a new article. Expressions of opinion from our readers would, we think, be welcome, and we invite correspondence on the subject. The time is very opportune to push consumption, both on the Continent and in America and elsewhere. Any supineness which may now be shown will be the subject of grave regret later on, when production again largely exceeds consumption, as it will almost of necessity under the present conditions.

THE TEA TRADE OF CHINA.—From a summary of the official statement by the Imperial Maritime Customs of China concerning the trade of the Celestial Empire last year it is clear that the planters in India and Ceylon have still some work before them in Europe. The exports of tea of all kinds from China amounted to 1,750,034 piculs, or 1,070,513 cwts. showing an advance of 84,638 piculs, or 100,759 cwts. over the total for 1890. Russia appears to be the only large market in Europe where the demand for China black tea is maintained. Supplies continue to be sent by sea in increasing quantities, shipments having risen from 93,467 piculs, or 111,270 cwts., in 1887, to 1,49,025 piculs, or 225,029 cwts., which is double the quantity; and while the consignments by sea and land to Russia in 1887 aggregated 267,000 piculs, or 317,857 cwts., they now amount to 287,000 piculs, or 341,666 cwts. The demand for China tea (chiefly green from India has doubled within last five years. There are

two facts worth noting—viz., that Russia is the only market that remains faithful to China, and that the demand for green tea for India has doubled of late, which is not at all to the credit of India, seeing that the out-put of tea from India and Ceylon is now close upon 200,000,000 lb. annually, and that tea is grown all round her borders. The Indian Tea Supply Company that started some years since to supply the natives of India with tea should have been able to absorb most of this foreign trade between China and India, as they certainly were in a position to offer a better article.

TEA IN FRANCE.—As the funds of the small company, lately started to work this business, are now limited, an invitation has been sent to several of the companies, and more especially those who had not supported the enterprise by money, to contribute descriptions of tea to be prepared specially and sent direct to France from Calcutta. This invitation, we are glad to learn, has been responded to from several quarters, and shipments of from ten to twenty chests promised. This will greatly help the enterprise, and it is to be hoped that the good example set by a few will before long be followed by other companies.—*H. and C. Mail*, May 27.

KITOOI FIBRE.

We again draw attention to this fibre in the hope that its production may be stimulated in Southern India, as we notice that there are brush-making companies springing up in the East. At Cawnpore, a new company, the "Cawnpore Brush Company," has been started, and this company has been employing hog bristles up to the present, but now has demanded Kitool fibre from Colombo. Messrs. P. Thompson & Co., of Coonoor, are also actively engaged in brush-making, and they also get their fibre from Colombo, though the fibre is produced in their immediate vicinity; in fact, the *Caryota Urens* grows luxuriantly on the Coonoor Ghat itself, but it appears that there is no steady effort to extract the fibre economically. Under orders from the Board of Revenue, Madras, the Collectors of Vizagapatam and Malabar report the existence in quantities of this fibre-bearing palm, but also report that the fibre cannot be extracted at less than 1 rupee per lb. This should not be so, as the first quality of Kitool fibre is sold in Colombo at R45 per cwt., and the samples obtained were not nearly equal to No. 1 Kitool of Colombo. The tree exists in abundance nearly everywhere in Southern India. Dr. Watt, in his Dictionary of Economic Products of India, thus reports upon the "habitat" of the *Caryota Urens*:—"A beautiful palm with smooth annulated stem, met with in the forests of the western and eastern moist zones. On the Western Ghats it extends to near Mahabaleswar. In the settlement report of the Ohanda district it is stated that this palm abounds in the Southern-Eastern corner of Aherce and might, with advantage, be extended to all parts of the district, for it thrives well wherever it is planted. It is common in Burma, Bengal and Orissa, ascending in Sikkim to 5,000 feet." In Orissa, according to Dr. Watt, Kitool fibre is known under the name of "Salopa," and under this nomenclature it was exhibited at the Colonial Exhibition 1886-87; samples of the fibre were sent from Orissa, Burma and Colaba in Bombay. Dr. Watt gives some facts regarding the employment of the fibre by corset-makers, and goes on to say, "these facts are alluded to in the hope of awakening an interest in an Indian fibre that has been much neglected." "For many years past Ceylon has done a by no means inconsiderable trade in Kitool fibre, but no person seems to have thought of India as a possible source of supply," and it now appears that the attempt to supply it from India was checked by a very easily to be understood error.

Dr. Watt states that a Mr. A. Rowbottom was the first to introduce Kitool fibre to European commerce, and that gentleman is reported to have stated that Indian Kitool is inferior to the Ceylon fibre. But at

the Colonial Exhibition of 1886, Mr. Rowbottom pointed out to Dr. Watt a sample of Ejooc fibre from the *Arenga Saccharifera* or the sago palm* as being the Kitool he had formerly seen as sent from India, and admitted that the sample of salopa (Kitool) shown him at the Exhibition was as good as any he had ever seen from Ceylon, and he seemed confident that a large trade could be done in the Indian fibre. Here, it appears, a very simple mistake of the fibre of the *Arenga Saccharifera* or true sago palm for that of *Caryota Urens* or bastard sago palm has been the means of putting in the background an industry that might add greatly to the prosperity of India, and the error made is the more extraordinary in that the true sago palm is by no means common in India it is only found wild in Manipur; while, as before said, the bastard sago palm, the *Caryota Urens*, the producer of the true Kitool fibre, is common all over the southern and western portions of India, in Bengal and in Burma, and it only requires to be exploited to be a great success. Such endeavours as have already been made seem to have been only half-hearted and made in a doubtful kind of way, as energy was damped by the idea that the Indian fibre was not as good as the Ceylon; this idea has found expression in several places, and has checked the energy of those who would probably have tried to produce it if they had known that the Indian product is quite as good as the Ceylon; but something must also be done to decrease the cost price in India.

We have already compared the price in Ceylon with the rates quoted by the Collectors of Vizagapatam and Malabar; as the tree grows wild in both these districts, the cost of the fibre can only be the cost of collection, and R1 per lb. for this appears absurdly high. Balfour, in his article on *Caryota Urens* states that the fibre is made by forest tribes in Ceylon. Surely there are forest people enough both in Malabar and Orissa, to whom the extraction of the fibre at something like paying rates should represent "wealth beyond the dreams of avarice." It is very probable that the Collector's reports on prices were based upon reports of persons who were specially engaged to collect the fibre, and had no skill in the matter, but who saw their way to make "a little bay while the sun shone." There is not the least doubt that if proper efforts are made, the fibre can be produced in India quite as cheap as in Ceylon, and it should be even cheaper, as manual labour in South India is much cheaper than in Ceylon, and manual labour alone is required for the production of this fibre. Now that a local field for its consumption is rapidly opening, we trust that some attention may be given to it. The Cawnpore brush factory finds that it is much preferred by Sowars of native Cavalry for horse brushes for obvious reasons, and the Regiments of the Hyderabad Contingent Cavalry all now use kitool brushes for the same reason, viz., the absence of the hogbristle, so repugnant to the true believer. Under these conditions, there is a large field open to its employment.—*Madras Times*, May 31st.

[Kitool fibre became of consequence in our exports during the rule of Sir George Anderson. It is collected by the villagers around Colombo and generally brought into the town on the top of baskets of charcoal.—*Ed. T. A.*]

THE TEA IN KULU has a heavy and excellent flush; there is no cholera anywhere near the gardens, and yet the flush is in imminent danger of being lost, because the Daogri teapickers from Bara Bhagal are one and all suffering from "funk fever." They ran away *en masse* and squatted down in a forest on the top of a mountain and there they stick and won't come down.—*Madras Times*.

*The sago palm surely not? This is the name of grand sugar palm of Java, the equivalent of our "jaggery palm" or kitul, but with a different style of leaf and bearing edible fruits.—*Ed. T. A.*

AMALGAMATING SMALL BREAKS OF TEA.

Advice from London by this and previous mails informs us of a movement on foot towards obtaining the co-operation of the Customs authorities of that port in reducing the number of parcels of tea submitted for sale at the public auctions. Undoubtedly, if this result could be secured, it would go far towards lessening some of the hindrances to free competition, which are operative under the arrangements as they at present exist. One of the complaints more frequently heard from the brokers is that the number of samples which have to be tasted before the sales come on is so excessive that it is extremely difficult for this operation to be got through in time. No doubt this difficulty has been materially lessened by the concession of late obtained with respect to the granting of the extra day on which Ceylon teas have the monopoly of the salerooms. But even this concession has not proved fully adequate to the necessities of the case. What the brokers chiefly desire is that teas should be offered in larger breaks, so as to minimize the number of samples to be dealt with; and the negotiations above referred to have been entered into with that object. If there were no objection to the course indicated being followed, we should certainly say that the steps proposed were likely to secure all that is needed. But we much fear, as we have already indicated, that proprietors will see objections to these; for many estate owners would certainly view with disfavour the produce of their garden being grouped for sale with that of others by a method over which circumstances must wholly prevent them from exercising any control. For we know how naturally jealous such men are of the reputation obtained for the teas of certain estates; and this they might justifiably think must suffer from their being mixed up for sale with those of brands of a lower or possibly wholly unknown repute. This consideration alone must, we think, prevent the well-intentioned action of the tea brokers from receiving approval on this side. But there is, further, a second side to this question, one which we do not think can be easily met. According to the provisions of the Merchandise Marks Act, all articles vended must have distinguishing marks, and must be sold with a guarantee that they are what those marks represent them to be. On no point more than on this have the London Customs authorities been more insistent; and we think we can see that, if the strict rules in this respect hitherto insisted upon are to be relaxed, the door must necessarily be opened to a good deal of systematic attempts at fraudulent representation, a matter it must be most important, if the reputation of Ceylon tea is to be kept up, to avoid. For it must be manifestly impossible, if, say, a dozen parcels of tea bearing different marks are to be grouped together for sale, to guarantee that the distinguishing marks will be maintained distinct and separate. If this be not wholly impossible, the attempt to surmount the difficulty foreseen must at least be attended with many obstacles; and we should say that an amount of labour would be entailed which would not improbably be in excess of that attending the tasting of an excessive number of samples, and this would certainly be likely to lead to confusion among the marks and consequent dissatisfaction to our planters. Naturally the brokers regard this subject mainly, if not entirely, from their own point of view. A reduction in the number of breaks to be dealt with would greatly simplify and reduce this work; and it can therefore be readily understood why the negotiations referred to have been initiated by them. But we

confess that it would seem to us that they would scarcely be justified in acting upon any concession in the direction sought which may be yielded by the Customs authorities without first consulting the wishes of their clients, the planters and merchants of this island, who would doubtless see reason to object to amalgamation of their teas with others unknown to them and under conditions removed entirely from their own control and decision. At the same time that we discuss these objections to the course proposed, we think that it must be evident that the alternative must rest largely with our local producers. At present these seem to regard lightly the despatch of a great number of small breaks; and it is certain that their doing so considerably hampers operations on the home side. It may be difficult always entirely to avoid the shipment of small parcels; but surely this might be effected much more frequently than it now is. Possibly, if the present system be indefinitely continued, it will be impossible for the brokers to avoid recourse to some measure of the nature we have indicated; and in that case our planters and shippers, after the repeated warnings they have received, will have no one to blame but themselves if the disagreeableness we have mentioned as on likely to follow the arrangements under negotiation result. It is manifestly time that some endeavour should be made on this side to avoid shipment until sufficiently large breaks can be accumulated for despatch.

QUEENSLAND SUGAR ESTATES AND TROPIC LABOUR.—The present produce of sugar in Queensland is about 60,000 tons per annum, but there is no reason, the *Australian Trading World* considers, why it should not increase year by year until it is 600,000 or a million tons or more. The district suitable for the cultivation of sugar, rice, and other tropical produce is, that journal says, of vast extent. Capital is readily forthcoming for the industry, there are no burdensome taxes upon the land, rent, even if taken at a good rate of interest on the first cost of the land, is almost inappreciable, there is but one difficulty, and that is—labour. Working under a tropical sun is not a white man's work.—*P. M. Gazette*.

WE have now entered upon the last quarter of the coffee crop year of 1891-92 and the persistency, with which exchange rules around 12d is disquieting. The exports of coffee from Rio and Santos during the past nine months have been large, and that the gold value of these exports has been absorbed without the slightest improvement in the exchange value of the Brazilian currency is a fact that invites study and investigation. The wild financiering of the provisional government, and the lunacy that attacked a part of the population of Rio in 1890 and 1891 unsettled confidence and no doubt led to a withdrawal of foreigners' money that had been invested here, but this drain, alone, cannot explain the fact that the gold equivalent of nearly 6,000,000 bags of coffee has disappeared, and one *milreis* is now worth less in gold than it represented nine months ago. What has become of the eighteen millions of pounds sterling that the coffee shipments of Rio and Santos represents? No one appears to know, and no one appears to care. The general answer to the question for an explanation of a drop in the gold value of the *milreis*, is "want of confidence." But it is difficult to obtain an explanation as to whether the "confidence" is lacking in respect of the government, or to the financial position, or both.—*Rio News*, April 5.

COLOUR IN PLANT LIFE.

Those familiar with the growth of flowers know how essential light is to the creation of colour. The most gaudy blooms and the most brilliant foliage if kept in the dark or over-shaded will become pale and almost white. This fact (according to the *Horticultural Times*) shows the presence in the plant of some chemical agent which is acted upon by the actinic rays. To some extent this chemistry of nature is understood by florists, who, by the use of chemical manures and other means, strive to take the greatest advantage of it. For instance, it is a common practice to mix alum and iron filings with the soil in which certain plants are grown in order to bring out special colours. The bluish-tinted hydrangea is the result of such treatment. Salts of iron, or sodium phosphate, added to the soil turn the crimson of the pæony to violet, and produces blue hortensias. According to Dr. Hansen, who has studied the subject very closely for many years, there are only three distinct pigments to be found in flowers—setting aside the chlorophyll, which forms the green colouring matter in all plants. These colours are yellows, reds, and blues. The yellows are mostly in combination with the plasmic sap, while the others exist chiefly in solution in the cell sap. The yellow pigments form an insoluble compound with fatty matters, and is termed lipochrome. Orange is formed by a denser deposit of the yellow, and the colour in the rind of an orange is identical with that found in many flowers. The red in flowers is a single pigment soluble in water, and decolorised by alcohol; but capable of being restored by the addition of acids. Lipochrome combined with this red pigment produces the scarlets and reds of poppies and of the hips of hawthorns; but the varying intensity of reds in roses, carnations, pæonies and other flowers depends on the presence of a greater or lesser quantity of acids. The blue and violet colours are also decolorised by alcohol, but reddened by acids. Florists have already succeeded in producing a very large scale of unusual colours in flowers, and there seems to be very good grounds for believing that it is possible so as to manipulate nature that she will produce blossoms of every conceivable tint and hue.—*Chemical Trade Journal*.

BARK AND DRUG REPORT.

(From the *Chemist and Druggist*.)

LONDON, May 26.

ANNATTO.—Dull seeds from Colombo sold at 1½d per lb. today.

ARECA-NUTS.—The recent arrival of 37 bags from Ceylon was offered for sale today. The whole parcel sold at 25s to 27s per cwt.

CINCHONA.—The following quantities are at present advertised for sale next Tuesday:—Ceylon and East Indian bark 1,760, Java bark 68, South American (Calisaya) 84, and African 139 bales; total 2,049 bales. The exports from Ceylon between January 1st and May 2nd show a trifling increase as compared with last season. They were in 1892 1,927,586 lb.; in 1891 1,804,935 lb.; in 1890 2,806,992 lb.; and in 1889 3,510,992 lb.

COCA.—Ceylon was unusually well represented at the sales today. There were 18 small bales from this island, of which 15 sold at fairly good prices—1s 1d per lb. being paid for fair bold greenish Huanoco-character leaves of good flavour, and 9d for browner and duller quality. There were altogether 570 lb. of this quality.

London, June 4.

CINCHONA.—Tuesday's bark auctions were fairly large, the catalogues being made as follows:—

	Pkgs.	Pkgs.
Ceylon cinchona ...	981 of which	862 were sold
East Indian cinchona...	1,445 do	1,302 do
Java cinchona ...	64 do	64 do
South American cinchona	121 do	44 do
West African cinchona	154 do	154 do
Total	2,765 do	2,426 do

The parcels offered were below average quality, and good lots were very scarce. Competition was extremely sluggish, and prices were hardly up to the low scale of the preceding auctions; the unit, in fact, cannot be placed above 1-16ths d. to 1½d per lb.

The following are the approximate quantities purchased by the principal buyers:—

Agents for the Auerbach factory ...	197,745
Agents for the Mannheim and Amsterdams factories	139,354
Agents for the Frankfurt o/M. and Stuttgart factories	95,986
Agents for the Brunswick works	38,696
Messrs. Howards & Sons	36,018
Agents for the American and Italian works	31,338
Sundry druggists	37,802
Total quantity of bark sold	576,939
Bought in or withdrawn	73,105
Total quantity offered	650,044

DIBRUGARH TO THE DUARS.

Travel, some wise man once remarked, is a liberal education. This idea is more widely accepted by the planter now-a-days that it used to be; and it is as rare now, as it used to be common, to come across a man "in tea" whose knowledge of the wily ways of the planter with the tea leaf, from the time he plucks it from its parent stem till he packs it in a lead-lined chest is confined to the usages and customs of his own particular district. Taking the Assamese as the species with whom I am perhaps most familiar, you find most of them have had a trip to Darjeeling; a good many who have put in some time on Cachar *teelas* or Sylhet *bheels*; and not a few who have had a run round the Duars, or who speak from personal observation or experience of the way they do things in that island where, according to Bishop Heber, "the spicy breezes" blow soft, and where, to continue the quotation, "every prospect pleases, and only man is vile." Good old Heber! you didn't mean to include the planter in your sweeping assertion about the villainy of man; but if your "shade" had been in a position to sum up the average opinion of the Indian planter during the last few years, since Ceylon started flooding the market with an utterly unnecessary number of millions of pounds of tea, thereby sending prices down by leaps and bounds; while at the same time, by smartness in advertising, and by a unity of action unattainable somehow by Mr. "Lo, the poor Indian" (Copper this time, I think—not Heber) it managed to make some startling big figures in its own prices, for small fancy lots; you would have been surprised to find what a prophetic vision you were gifted with! Ceylon has been a *bête noire* to the Indian planter any time the last half-dozen years; but time brings round its revenges; and we are beginning to "chortle" over the fact that the place that makes thirty-guinea tea, can also make three-penny tea; and is likely to do a good deal more of the latter than the former.

The value of varied experience does not always come out at once. We live and learn; and a good deal we learn in one district has to be unlearned again in another. Circumstances alter cases, which is trite, but true. I knew a man who went to the Terai after a successful career of some years in Assam and who started to work his Terai garden on Assam principles, and talked very big about the reformation in tea he was going to introduce. But soil, climate and labour were essentially different, and that man wasn't a success. Indeed, until a couple of years' experience of his new surroundings brought wisdom, he was a distinct failure. But, nevertheless, there are wrinkles to be picked up in every district that will bear transporting to others; and the wise man who travels is electric, and can select and assimilate a dodge here and a wrinkle there which, slightly modified perhaps to suit particular circumstances, will place him miles ahead of the stay-at-home semi-fossilized individual who works in one groove, and never gets a new idea.

A trip on the Brahmaputra is a very different thing now to what it used to be some half dozen years ago. The daily mail-boats, barring occasional accidents due to fogs or sandbanks, run almost as regularly as trains; and you can ride down to your own particular *ghat* a little before advertised time, and calculate with almost absolute certainty on catching a steamer without much delay; and you can be sure

of arriving at your destination within an hour or so of when you expect to. The very worst that can possibly happen to you is, in the case of a really bad "grounding," twenty-four hours delay, till the next day's boat comes, and either hauls you off, or takes you and the mails along. Considering what an uncertain, constantly changing sort of river the Brahmaputra is, this very rarely happens. It did in my case coming down; but then I always was an unlucky sort of man. We stuck hard and fast in a narrow channel leaving Silghat and spent a solid night and day laying out anchors at absurd angles, and steaming hard on a sandbank, with the helm hard over the wrong way. With my usual luck I was the only passenger, so I put in the time helping the *Serang* with my spare stock of profanity, and other general assistance, till the next day's mail-boat came and hauled us off. She then went straight away in the most heartless manner, leaving us to hawl in fathoms on fathoms of sundry chains and hawsers, and pick up various anchors; so it was rather good fun when we overtook her, a few hours later, hard and fast herself in her turn; hauled her off, and went on our way rejoicing, leaving her to pick up her *disjecta membra*. The Assam mail boat now-a-days is a fairly comfortable steamer; they give you very decent food on the whole; and, considering the fogs and other difficulties of the river in the cold weather, and the necessity for a good deal of night running to make up for lost time, the *Serangs* get on wonderfully well. But when you do ground badly—or get into serious trouble;—well they mostly want a new breed of *Serang*—with "heads."

As a contrast to the way the Assam *Serangs* get into a *ghat*; bumping head first into the bank (lucky they are soft mud) or jarring roughly up against the receiving flat, after ten minutes of "back her easy," "stop her," "easy ahead," it is a treat to see the way the Damukdia-Sara steamer, crossing the Ganges en route to the Duars, is gently laid alongside the receiving flat,—gangway to gangway to an inch almost,—the hinged platform of the flat (a sort of drawbridge in its way) dropping into its place on the steamer without a hitch. But then the "skippers," have a lot of practice over one small reach of river backwards and forwards several times a day; and must get to know the strength of the current, the exact amount of "easy ahead" required, and how many turns of the helm over to starboard are necessary to lay the steamer neatly in her place, pretty accurately.

It is a wonderful change from the sweltering heat of Calcutta in April, to wake up in the N.-B. R. carriage somewhere below Julpaiguri and feel the cool fresh morning air. One seems for the moment to have got into a new world. And yet it can be pretty hot in the Duars, too. An afternoon or two—still, sultry, and yet steamy after recent heavy rains—in one of those marvellous corrugated iron, semi-cylindrically roofed erections that a mad Manager and a fit of temporary insanity on the part of the Agents have inflicted on one or two gardens in the district in lieu of hungalows, gives one quite a realistic foretaste of the climate of the hereafter, as arranged for unregenerate outsiders by the "unco'-guid." The man who expects his Manager to reside in a corrugated iron hungalow—walls as well as roof, mind you—through April and May, should be given the proverbial bushel of brimstone and box of matches to enable him to start a little place of his own, and grasp the situation generally. But "every sorrow has its twin joy." (This remark does not apply to corrugated iron hungalows.) The steamy heat—the astounding alternations of four and five inch showers of rain in a couple of hours with blazes of sun sufficiently strong to blister a brick,—though extremely unpleasant and trying to the human exotic, are "just gran' weather for tea;" and the ten and even twelve maunds per acre one hears of here and there are due, no doubt, to the forcing of these alternations of rain and sun.

It is aggravating to a man who has an interest in an Assam garden which makes a steady loss year after year, to hear one's Duars friends casually mentioning 20, 25 and even 40 per cent. profit as the result of the season's working. I was carefully brought up, and always understood it was considered

rnde to call your host a liar at his own table; so I was restrained by etiquette from giving vent to my first impressions on hearing these astounding statements. Afterwards I was glad I restrained my first impulses. I might have hurt my friend's feelings;—and,—he was a bigger man than I am a good deal,—he might have hurt me. Besides, what he said was perfectly true. The share lists in the daily papers bore out the statements, not to mention published reports and accounts shown. "Nedem" is quoted 20 per cent. *ad interim*; and there are other concerns, not quoted, that have done even better. I was told that "Matelli" paid 40 per cent. last year. And yet people say "tea doesn't pay." Somehow, I fancy it is a trifle better than the average modern gold mine. I say *modern* gold mine advisedly. The ancient gold mine—the kind that was alluded to when comparing any really lucrative business or investment to "a regular gold mine," was quite another affair altogether. You can buy modern (Bengal) gold mines just now wholesale, at so many for the rupee. Of course, it is not every Duars garden that pays 20 per cent. Some of them don't pay at all, and might as well belong to one of the good old well established Assam concerns that go on sinking shareholders' money, and scoring "nil" up against their names in the dividend column year after year, with a persistence worthy of a better cause. Take it all round, though, one gets a little startled at first at 25 and 40 per cent., I fancy that profits on tea are pretty evenly divided amongst the districts. I am just visiting a garden in Sylhet that paid 25 per cent last year, and carried a good sum forward besides. A few gardens here and there pay exceptionally well: a good many pay very fair interest on the money invested; from three to ten per cent, say; and the rest don't pay at all,—and never will. The sooner a lot of this class are shut up, the better. They uselessly drain the pockets of their unfortunate shareholders, and increase production without a hope of profit from their sales. Gardens that cannot make more than three to four maunds an acre cannot produce their crop cheap enough to face the markets of the present and the future, however well they may have done in the past.—*Indian Planters' Gazette*.

PALM HONEY.—A curious industry of Chili is that of the manufacture of palm honey, of which there exists a centre of production in the hacienda known as "Palmas de Ocoa." The improvement in the methods of extraction has increased the annual production to about 100,000 piastres. In one of the warehouses of the Palmas de Ocoa establishment there are at present 200,000 tins containing about 200,000 litres of honey. The residue of the palm remaining after the extraction of the honey is sold to a packing paper factory, and the idea has been entertained of establishing a factory for hats made from the palm fibre which is never used, but from which the best profit possible is drawn.—*Indian Agriculturist*, June 11.

THE TEA GARDENS OF ASSAM.—From the most recent official returns on the subject it appears that the large tea gardens in Assam are driving out the small. Thus last year, some forty-three gardens were struck off the register in Kamrup as either abandoned or unworked; but their total acreage was very little more than the additions the Cachar planters made to their holdings in the same period. On the whole, there was a net decrease of thirty-five gardens; but an increase of over two thousand acres in the total area under tea in the Surma and Brahmaputra valleys. Despite the complaints of the planters that the competition of Ceylon is forcing down the prices, their own operations are steadily extending and the yield last year reached the enormous total of ninety million pounds, or some eight million pounds more than in the year preceding.—*M. Mail*, June 10.

CEYLON ASSOCIATION IN LONDON.

The fourth annual meeting of this Association was held on the Board Room of the New Oriental Bank Corporation, Limited, 40 Threadneedle Street, on Monday afternoon, 30th May.

Mr. J. Whittall (Vice President) was in the chair, and the following gentlemen were also present:—The Hon. Sir Arthur H. Gordon, G.C.M.G., Sir Arthur N. Birch, K.C.M.G., Sir George W. R. Campbell, K.C.M.G., Sir Richard Cayley, Sir E. Noel Walker, K.C.M.G., the Hon. P. Ramanathan, Dr. Trimen, Messrs. James Alexander, W. Herbert Anderson, J. L. Anstruther, Alex. Brooke, R. A. Cameron, J. Capper, Walter Church, J. F. Churchill, Crabbe, L. F. Davies, Thos. Dickson, Channing Esdaile, John Ferguson, A. Folkard, W. Gow, Thomas Gray, Norman W. Grieve, Gubbins, John Hamilton, A. L. Hutchison, Jas. B. Keith (Messrs. Arbutnot, Latham & Co.), J. M. Maitland Kirwan, T. C. Owen, H. Porter, A. Ralph, Russell B. Reid, W. Rollo, H. K. Rutherford, C. J. Scott, Chas. Shand, James Sinclair, W. Bowden Smith, Wm. Somerville, A. G. Stanton, T. Stretch, Ernest Tye (Indian Tea Districts Association), Geo. White, S. J. Wilson, O. Young, and Wm. Martin Leake (Secretary).

The Secretary read the following letters:—

Colonial Office, Downing Street, 27th May 1892.

Sir,—I am desired by Lord Knutsford to say that he has received the copy of the Report of the Executive Committee which you have been good enough to send him and that his lordship observes with interest the progress which the Ceylon Association has been making.—I am, sir, your obedient servant,

(Signed) H. W. JUST.

To the Secretary to the Ceylon Association in London.

5, Knaresborough Place, Cromwell Road, S.W.,

22nd May 1892.

Lord Chelmsford regrets that absence from town will prevent his being present at the annual meeting of the Ceylon Association in London on Monday, 30th May.

Hotel Victoria, London, 25th May 1892.

The Ceylon Association in London.

Gentlemen,—I wish to express my thanks for the kind manner you have alluded to my name in your annual report. I have given the best I had to Ceylon in America, and being English in not knowing when I am whipped, I go back to fight it out if possible on some new lines that my visit here has suggested. Mr. Rutherford's proposal not going through, leaves the Company in worse shape than ever. Thanking those of you that I have had the pleasure of meeting, for your kind and courteous reception, I am, yours most cordially,

(Signed) S. ELWOOD MAY.

Indian Tea Districts Association, 14 St. Mary Axe, London, 24th May 1892.

Dear Mr. Leake,—Thank you very much for sending me a copy of your Annual Report which is interesting to read. I think perhaps it would be more accurate to say that the Palais Indien Tea Houses, Limited, has been hitherto worked "in the interest of *Indian Tea*," instead of in the interest of this Association—as the Association itself was not so much concerned in the success of the enterprise as those members who joined the guarantee fund. It is however a small point—and not perhaps worth writing about.—Yours very truly, (Signed) ERNEST TYE, Secretary.

The CHAIRMAN rose and said:—The duty devolves upon me to take the chair on this occasion, owing to the death of our late lamented President, the Right Hon. Sir William Gregory. It is a loss to the Association which we must all deeply deplore, for if he was not the founder of the Association he was with us and of us from its first inception. At all times he was ready to assist us with his valuable

advice, and rendering us such services as few others could give from his long connection with Ceylon—not only as the Governor of the island, but also as one personally interested in its planting resources. Ceylon has indeed lost a true friend in every sense of the word in Sir William Gregory, and many of us a good friend. (Hear, hear.) A resolution will be brought before you later which I am sure will meet with your approval and warm sympathy. It is also my sad duty to notice the loss of many other friends; not only interested in Ceylon, but also members of our Association. We have to mourn the death of Sir James Longden, of Sir John Cooze, of Sir J. F. Dickson, and last, but not least, of Mr. David Reid. But, gentlemen, I have also to announce to you with a great deal of satisfaction that the Hon. Sir Arthur H. Gordon has kindly consented to be our Chairman. (Cheers.) You know already what he has done for the Association. (Cheers.) You know the interest that he takes in all matters connected with Ceylon, apart from his other great abilities. I am sure, therefore, that you will accept his offer and elect him with acclamation. Before proceeding with the business of the meeting, therefore, I will at once propose that Sir Arthur H. Gordon be our President for the coming year. (Cheers.)

Mr. THOMAS DICKSON seconded the motion. Sir Arthur Gordon had attended the meetings of the Association, and had given it his utmost assistance. (Cheers.) He was sure that Sir Arthur Gordon would be able to fill the position of President with that ability which they required after the loss of Sir William Gregory.

The motion was carried unanimously.

The Hon. Sir ARTHUR H. GORDON then took the chair. He said:—Gentlemen—I have in the first place to thank you very sincerely for the honour you have done me in electing me as President of this Association—an honour which, notwithstanding what my kind friend on my left (Mr. Whittall) has said, I was far from offering to accept, and which I have not accepted without some hesitation and some reluctance. The Association is in possession of such admirable officers, of such a Vice-President and Secretary, as to render the duties of its President comparatively light. Yet even with that assistance, the post of President of such an Association is not otherwise than an onerous one. And though that be the case at any time, it is more than ever and especially the case when one is called upon to succeed such a man as he whose chair I am sorry to be called on to fill. I will not say more just now about our late President; what I shall have to say about him comes after, when we have to discuss the motion which has been put into my hands. All I will say at this moment is this: that if I cannot equal him—and I cannot in many respects—in readiness of speech; if I cannot equal him in graciousness and agreeableness of manner, there is at least one point in which I will not yield even to the memory of Sir William Gregory, or to any other man; and that is in regard to my determination to discharge conscientiously and faithfully and energetically the duties of the post which you have thrown upon me. (Loud cheers.) Our Association is as yet a young one; it has not attained that strength and those powers which it may acquire, and which I hope it will acquire if its life be prolonged. (Hear, hear.) It is perhaps hardly conscious of the powers which it possesses. Such an Association as this, when it speaks with anything like unity or unanimity, speaks with great authority and cannot but carry the very greatest weight with it properly handled, properly conducted, our opinions deliberately and firmly expressed will, I am sure, carry with them a very great force. They will

be listened to respectfully at the Colonial Office, and they have every prospect of going far among the considerations which determine any decision which may be made. (Hear, hear.) It will be my duty, my care, to maintain the influence which the Association already possesses, and to strengthen it as far as possible, and to promote, by every means in my power, the unity and harmony of our deliberations. Now in the ordinary course of things I should move the adoption of our annual report, and should give you something of a sketch of the proceedings during the past year, and of the course to be adopted in the coming year; but considering that I have not occupied the chair for more than five minutes—(laughter)—I think that it would be more satisfactory to you generally, as to myself, that that duty should be discharged by our Vice-President, who has kindly undertaken it? But while he was undertaken to move the resolution submitting to our approval the annual report of the executive committee, the report has one clause which I cannot allow to pass out of my hands. It is that which expresses our sense of the loss we have sustained in the death of Sir William Gregory. I do not think many words can be required to recommend that resolution to you. All, or almost all, here knew Sir William Gregory, and all who knew him regret his loss. (Hear, hear.) Nor need I dwell at any length now on his career. With his life as a member of the House of Commons, with his position as an art critic and a connoisseur, we have here no concern. Neither have we any concern with the position which he occupied with London Society. But there are ways in which we were specially concerned. Sir William Gregory was bound to us as being a Governor of Ceylon—the one Governor of Ceylon, I believe—who, after he had left that island, never allowed his interest in it to slacken or grow cold, and who, alone among all previous Governors, revisited the island he had once governed no less than three times after he ceased to influence its destinies. (Cheers.) Still more is he connected with this Association as its first Chairman, and as a Chairman he was unrivalled. (Hear, hear.) It was a position in which he was specially happy. He was gifted with great tact: he knew how to be consulted. He brought business on, and generally brought it to a successful issue. And yet where circumstances made it necessary, he could be stoutly firm. Most of those in this room have known him as a personal friend, and to those who have known him as a personal friend I need say no more, because they know all that I know and they would say all that I can say. The cordiality of his kindness—that is the only thing I will add—was thoroughly real. It was not only a charm of manner, but it showed kindness of heart. (Cheers.) I had a letter from him written only a few days before his death, on the very night on which that seizure came to him. He was then aware that he was in a very critical condition. He was thinking of starting the next day for Marseilles on his way to Algiers, but he was perfectly aware that it was probable that he would never return from Algiers, and he said so in his letter. And in the prospect of his death he asked me to take charge of various little matters in which he took an interest. Now every one of those was about some little act of kindness to somebody in connection with Ceylon. Some would call them trifles which he might have been excused for forgetting, or disregarding in such circumstances. It touched me very much, and I think it worth repeating. (Hear, hear.) To you, gentlemen, and to others connected with

Ceylon were his last thoughts turned. (Cheers.) But if his loss is grievous to us as an Association, what must it be to the widow he has left and to the boy he has left without a father just when he is going out into life? I will now merely read the resolution which has been put into my hand:—“That this Association deeply deplores the death of its late President, the Right Hon. Sir William H. Gregory, K.C.M.G., and desires to record its grateful sense not only of the services rendered by him to the Association, and to the tact and judgment displayed by him as its head, but also of the lively and unflinching interest felt by him in all matters connected with the well-being and progress of Ceylon, as well as of the genial courtesy and unfeigned kindness shown by him to all who came from thence. Nor can the Association refrain from bearing its testimony to the ability and success with which he conducted the affairs of the Island as its Governor and contributed to the development of its resources at an important period of its history.”

Sir ARTHUR N. BIRCH, K.C.M.G., in seconding the resolution, spoke of his long connection with Sir William Gregory, and of the great esteem and almost affection inspired by him. Sir William had always thrown his heart into his work; he loved Ceylon and the people of Ceylon. His work was always done thoroughly. (Hear, hear.) When he resigned his Governorship of Ceylon he did not resign his esteem for the island. Persons of every class and of every creed had always a welcome at St. George's Place. To the last moment of his life he was thinking of Ceylon. They all mourned him as a lost friend, for it was as a friend that they had regarded him in his life. (Hear, hear.)

The resolution was carried unanimously.

Sir A. H. GORDON then moved:—“That a copy of the foregoing resolution be transmitted to Lady Gregory, together with an expression of the sincere sympathy felt for her by the Association in her present bereavement.”

Sir GEORGE W. R. CAMPBELL, K.C.M.G., seconded the resolution, which was also carried unanimously.

Mr. J. WHITTALL, in moving the adoption of the report, said:—“We have embodied the labours of the year in this report. The past speaks for itself, and in the future we have the assurance in our President that he will only add to the success of the Association. (Cheers.) I am glad to say that our numbers are increasing, and, I hope, also our usefulness and influence. And, what is still more satisfactory, our labours have been appreciated by our friends on the other side; not only by the Planters' Association, but by the other public bodies of Ceylon. To our Executive and Tea Committees we have to tender thanks for their regular attendance, and for the eager way in which they have tried to promote the success of the Association. (Hear, hear.) I do not think it is necessary for me to add anything more, and, if you have no questions to ask, I will propose that the reports and the statement of accounts be accepted.”

Sir RICHARD CAYLEY seconded the motion.

Mr. H. K. RUTHERFORD said as one of the Executive he was afraid that the Committee would have a blank report to make to the members at the end of the year, and that they were likely to be in the happy position of the country that had no history. (Laughter.) He had anticipated that Mr. Whittall would have said something as to the Military Contribution, as this was really the only matter of importance in the report. This protest was drawn up by Sir Arthur Gordon, and he desired to tender the thanks of the Executive and the members of the Association for the very able manner in which this work had been done by their new Chairman. (Cheers.) The report of the Tea

Committee spoke for itself, as it was plain, to the point, and very practical, and showed that good and useful work had been done. The entrance of Mr. James Sinclair into the room reminded him how this Association came to be formed. At the time of the agitation for the Haputale Railway he was driving in Dimbula with Mr. Sinclair, who observed that to push matters on Ceylon ought to be represented in some way in London, so that the home Government might feel the weight of the arguments of an authorized body in England. It was arranged between him and Mr. Sinclair to bring the matter before the Planters' Association at its next meeting. When the time came Mr. Sinclair's modesty got the better of him, and the duty devolved on him (the speaker) both of proposing and seconding the resolution. (Laughter.) However, from this the Ceylon Association in London was started, and he thought it only right they should know that they owed a debt of gratitude to Mr. Sinclair for the inception of that institution. (Cheers.)

Mr. J. FERGUSON said:—Sir Arthur Gordon and gentlemen,—I have been requested to say a few words on the report in order to emphasize if possible that portion of the Tea Committee's remarks referring to the work done by Mr. Elwood May in America. But first I would like with your permission to give expression to what I think is the general satisfaction felt with the tenor of your report on this occasion. Not only in respect of military expenditure, but in regard to other controverted as well as practical subjects, the Executive and Tea Committees have dealt in accordance with sound sense, discretion and impartiality. (Hear, hear.) Then, in respect to the high testimony borne in the report, by our Chairman and other speakers, to the memory of Sir William Gregory, I should like to add a few words. I may say that when he came to Ceylon, there was some doubt as to whether Sir William, then Mr. Gregory, would prove a success. He had no previous colonial experience; he was well on in middle life, and he was following one of the ablest colonial Governors in Sir Hercules Robinson. (Hear, hear.) But we very soon found that we had got no mere *dilettante* or orator but a really able, hard-working administrator who brought with him moreover a freer atmosphere, broader views, and a more genial spirit than we had been accustomed to in a Crown Colony. He was many-sided too; for while his revival of the North-Central Province, large expenditure in irrigation works and education showed the prominence he gave to native interests no less did the Colombo Museum, Harbour Works and Railway Extension indicate his appreciation of the need of modern improvement. (Hear, hear.) His connection with Ceylon continued to be unique to the last, not only through his revisiting the island again and again after he had retired, but through his investment, as a private gentleman, of capital in the development of its industries. To the very end of Sir William Gregory's life, his thoughts were given to our colony, its people and their best interests, and I believe no place was more deeply written in his heart than that which he had governed so well and loved so well. Now as to Ceylon tea in America I have for myself, and I am sure many more in and out of this room, to express our high sense of the good work done by Mr. Elwood May and his American-Ceylon Company in promoting a taste and demand for Ceylon across the Atlantic. (Hear, hear.) I have not met Mr. May in private, nor had any personal communication with him; but twice I have heard him speak in your Association Rooms, and on both occasions I have been struck

by the great commonsense, moderation, as well as earnestness of his remarks and the clear apprehension which he seemed to have formed of the great task before him. Of course, if the United States is to be captured for Ceylon tea, there must be a vast amount of advertising, and very loud advertising too, to attract the attention of the people; but Mr. May showed us how it was his object all along to avoid anything like "boom-ing" for mere temporary purposes—how he had refrained from securing applause, as no doubt he might have done here and in Ceylon, by placing a million or more pounds of our tea among the dealers all over the States, before the people were ready to buy it or any demand had been created. How rather it was his object, dealing as he felt convinced with a good article to build up the trade slowly but surely on a real substantial foundation. (Hear, hear.) I was sorry, however to learn that the return for all the labour, time and thought he—a gentleman of independent position and means—had given to this object, had been so discouraging as to cause him to speak of withdrawing unless he found that those more immediately concerned in Ceylon and England were ready to co-operate more freely. I am very sorry now that the scheme proposed by Mr. Rutherford, as already referred to, did not meet with a response in Ceylon. I do hope something may be done out there to prevent any chance of the collapse of the Company on the withdrawal of Mr. May. His letter read today is, I am glad to see, more hopeful. I can with the fullest confidence speak of the great value of the advertising work he has done, through leading American papers, for I have had letters from personal friends among the journalists, referring to the advertising contracts. Moreover it is certain that Mr. May's work has already borne good fruit in the interests of our planters. The increased consumption of tea shows this, and I have had placed in my hands since entering this room some figures prepared by Messrs. Gow, Wilson & Stanton, which serve to show the encouraging increase in the consumption of Ceylon and India—but especially Ceylon—tea in the two years that Mr. May and his Company have been chiefly at work. Here they are:—
Tea exports to the United States and Canada from 1st January to 30th April.

	1890.	1892.
	lb.	lb.
Ceylon ..	166,680	433,871
Indian ..	450,984	518,881
Total ...	616,664	952,752

An increase of 160 per cent in the consumption of Ceylon tea in two years is surely very notable. (Applause.) Nor is the increase in Indian tea to be despised; for in this matter (both countries are really fighting China and Japan, and considering the importance of America as compared with any other tea-consuming countries outside the United Kingdom, I hope the Ceylon Tea Fund Committee will see their way to co-operate with Mr. May and the American-Ceylon Company in the important work of still further placing Ceylon tea before the American people. (Hear, hear, and applause.)

SIR GEORGE W. R. CAMPBELL, K.C.M.G., said:—I am interested in tea to a considerable extent myself, and I saw a great deal of Mr. Elwood May on his late visit. He was recommended to me as a man of great business ability and social standing in New York. It was also on excellent authority made clear to me that he has made most unprecedented efforts to push Ceylon tea in America, and that he is suc-

ceeding to a very great extent. He has spent between two and three million dollars in advertisement. Everyone here will have noticed from the tone of the letter which has been read that Mr. May is not particularly pleased—that he does not think he has received sufficient support from Ceylon men. And he is not alone in thinking that (Hear hear.) Several leading Ceylon men have said to me that they think he has not been sufficiently well-treated in the Chicago business (Hear, hear.) If he and our Commissioner could pull together all would be well. The funds at the Commissioner's disposal are small, and they alone will not bring Ceylon forward in America; but if Mr. May and our Commissioner are ready to be both pulling together we may most effectually get the thin end of a very large trade into America. (Cheers.) I do not know that Ceylon can afford any more money than has already been put at the disposal of the Commissioner. But I think if we back up Mr. May a little more, and strengthen his hands a little more, it may have the best effect. (Cheers.)

The CHAIRMAN:—Will my friend Sir George Campbell offer any suggestion as to how we can strengthen Mr. May's position?

Mr. W. M. LEAKE said:—I have seen a great deal of Mr. May while he was in London recently, and I quite agree in the opinion of the previous speakers as to his ability and as to the probable value to Ceylon of all he has done in the way of pushing Ceylon tea in America. But it seems to me that the real difficulty at the present time lies in relations between Mr. May and our Chicago Commissioner. It is no use blinking the fact that for some reason—I know not what—these gentlemen are not working cordially together. Everybody is talking about the matter, and it is impossible to discuss it to any good purpose unless the true position is recognized. (Hear, hear.) If Sir George Campbell could propose some effective method of bringing Mr. May and the Commissioner into cordial co-operation, all would be well. I hope I have not been too bold in speaking thus openly of the state of affairs.

Sir GEORGE CAMPBELL, in reply to the Chairman, said:—Mr. May himself suggests that some of the Ceylon men and the men in London interested in Ceylon might give their names as directors of the Ceylon American Tea Company; also that the planters should take a few more shares than they have taken—showing their interest in Ceylon affairs not only in this way, but by giving some of the money required to be expended at Chicago in conjunction with his efforts. He says that he can get plenty of support in America, but people there hang back, saying: "If your own men in Ceylon and London take so little interest in the enterprise it cannot be such a good thing as you say it is." (Hear, hear.)

Mr. J. WHITTALL said that he had had many conversations with Mr. May, who had tried to get money for his undertaking in America and in this country. He had not succeeded in doing so; and he (the speaker) thought his failure in this respect was owing to the high prices at which it was proposed to sell the tea in the United States. Ceylon people wanted to see large quantities of cheap tea sold. (Hear, hear.) If Mr. May did not alter his tactics and sell tea at lower prices, Ceylon would derive very little benefit from his efforts, and he would do very little good with his company. That was his (the speaker's) view of the case.

The motion was carried unanimously.

The CHAIRMAN:—I have how to commend to the Association another motion, and one which I trust is not likely to be received with any dissent. It is a motion in which I am myself specially interested. I have to move that Mr. Whittall be

re-elected Vice-President. (Cheers.) I hope you will pass that motion and so strengthen my hands as President of the Association (hear, hear).

Mr. ALEX. BROOKE seconded the motion, and it was carried unanimously amid cheers.

Mr. J. WHITTALL:—While thanking you for the honour you have done me, I must say that after three years' service—except for your unanimous wish—I should be very reluctant to accept the post. The position of Vice-President to such an Association as this is not all beer and skittles (laughter); and I am not getting younger. I hope that before we meet next year a younger and more able man—(No, no)—will be ready to take my post, but you may always count upon my best support and assistance to the Association. (Cheers.)

Sir ARTHUR N. BIRCH, K.C.M.G., moved the re-election of Mr. W. M. Leake to the post of Secretary to the Association. (Cheers.)

Sir GEORGE CAMPBELL, K.C.M.G., seconded the motion, which was carried.

Mr. W. M. LEAKE said that he was much obliged to the gentlemen present for once more electing him as Secretary. There was a touch of sadness in it to him on this occasion, for it was his fourth year of re-election and every previous year they had had the same President, the same from the beginning till now. He hoped that he would not be altogether out of order in referring again to the late Sir William Gregory and to the resolutions that had been passed in regard to him. (Hear, hear.) He had noticed that no representative of the Planting Community had spoken in support of the resolutions, and he would not like it to go out to Ceylon that this meeting had closed with no attempt to remedy this omission. (Hear, hear.) There were many in the room who had more right than himself to speak on behalf of the planters of today, but going back to the date of Mr. Gregory's Government of Ceylon he felt himself entitled to speak for the planters of that date, for only a week or two before his arrival in Ceylon as Governor he (the speaker) was elected Chairman of the Planters' Association, and within a month or two he was nominated by the planters (a novel thing then) their representative in the Legislative Council. Now what particularly struck him at that time in Mr. Gregory's attitude towards the planting enterprise was his foresight and caution, attributes which he thought had not been specially mentioned in the speeches that day. (Hear, hear.) The new Governor arrived in Ceylon at the very height of the coffee era: for three years the island had exported a million hundredweights of coffee, a quantity never reached again: new products were hardly thought of. Mr. Ferguson was just on the point of beginning his agitation for a railway to Uva based on prophecies of largely increased crops in the future—an agitation which, though based on delusive data so far as coffee was concerned, was yet to be of such benefit later to Ceylon. (Cheers.) Arriving in Kandy under such circumstances as these one would have thought that Mr. Gregory's first wish would be to visit some noted coffee estate to learn about the cultivation of that plant. On the contrary his first trip made before he had been a month in the Island was to Looolecondura estate to see all that was being done there in the cultivation of cinchona and tea. (Hear, hear.) The new Governor from the first felt the gravest doubts as to the permanence of the coffee industry, and though for a few years owing to an extraordinary rise in price there was a sort of "boom" of prosperity in which the Colonial revenue shared. Sir William Gregory was never deceived. Coming as he did a perfect stranger

to the Island this was a singular instance of foresight. (Hear, hear.) He cordially endorsed all that had been said that day as to the relations of Sir William Gregory with the Association. Sir William was pre-eminently fitted to preside over such an institution and by his help it was enabled to achieve at once a position which without him it might have taken very long to reach. The influence of the Association with the authorities on this side was altogether due, as was stated in the report, to the tact and judgment of its late President. He hoped he might be excused for making this long digression. (Cheers.)

Mr. J. FERGUSON:—In one word I would like to explain that Governor Gregory arrived in Ceylon in 1872; and in that year there was only one man in the island—and to his honour he it said—who had any doubt as to our coffee-planting enterprise surviving the fungus attack, and that was the late Dr. Thwaites, of the Peradeniya Botanical Gardens. No doubt Governor Gregory paid attention to Dr. Thwaites's opinion, and deserves great credit for so doing; but much more for being the first Governor who took special interest in the culture of new planting products as to introduce them by special paragraphs in his annual opening speech to Council. Thus tea, cinchona, cacao and cardamom culture were kept before the public and pressed upon planting attention. In respect of Railway Extension we (of the *Observer*) always gave prominence to our firm belief that new products would make up for any deficiency in coffee, though in Sir Wm. Gregory's day none of us, and no one in the island, expected to see coffee so completely superseded by tea. (Hear, hear.)

Mr. J. WHITTALL moved the re-election of the Executive Committee, with the addition of the name of Sir G. W. R. Campbell, K.C.M.G., and of the Tea Committee.

Mr. THOS. DICKSON seconded, and the motion was carried.

A vote of thanks to the directors of the New Oriental Bank Corporation for granting their board-room for the meeting was unanimously passed, and the proceedings closed with the usual compliment to the Chairman.

NEWS FROM BRITISH NORTH BORNEO.

Kandy, June 18th.

A first class manager has been appointed to take charge of the estates of the company in which Messrs. Shand and Henry Walker are interested. Mr. Pryer's company are going in for planting 200 acres of Liberian coffee. There is some splendid soil in their holding.

The North Borneo holders of shares in tobacco companies are much encouraged by the following intelligence received from home:—

Greatly improved prices ruled at the Sumatra tobacco sales held in Amsterdam on Friday. The bearing of the advance on the position of the leading English company, the British Deli-Langkat, is the most interesting feature of the sales, and shareholders will be pleased to hear that the prices obtained were well ahead of the valuations and nearly double the average prices of last year. The greater part of the British Deli-Langkat tobacco sold on Friday was valued at 118 cents and sold for 155, while the remainder was valued at 91 cents and sold at 101. The average of 128 cents is equivalent to two shillings a pound, whereas 75 cents, or one and threepence, was with difficulty obtained last year.

Two causes have combined to produce this advance—the exhaustion of the large stocks laid up by American cigar makers before the McKinley Tariff came into

operation, and the diminution in the area under tobacco in Sumatra. The weaker companies have gone to the wall, and about half of the tobacco land has gone out of cultivation. The well-managed companies which survived the crisis will benefit still more in the next financial year; meanwhile the prospects of the British Deli-Langkat have undergone a wonderful change since the issue of debentures in January. Then the Directors counted on little more than £50,000 as the revenue for this year, but if Friday's prices be realised for the entire crop of 1,400,000 lb. the revenue will be at least £135,000. The surplus supply of coolie labour in Sumatra, owing to the reduction of the cultivated area, has enormously brought down the working expenditure, and altogether it is not surprising to find that British Deli-Langkat shares have risen from the miserable prices at which they were quoted some time ago. The changed prospects make the debentures a very tempting holding, but they are nearly all in the hands of the shareholders, who are not likely to part with them.

It is a pity such a boom in tobacco did not come earlier, so that the Ceylon Tobacco Company might have shared in it. I fancy however the holders of the land sold by the local company will do better with cacao, coconuts and tea than in tobacco. W. D. G.

NOTES ON PRODUCE AND FINANCE.

TEA SHARES AS AN INVESTMENT.—In last week's *Grocer* Mr. James Llewellyn-Hughes, once a tea planter, and still kindly remembered in the tea districts of India, points out that from an analysis of the accounts of eighty joint stock companies registered in Calcutta, and representing an aggregate invested capital of R2,54,58,150, a total net profit for the year 1891 was made of R1,252,605 or 4.88 per cent on the capital. "This," he says, "compares with 2.54 per cent, or barely 2½ per cent paid in 1890, and 4.18 per cent in 1889." We believe it is no secret that Mr. Llewellyn-Hughes is not enamoured of tea planting as a remunerative occupation, and he points out with something like triumph that there were eighteen companies that made an actual loss of from 2 per cent to 3.62 per cent. Mr. Llewellyn-Hughes, in his reference to the poor return paid by many of these Calcutta companies, omits to mention certain gardens, like the Bargang Company, Assam, the Nedeem, Western Doars, which have, according to the *Pioneer*, paid steady dividend of 2.0 per cent, and the Matelli Company, which has paid as much as 40 per cent to its shareholders. But Mr. Llewellyn-Hughes might with advantage turn his attention to the London Tea Companies for the other side of the picture. A table supplied by Mr. Ernest Tye, giving the results of working in 1891, shows that the fifteen companies who have published their reports, with an aggregate capital of £1,094,057 and a planted area of 22,814 acres of tea have realised net profits which amount to £89,204, or equivalent to a dividend of 8.15 per cent on the whole capital invested. This indicates conclusively, Mr. Hughes notwithstanding, that, by economy of working and careful manufacture of really good teas, tea planting in India as an industry can hold its own against any country, and is not to be despised as a remunerative investment.

A BIG CHEQUE FOR TEA DUTY.—It seems rather hard on Mr. Lipton that, because he hob-nobbed with Arabi in Ceylon, he should be referred to in the House of Commons as a "vulgar advertiser." He has, by the way, just paid Her Majesty's Customs a cheque for £15,359 8s. for tea duty. This is said to be the largest amount ever paid by any one tea dealer, and under the old rule of duty it would have amounted to upwards of £23,000. Anyway the Government have nothing to complain about his love of advertising. A man who desires to open tea shops all over the world cannot be expected to go about *incognita*, or speak in whispers.—*H. and C. Mail*, June 3.

TEA SELLING COMPANIES.

Under the title of the Star Tea Company, Limited, a company has been registered with a capital of £80,000 in £1 shares, to acquire the businesses of tea merchants, grocers, Italian warehousemen, wine and spirit merchants, druggists, and café and hotel proprietors now carried on by Joseph Cadman at various places throughout England and Wales, under the style of the Star Tea Company, in accordance with an agreement, made April 9th, between Joseph Cadman of the one part and Harry Webster, on behalf of this company, of the other part, and to develop and extend such businesses in such manner as the company may see fit. The first subscribers (one share each) are:—J. Cadman, 157, Commercial Street, E.; P. Cadman, 28, Adelaide Crescent, Hove; E. S. Cadman 28, Adelaide Crescent, Hove; A. Cadman 28, Adelaide Crescent, Hove; E. Cadman, 28, Adelaide Crescent, Hoes; F. R. Spofforth, 59, Beardhurst Gardens, Hampstead; A. W. Cadman, 90, Wigmore Street, W.; J. A. Belder, 4, Regent's Park Terrace, N.W.

The prospectus has been issued of S. Davis, Sons and Goodbody, Limited, tea merchants, London, Dublin and Belfast, with a share capital of £70,000, divided into 4,000 six per cent cumulative preference shares of £10 each (£40,000) and 3,000 ordinary shares of £10 each (£30,000). The company has been formed for the purpose of acquiring and working as one concern (a) the wholesale tea business hitherto carried on by Messrs. S. Davis and Sons, Limited, at 11, Rood Lane, London, and 17 and 18, High Street, Dublin, and (b) that of Messrs. Francis Goodbody & Co., 9 Mincing Lane, London, and 41, Victoria Street; Belfast, wholesale tea merchants.—*H. and C. Mail*, June 3.

◆

PRODUCE OF THE COCONUT, AREKA,
KITUL AND PALMYRA PALMS
EXPORTED FROM CEYLON.

Premising that the quantity of the produce of the coconut palm exported from Ceylon, although very considerable, is far less than that locally consumed, the proportion being likely to be lessened from the effect of the heavy tax on kerosene oil, by the people again resorting to coconut oil as an illuminant, it may be interesting, with reference to proposals to levy an export duty, to see what the quantity and value of articles derived from the most economically valuable of all the palm tribe were in 1891. The figures are, for

Coconut oil	426,689 cwt.	R5,309,000
Coirfibze	38,888 "	291,000
" manufactured	67 "	7,000
" rope	10,904 "	136,000
" yarn	100,690 "	604,000
Copra (dried kernels)	68,907 "	921,000
Poonact(oil cake)	184,949 "	559,000
Coconu s, 384 bags and No. 7,421,000		288,000
Coconut shells,	7,099 packages	60,000
Cadjans	210 "	47
Arrack	101,378 gallons	103,000
Coconut laths and rafters, No. 586		150

Total value R8,278,197

A fraction of the "palm" sugar exported was, probably, the produce of the coconut palm, but the value of this article and the husks (R4) may be disregarded. Taking the round number of R8,280,000 as the value of coconut produce exported, a duty of 1 per cent on this sum would realize a revenue of R82,800. If the duty were levied at the rate of 2½ per cent the amount collected would be R207,000. It may be well to see what the quantity and value of the exported produce of our other palms are. The produce of the araka palm is, like that of the coconut, consumed locally to a very large extent, the narcotic nuts at any rate; but the export is considerable. Last year the figures were:—

Arecanuts—25 packages and 99,206 cwt. R906,963. At 1 per cent the revenue from this article would be R9,069; at 2½ per cent R22,672.

The kitul palm yields a very large portion of the sugar consumed by the natives of Ceylon, but we do not think any of it is exported. The fibre, used chiefly as a substitute for bristles, is, however, of some mark in our exports:—

Kitul fibre, 2,100 cwt.	R67,092
" rope 2 "	15
" laths and rafters, No. 550	90
Total value		.. R67,197

At 1 per cent the collection would be R671: at 2½, R1,677. The produce of the palmyra palm exported has fallen off, from gradual destruction of the valuable trees, we fear. The exports in 1891 were:—

Palmyra laths and rafters, No. 177,602	R44,306
" sugar and jaggery* cwt. 3,325	R11,846
Total value .. R56,152	

At 1 per cent this value would yield R561; at 2½ per cent R1,402. The valuable leaves of the grandest of all our palms do not figure in our exports, either as olas or as leaves prepared for writing on; but we cannot doubt that they contribute somewhat to the 222 packages of "mats, bags and baskets" valued at R1,114 exported last year. The aggregate value of the products of the four palms which are named in the export returns is thus made up:—

Products of the coconut palm	.. R8,278,000
" areka "	.. 907,000
" kitul "	.. 67,000
" palmyra "	.. 56,000

Total value of palm produce exported .. R9,308,000

or somewhat over £600,000, at R15 to the pound. The value of the products locally consumed must be at least twice that sum.

◆

A CORRESPONDENT writes:—"Coffee in Wynaad looks worth £200 an acre, but there is such a mass of leaf that the puzzle is to find one berry—a cursed puzzle that will probably continue to puzzle us at crop time." We hope not.—*Madras Times*.

We hear from British New Guinea that Sir William MacGregor has over 20,000 coffee trees planted for his Government. Last season he got some tribes to plant over 300 for each man. Two tribes put in 10,000 nuts and, in addition, established a village police. As to the other side of the picture his Honor the Administrator has had to encounter sad disappointments in relapse, distrust, savagery, cannibalism, and such like drawbacks. But it must be remembered that New Guinea has been shunned by all the world until now and has been left out of the current of progress. It is evident, however, that it will become into line if patience be but exercised. Within the last few years scores and scores of thousands of natives have laid aside their arms. Our old friend evidently is of opinion that Providence does not desire that either lands or hands shall be permitted to remain idle and he is using every exertion to utilise both under his system of Government. His life is not being wasted; but he must be drawing heavy drafts on the strength by the maintenance of which only can it be sustained.—*Fiji Times*, April 20th.

* The heading in the Customs returns is, "Sugar: palm and jaggery," but we feel certain that all but a fraction is palmyra jaggery.

MY MISSION TO SOUTHERN INDIA.

By E. J. Young.

Having been appointed Commissioner by the Planters' Association of Ceylon to visit the Districts of Southern India, and report on the best means of increasing our labour supply; I sailed on 22nd January 1892 from Colombo per S.S. "Bengal" and landed at Madras on 25th, and duly presented my credentials from the Ceylon Government to His Excellency the Governor.

I met with a kind and friendly reception from Lord Wenlock who assured me that he and his Government would do everything possible to further the views of the Planters of Ceylon; and that the more coolies went over the better pleased he would be, as emigration was conducive to the best interests of both countries.

The migration of Tamils to and from Ceylon is entirely voluntary and it is probable that from the date of its first European colonization this Island has attracted labour from the South of India. Coolies are free to return whenever they please, and as in many instances they do not go back to India this must be taken as an indication they are content to remain in the land of their adoption.

I compute that on an average about 75,000 Tamils come over to Ceylon every year from the Southern districts, and that of these about 60,000 return. The others settle permanently in the Island.

From all classes I heard only praise as regards the general good treatment of the coolies when in the Island. The Collector of Chingleput, who has had long experience at Tanjore, Madura, &c., assured me he had never heard a single complaint from the many coolies he had met on their return from Ceylon; they invariably spoke well of the place, and were anxious to go back; which could not always be said of other countries they had visited.

Excluding feudatory states, the total enumerated population of the Madras Presidency, on 26th February 1891, was 36,630,440 which is 4,803,327 or 15.53 per cent increase on the Census of 1881.

The population per square mile was 252 against 218 in 1881.

So the native population in the Madras Presidency increases roughly speaking at an average rate of 1½ per cent per annum. However, from all I could gather the increase in the districts from which we chiefly draw our labour supply, can safely be put down at 2 per cent. per annum; and that in the face of a heavy emigration to many countries.

This steady annual increase to the already congested population constitutes the great difficulty ahead for the Madras Government.

On mentioning to Lord Wenlock my anxiety to find fresh fields for recruiting he suggested I should turn my attention to Obingleput and North and South Arcot as admirably suited to the purpose:

North Arcot population	...	2,178,226
South Arcot do	...	2,159,813
Chingleput do	...	1,137,333
Total		5,475,372

These three districts are new fields from which we have drawn but few coolies in the past. The inhabitants are mostly Tamils, similar to those in Ceylon. They speak the same language, and go in large numbers to the Straits, Burmah, Natal, and even Mauritius; but few, however, and only in times of great scarcity come to Ceylon. The long and expensive journey precludes their taking advantage of our labour market.

I went to Chittoor the capital of North Arcot, a railway journey of about 100 miles North of Madras;

and there met several old Ceylon canganies and coolies and had long talks with them and listened to their grievances.

The Collector was exceedingly kind, and took an immense amount of trouble in getting his native assistants as well as Ceylon emigrants from long distances to Chittoor in order to go thoroughly into the different questions, and hear all that had to be said in the matter.

Owing to want of rain during the last monsoon, and the consequent failure of crops to some extent, the present time is a most favourable one in which to commence recruiting in North Arcot. If the South-West monsoon fails, a general famine is predicted.

Two old Ceylon canganies offered to return with me accompanied by 100 coolies, if I would engage them and give them employment. And the Assistant Collector thought two or three thousand coolies could be got at once on certain terms.

But as already pointed out the long and expensive journey to Ceylon prevents the Tamils from the Northern Collectorates taking advantage of our labour market.

At present Madras is almost the only known route to him; and it costs with batta at least R15 for an Arcot coolie to reach Colombo. And where is a wretched famine stricken peasant to raise such a sum for himself much less for his wife and family?

Of necessity the needy emigrant is driven to the Natal or Mauritius recruiters who not only give an immediate advance in ready cash, but also provide food, clothing, and a free passage to either destination as the case may be. What possible hope has our free emigration against a system of this nature.

The lesson learnt throughout on this question only verified what I have been advocating at home, viz., cheapening of travelling to the coolie, and prevention from robbery and ill-treatment when en route.

The strongest and best endeavours of the whole planting community should be exercised in this direction; for I am confident it is the keynote of the labour question.

The foregoing remarks regarding North Arcot also apply to Obingleput, the district in the immediate vicinity of Madras;—which would prove a good field for recruiting provided the cost of going to Ceylon were met by the employer or the present exorbitant demand for cost of passage from Madras greatly lessened.

South Arcot is a very rich and fertile district and well watered, and has large Sugar and Spirit factories employing a great number of hands. Hence the people learn high wages and are well off; and there is little or no prospect of getting labour from thence.

North Arcot and Chingleput are the only fresh fields visited which could be tapped with any benefit to ourselves.

All efforts to induce the B. I. S. N. Co. Agents at Madras and Cuddalore to reduce their present absurdly exorbitant fare of R12.50 to R6 per head per deck passage to Ceylon entirely failed. Whilst this heavy demand is made on the poor emigrant to Ceylon this Company carries a coolie to Burmah from the Northern parts for about R6, and I was told in some instances to Singapore for even less; both places being further away than Ceylon.

When in Madras I went fully into the question of the indentured coolie for Natal, Mauritius, Straits Settlements, &c., and got from the officials the forms which the emigrants sign before embarking.

These people are engaged for 5 or 10 years; only the lowest, and vicious classes go,—it is a bad system, and leads to all manner of abuses; and would never suit us, or be tolerated in Ceylon.

The Collector of Chingleput when writing to me on the subject of recruiting most correctly describes and warns us against the Natal and Mauritius recruits as follows:—

"If you are led to doing anything, I certainly advise recruiting by decent individuals.

"Recruiters as a class are looked on as the off-scourings of society and men to be contemned."

The Ceylon system of free emigration is far the

best suited to our requirements; and nothing should induce us to depart from it.

I was informed by the Madras Government that the restrictive quarantine rules enforced at the Ceylon ports were doing great harm to free emigration; and, moreover, the complete and sudden stoppage about February 1890, of all access through the Northern parts had thrown thousands of coolies back on their own resources; given the country a bad name, and altogether done incalculable injury to the poor emigrant, as well as the Ceylon Planter.

At Tanjore and its neighbourhood I met many old Ceylon Canganies and Coolies and first got into the regular stream of emigration Ceylon ward.

It was a surprise to me to learn from the Collector of Tanjore, that many coolies who used to go formerly from these parts to Ceylon are now in Burmah, or the Straits Settlements, but he could give no explicit reason for this change further than he heard it was owing to the Quarantine rules enforced at Ceylon ports.

My surprise was turned into astonishment when the annexed table of immigration from Tanjore ports was shown me. The full table and the corrected one are annexed,—but, taking the totals for 21 months, about 80,000 emigrants from Tanjore ports to Burmah and the Strait Settlements against 10,000 to Ceylon. This shows a serious discrepancy against us and a steady falling off month by month against Ceylon, and in favour of our rivals.

Negapatam is 50 miles from Tanjore and is the chief seaport for the district. It is a town of considerable size and importance, and probably contains 100,000 inhabitants. I made up my mind to proceed there from Tanjore and go fully into the emigration question with Messrs Adamson McTaggart Co., agents for B. I. S. N. Co., at Negapatam, Tondi and Tuticorin.

Mr. McTaggart, the head of the firm, takes great interest in the Ceylon labour question; and induced the shipping Company to put on the "Amra" which now runs most successfully from Tuticorin to Colombo; and also another Steamer the "Aska" between Negapatam, Tondi and Paumben to Colombo.

Both these lines have been a great boon to the emigrant, and the former has proved an immense success, but the latter only a partial one owing to the Quarantine rules.

The "Aska" for want of traffic was taken off for sometime, but Mr. McTaggart promised she should resume running shortly and he agreed to reduce the fare for Coolies from 4 to R3 per head from Negapatam and Tondi to Ceylon. So there will be a uniform rate of R3 per head for deck passage from Negapatam, Tondi, and Tuticorin to Colombo; which might, with advantage be reduced presently to R2 per head or even less.

I found the Negapatam B. I. S. N. Co. Agents very bitter against the Ceylon Quarantine rules; and the way in which they are administered. Indeed they are not singular in this respect; for wherever I went, the same cry of abuse from officials as well as non-officials, against our obsolete Quarantine rules and obstructive policy followed me.

I was met on all sides with the same inquiry, viz. "That as neither Burmah, Rangoon, Penang, or Singapore have or require these restrictive regulations, why should Ceylon need them more than places equally large and important as herself?"

As far as I am capable of judging Quarantine appear of little practical use, its only effect is to restrict commerce and free intercourse, and it is quite out of date; and it is our duty to modify, if not entirely remove those barriers which have been erected by prejudice and ignorance.

However, after full enquiry from numerous sources, there is not a doubt in my mind, these restrictive rules have cost the agricultural interests of Ceylon many thousands of coolies; and that it is mainly to this cause that the shortness of labour during 1890-91 is ascribable.

Ceylon's troubles in this respect date from the stopping of the North Road. I think in February 1890. and its disastrous consequences are only too well known to need repetition here.

The B. I. S. N. Co., Agents at Negapatam gave me copies of correspondence with the Ceylon Government on the Quarantine question, together with a memo of their own opinions and experiences of the same, all of which are annexed hereto.

If the Ceylon Government cannot see its way to remove, or at all events greatly modify these rules, then no time should be lost in starting a new port of call, say at Negombo on the mouth of Kelani where the Tamils could be landed free of all restrictions, and it is found absolutely necessary put into Quarantine on shore. If this suggestion is found impracticable then a floating Quarantine might be started in the Colombo harbour.

The old districts, from which we have heretofore drawn our principal Labour supply are Tanjore, Madras, Trichinopoly and Tinnavelly; and comprise a population of about 10 millions. They are so near Ceylon that the cooly can get over with ease, and at a small cost of money and time; hence the traffic between the South ports and Ceylon is constant and mutually advantageous to the people of both countries.

At certain seasons of the year, when labour is in demand the labouring classes of the Southern district flock over to Ceylon; and when they have worked for some months, and saved a few Rupees return again to their own native villages to assist in harvesting the crop or ploughing their ancestral fields.

This free emigration is an admirable system; gives confidence to the employer and employed; and keeps up the steady flow of labourers between the two countries; and it should be fostered in every possible way by both Governments.

There can be no doubt that private and public works are on the increase all over Southern India. The cultivated area is also steadily advancing year by year. Money is more plentiful than it used to be, and it is the general opinion of native officials with whom I came in contact that ere long wages must rise all over the Presidency. They have already done so where commerce and modern industries are centred.

At present a cooly earns from 3 to 4 annas according to locality against our 6 to 7 annas per diem; but it must be borne in mind that Ceylon's credit, that work and wages here are steady and uniform, whilst in India they vary much according to circumstances and locality.

There can be no doubt that the best attention of the Planters' Association should be turned towards making the journey for the cooly to and from Ceylon as easy, cheap and attractive, as possible; and with that object in view an important meeting was held at Trichinopoly on 19th February consisting of Mr. W. S. Betts, Managing Agent for S. I. Railway, Mr. H. B. MacTaggart representing Managing Agent B. I. S. N. Co., Calcutta, and myself.

Annexed will be found a copy of what transpired, and the arrangements entered into subject to the approval of the Ceylon Government and B. I. S. N. Co.

Our object was to amalgamate rates and grant through tickets. For instance, say a cooly arrives at Chittoor Station, and demands a ticket for Nanuoya; he would be provided with a through pass which would cover the steamer across as well as the railway journey up to Nanuoya; and besides this, he would be protected and taken care of the whole way through, instead of being robbed and ill-treated en route under the present no method.

The cost of the land journey would be exactly 1 cent per mile, and he could choose between 2 routes from Chittoor to Colombo, as follows:—

Chittoor to Negapatam per rail	R3 0 0
Steamer fare to Colombo	- „ 3 0 0
	<hr/>
Total	R6 0 0
Chittoor to Tuticorin per rail	R4 13 0
Steamer fare to Colombo	- - 3 0 0
	<hr/>
Total	R7 13 0

The cost of the same journey via Madras as previously pointed out would be at least R15; so this system will be a great saving of time and money to the cooly, and do away with any necessity of travelling via Madras, which is really out of the way. Such a system properly carried out would tend greatly to reduce the present high coast advances made to Canganies. And, I may here mention, that Messrs. Thos. Cook & Son are now quite prepared to support this scheme, and convey any number of coolies from any Railway Station in Southern India to any Railway Stat on in Ceylon and vice versa.

I consider the present steamer rate of R3 for deck passage from Tuticorin to Colombo too high, and it should be reduced to R2 per head or even less. The Ceylon Government on behalf of the planting Community might with advantage enter into some agreement with the B. I. S. N. Co., to reduce the fare. I have only to point out that the distance from Tuticorin to Colombo is 150 miles by sea, and as the steamer fare is R3 it comes to exactly 2 cents per mile, or double the cost of travelling per rail, which exposes the absurdity of the high charge.

After due consideration I am now averse to a free ferry between Tuticorin and Colombo, as it would be liable to flood Ceylon with an undesirable kind of labour, as well as the criminal classes of India.

Tuticorin has now become the popular Port of embarkation for coolies proceeding to Ceylon, and no less than 40,849 came during 1891. I possess no tables to show how many landed there from Ceylon during the same period.

A demand of $\frac{1}{2}$ anna, or 3 cents is exacted by Government from every cooly who lands or embarks at Tuticorin. A sore tax on the poor emigrant not only in a direct sense, but also as a means of giving facilities to underlings for extorting black mail.

To illustrate my meaning, I may relate an apocryphal anecdote told me by the Master Attendant. He said he came up unheard behind a Peon who was demanding in a menacing manner from some coolies who had just landed from Ceylon 2 annas for each package in their possession as *Port Dues*.

I am afraid a great deal of this sort of thing goes on; and it should be stopped by the strong hand of Government.

As there is not the slightest convenience at the wood Jetty to protect the cooly from sun and rain, it seems to me an unnecessary demand which should either be removed or something given in lieu, in the shape of shelter for emigrants; where they could wait and rest before embarking. I am sure the matter has only to be brought to the notice of the Madras Government to be speedily rectified.

It is absolutely necessary for Ceylon to appoint an agent on or near the spot to watch over her labour interests in Southern India; and the following suggestion appears to me an easy and practical way of overcoming the difficulty at a small outlay.

That Mr. Jardine should be made Ceylon Inspector of Labourers for the Madras Presidency, with a adequate addition to his salary for extra work to be performed.

It would be his duty to proceed once or twice a year North to Madras; and South to Tuticorin, keeping in touch with the shipping agencies at the different Ports. Also to bring to the notice of the Madras Government any cases of ill treatment of coolies that may be brought before him and to prosecute in the courts such cases when necessary; and report regularly to his own Government on all matters connected with the Labour question.

Mr. Jardine's duties at Mannar must now be very light, and I am sure he could easily spare the time and most efficiently carry out the additional work I have sketched for him above.

The present Ceylon wages are ample for the coolies services and compare favourably with what he can earn at home or elsewhere; at the same time, I think more could and should be done for him by the supply of cheaper and better rations. Now that the paddy tax has gone, the sister food tax levied on rice

at the Customs *must necessarily follow suit*, this would considerably cheapen rice, and it should then be a rule to sue it at R3 per bushel. But instead of $\frac{1}{2}$ bushel $\frac{1}{2}$ should be issued to the cooly. And a half Rupee in hand in lieu of the rice. This was suggested to me by several Tamils who complained that by the present system they got $\frac{1}{2}$ bushel rice per week, part of which they had to sell at a ruinous sacrifice in order to purchase curry stuff. Half rice and a half money would obviate all this.

Another question which was brought prominently to my notice, and bitterly commented on, was that of the careless planter, who instead of getting out cash from the Bank and personally paying his coolies, entrusts this most important duty to a deputy in the shape of the conductor or Head Canganey, and hands one or the other a cheque for the full amount of wages due to a large body of men. In many such cases, poor coolies are most unjustly treated and naturally leave the Island abusing the country, and work incalculable injury in the Indian village, by preventing others coming over. Though this is not a common custom and generally only practised in the case of small gangs who are paid off from estates, yet the effect produced is a very bad one and it cannot be too strongly condemned.

In each Collectorate or District a Weekly "Gazette" is published in English and Tamil which goes into every village, and is read by the people. It was proposed that the Planters' Association should make known its wants through this channel, and more especially in the New Districts to be tapped for a fresh labour supply. This struck me as an admirable suggestion which might be acted on advantageously provided a carefully drawn up notice in Tamil and English with full particulars as to wages and general terms of service were given. The cost of such advertisement would be insignificant.

Having for many years been accustomed to the Tamil cooly in the midst of his changed condition in the cooly lines of some large coffee or Tea Estate, it was a pleasure to me subsequently to study him in his native haunts.

What impressed me most of all during my wanderings was the happy and contented state of the people throughout the Madras Presidency.

Of course in highly congested districts, where coolies are too abundant and work is scarce, the direct and inevitable result can only be extreme poverty; but it would not be fair to quote examples from such cases. Indeed I often read and heard of famine and scarcity; but never witnessed or saw any of its evil effects, whilst the people seemed most happy and contented wherever I went; and nothing could exceed the industry energy, frugality, and hard working characteristics of the race.

Our old friend the Tamil seemed to be always at work morning, noon, and night; and when not reaping harvest or ploughing; he was hard at it drawing water to irrigate his fields; but whether at work or play, he invariably seemed contented and bappy.

I was greatly taken with the fertility of the soil and fine cultivation witnessed in many parts of the country I passed through, and more especially in the drive from Cuddalore to Tanjore, and on to Negapatam. The fields were beautifully cultivated and bearing crops heavily laden with grain, and indeed reminded me more of Kent than anything one could have imagined in the East. I was told on good authority the value of the best paddy lands was from R1,500 to 3,000 per acre. These lands always give two and sometimes three crops during the year.

The serious drawback to Ceylon is the great scarcity of foodstuffs; whilst liquor is too abundant and ridiculously cheap. I am sure the Government could with a little trouble, and guidance enhance the one, and obviate the other.

Thousands of acres in the North of the Island are suitable for Indian Corn, Raghi, Camban, and other dry grain cultivation; and with regard to the latter, a lesson might with advantage be learnt from the Madras Government, and both arrack and toddy so

heavily taxed that whilst the revenue remained the same the quantity produced would be reduced to say about half the present amount; undoubtedly this would prove an unpopular measure; but that it would be for the good of the people, no one who has studied the annals of crime in the Island of Ceylon can doubt. Crime accompanied by violence, steadily advances with the increased sale of arrack and toddy; and brings in its train sorrow and misery to thousands of families.

My best thanks are due to H. E. Lord Wenlock and the Madras Officials for the great kindness and hospitality shown me during my tour through the Madras Presidency,—all did their utmost to assist in every possible way to make the mission a success and nothing could exceed the kindness with which I was received. EDWARD J. YOUNG.

MINUTES OF A MEETING AT TRICHINOPOLY ON THE
19TH FEBRUARY, 1892.

Present:—Mr. Young, Mr. Mactaggart, British India Steam Navigation Company; Mr. Betts, South Indian Railway Company.

1. The question of improved arrangements for the conveyance of the cooly traffic between India and Ceylon having been discussed.

2. It was suggested that a bi-weekly steamer from Tuticorin and a weekly steamer from Negapatam should be run on fixed dates by the British India Steam Navigation Company to Colombo, and vice versa, and that through tickets be issued to cover the service from the principal Stations on the South Indian Railway Company to any Station on the Ceylon system of Railways and vice versa. This Service to include the putting on board of the Coolies at starting port and the landing of them at port of destination. The contracting parties to give notice that they cannot take responsibility for any detention to passengers caused by quarantine regulations or other unavoidable reasons.

3. The Railway and Steam Companies will do their best to protect and see the coolies are well treated en route.

4. An arrangement to be made for the settlement of accounts monthly between the two Railway administrations and the British India Steam Navigation Company.

5. This through service to be confined to the "Amra" and "Aska" steamers which have been specially built for this traffic. If this system of through hooking proves successful the question of extending it for 1st and 2nd Class traffic will be considered.

6. It is considered desirable that a tri-weekly service between Tuticorin and Colombo should be introduced for the sake of improving the movement of traffic; but Mr. Mactaggart represented that it would be necessary in the event of such a service being organised that some inducement in the shape of a subsidy for the carriage of mails by these small steamers should be offered to the British India Steam Navigation Company.

7. A strong representation to be made to both the Governments of Madras and Ceylon that the route via Tuticorin should be utilized for the conveyance of all mails between the two countries; as Colombo is now an important centre the improvement of the service between that port and Tuticorin would serve both the public and the postal authorities.

8. Mr. Mactaggart on behalf of the British Steam Navigation Company pointed out that if the service has to be maintained with any degree of regularity, it will be necessary that the present stringent quarantine regulations at Ceylon ports should be modified.

9. The introduction of this proposed system of through booking &c., to be contingent upon the approval of the Ceylon Government, and of the Planters' Association Managing Agents of the British India Steam Navigation Company.

MEMORANDUM FOR CEYLON GOVERNMENT BY MESSRS.
ADAMSON, MCTAGGART & CO., AGENTS FOR B. I. S. N.
CO., AT NEGAPATAM AND TONDI.

The action taken by the Negapatam Agents in connection with the Correspondence with the Ceylon Government regarding the Bills of Health, has been to stop shipment of passengers from Negapatam, Tondi, and Pamban, to Ceylon ports, whenever a death from cholera takes place; as the Port Surgeons at ports of destination hold to themselves the right of judging whether the ports of shipment has cholera in a sporadic or epidemic form irrespective of the statement in the Bills of Health. The consequence of this policy has been the shutting out of hundreds of passengers every week throughout the year 1891, and these passengers have found their way to other colonies where no such absurd restrictions are in force.

On several occasions when cholera existed here in a sporadic form only, passengers at great inconvenience and expense to themselves and loss of time and money to the vessel have gone to Northern ports (which were not infected) by road or rail for embarkation.

The Surgeon at Kargasantori is unnecessarily strict in the observance of quarantine regulations and has practically stopped the flow of passengers from Negapatam to North of Ceylon during the year 1891 on this account. He also causes unnecessary detentions when a vessel arrives in port late in the afternoon by refusing to go on board if it is near 6 p.m. or a little after that hour, saying "he is not called upon to embark after 6 p.m." The consequence in such cases is that the vessel has to remain till the next morning and thereby loses a day and falls out of the regulated sailings from other ports.

(Signed) A. Mc. & Co.

Negapatam, 15th Feb. 1892.

MEMORANDUM QUARANTINE RULES AT NEGAPATAM BY
JOHN CARSON, MASTER S. S. "NAWAB."

The Quarantine regulations enforced at the Ports of Colombo and Galle are very restrictive and lead to great inconvenience and loss of time.

These remarks apply in a great measure to voyages from the Port of Negapatam to Galle and Colombo.

I have only once been detained from Tuticorin to Colombo, as follows from my log:—"July 4th, 1890, left Tuticorin for Colombo, July 5th arrived at Colombo, 7 a.m., put into quarantine, and 7 a.m., July 6th taken into a berth and coolies removed on shore. No sickness whatsoever amongst them only a foul bill of health. Left Monday, July the 7th for Galle at 7 a.m., so we have lost two clear days."—This has never occurred since from Tuticorin.

When we have had foul bills of health from Negapatam, I have invariably slowed down so as not to arrive at Galle before the prescribed time of 72 hours and thus saved detention, but at a loss of two days to the steamer. I preferred being at sea to detention in Port.

I have been in the habit of calling at the various Coast Ports for past 20 years, and have never experienced any delay through quarantine regulations at any of the Indian ports similar to that of Ceylon and think these regulations should be considerably modified, if not done away with altogether, excepting in case of a serious outbreak.

During all the years I have been trading to these Indian and Ceylon Ports I have never had a single case of cholera on board. I may point out that when a clean bill of health has been unobtainable at Negapatam, I have in some cases proceeded to Karikal, 9 miles further up the Coast and shipped and got a clean bill of health. This clearly shows the nonsense of the rules enforced at Ceylon.

(Signed) JOHN CARSON,

March 18th, 1892.

Tanjore Collector's Office,
Vallam, 22nd February 1892.

Dear Mr. Young,—I find that the figures of emigration to end from Ceylon which I gave to you the other day do not include figures for the minor ports. I enclose herewith a corrected statement.

The figures for Ceylon are not quite so bad as the former statement made out.—Yours sincerely,

(Signed) H. M. WINTERBOTHAM.

E. Young, Esq.

FROM THE METROPOLIS.

LONDON, June 3rd, 1892.

TEA PROSPECTS.

It is quite evident now that most of the Ceylon planters have gone in this year so far for finer plucking and therefore finer teas. The average quality is pronounced decidedly better, and the continued low exports (comparatively) show one great result of the change in harvesting and manufacture; but the prices in Mincing Lane have scarcely justified this course. At any rate, there is now again so close an appreciation between the prices paid for fine, medium and common teas as to encourage the manufacture of quantity rather than best quality. Whatever Mr. Hawes may say to the contrary, the home trade and Lanc buyers do not offer encouraging prices for fine teas, and accordingly it is not unlikely that the latter half of 1892 may see rather coarser plucking once more set in, though I trust no one will dare to send home the absolute trash experienced and condemned in some cases last year.—I hear from a gentleman in the Provinces that the latest fad in tea is a desire for "unfermented tea." "Could you," he adds, "get anyone to send us home a sample of leaves dried in the same way as *coca*? All the bruising and manipulating is supposed to be so much humbug—'why not send it home with the *theine* sealed up in its natural vessels?' say the wisacres." There are doubtless good reasons which the Chinese long ago discovered, but meantime to satisfy British faddists there can be no harm in trying the experiment above referred to.—Referring to the recent correspondence on Ceylon Tea in the *Financial News* and Mr. T. C. Owen's remarks, it is of interest to give the following further details from a letter which Mr. Owen has kindly sent me:—

In your review of Ceylon tea you refer to the aroma from new land; and I find from my personal experience that do what you can this delicate flavour cannot be got again. In Goomera, for example, I tried fine plucking for two months this spring; I sacrificed 33 per cent of my quantity, and do what I could I could not do more than raise the value of tea from 7d or 7½d to 8½d or 9d! Armstrong, with whom I discussed the matter a week or so ago when he was in town, says his Rookwood experience is exactly the same. I think Hawes is right in saying that new gardenes possess a certain delicate flavour which they afterwards lose; he is wrong when he attributes this to any exhaustion of the bush from over-plucking and the "greed of the average planter." No doubt, if it paid us we could all greatly improve our quality by plucking finer, and thus not only get better leaf but also have more factory room; but I fear that in few cases should we again get what you call "aroma," and what I call a delicate "flavour," which characterises tea from new land. Portswood is an example of a very high estate with exceptionally fine soil that has preserved the delicate character of its tea for an unusual period, and I trust it will continue to do so and prove that to every rule there is an exception. I am glad to be in England again for a hit, but we leave in October for Ceylon again.

WYNAAD AND CEYLON.

(From our South Wynaad Correspondent.)

I have been travelling recently and during my tour I have obtained some exceedingly interesting information about tea planting in Ceylon. My authority is excellent, that of a keen and appreciative observer, who has the interests of tea very much at heart; and who in such interests has been fulfilling the character of "a cheil takin notes." I asked him his

opinion of Ceylon as a tea-producing country, and his reply to this question was long and somewhat startling. Condensed, it appeared to me to be much as follows:—

"You ask me for my candid opinion of Ceylon and its tea prospects in particular. Ceylon appears to me to be considerably overrated. It is by no means the bugbear to Indian enterprise, which you Indian planters appear to consider it. Planters are opening there still for tea, but they never will be able to supply the estimated amount, if their export of that product is put down at 85 million lb. for the current year and from 100 to 150 million lb. for 1892-1893. This year's export will probably reach hardly 70 million lb. so that the 150 or even 100 million lb. crop is far from likely ever to be realised, especially when it is taken into consideration, the fearful manner in which the bushes have to be systematically hully ragged even to be able to get the present yield. It only requires a little thought for one to arrive at an idea of the unsuitability of the soil left in most of the island to produce a continuous and paying supply, when it is remembered that for generations the civilised portions of Ceylon have been subjected to a continuous drain, first from coffee, then cinchona, and now tea; and this without any opportunity of recuperation of all the chemical constituents so essential to the production of good tea, and that it is now so thoroughly impoverished as to be incapable of supplying the world with anything better than a mere wceddy sickly-looking representation of tea. There are, of course, estates which are the exception, and those exceptions may perhaps weather the trying times which are not far distant.

"It is a well-known fact that the home markets have been grumbling for some time, at the utter rubbish that is now being shipped in the name of tea. This cannot be improved upon, in Ceylon without manure, and it is admitted, though unwillingly, that instead of a tendency to improvement by age (as in India) the bushes are gradually but certainly deteriorating. No factory with the best machines going, can possibly turn out flavoury teas from leaves without hody, one must go to the field for that. But when it is not in the soil to produce the body well, but one conclusion can be drawn!"

"I saw," continued my friend, "some of the best tea and soil on the island, and on one estate, which has to send its leaf to a factory several miles off, only 140 to 200 lb. per acre can be got, as it has to be plucked so very fine, and a coolie who gets from 5½ to 6½ annas a day only brings in 8 to 9 lb. of leaf per diem; thus costing from half to three-quarters of an anna per lb., for plucking alone; so small is the leaf and poor the flushes. Then again, the poor bushes never get a rest. The buds are continually plucked until the hush becomes so weak that it can produce no more. It is then pruned, generally every second year, to give it a sort of filip, and if it survives the pruning, the unmerciful plucking recommences. You may imagine what the flushes are like, and that fine plucking is necessary when only the tip and two leaves have anything like sap in them. When I first arrived in Ceylon, on note-taking went, I was very favourably struck by the manner in which they went in for tea, and was quite prepared to believe all that was said and promised of the island in that line, but I have just passed through their best tea flushing time, and have seen for myself how very near they must be to a crisis."

From what I could gather from my friend, Ceylon in no way heats Wynaad in climate for tea, and our soil, those large portions of it, which have now laid fallow for many years, must be infinitely superior to that of the island, whilst the labour is so immensely cheaper and easier to obtain, that it seems at first sight simply extraordinary that we should be so far behind our Ceylon brethren in enterprise and success. But here my friend solved the problem.

Said he:—"You Wynaad planters are like men without legs, trying to run a race. Ceylon has neither your climate, nor your soil, nor your facilities for labour. But Ceylon has two immensely strong supports,

which you unfortunately wholly lack, the Government, and the Press; Government, and the planters are one, and the trinity is completed by the *Ceylon Observer*. In Ceylon, the planter is a personage, the press watches his interests. The press blows his fame abroad, and sends the electric light of its powerful influence upon those interests. The Government backs the press, what would Ceylon be without the planter? He is fostered and cared for. He is not allowed to tumble down and hurt himself. Whereas in India every official regards the planter as an interloper, a troublesome! worrying tramp only fit to be deported. Who is he? oh! only a planter: well then, tell him to move on. And as far as the press, with the exception of the *Madras Times*, what paper considers it worth while to take up the cudgels in the defence and interests of the planter? You are poor, and you struggle bravely, but what of that, when no hand is stretched out to give you a friendly lift. If your Government would encourage your claims to notice, capitalists would soon find out the rich capabilities of your soil, and the advantages of your climate and labour. If some one would set the ball rolling, the thing would grow of itself. But unfortunately, therein lies your principal difficulty. In Ceylon a vast amount of invested capital is interested in keeping the ball rolling. What would the banks, and the big companies do if it and when it stops? As I said before, Government is one of the legs which you require to wiu your race, the press is the other. Let the *Madras Times*, for instance, go on as it has begun, and more, in the interests of planter, and you will inevitably find yourselves pushed forward into the notice which at present is so absolutely essential to your well-being. The capitalists will have their eyes opened to advantages to which they now remain obstinately blind, and the future of Wynaad would become assured, and its now barren acres flourish exceedingly. It behoves you *all*, to put your shoulders to the wheel. Let your Associations make tea a subject for especial consideration. Worry whenever worry can prevail. Good times must come for you, but I grant you the Indian planters are very severely handicapped. There are lots of young fellows in Ceylon, with money earned by the sweat of their (*fathers'*) brows. These would be the men for Wynaad, and Wynaad the place for them, if they knew what was good for them. But naturally Ceylon does not care to see its plump pigeons become birds of passage and the pigeons themselves prefer a merry life on their own little island. "It's so jolly here," I've heard them say, as if being jolly was all a planter had to think about."

So spoke my friend. And in spite of a fear lest my editor should cry, "bold enough," I venture to supplement his remarks with a few of my own. I have lately seen a report by a well-known Mincing Lane firm, on some experimental samples lately sent by a neighbour. I don't think anyone need say that Wynaad is unsuitable for producing good tea after this. While as to *quantity* there is no fear on that score. Here with the report, dated March, 1892:—

Description.	Value per lb.
Pekoe Souchong	... 1s 2d at 1s 8d
Pekoe	... 1s 8d at 1s 9d
Orange Pekoe	... 2s 4d at 2s 6d
Broken Pekoe	... 1s 8d

"These teas are evidently from finely picked leaf and are well made. The liquors have good strength and flavour, and are in every way satisfactory. We may add that we now rarely see better tea."

What has been done under discouraging circumstances, may surely be yet improved upon, with decent encouragement. *Verb. Sap.—Madras Times*, June 14.

[We quote the above because it is well to hear all that is said against as well as in favour of Ceylon as a tea producer; but we need scarcely say that we entirely disagree with the pessimist view expressed regarding the soil and climate of Ceylon for tea-growing and the progress and permanency of the enterprise.—*Ed. T. A.*]

COFFEE AND ITS POSSIBILITIES

Aside from its use as a beverage, which "comforteth the heart and aideth digestion," coffee has great possibilities because of its pleasant, agreeable flavor. In order to stimulate its use, we give directions for preparing a variety of dishes, all of which will be found to be excellent. Only the best varieties of coffee must be used, great care being taken to avoid those of rank and bitter flavor. A mixture of two-thirds Java and one-third Mocha or extra high grade of fine old bean Maracaibo should be used or any of the finer descriptions of Guatemala or other Central American coffee. Use only that which is freshly roasted and freshly ground.

COFFEE FRITTERS.

Cut some stale bread into neat and rather thick slices, and soak these in very strong, freshly made coffee. Beat up the yolks of one or two eggs (according to the amount of fritters you wish to make), flavoring them with a little sugar and a few drops of strong coffee; brush the slices of bread with this, and fry at once in hot oil or butter; when just crisp and a light golden-brown tint, lift them out, drain them well, and serve them at once, sprinkled with sugar. Of course, all crust should be removed from the bread, and the coffee should be both freshly roasted and freshly ground and of very good quality if the fritters are to be a success. The outside should be just crisp enough to eat short, though the inside should be soft and very strong of the coffee.

COFFEE BLANC MANGE

is made of equal parts of coffee and milk—a pint of each; to the whole add four spoonfuls of corn starch, the same of sugar, cooked three minutes and then poured into wet molds to harden.

COFFEE JELLY

is a very acceptable dessert, especially if served with whipped cream. Put one ounce, or half a package of gelatine to soak in one coffee-cup of cold water and two of strong, clear coffee. Stir in one full cup of sugar and then the gelatine. When boiling hot pour into molds. Any liquid or any food that contains gelatine should never quite boil, or it weakens the glutinous properties we need.

A COFFEE CHARLOTTE RUSSE

is out of the ordinary line, and is made by soaking half a box of gelatine in half a cup of cold water. To one pint of thick cream add one small cup of sugar, and one cup of strong, clear coffee. Beat all till thick with an egg-beater; then stir two spoonfuls of hot water into the gelatine and stir into the cream, eating as well. Line a mold or pudding dish with lady fingers, or sponge cake slices, pour in the mixture and set upon the ice.

A delicate dessert is made of one quart of strong coffee, two-thirds of milk, half a box of gelatin, one small cup of sugar and three eggs. Allow the gelatin to stand in the milk for an hour, then beat the yolks and sugar together and stir into the milk. Put into a milk boiler and stir until the mixture thickens. Have ready the whites of the three eggs beaten to a stiff froth, and the moment the kettle is removed from the fire stir them quickly in, and pour into molds, and when cold place on the ice to harden.

COFFEE CAKE

made in layers is very nice. For the filling use the whites of three eggs, one and a half cups powdered sugar, and two large spoonfuls of very strong coffee. Beat all till light and smooth, and spread in as in chocolate cake.

Another way is to substitute coffee altogether for milk. It makes a dark, rich, delicious cake. Cream together one cup of butter and two of sugar, then add the beaten yolks of five eggs, then gradually add one cup of strong coffee, then three and a half cup of flour—in which has been mixed two spoonfuls of baking powder. Some flour swells, when moistened, more than other brands. This mixture, or batter,

should be quite stiff. Add one level teaspoonful of salt, the same each of ground cloves, allspice, cinnamon and a little nutmeg. Then add one cup of seeded or seedless raisins, one cup of currants, a generous allowance of thinly sliced citron, and one spoonful of brandy or wine.

Another recipe for coffee cake is as follows:

Three-quarters of a pound of butter, three-quarters of a pound of sugar, one pint of molasses, two teaspoonfuls ground cinnamon, two teaspoonfuls ground mace, two teaspoonfuls ground ginger, one teaspoonful ground cloves, one teaspoonful ground allspice, four eggs, whites and yolks beaten separately.

COFFEE ECLAIRS.

One ounce of butter, six tablespoons of water, one-half pound of sugar, one gill of strong coffee, 2½ ounces of flour, four eggs and coffee filling. Put the butter in a saucepan on the fire with six tablespoons of boiling water. When beginning to boil, add the flour (about the quantity indicated, perhaps a pinch more). Stir with a wooden spoon three minutes, or until it leaves the sides of the saucepan and is very stiff. Remove, and add, one at a time, the eggs, stirring each in very thoroughly. Have ready, slightly greased, an éclair-pan (they can be had made of sheet-iron, and are very good). Set in quick oven for about 15 minutes. Watch very carefully, as, if the oven is too hot, they may scorch. They must not brown. When done, make an incision in the side of each and fill with sweetened, whipped cream flavored with coffee or with coffee filling made as follows: Make a cupful of strong black coffee, Mocha and Java mixed; add to this a little cream, about one tablespoonful, and half a cup of sugar. Bring to a boil and stir into it two heaping teaspoonfuls of corn starch blended with a little cold coffee. Have two eggs beaten in a bowl. When the coffee has boiled three minutes, stirring all the while, pour it gradually upon the eggs, stirring briskly. If not quite thick enough, set over boiling water on fire, and stir until the egg sets a little. Do not boil or it will curdle.

Icing for the Eclairs—Put into a china-lined saucepan the sugar and one gill of very strong, good coffee; a mixture of Mocha and Java is best. Boil it until it makes a thread when dropped from the spoon. Drop a little into a cup of cold water; take it between thumb and finger and if it makes a fine thread without breaking, it is ready. Remove from the fire and stir until it begins to thicken slightly; then coat each éclair with it.

COFFEE ICED FROTH.

Mix together one quart of pure cream, one-half pint of very strong coffee, three-quarters of a pound of sugar. Strain and whisk until it is converted into froth; then place lightly in glasses.

FROZEN COFFEE.

Grind three-quarters of a pound of fresh roasted coffee quite fine and put it into a gallon jar, first scalding the jar with boiling water. Put three quarts of water into a kettle on a quick fire; at the first boil pour it on the coffee, stir well, cover and set a warm place to draw. Stir occasionally for five minutes, let stand till well settled, pour off the clear coffee through fine muslin, add water to make three quarts, dissolve one and a half pounds of sugar in it and cool. Place in a freezer, add the white of one egg, and freeze as directed above to a soft mush, like wet snow. Serve in tall goblets.

This is a very popular ice in France, and is called "Café frappé à la glacé;" also "Café moussoux."

COFFEE CREAM.

One-half ounce of gelatine, one gill of strong coffee, one gill of sugar, three gills of cream. Soak the gelatine one hour in one-half a gill of cold milk. Add the boiling coffee and the sugar. Stir and dissolve. Place it over boiling water on the fire if not quite melted, and stir until dissolved. Remove from the fire. When cool, stir in the cream. Rinse out a mould with cold water. Strain the mixture

into it, and set away on the ice to harden. Turn out on a cut paper and serve immediately.

COFFEE ICING.

Take a gill of very strong, well cleared and strained coffee; stir into it powdered sugar until thick enough to spread. Cover the cake and set away for one or two hours in a cool place. If a thicker icing is wanted add a second layer.—*American Grocer.*

SOME NOTES ON PALM OIL.

A gentleman who knows the palm oil regions well has supplied the following information: The Elais Guineensis commences to bear after the fourth year, and though it has never been cultivated, yet in some parts anyone cutting down a palm tree must plant two others, and in other places the cutting down of palm trees is forbidden on any pretence. The trees do not come into full bearing till about the tenth year, when they may bear in the first season of the year four to six bunches, and in the latter season two to four. All the nuts when young are dark—of course, some darker than other—and as they ripen the color changes to all the shades that oranges assume. There are no black nuts. The processes of making the oil varies in different parts, but essentially it may be said to be by two processes, viz: by pressure, and by boiling. On the Liberian coast both processes are in use, but on the Gold Coast and the Oil Rivers only the latter process is adopted. In both there are similar points, viz: 1. The bunches of nuts are left some few days after cutting before anything is done to them, not only for the purpose of getting a sufficient quantity together, but to facilitate detaching the nuts from the bunches. The nuts are fixed so closely and firmly that it is very difficult to knock them off, but by leaving them a day or two they get fully ripe, and will of themselves fall out of the bunch. 2. In both processes the nuts are boiled to facilitate the detaching of the fibre carrying the oil from the hard shell, of the nut or kernel cover. 3. The nuts, after this boiling, are either beaten in wooden mortars or are trodden by the feet in troughs made in hard clay, not stone. In the dry process, after the fibres have been heated in an iron pot, it is put into a bag and pressure applied in the fashion of a tourniquet. The oil has then some of the watery juice of the pulp, and has to be left to settle, when the water carries down the pulp and the oil can be readily poured off, but if left too long fermentation sets in and the oil will reabsorb the pulp and the water, and then will commence that unpleasant smell which some of the oils brought to this country emit, and this is in proportion to the amount of the pulp left in the oil and the fermentation. In the wet process nuts, after boiling, are placed in vats or troughs made of clay, and, with a proportion of water, are trodden till the fibre is detached from the nut or shell. The nuts are then washed in hot water, and the fibre and this hot water are mixed and placed into a double row of pots made of earthen ware with a fire between them, and as the oil rises to the top of pot it is skimmed off and put into the next in the row, and this goes on till all the water and fibre have been passed through the process, the oil taken out of the last pot being quite pure and free from any impurity, and best Lagos oil is this pure oil. But tricks there are in every trade, and as it is the property of palm oil to undergo fermentation if some of the pulp and water is left in it, and this increases the bulk, and the oil is bought by the liquid measure, so there are unscrupulous men who purposely leave this pulp, and even later on some of the middlemen whose hands it has to pass through will and some wild sweet potato, which will start a fermentation even in the best of oil. Palm oil when new, and if pure, even after years, has a pleasant odor of violets and sweet almonds. The hardness or softness of the oil depends on the soil or the process of manufacture more than the color of the nut. On the Liberian coast the river Sanguin divides what is called the Basso from Kuro country. On one side the

soil is hard, and on the other soft, Basso being more clayey and the wet process being generally adopted, whilst Kromo uses the dry process, the soil being more sandy.

The total import of palm oil into England is about 50,000 tons, valued at over £1,000,000, but it is considered that this is an exceedingly small commerce compared to what might be the case were the enormous resources fully, or even moderately, utilized. For miles along the west coast of Africa, extending between Cape Bianco and St. Paul di Loando, there are vast forests of palms, the oleaginous fruit of which has, for centuries, rotted unused upon the ground. The oil palm forests at the back of the coast line of Cape Palmas and Elmina are said to be practically inexhaustible; and so in the neighbourhood of Fernando, P., immense tracts are covered with the trees. Lagos furnishes the purest oil; for there are in commerce regular and irregular oils. When analyzed if the water and impurities exceed 2 per cent, an allowance is made; for often these oils contain 10 to 15 per cent of water and impurities.

Palm oil is eaten as butter by the natives, and used for anointing their bodies. Here it is used in the manufacture of soap and candles, and in South Wales in the preparation of tin plates. Its non-drying qualities render it valuable as a preservative of the surface of the heated iron sheet from oxidation until the moment of dipping into the bath of melted tin, the sheets being rapidly transferred to that from the hot oil bath, which consists almost entirely of palm oil.

In 1871, as well as in 1880 and 1891, the imports of palm oil into the United Kingdom exceeded 1,000,000 cwt. From 10,000 to 15,000 tons of palm oil are shipped direct from Africa to the Continent. The price of the oil has ranged from 35s per cwt. in 1883 to 23s in 1800.—*Oil, Paint and Drug Reporter.*

MIMUSOPS HEXANDRA (SAPOTACEAE) is thus noticed in the proceedings of the Madras Agricultural Society:—A large tree with elliptic-ovate obtuse or emarginate leaves and sub-terminal clusters of greenish-white flowers in 2 to 5 together. Our tree in the garden had its top broken off by the cyclone of 1888 and so now only measures 28 feet in height. The tree is a native of the Deccan Peninsula and Ceylon, is cultivated in North-West India where the ripe olive-shaped yellow berry is well known in the bazaars under the name of "Kirrni" but is said to be powerfully astringent. Watt's Dic. Ec. Products of India, vol V., p. 251—says "heart wood red, very hard tough close, and even grained; weight 60 to 72 lb. per cubic foot, used for sugar mill beams, oil-presses, house-posts, &c., and recommended by Brandis as an excellent wood for turning. It is figured in Wight Ic. t. 1587, under the name of *Mimusops indica*."

SUNFLOWER SEEDS.—The sunflower, after serving for a time to delight the more florid types of aesthetes, is now at last—like some of its worshippers—settling down to honest work. In Southern Russia it is extensively cultivated, principally for the bright yellow tasteless oil yielded by its seeds. This oil is said to be superseding olive oil throughout Southern Russia, just as that expressed from cotton seed is exported to Europe to get the custom-house brands, and then reimported with these testimonials of its place of origin having been Italy or France. Yet even in these lands earth-nuts from Africa supply not a little of the "pure Florence oil." The seeds of the sunflower, like those of flax (linseed) similarly treated, are, after being pressed and the leaves mixed with clay, given as food to cattle, while the stalks serve, as do those of the wild species in some parts of the western prairies, for fuel. In common with the eucalyptus, the sunflower is affirmed to dry marshy ground and counteract the development of malaria germs. But this, we fancy, is simply because it soaks up the superfluous moisture. On the other hand, as most gardeners know to their cost, the plant soon exhausts the soil in which it is grown.—*Home Paper.*

THE CONTROVERSY AS TO QUANTITY
AND QUALITY IN CEYLON TEA:
VIEWS OF AN EXPERIENCED
PLANTER.

We are glad that Mr. John Ferguson's letters in the *Financial News* are to be supplemented and the conclusions he stated verified by the very able letter from a planter of wide experience and of keen powers of observation, who occupies a post of great responsibility in Ceylon. The gentleman in question sends us copy of his letter for publication, with a note to the following effect:—

"By the last mail I sent copy of the enclosed letter to Mr. John Ferguson in London, and asked him to read and forward to the editor of the *Financial News*. If you care to publish it please do so. There is nothing new in it; but it may induce some other planters to come forward and discuss the matter. As regards what home critics write I refer in my letter to the advice so frequently urged by the brokers in their circulars: *we understand our business better than they can tell us from London.*" It will be seen that the writer has no doubt as to the stability of the tea enterprise in Ceylon, but he is anxious that, in justice to local managers, the effects of cultivation of our new staple on old and largely exhausted coffee land should be appreciated. From such land or any land at low altitudes, it would be most unreasonable to expect tea of equal quality to that grown in virgin soil of superior richness at high altitudes. The wisdom, therefore, of proprietors of the former class of estates is to cultivate with reference to quantity, being contented with medium quality. In truth proprietors of tea property must study what will *pay* more than what will please exigent brokers or amateur critics at home. The misfortune is, as was proved in the case of the late Mr. James Taylor, that some non-resident proprietors devoid of, or having had but little, local and practical experience share the ignorant prejudices of the brokers and the critics. The writer of the letter does not fail to point out the influence of pruning on the quality of tea. The best tea-maker in the world cannot make tea of the highest quality from the first few flushes which succeed the pruning process,—a process which has to be performed annually in the case of many lowcountry estates, while on properties at great elevations pruning can be safely deferred for two and even three years. Finally the important influence of abnormal meteorological conditions, such as prevailed last year, are adduced, as showing that in the face of masses of leaf forced into existence by excessive and, therefore, crude and flavourless in juice, while the atmosphere is chronically damp, the most skilled expert cannot make fine quality tea. Ceylon is, we hold, exceptionally favoured in being able to produce fine teas at high elevations and medium teas, from sea level to 3,000 feet above it. To the owners of lowcountry properties quantity compensates for quality; while the more limited quantity yielded at high elevations (which, however, is greater than was ever anticipated) pays equally, from the higher prices obtained. What many brokers and others seem to desire and expect is that Ceylon should export all and only high quality tea, whatever the state of the market and the prices offered may be. This Ceylon cannot do: cannot afford to do. It is no new experience that the buyer should cry "It is naught! It is naught!" But the cry as applied to Ceylon tea is as unreasonable as it was when used with reference to products in the markets of Palestine in the era when the book of Jewish Proverbs was compiled. The letter will be found in another column.

THE IMPORTS AND DELIVERIES OF TEA
FROM VARIOUS SOURCES IN THE
LONDON MARKET IN THE
SEASON ENDING MAY 31ST:
GREAT INCREASE IN DELIVERIES OF
CEYLON TEA.

The Indian tea season extends from June of one year to May of the next; and Messrs. Gow, Wilson & Stanton in their latest circular have made up the figures to May 31st of the present year, which are certainly encouraging to Ceylon planters as far as relative consumption is concerned. The total imports from India, Ceylon, Java, China, &c., in the past three seasons ranged from 28½ millions of pounds down to 220,800,000, and up this last season to nearly 238½ millions. Deliveries have been more than in proportion, rising from a little over 224 millions to 228,700,000, and this last season to no less than 241,337,000 pounds. While the deliveries of Indian tea have risen in the three years, only from somewhat over 101 and 100 millions to somewhat over 108 millions, the increase in the deliveries of Ceylon kinds have increased by leaps and bounds, from under 32 millions to 42,615,000 and finally no to less than 61,359,000. That is to say, while the deliveries of Indian tea increased in three years by less than 8 millions, the deliveries of Ceylon teas nearly doubled in the 3 years, the increase being 29 millions. Java has fluctuated, but the average of deliveries is under 3½ millions. China, meantime, has gone down from 87,652,000 and 81,382,000 to 68,600,000, only 7 millions more than Ceylon, so that probably next season will see Ceylon ahead of China; a result no sane person would have ventured to predict a score of years ago. Those who are so fond of decrying the quality of our Ceylon teas had better solve the problem of their being so much in demand by consumers. The deliveries of Ceylon tea in May were within 2,600 lb. of the round 6 millions of pounds, against 9½ millions lb. Indian, 5,051,000 lb. China, and 257,000 lb. Java. Stocks of Ceylon tea are higher in comparison with other kinds, but this will be remedied, and we trust prices may improve. Average prices for Ceylon teas during the season are not given; but if so given they would certainly compare well with those for the Indian districts. In India as in Ceylon, with some exceptions, the teas grown at high altitudes realize prices in proportion to elevation. Darjiling, on the side of the Eastern Himalayas, where, as in Ceylon, tea is cultivated up to 6,500 feet, takes the lead with an average last season of 11½d per lb. Assam comes next with 10d. The Terai (below Darjiling) follows with 9d. Why the high-grown teas of the Nilgiris should be down to 7½d, and those of the Kangra Valley, Kumaon and the Dehra Doon should average only 7½d, is a question which we should like to see answered. Of course the cold of the mountains of Northern India may be too severe, or droughts may operate deleteriously. An altitude of 6,000 feet, in from 27° to 30° North in India is equivalent to fully 8,000 feet in Ceylon, so near the equator as 7° North, and within the influence of both monsoons.

COFFEE PLANTING, &c., IN CENTRAL
AFRICA.

Milangé, 25th February 1892.

Since writing to you in August last there have not been many changes here. We are now well through our wet season and I have managed to get over 100 acres of coffee planted and would have finished double 200 acres had it not been for want of labour. I find that the African villager after he has earned

enough of calico to cover his nakedness his requirements are nil, and it will take a long time before we can induce him to take to luxury: he must be educated to them, and nothing but time and civilizing influence brought to bear upon him will do it.

We have other fields for labour although distant, which can be tapped and must be, as we can never depend upon other than immigrants from the Lakes district and other parts of Nyassaland where there is a teeming population, for coffee cultivation, for just at the time when labour is most wanted during the wet season our local supply fluctuates so, and sometimes fails altogether, that its a hopeless job. I am making arrangements to get Atonga labour from Lake Nyassa: they come for 12 months. Buchanan Brothers and the African Lakes Company always have Atonga labour under an engagement.

Smallpox has gone right through the villages about here committing great ravages amongst the people.

I would have liked to let your readers know upon what terms land can be bought or leased from the British Central African Administration, but cannot get a reply from the Commissioner on the subject. He has put a stop to purchases from native chiefs, and delays settling all land questions, for what reason no one knows. Some say he is grabbing all he can for Rhodes who is paying £20,000 per annum for 2 years for B. C. A. A. However, be this as it may, it is to be hoped that a fair and equitable settlement of all claims will be made soon, as long and vexatious delay disgusts settlers, and bars advancement and enterprise.

The African, as a labourer, if he could be only compelled to work, beats the Tamil cooly to sticks for physique and everything else: they do twice as much work; but it is more through fear of the white man than anything else. This fear will, no doubt, wear off in time; in fact, my near villagers are beginning to what would you call it, too fond of malingering or idling when the master's back is turned, just like the Tamil cooly.

The administration forces at Lake Nyassa have met with a serious reverse, and the loss of poor Capt. Maguire and others. Since they were here and conquered Chikumba they have marched through the country with success in every instance of opposing chiefs till the present.

The Lake Nyassa tribes are numerous and straggling and it seems absurd our Administration's small force trying to conquer them by force of arms, which has resulted in raising a nest of hornets about quiet and inoffensive planters, missionaries and traders, who are now threatened by the combined forces of the powerful chiefs at the south end and s.-east shores of Lake Nyassa to be driven out of the country.

The Commissioner and the remainder of the deceased Captain's force have retired to a small fort named Fort Johnstone on the Shiré at the entrance to the lake where Makangeries and Makandangis forces have appeared in a hostile attitude, but fortunately retired after having a look and nothing more. Now I hear that the Sikh soldiers have rebelled because they don't get wheat flour and I don't wonder at it: those soldiers have put up with more than any other class of men would. It appears no provision has been made for feeding the poor fellows, and they have actually been nearly starved at times, having to depend upon obtaining native food. Indian corn, and millet of which the people here only grow enough for their own consumption, as there is no market for more.

Although endeavours have been made to obtain supplies locally causing almost a famine in some districts, the supply has been totally inadequate for so many months, of course Zanzibaris included. These latter rascals have in some instances, which have come under my notice, actually with loaded rifle extorted from the natives and made the robbed carry food for the robber. Enough on this subject. Most of the residents here, at least those whom I have seen, say that we were better off without the so-called B. C. A. A., and I am of the same opinion.

The country is not developed enough yet to require administration and cannot support it. How

on earth are the people to pay gun taxes and all sorts of other taxes when there is no money in the country, and the monthly hire of a labourer is only enough of calico to keep himself and family from shameful nakedness? It is said the taxes can be paid in kind, fowls, grain, &c. What is the use of that when there is no means of converting the produce into money, 300 miles away from the coast, and some parts over 1,000 and Indian corn flour selling at 1d per lb. at home. Ivory there is none except in the far distance where the B. C. A. A. forces dare not go I fear to collect it. "Ah! well, we shall see by and by they say."

Coffee is looking splendid at present after so much wet weather. We have had over 40 inches of rain since Nov. last to date, and 118 days were rainy during last year—Jan. 18, Feb. 24, March 14, April 6, May 3, June 2, July 4, Aug. 3, Sept. 4, Oct. 5, Nov. 15 and Dec. 20. So you see we have perfection of a climate for coffee, at least I think so; but we have many difficulties to contend against which I cannot find time to enumerate at present.

The suitable land within reasonable distance of river transport is all taken up by private individuals except what is claimed by the Commissioner for the British Crown or Mr. Rhode's administration whose representatives here seem to try and ride the high horse over enterprising traders and planters who have been here for years and question the B. C. A. A.'s right to land, which the officials propose to take from them, only allowing one planter to hold 250 acres whether he has a title to 1,000 or not, and whatever price he may have paid for it, at least so the rumour goes; that such is to be the decision of the Commissioner when he holds the land courts, of which I made mention in my last letter, but no fixed date is yet known.

It is a pity we have no newspaper here like the Old Rag to take up our cause of discontent. I can only say, without going into details that should the Commissioner carry out all the schemes that he is reported to entertain, with reference to the planting, trading and mission enterprise, we may all shut up shop, and leave the country.

It is agreed upon all hands and the missionaries are the most sanguine that we were better before and would be much better off now, if left without Rhoe's administration which is forced upon us unnecessarily.

The only good they have done is to start a postal service, but that we had before: the African Lakes Co. did the work as well at less expense. The road which was to be carried through to Lomba and Lake Nyassa was started, but only about a mile completed, then deserted for want of funds, they say. So we are not to get a road for goodness knows how long, leave alone tramway. So full of hope 8 months ago but now in despair about getting away our bumper crop 2 or 3 years hence. I hope I won't tire and disgust you about our Government affairs, but I am sure your notice of our little grievances would bear weight at home and be the means of some inquiry being made into the conduct of the B. C. A. A.'s behaviour to both native and European British subjects.

P. S.—In your *Observer* of 21st February I see a letter signed, "Afrikander," warning intending voyagers to East Africa (I don't know what part he refers to as I have not seen the advertisement alluded to) about malarious fever. I can endorse every word the writer says, as the plain and unvarnished truth, if he refers to Nyassaland. If I have been once down with fever I have been twenty times, since I came here; but still stick to it in hopes that the place may become more healthy as the country is opened up. The mortality amongst young men in this country is fearful to think of: since I came here amongst a small European community (about 50) there have been about ten deaths mostly from fever, the last being a fine strong specimen of a Scotchman, poor David Buchanan who has been planting here for years.

MILDURA.

[Mr. W. A. Tytler sends us the following cuttings, and writes:—"Please mention that I sent them to show I mean honestly by your readers, so as to show them both sides of the question."—Ed. T. A.]

MILDURA IRRIGATION COMPANY.

An extraordinary general meeting of the shareholders in the Mildura Irrigation Company was held last week at Mildura to appoint a committee to confer with the directors as to the working of the company. The chair was taken by Mr. W. B. Chaffey, one of the directors, and Messrs. F. Hodge and W. M. Paterson, directors, were also on the platform. Mr. N. Jamieson, in moving the first resolution, said that it was originally intended simply to appoint a committee to confer with the directors, but within the last week, in consequence of representations made to them, the directors agreed to enlarge the field of action by empowering the proposed committee to make the fullest inquiry into the position and working of the company. The present action had been caused by the uneasiness and mistrust felt throughout the settlement. This feeling was mainly attributable to ignorance in regard to the formation of the company, its right standing, and the extent of the liability of the shareholders, and also as to the distribution of the shares and the powers conferred by their possession and as to the precise relations of the company with Chaffey Brothers Limited. The resolution was as follows:—"That a committee be appointed to confer with the directors, and to inquire into the constitution, finance, and general management of the affairs of the company; that for this purpose all documents, books and papers the property of the company be open to them for inspection, and that the officers of the company be instructed to give the committee every assistance and information, and that the committee report on the above and any other matters connected with the interests of the company to the annual general meeting in May, or to a meeting of shareholders to be called for that purpose;" and it was carried unanimously.—*Sydney Mail*, April 23rd.

WATER RIGHTS AT MILDURA.

MILDURA, May 4.—The first sitting of the County Court in Mildura was held today under Judge Gaunt. There were ten cases on the list altogether, one of which, *Cobram and Mahony v. The Mildura Irrigation Company*, for damages arising from insufficient water supply, was of considerable importance as touching settlers' general water rights in connection with the company.

In opening the case the plaintiffs' counsel, Mr. C. E. Sewell, said the action was brought to recover the sum of £187 6s for losses sustained by them owing to the refusal and neglect of the defendant company to supply sufficient water, whereby certain vines and vegetables were destroyed. In order to have a clear idea of the matter, he said it would be necessary in the first place to refer to the agreement between the Government and Chaffey Bros. Limited. One of the conditions of that agreement is that in every sale or transfer of land by Chaffey a sufficient water right shall be secured to the purchaser to be held with and run with such land as a perpetual easement, so far as the same may be secured by the licenses. As a convenient mode of securing this water right, Chaffey Bros. created a separate company under the title of the Mildura Irrigation Company. The plaintiffs bought a section of land, being a portion of 50,000 acres granted to Chaffey Bros. under the agreement referred to. On making the purchase they, as do all other purchasers, signed an agreement accepting shares, one share for each acre purchased in the Mildura Irrigation Company in satisfaction of the water right, thereby relieving the Chaffey from the water conditions in their Crown grant. Mr. Sewell, however, contended that the purchasers were still entitled to not less than the water rights conditioned in the Government grant, but a clause in the agreement stipulates that the water may be supplied at such times and in such quantities as directors of the Irrigation Company think fit.

Judge Gaunt said, before considering what the plain-

tiffs were entitled to, it must be ascertained whether a shareholder could sue the company. This was an action to recover damages from a corporation of which the plaintiffs were members.

Counsel argued that his clients were entitled to sue the company for breach of agreement.

Judge Gaunt said he knew of no case of the kind. A member of a company was in the position of a partner, and could not sue for damages. They were not now considering the Chaffey's agreement. The plaintiffs in signing the agreement had discharged them from liability. Whether the Chaffey could thus relieve themselves of responsibility by handing over their duties to another party—namely, the defendant company—was not a matter then before him.

Mr. Sewell:—Then have the shareholders no remedy?

His Honour:—They have as shareholders certain powers in respect to the company itself.

Mr. C. E. James, for the Irrigation Company, said the defence rested on the following points:—(1) The company was under no agreement to supply sufficient water to plaintiffs' vines and vegetables; (2) that, in fact, there was a sufficient supply; (3) that this supply was given as an act of grace; (4) that there was no obligation on the part of the defendant company to supply any water before the necessary works were constructed. Even if the liability of the company were admitted the action was improperly brought, and the remedy should be sought, if at all, at equity, not at common law. For the defence it could also be shown that the plaintiffs' loss was due to their negligence and incompetence. He (Mr. James) regretted that a technical question had arisen, as the defendant company would have preferred to go into the matter on its merits. At the same time he contended that the plaintiffs, as shareholders, were co-partners, and as co-partners should have sued in equity.

His Honour said that was his view of the case, and the plaintiffs were non-suited, costs to follow the verdict.—*Australasian*, May 14th.

THE CEYLON TEA INDUSTRY.

Ceylon, 14th June 1892.

To the Editor, the *Financial News*.

Sir,—The correspondence published by you under the above has been copied into the Ceylon papers, and, no doubt, has been read with much interest by a large proportion of the planters here.

Mr. John Ferguson's letter to you of 19th May has put the matter fairly before you; he has grasped the subject with great clearness.

I venture now to make a few comments, because there is not a little, but a very great misconception of the matter of tea growing and its manufacture existing in London, and I, and a good many other planters, have suffered from the position of knowledge wrongly assumed by non-practical men at home, who invariably cry for quality, *quality*, without in the least knowing how this speciality is attained on the majority of estates.

In the first place, it is, no doubt a well established fact that the Ceylon climate is the best known for the vigorous growth of the tea bush and consequent "flushing." Rain falls in every month of the year. The soil never becomes parched, and bushes in many districts are ready for tipping from 7 to 8 weeks after pruning. Compare this condition with Indian seasons, where they have two months' drought and the plucking is done in about six months of the year. So much for our *climate*: a few words now about the soil.

None of your correspondents appear to have laid stress on the fact that the great majority of estates are not opened out on *virgin* soil, but on coffee estates from 20 to 50 years of age; this fact must influence the *quality* according to the circumstances of each estate, its particular district, and the 'lay' of the land and the number of years the land has been exposed to the sun and washed by heavy

storms. How often has it been noticed that estates after getting strength and a little flavour go off into medium and "common" teas, directly the bushes approach the "full bearing" stage. Brokers at once compare the quality with the earlier shipments, and the proprietors and others assume it is the fault of the manager, who does not give the close attention with which he was credited at first; the novelty of *manufacture* has evidently worn off! Then follows trouble, because the brokers and the proprietors have steadily opposed his plea for *quantity*. Now suppose a manager has strict orders to produce quality from old coffee land at say 3,000 feet elevation—only the finest plucking can possibly give him the desired result, but the quantity per acre is so woefully small and the cost of production so much increased, it does not pay. I could name one estate, which headed the list of averages and was the pride and glory of the proprietors at home and the envy of others not getting half the price for their teas in Mincing Lane, but, what happened? This estate, which got an average of 1s. 10 $\frac{1}{2}$ d., has had to drop its pride of place and come down to the hard facts of profit and loss, *i. e.* Quantity *versus* Quality. As a matter of fact, the estate was being strained to compete with those at a high elevation, whose soil was never exhausted by coffee, estate too, which have all the natural advantages of rich soil and great elevation, a combination only which can produce the class of tea with fine flavour and for which a high price will always be paid in England. Such also has been the case with other estates more or less. It is also found with more ripened experience that the yield from estates at a high altitude and in good soil is much greater than was anticipated in the earlier days of tea planting.

Finally to show what in my opinion is the common mistake at home, *viz.* The quality and quantity thereof, presuming the desired end is to make an estate yield a good dividend, and that estates favorably situated as regards elevation and soil *only* can produce high class teas to pay, those old (coffee land) estates at lower elevation should not be forced by proprietors to compete for high prices; they should be satisfied with prices even lower than the "average for all Ceylon" and rest assured that with cheap working and high yields per acre, it is the only way to make estates so situated remunerative the opposite result will inevitably occur if fine plucking is adopted. I do not go into the question of "the survival of the fittest." When the struggle comes, we shall naturally know more than we do now; but, so far as Ceylon Tea *lasting* and its *stability* being in danger, I have no fear. There are, of course, a number of estates with poor soil, and heavy rainfall and which were cheaply converted from coffee into tea, without any consideration as to *yield*, which will sooner or later cease to pay but these estates in no way affect the general permanence of tea in Ceylon. The instances quoted by Mr. John Ferguson of Looe Condera and Mariawatte estates are, however, somewhat exceptional, as the old field of the latter and all the former were not at any time in coffee, but were planted in virgin land and, so far, have had every advantage, especially Mariawatte which has been freely measured. The late Mr. James Taylor informed me, that the old tea on Looe Condera yielded over 380 lb. per acre for many years; this was with *fine* plucking, without which, he said, he could not produce teas of the quality for which that estate was renowned before the present competition prevailed.

The letters you have recently published from Mr. Hawes, Messrs. William James and Henry Thompson, contain interesting information, but I am impressed with the fact that the area in Ceylon at present in bearing, which can produce the *finest* teas, is limited in proportion to the area yielding "good medium," "medium" and common teas, and that it is a fallacy to try and force the latter to compete with the estates at high altitude.

Mr. John Ferguson has so clearly recorded the facts and figures connected with Ceylon tea, there is nothing much to say without repetition, but I may add that some misconception of the tea enterprise exists in India as well as at home. I

have recently had the pleasure of showing an Indian tea planter of experience some of the estates here, and he writes informing me that he was much surprised at the exceedingly fine growth of the tea and the forward state everything was in—the cultivation is the best he has ever seen, and he *regretted* to find that the soil, climate and circumstances generally, were much more favourable than he had been led to expect.

From a long experience of both coffee and tea planting, I find that the practical planter is the man, who is most diffident, the longer he works the more he finds there is to learn, but home theories are full of fallacies—the result of pure imagination and conceit.

The chemical constituents of the tea leaf improves according to the length of time it has run from pruning. Some of the lower districts have to be pruned once a year, while estates at 6,000 to 6,500 feet will run as long as three years. The weather too is of the greatest importance, solar influence causes a rapid elaboration of the sap which improves the quality of the green leaf and also causes a good wither in the factory. The manager's work is thus made easy, for with ordinary care he is bound to turn out his best teas. No doubt, the last two abnormal seasons and especially 1891, which was an exceedingly wet one, caused an enormous rush of leaf, which, being filled with crude sap, resulted in a preponderance of common teas but, to be told by our London friends we are making a mistake in losing sight of *quality* is ludicrous. Practical men know it is much easier to turn out good tea under favourable circumstances than "medium" or even "common" in protracted and abnormal wet weather. Dryers and fans are now being erected in most factories, and nothing is neglected, which conduces to the good quality of our teas.—Yours faithfully,
TROPICAL RUSTIC.

CULTIVATION VS. DRAINAGE.—In the rainy season the surface crusts every day: "scalding" is largely the result of want of air, the failure of the roots to secure the supply of oxygen which they require, and which they can secure only through the breaking of the crust. We have seen tomatoes kept healthy and fruiting right through the rainy season, and that in the flat woods, by having the crust well broken after every rain with a garden rake. But this rule is imperative, it must be done after every rain, and, better still, every day, rain or no rain.—*Florida Dispatch*, May 5.

THE SUPPLY OF PALM OIL.—The total import of palm oil into England is about 50,000 tons, valued at over 1,000,000l. but this is an exceedingly small quantity compared to what might be the case were the enormous resources even moderately utilised. For miles along the West Coast of Africa, extending between Cape Blanco and St. Paul de Loando, there are vast forests of palms, the oleaginous fruit of which has for centuries rotted unused on the ground. The oil palm forest at the back of the coast line of Cape Palmas and Elmina are said to be practically inexhaustible, and in the neighbourhood of Fernando Po immense tracts are covered with the trees. Lagos furnishes the purest oil. If the water and impurities in the oil exceed 2 per cent an allowance is made, for often these oils contain 10 to 15 per cent of water and impurities. Palm-oil is used in this country in the manufacture of soap and candles, and in the preparation of tinplates. Its non-drying qualities render it valuable as a preservative of the surfaces of the heated iron sheet from oxidation until the moment of dipping into the bath of melted tin, the sheets being rapidly transferred to that from the hot-oil bath, which consists almost entirely of palm oil.—*Chemist and Druggist*.

THE LONDON CUSTOMS AND ADULTERANTS.

It was only recently that we took occasion to allude to endeavours being made at home with the object of inducing the Customs authorities of the port of London to consent to a modification of its present arrangements with regard to the grouping together for sale of small breaks of tea. We shall yet have to wait some time, we suspect, before we can learn whether those authorities can be sufficiently influenced to induce a relaxation by them of the existing rules made and carried out in this respect. But we now learn that the London Chamber of Commerce is about to institute a further attack upon the practice of these same Customs authorities, one which we feel sure will not be open to objection to its possible results in the degree that the application first above referred to is. It will be within the recollection of all of us how Mr. Gladstone at one time proposed to refuse to allow any mixture of coffee with other substances to pass through the Customs. This resolution was hailed with great satisfaction by all planters raising natural products; and the disappointment was equivalently great when, just at the moment that we believed this resolution was to be given the force of law, the then veteran Premier changed his mind and allowed these mixtures an entry provided only they were labelled as such. It was said at the time that this change had been entirely due to the remonstrances of a leading member of the then Cabinet under Mr. Gladstone's leadership who were personally largely interested in the manufacture—or preparation rather—of these mixtures. Whether that was the fact or not, it is certain that since that date coffee adulterated with chicory and other substances has been permitted entry. That great abuse should exist under this permission was to be foreseen; and it would now appear that that powerful body, the London Chamber of Commerce, is recognizing that this is so. Representations are, we learn, to be made by it exposing the evils done to legitimate trade by the permission accorded. The Chamber will not seek, it is said, to insist on the entire exclusion of mixtures of this character, but it will represent that under existing rules it is perfectly possible to introduce articles which may contain but ten per cent only of the leading ingredient, and it will be urged that this proportion is by no means infrequently to be detected. What the Chamber wishes therefore to bring the authorities to insist upon is that every label shall specify not only the nature of the admixture but the proportion of each of its ingredients. A false representation as to this proportion would of course subject the importer to an entire loss of the article dealt with, and probably, in addition, a very heavy fine. It is the case that we here in this island no longer feel the interest in this question that we had some years back, when the prosperity of Ceylon depended almost entirely on the success of its coffee industry. Tea does not lend itself readily to corresponding debasement by admixture; and although the blending of Ceylon tea with inferior kinds is an evil which might be checked had such blends to pass through the Customs, the application now to be made could scarcely affect our present staple. But after all coffee is still an article of export with us; and it is yet on the cards that the future may see this increase. He would be a rash man who would prophesy dogmatically that this may not be the case. We shall therefore welcome the interference of the London Chamber of Commerce should it result in producing fresh obstacles to the introduction of adulteration in whatever form they may be pre-

vented. There is an underlying principle in this which cannot fail to affect the interests of all raisers of natural products.

INDIAN TEA AT CHICAGO.

A correspondent writes to the *Englishman*:—Messrs. Gow, Wilson and Stanton's remarks ament the representation of Indian tea at the forthcoming Chicago Exhibition are very much to the point, and it will be, indeed, a pity if an opportunity such as this is lost in consequence of any petty feeling on the part of planters or others. A certain amount of money is required before any steps can be taken, and to raise, or help to raise, this sum it has been proposed by the Committee in Calcutta, in whose hands the matter has been entrusted, that the different tea gardens subscribe a sum which will represent, on the average, a tax on the tea produce amounting to about 3·10ths of a pie per lb., and when it is considered that the payment of this tax will go far towards obtaining a substantial price for Indian teas in years to come, by opening out new markets to them, it will surely be a pennywise policy for planters to withhold their subscriptions at the present moment. A lot has been written and spoken of the desirability of getting merchants, agents, brokers, shippers and others to subscribe, but the fact that some of these have already subscribed, and that many are daily subscribing in a manner which, although not apparent to the general public, is none the less effective in the interests of tea by way of finding new agents and markets for the disposal of the produce, has been rather overlooked. With merchants, agents, and shippers the tea industry forms merely an item of their business, whereas to the tea proprietor and planter it is "bread and butter." To whose interest then is it that the utmost endeavours be made to uphold the industry and to push it whenever possible? The present endeavour is for the common good of Indian tea, and all connected therewith, and it would be childish for those connected with one District to decline to subscribe unless some special effort was made to push the produce peculiar to their District as distinct from other Indian tea at the forthcoming Exhibition. What is wanted, first, is to obtain a footing by letting Indian teas and their superior qualities become known; and when this is done, the qualities peculiar to certain Districts will doubtlessly assert themselves. If, then, the representation of Indian teas at the forthcoming Exhibition and their pushing in the American markets is to be a success, planters and proprietors should not hesitate, but come forward at once, and as one man, with their subscriptions, and leave them to be dealt with by those who have been entrusted to look after their interests in the matter. Ceylon has subscribed a very fair sum, indeed, and would doubtless subscribe as much again were they called on to do so for the purpose of pushing their teas; and why India with her larger acreage and yields should be so far behind would puzzle one to imagine unless it is a want of unanimity among the Indian planters and proprietors.—*M. Mail.*

LORD CROSS ON THE LABOUR LAWS.

In reading the recommendations of the Viceroy on the revision of the Labour Laws, it is not surprising to find that Lord Cross expresses an almost pathetic regret that the relations of employer and labourer are to continue to be regulated by Act XIII. of 1859, side by side with the more elaborate, the infinitely more elaborate provisions of the Labour Law, properly so called. The views of the Secretary of State on the subject of the Artisans' Act, now perhaps the most strikingly brief and compendious enactment in the Indian Statute Book, must have been known to the Government of India. It is confessedly an Act not passed to meet the requirements of the Assam tea planter, being merely a short enactment passed to prevent the fraudulent taking of advances by artisans in presidency towns, It was intended to enforce the pre-

formance of tasks for which such advances had been taken, or at the option of the employer, the refund of the advance. It is known that its practical effect, in its application to tea-garden labour, is not to bring about the repayment of advances; for these are usually of trifling amount, and their refund is never demanded. The real working of the Act is to punish, by a side wind and a manifest distortion of its original purpose, the offence of deserting from tea-gardens after entering into an agreement to labour. The Act is usually applied, not to the new immigrants, who have cost the employer large sums of money, and upon whose labour he has just and equitable claims, as the only possible means of recouping his expenditure, but to time-expired labourers who are induced by the payment of an advance, not usually of very large amount, to give an agreement to labour for a term of days, months, or years. All these considerations, added to the expressed dislike of the Secretary of State to the application of the Act to tea-garden labour, constitute a very serious indictment, and it is interesting and useful to see what circumstances have induced the Government of India to hold fast to this ancillary and indirect means of preventing the desertion of labourers from tea-gardens.

In the first place, it is obvious that Lord Cross's distrust of the Act of 1859 is largely due to the fact that he is a trained lawyer and law-maker. It is obvious that to a man with such a training and with the habits of thought bred of it, a law, not only dangerously brief and summary in its wording, but admittedly wrested from its legitimate purpose, would not present itself in an attractive aspect. But it is not on this aspect of the matter that Lord Cross dwells in despatch. He looks with misgiving to the possibility that if the Act of 1881 be superseded, or if it be administered with such vigour as to distasteful to the employers of labour, the older Act may furnish a loophole of escape to planters who find it necessary to use the forms of law to prevent their labour force from deserting them. It is clear that there is force in this reasoning, and it is instructive to note how the Government of India meet and parry this dialectical difficulty. Their answer is, in effect, an appeal to experience, and is therefore an acceptance of the views of the Government of Assam, which alone has opportunities of watching the working of the two laws on the spot. In effect, the Government of India reply that though in theory Act XIII. in 1859 may be indefensible, in practice its working is on the whole beneficial to the interests of the coolie. Act I of 1882 is valued, it is pointed out, not so much because it affords more elaborate and more stringent means of enforcing discipline, but rather because it concedes the invaluable privilege of private arrest of runaways. Consequently, on gardens which are much subject to desertion, the use of Act I of 1882 is imperative, especially in out of the way places where recourse to magisterial aid, and the roundabout process of summons and warrant is expensive and dilatory. Hence it happens as a matter of practice and experience, that contracts to labour are enforced under Act XIII. of 1859, chiefly where tea-gardens are favourably situated from a coolie's point of view, and where the inducements to desert are merely the hope of getting better wages on another garden, or the mere love of change which is the common possession of human nature. It is used then, chiefly as a means of protecting the employer against other employers, and is supplemented by the action of Tea Associations and the force of public opinion, which makes it more or less incredible and disgraceful for one employer to help himself to the labourers of another. Practically, therefore, Act XIII. of 1859 is used in gardens which are popular among time-expired coolies, men who have had some experience of the conditions of life in Assam, and may be safely deemed to be able to take care of themselves. To such gardens as these it were a waste of energy to apply the elaborate provisions of the newer Act. Again, prosecutions under Act XIII. of 1859 are comparatively rare, the punishments inflicted are noticeably lighter, and it seems probable that the Act is used simply as a means of preventing coolies from taking advances in

one garden after another with no intention whatever of performing their share of the bargain.

It must be admitted that all this is a strong, practical answer to merely theoretical objections to the Act, objections which may be summed up in two observations—firstly, that the Act was framed to meet a different state of things from that to which it has been applied; and, secondly, that its working is one-sided and hinds the employer to no duty whatever other than the payment of a small advance. It does not even, it must be remembered, expressly provide for the payment of wages. It seems likely, indeed, that the Act as originally framed, contemplated the advance whole sum due for the performance of a stipulated tax. But in practice a magistrate would doubtless refuse to enforce a contract under Act XIII. of 1859, unless the wages usually mentioned in the contract were duly paid. Experience, therefore, shows that the Government of India are right in holding that the short and simple provisions of Act XIII. of 1859, practically furnish a stepping-stone towards the freedom of contract, the untrammelled migration, and the abolition of the penal conditions of the contract which is its avowed aim. The Act which the Secretary of State views with characteristic distrust—the distrust of a man of business who likes theory and practice to agree, furnishes one more example of the fact that the most elaborately and anxiously compiled enactments often fall short of the hopes of legislators, while judicial and executive discretion can use as a useful tool laws which at first-sight bristle with opportunities for mischief. And this must always, especially be the case in India, where legislation is the work of men not always in touch with the needs of those for whom they legislate. It is often well to leave subsidiary details to the administrators by whom Indian laws are enforced, and of this fact the Government of India have, consciously or unconsciously, furnished one more instance.

Admitting all this, it is well that all who are interested in the prosperity of the tea-gardens of Assam, should remember that a Tory Secretary of State has laid down, in a declaration which shows absolutely no sign of being framed to court popular favour on the eve of a dissolution of Parliament, that a system of enforcing contracts to labour by fine and imprisonment is not one which commends itself to civilised governments. It seems to us to be the obvious duty of employers of labour to restrict the use of the Labour Law within as narrow limits as possible, lest they should one day be non-plussed by the liberation of their coolies from the penal necessity to labour. The matter has now been discussed *ad nauseam*. The theory that planters require to be reconed the cost of importing coolies, has been proved to apply only to newly imported coolies, and is therefore no agreement for putting time-expired labourers under penal contracts. It has been tacitly admitted that the maintenance of the tea industry depends upon penal enforced contracts extending over long terms of years. It is a system which can only be defended on the ground, expressly and repeatedly urged by the Government of India, backed up by the quoted opinions of missionaries and officials, that after all the state of labourers imported into Assam is better, (in many cases it would seem incomparably better) than that of the friends they leave behind in the poverty stricken hovels of Behar and Orissa, and of the eastern districts of these Provinces. Against this must be set off, as the Government in India very candidly admit, the excessive mortality among new immigrants into Assam. This point has been noted by the Secretary of State, who, in the language of common-sense, seems to say—"Very well, you may go on as you are for the present, but you really must try and reduce the mortality." Whether this can be done, remains to be seen. In one respect, Assam is more favourably situated from a sanitary point of view than in former days. There can be but little extension of tea cultivation with so bad a market for tea as has prevailed during recent years, and it seems to be the opinion of the best judges that

it is on new clearances that the most fatal mortality occurs. We may congratulate the Government of India on making the best of present conditions, and yet hope, with the Secretary of State, that the time is not far distant when Assam will be linked to India by rail, and when the landless labourers of poorer provinces will throng to fresh fields and pasture new in such numbers as to make the maintenance of a special labour-law unnecessary.

We cannot doubt that the planters themselves, and their agents in Calcutta, will be among the first to welcome the change. Under present conditions many a planter has occasion to shake a gloomy head when a new batch of wretched aræmic, half-starved creatures are consigned to him to be his coadjutors in doing battle with the jungle. Some will live, become acclimatized and do good work in time; some will die; all will be useless and a source of anxiety and expense for many a long day. But the planter has no choice, and he has to make the best of the poor creatures who are tied to him by penal contract. He, too, must look forward with eager hope to a time when, without offering extortionate wages, he shall have a choice of labourers, and be able to pick out sturdy men and women for work which involves much exposure and steadier habits of labouring than most Indian races practice. But a change so radical as this will not be effected within many years; the railway itself may fail to attract labourers beyond the jute mills of Serajganj and Narainganj. In the meanwhile, it is reassuring to find Government buckling itself to the task, of seeing that the penal conditions of the law shall only be enforced on gardens on which the state of coolies, in the matter of health and wages, is really better than it was in their own country. This it can only do if it is well and loyally served by its subordinates in the performance of an invidious and disagreeable task, lightened, however, by the knowledge which the recently published despatches afford, that it is work which is held to be of the highest importance by the Government which they serve, and from which they will obtain what we are convinced, the fullest and most vigorous support.—*Pioneer*, June 14.

COTTON CULTIVATION IN GUZERAT.

Through the exertions of the writer the Gaekwar's Government were induced some time ago to issue an official notification under the signature of Khan Bahador Kazi Shahaboodin, C.I.E., then Revenue Commissioner of the State, which contains some very useful suggestions and practical directions for the cotton cultivators and traders living in the towns and villages of the Baroda districts. I subjoin a translation in English of this important document which is written in Guzeratee. It will I think be read with interest by the Bombay cotton merchants as it practically give effect to all their suggestions as to the proper mode of growing and preparing cotton for sale by the cotton growers of Baroda. Prizes should annually be awarded to the first class cotton growers the industry encouraged and made to flourish by all means in the power of the Government; and improved implements of husbandry introduced and brought into use. The worthy Kazi Saheb says in the official notification in unmistakable language that good seed should be sown in the territories of his Highness the Gaekwar to produce really good cotton, and unless this advice is strictly carried out by the cultivators, there is, I think, no hope of improving the cotton grown by them. They have good soil, plenty of water, field labour is cheap, and if there is a little more encouragement and guidance by the State, the prospects will soon improve. All that is wanted is careful nursing and rearing of the young cotton plants and seedlings, growing and sowing on scientific principles and judicious selection of cotton seeds. I daresay there is more growing, ginning, spinning, and weaving of cotton in India than in any other Asiatic country, and the Indians ought to be careful of this great source of wealth and industry for their country. If the Indians are not cotton-walks, they are nothing.

Much of India's future prosperity depends upon the exports and cultivation of good cotton, and I trust it will not allow this valuable industry to slacken, or be lost, for want of a little energy. In this direction Mr. Sheppard, the Revenue Commissioner, N.D. has done much valuable service, and is entitled to gratitude of thousands of poor cultivators in Guzerat. This is the notification alluded to:—

NOTIFICATION AS TO THE MODE OF PREPARING COTTON FOR SALE IN THE BARODA DISTRICTS.

"The cotton grown in the territories of this Government, owing to some mismanagement (or improper manipulation) in regard to it is not of so superior a quality as it might (or ought to be), or as it could be wished. For this reason the price it obtains is rather less, and the cultivators suffer loss. Therefore, some practicable suggestions that have been received from respectable Bombay merchants, who are in a large way of business, are here undernotified.

2. Cotton seed of good quality should be carefully selected, and from the time the plants shoot or grow up the cultivators should from time to time tend or nourish them carefully.

3. The cotton produced near Broach is much better in quality than that grown in the Baroda State. Therefore, it would be a very good thing if the cultivators endeavoured to sow cotton-seed as used in that part.

4. It appears that in many parts of the territories of this Government it is the custom to keep *kuppas* for several days in a pit dug into the ground, five or six hands deep. The *kuppas*, while it thus remains in the pit, absorbs moisture, and thereby becomes dingy, or discoloured, and of a dark hue, owing to the rubbish of dry leaves with which it gets mixed up. It therefore seems probable that if the custom were discontinued, good consequences will ensue. It would be proper to keep the *kuppas*, if it is all to be kept, under a roof or *dehela* (store-room.)

5. It also appears that small retail dealers and cultivators, who grow *kuppas*, and who raise money upon their products before the *kuppas* come to maturity (they are generally to be found in Nariad, Raji, Padra, Bal, and other villages, here *kuppas* of a coarse and inferior fibre grows) mix inferior kinds of cotton with really good stuff whereby the cotton produced in this State comes to be received as of a low quality. This should not be done.

Another suggestion to be also made is that *kuppas* should be cleared or ginned in these gins or mills which may be fitted with the latest and new mechanical improvements, as the cotton cleaned in these gins is the best and purest. The requisite brightness and purity cannot be obtained by having *kuppas* ginned or cleared by gins of inferior order and antiquated by time; thus it makes a difference in price. The ginning mill in the town of Nulla, in the Dabhoi district, is said to be a very good one, if the merchants and cultivators would act up to the suggestions herein-before mentioned, the quality and growth of cotton mill improve, and it will fetch a good price. "Be it directed to the Patels and Talates of the towns and villages through the gracious Suba Saheb (Khan Bahador Kazi Shahaboodin, C.I.E.) This is to be read out and explained to all the cultivators."—*Indian Agriculturist*.

TEA IN WYNAAD.

This heading must by now be familiar to all our readers, and those in whom it has bred contempt, may feel inclined to remark that, considering what it usually precludes, it is not unlike that other well-known heading, "Snakes in Iceland." However, there is tea in Wynaad, and tea that produces leaf which can command the market in Mincing Lane, but wherefore is it that there has been so little extension of cultivation in this district? Our South Wynaad correspondent in a recent interview with a planter who had travelled through Ceylon, published in these columns a day or two ago, repeated what has already been frequently stated by us, that in every natural facility this Southern

Indian district is the equal or superior of Ceylon and, as already proved, the tea grown here is of a better quality.* We had hoped before this to have announced that a large acreage was being thrown under this cultivation during the present monsoon. But it was not to be, and it is hard to trace the exact reason. In the interview referred to, this remark appeared:—"Ceylon appears to me to be considerably overrated. It is by no means the bugbear which you Indian planters appear to consider." Is Ceylon the bugbear that is frightening men from opening out tea in Wynaad? We are inclined to think not, but that it is rather a bogey of their own creation, yeelp labour.

While we are fully aware of the difficulties that have arisen within recent years in obtaining an adequate labour supply to carry on the cultivation of coffee, which does not require the same amount of manual attention as the tea-bush, we are yet at a loss to understand how such an argument can be applied when no organised and combined attempt has been made by Associations in the various districts to tap those vast sources of labour which furnish Ceylon, Burma, the Straits Settlements, Mauritius, Natal and other countries with the labourers necessary for their agricultural enterprises. It is urged by some that Tamils from Chingleput, Arcot, Tanjore and other Southern districts will require higher rates of pay than at present in vogue, but so far the coolies that have come up from Coimbatore have been content with the current rates, and until it has been incontrovertibly demonstrated that that labour, which now figures in the emigration returns of this Presidency, cannot be procured by Wynaad for the same sum as is now paid in that district, such an argument cannot be maintained with reason; nor should it be adduced by any planter or any man connected with the planting industry who has the welfare of Wynaad really at heart. But even supposing that a higher rate of pay must be given to obtain the labour necessary for successful tea cultivation, which course we may ask, is the wiser: to refuse it and to allow Wynaad gradually to relapse into a lantana jungle; or to pay it with very good prospects inaugurating a season of prosperity and affluence?

We refuse to believe that the planter himself is lacking in enterprise, and we feel certain that if once tea were started, the labour which the industry required, would in a very short time be forthcoming. If planters had paid heed to the advice not to open out cultivation because it would be impossible to procure the necessary supply of coolies some twenty years ago, what is now the most successful coffee district in Southern India would still remain a malarious bamboo jungle. We refer to South Coorg, where, owing to its extreme unhealthiness, and the prevalence of malaria, there was at first much difficulty in obtaining coolies. In like manner, we know of many coffee estates which are now flourishing, where equal difficulty was experienced, and where for the first two or three seasons, it appears the height of folly to attempt to cultivate for this very reason. In a previous article we remarked, "the difficulty of labour has always been the difficulty, with tea cultivation but this can only be solved by practical experiments," which we hoped at that time would soon be done, having always believed that such a practical experiment would be crowned with success. In the meanwhile, however, but little cultivation is being carried on, secured by this bogey, the creation of timid or prejudiced minds. If planters are going to wait until the labour comes begging to their doors, they will have to wait for many and many a long day. Like Mahomed, they must go to the Mountain, but until their fields are ready for the labourers, it is idle to bewail that they will not come. The whole history of the planting enterprise in India and in every other country teaches that success is only to be won by overcoming difficulties, and the greatest of these always has been connected with the labour supply. Tea in Wynaad pays, and we sincerely trust that planters will not permit themselves to be blinded, and the Companies

* Small, first samples are no proof.—Ed. T. A.

will not be frustrated by any such foolish or prejudiced cry, that it is impossible to arrange for an adequate labour-supply.—*Madras Times*.

[Apart from the labour difficulty, capitalists no doubt are influenced by the consideration that the tea grown in India and Ceylon is already about equal to and likely soon to be in excess of the market demand.—Ed. T. A.]

TEA IN FOOCHOW.

May 21st.

A couple of benevolent persons, as they style themselves, have been going about the different tea districts exhorting the planters to pluck up their tea plants and grow sweet potatoes or any other crops they may choose, as the present low prices and unprofitableness of growing tea is a clear proof that the money got from the *huangyang* or foreign devil is bad *fengshui* and the sooner tea growing is put a stop to the better.

Several Manchu tea buyers have arrived to make their annual purchases for the use of the Imperial household and the officials of Peking. Money is sent down in advance and entrusted to a man whose headquarters are in Sin-Chune-Kue. A great variety of teas is taken, all of the finest quality of course; and all specially prepared. A tea that corresponds to Pouchong is most largely taken, and amongst other kinds Flowery Pekoe and Green tea. Price being no object, fabulous figures are paid for the choicest quality running up we are informed, as high as Tls. 300 per picul. The orders which are retailed out in the different districts are much sought after, as, naturally, there is a good profit attaching to the business.

May 28th.

We hear that a teaman having obtained the loan of a couple of thousand dollars went up to one of the Tea districts with them taking four or five men in his company. That was some twenty days ago now and nothing has since been heard of him. It is feared that either he has been murdered by the four men he took with him, or that the whole company has fallen into the hands of highway robbers. While waiting for the mystery to be cleared up, we fear the prospect of the advancer ever seeing his dollars again is small.

The authorities are adopting stringent measures to stop *in toto* the use of kerosine oil in the city, spies being set on the watch night and day, to catch buyers and sellers. Several of the unfortunate dealers have already fallen into the traps of these runners and are paying dearly for their disobedience. Fear of fire is the ostensible reason for the suppression of the use of this oil; but it is pretty generally known, that the real reason is to help the trade in tea and other vegetable oils.—*Echo*.

Writing on the 28th ult. a Foochow correspondent of the *Daily News* says:—The arrivals of new tea crop are reported at 35,000 chests. But few musters have been shown so far. There is nothing in these to lead to the expectation that the quality of the crop will be any better than last year. It is thought improbable that the market will open within a fortnight of the present time.

COFFEE PLANTING, &C., IN CENTRAL AFRICA. —Our readers may recollect our publication of a letter from Mr. Henry Brown, formerly of Ceylon, detailing his adventures, fighting amongst the rest, in Central Africa. That letter was written in Aug. 1891. Mr. Brown wrote again in October, but the letter has not come to hand. We now publish a letter from Mr. Brown dated so far back as February of this year, so that "post haste" does not have much significance in Africa. It will be seen that Mr. Brown had succeeded in planting 100 acres of coffee, which looked well; but labour and transit difficulties seem likely to delay extensive enterprise.

GUM BARKS.

BY DAVID HOOPER.

Gum bark, or Pishin-puttai of the Tamils, does not refer to the bark of a tree which exudes a gum by bruising or incision, but denotes a bark which has such mucilaginous properties that it could be used for special purposes in medicine and the arts, where the white of egg would be used elsewhere. Barks of this description occur in the natural orders Malvaceæ, and Laurimææ, and students of materia medica know that drugs of these orders, marshmallow root and the barks of arboreous cinnamons, for instance, contain a peculiar mucilage, which is not precipitated by alcohol. A typical gum bark of the East is that of *Kydia calycina*, a malvaceous tree, growing extensively on the slopes of the Nilgiris, and largely employed in sugar refining under the Tamil name of Kadularangy-puttai. On soaking a portion of this dried bark in water it rapidly swells, and the inside becomes coated with a slimy mucilage. The inner layers of the fiber may then be removed like pieces of lace, and the gum is seen to be occupying the spaces between the longitudinally disposed fibers, apparently formed from the cellulose of the broken cell walls. The bark of *Kydia* is sold in the bazars, and the decoction is taken as an astringent and tonic, and the Vythians or native doctors consider it to be a specific for diabetes.

Dr. Mohideen Sherif, in the "Supplement to the Pharmacopœia of India," gives *Tetranthera Roxburghii* as the botanical origin of Pishin-puttai, but offers no description of the drug under that heading. Mr. Hollingsworth, of the Madras Medical College, some time ago supplied me with an authentic specimen of the bark of *Tetranthera laurifolia*, or as it is now called in the "Flora of British India," *Litsæa sebifera*. The bark was of a reddish brown color and slightly balsamic order, very different to that of cassia or cinnamon. The thickness was a quarter of an inch, and when soaked in water it became very mucilaginous. It offered, on analysis, distinct reactions for an alkaloid, which had the characters of laurotannine, a poisonous base lately discovered by Dr. Greshoff in the barks of several species of Javanese lauraceous plants.

About two years ago a collection of drugs for identification was sent to me by Dr. P. S. Mootoo-swamy, of Tanjore, and among them was a specimen of Pishir-puttai which, he said, was collected from trees growing in the jungles near Point Calimere. This bark had a most agreeable odor, resembling, but not identical with, Indian cassia, and the taste was decidedly sweet. It made a slimy mucilage when mixed with water and contained some tannic acid, but no alkaloid resembling laurotannine could be separated from it. The bark is sold in the bazars and it is known as Mydalakady among Mohamedans. It is used in medicine for its mucilaginous, demulcent and refrigerant properties. By powdering the bark with some benzoin, mixing it into a paste with a little water, and smearing this on reads, and drying them in the sun, flavoring sticks called Sambooranyvathe are made, and are burnt as an incense or perfume. I have not been able to obtain the botanical source of this particular variety of gum-bark, but I am inclined to believe from its odor that it is an arboreous cinnamon.

From Travancore I have received on different occasions three specimens of gum-bark, all varying the one from the other. The first was a thick, red-colored bark, a commercial article on the western coast, supplied to sugar refiners. The botanical origin could not be ascertained; it differed in physical characters from the barks previously mentioned, and yielded an alkaloid having the reactions of laurotannine. Probably it was a *Litsæa*. The second description of gum-bark was that of *Kydia clay-cino*. The third specimen was sent by the Conservator of Forests for Travancore; it was named in Malayalam *Ava-tholi*, and derived, it was supposed from a species of *Cordia*.

I have recently examined some samples of gum barks from the Madura district of Southern India,

and stated to be used by the hill villagers in increasing the alcoholic strength of sago toddy. The plants yielding these barks were up to this time only known by their vernacular names, but as leaves, flowers, and fruits were also sent these enabled them to be identified. The request was also made that they should be analysed to ascertain the nature and effect of their use in native spirit manufacture.

The seven specimens of bark were as follows:—

1. Kadaly-marum*—*Olea glandulifera*
2. Koppa-marum—*Litsæa Zeylanica*.
3. Karukathan-gundu*—*Hiptage Madablota*.
4. Mullu-gundu—*Jasminum flexile*.
5. Pungala-marum—*Ligustrum Roxburghii*.
6. Sudala-marum—*Litsæa wightiana*.
7. Kumala-marum—*Gmelina arborea*.

The *olea glandulifera* is a stout, tall tree with white flowers and small black fruit. The bark is of a greyish color with whitish specks, about 1—6 of an inch thickness, breaking with a close granulated fracture, inner surface brown.

The *Litsæa Zeylanica* is a moderate sized tree with yellowish-white flowers and black fruit; the leaves are ribbed and whitish on the under surface. The bark is grey and covered with lichens, smooth, one sixth of an inch thick, fracture close, showing, white, glistening fibres running through the red substance of the middle and inner layers, brown and smooth internally. The bark gives off a fragrant odor when burning.

The *Hiptage Madablota* is a woody climber, reaching to the tops of trees over 100 feet high. The stems are from half to three-quarters of an inch in thickness, and covered with a thin, smooth, reddish-brown bark enclosing a yellowish wood.

The *Jasminum flexile* is also a climber. The stems are about one inch in diameter, very woody and knotted, covered with a light yellowish-brown papery bark, exfoliating on the surface.

The *Ligustrum Roxburghii* is a stout tree about fifty feet in height. The bark is colored russet-brown and is a quarter of an inch or more in thickness; fracture close, showing thick white fibres running through the brown middle and inner layers.

The *Litsæa Wightiana* is similar to *L. Zeylanica* in many respects. The bark has a greyish-green epidermis beneath which is a chocolate-colored surface; the fracture is short and light colored, becoming red or brown by exposure to the air.

The *Gmelina arborea* is a common tree in the plains. The bark is about half an inch thick with a rugged, black and yellowish brown surface, middle layer hard and brown, fracture granular, ochreous within.

Some documents accompanying these specimens stated that the barks of these trees were used "to increase the intoxicating effects of sago toddy." The bark is simply placed in the toddy and left there for two or three days. The bark No. 3, it is said, is not so frequently used, as the resulting liquor causes headache when drunk. With reference to No. 7, it was said that a tenth part of it would answer the purpose in the absence of other barks.

It will only be necessary to give the results of the chemical examination of these barks, in so far as they are likely to explain their action in the fermentation of sugar. Three of the plants curiously enough belong to the natural order Oleaceæ; these are *Olea glandulifera*, *Jasminum* and *ligustrum*, and like other plants of this order contain a peculiar bitter principle, soluble in water and alcohol, and a yellow coloring matter called quercetin. Two other barks of the series belonging to the same natural family of the laurals, and have a similar composition; these are the *Litsæas*. The *hiptage* bark contains tannin and is simply an astringent; and the *Gmelina* belongs to a class of plants distinguished for their bitterness.

The amount of extract dissolved out of the bark by water and alcohol respectively were determined in order to ascertain their relative proportion, as it would seem that in the absence of much resin, the

* Marum=tree, gundu=climber (Tamil).

excess of water extract over the spirit extract would indicate mucilaginous matter, and on the barks being placed in the toddy, which in a fresh state is a watery solution of sugar, with some albuminous matter, the extract would dissolve, but as fermentation proceeded alcohol would be formed and the mucilage would be insoluble and precipitate, carrying down with it the viscid albumen and thus allow the sugar to ferment more rapidly. From the fact that other gum barks besides the *litsæas*, such as *Kydia calycina* and *Guazuma tomentosa* are largely used in clarifying sugar, it is evident that some such object as this is intended in their employment. The astringent qualities of most of the above-mentioned barks are no doubt used for the purpose of forming insoluble compounds with albuminous matter in saccharine solutions; just as hops are used to remove this substance from malt liquor in the ordinary process of brewing beer. The hops are found to prevent in a great measure the tendency of the beer to become sour, in consequence of the conversion of alcohol into acetic acid, and in warm climates where such liquors are apt to run into the acetous fermentation very rapidly, it is necessary to employ astringent drugs to regulate the formation of alcohol and prevent the development of acetic acid.

The natives consider these barks a necessary ingredient in making spirit, for the following reasons. Firstly, they diminish the great sweetness of the toddy sugar. Secondly, they render the spirit more intoxicating. The first of these phenomena is accounted for by the chemical fact that sugar breaks up during fermentation into two other bodies, alcohol and carbonic acid; and in the second place the barks enable the operator to obtain a larger proportion of alcohol from his toddy than he could get from leaving it to brew without such adjuncts. The analyses of the barks, with the exception of the *litsæas*, which contain laureto-tanine, has revealed no principle of poisonous or intoxicating properties, therefore the idea of their directly communicating a potency to the spirit is not sufficiently established, and, besides, as the spirituous liquor is submitted to distillation afterwards, any alkaloid, such as strychnine, would be left behind in the retort. Some of the barks are aromatic and these most likely are used to flavor the resulting spirit which would be the case if the aroma resided in a volatile oil. It is probably a spirit of this kind that Dr. Ainslie refers to under the title of *Puttaicharagum*, or bark spirit, an alcoholic liquor in which barks of various *acacias* are used in the manufacture.—*Oil, Paint and Drug Reporter.*

THE APPARATUS REQUIRED FOR COLLECTING INSECTS IN INDIA.

The following are Mr. E. C. Cotes' methods:—

Killing Bottle.—A simple and effective killing bottle is made as follows:—

Two or three lumps of cyanide of potassium, each as big as an acorn, are dropped into an empty quinine or other widemouthed glass bottle enough plaster of Paris, made by mixing the dry powder with water to the consistence of cream, is poured in to cover of the lumps of cyanide. The bottle is let open for a few hours, until the plaster has set hard, when it is tightly corked up and after remaining closed for a day or two is ready for use.

The plaster and cyanide set into a solid mass, which sticks fast at the bottom of the bottle, the object of the plaster being to hold the cyanide in place, and the whole mass has a smooth, even surface from which insects can be easily picked-up, the glass sides of the bottle enabling the insect to be easily seen.

A few minutes in a good killing bottle, thus made, is sufficient to kill most small insects, but some of the larger species of insect require to be kept in it for several hours to insure their not reviving.

A killing bottle, when carefully used, should last for a good many months, a great thing being to keep it tightly corked up and always to close it quickly

after taking out or putting in an insect, thus allowing as little as possible of the cyanide vapour to escape.

Old quinine bottles do very well for all ordinary purposes, as killing bottles, they are cheap and of a convenient size, but are not big enough to take the largest moths and beetles, so for these a larger size of bottle should be obtained.

Killing Butterflies.—All insects can be killed in a killing bottle but for butterflies it is quite sufficient to fold the wings together over the back, and then to pinch the thorax between the finger and thumb; this kills the insect without injuring its wings.

Preserving Insects in Alcohol.—Eggs, pupæ, and soft-bodied insects (such as caterpillars and grubs) can be at once killed and preserved by dropping them alive into strong alcohol, where they do not putrefy or shrivel up as they would be liable to do if it were attempted to dry them.

Small Insects.—All small insects, when taken out of the killing bottle, should be at once pinned, or else gummed on to little pieces of cardboard or mica, great care being taken in gumming them not to smear the gum over their bodies; the little bits of card or mica can be pinned down into cardboard boxes, and thus closely packed to travel.

Medium-sized Insects.—Medium-sized insects (including all butterflies and most moths) can be wrapped in soft paper, when they come out of the killing bottle, and as soon as they are dry, can be packed lightly but closely together into tight-fitting tin boxes, with a few lumps of camphor or naphthaline; in this way they can be sent long distances by post without fear of injury. Simply drying the packets, which contain the insects, separately in the sun and air for two or three days being quite sufficient to preserve their contents.

Large Insects.—Large insects, especially those with stout abdomens, require to have the contents of the abdomen removed and the shell stuffed with cotton wool, after which they can be dried and packed like the medium-sized insects above.

Keeping Dried Insects.—All insects when thoroughly dried can be kept in any close-fitting box or case which contains a little camphor or naphthaline. It is essential, however, for the case to be itself perfectly dry and practically air tight.

Insect Net.—A simple and serviceable net for catching insects can be made out of mosquito curtain stretched on a cane hoop with a bamboo handle attached.

Forceps.—A pair of forceps, which can generally be made locally, will always be useful for picking up small insects.

On sending insects for determination.—In sending specimens of insect pests to entomologists for determination, each pest should be kept carefully by itself, and when possible specimens should be sent, in all stages of development and in considerable numbers, accompanied by any notes on the habits of the insects and a full account of the nature and extent of the damage, also any specimens (such as half eaten leaves, bored wood, damaged grain, &c.), which throw light on the nature of the attack.

Live specimens are always easier to make out than dead ones, so they should always be sent when there is a reasonable probability of their surviving the journey; chrysalides and cocoons, especially, should be sent alive packed in a perforated box with leaves or grass.

So little is at present known of Indian entomology that the exact determination of species is often a matter of very great difficulty. Hence the necessity of furnishing full particulars and also of collecting a considerable number of specimens in each case, as these are often of great assistance in making out the affinities of an insect, and in any case from a most valuable record for comparison.

Materials.—The following materials are sufficient for collecting a vast number of insects, and would probably last one collector for at least a year.

In the absence of price lists it is impossible to say what the exact cost would be, but from R5 to R20 would probably buy all that could possibly be wanted by one collector.

For collecting ordinary dried insects the following will be sufficient:—

- Four ounces of cyanide of potassium.
- A pint bottle full of dry plaster of Paris.
- One pound of camphor (or better naphthaline.)
- A couple of wide-mouthed bottles with corks.
- Three yards of mosquito net.
- A few pieces of cane and bamboo.
- Some small tin boxes.
- A packet of thin white brown paper.
- A pair of forceps.
- A needle and thread.
- A ball of string.
- A yard or two of mulmul.
- A pocket knife.

If larvæ and other soft bodied insects are to be collected; the following should be added:—

- One quart of strong spirit (or better pure alcohol.)
- Some empty bottles with corks.
- A little wax for closing bottles.
- If very small insects are to be collected, the following should also be provided:—
- Two or three sheets of fine cardboard.
- Two or three packets of small pins.
- An ounce of gum arabic.
- Small cardboard boxes of various sizes.

Tough Collecting.—The above list contains all that is likely to be wanted by a collector; but a great deal can be done with very much simpler materials; for instance, when other apparatus is not at hand, any insect can be killed and preserved by dropping it alive into a bottle of alcohol (or even whisky), though its colours will always be more or less damaged in the process, and it will consequently not make a good cabinet specimen afterwards.—*Indian Agriculturist.*

COFFEE IN SIAM.

It ought to be apparent to those who watch the signs of the times that coffee cultivation in Siam is likely to prove a very profitable speculation for those who make a venture in that direction. We do not wish it to be understood that such an undertaking will prove a success if any of our Siamese friends make the essay of planting coffee by deputing someone else to see it done in the manner that is so often adopted in this country. No. But to make a success of an industry which has yielded enormous profits in other parts of the world notably in Ceylon, the whole matter should be taken up in a perfectly business-like manner and the management put under the control of those who have undoubted experience of planting in all its branches, and the management of that very important factor to success in planting enterprises—labour.

We are induced to revert to this subject by a Price-current of Messrs Rucker and Bencraft which we have before us. This so completely bears out everything we have written about the position of coffee in the home market, that we cannot do better than point out the figures which must at once strike the attention of an investor. The Brazil crop which was estimated as the largest ever known has only so far turned out some 400,000 bags more than the crop of 1888/89 and the present stock in London is actually less by 111,000 bags than it was in 1889. Then let us look at the market. In former years, when Ceylon and India exported freely, the difference between the two qualities ranged from 10/ to 15/ per cwt., and when it rose to 20 it was apparent that either Rio must rise, or Ceylon fall, at least 5/ to place them in their normal position.

But at the present moment, when good well-cured coffee is scarce, Brazil is selling at 66/ to 72/, whilst middling Plantation Ceylon is fetching 104/ to 105/. The Central American bean, which is cleaned and cured like Ceylon plantation, is quoted higher even than Ceylon; Costa Rica 108/, Honduras 110/, these being localities where the plantations are yet young and where the leaf disease is unknown. Siam holds out the prospect of producing coffee under the same conditions and commanding similar values. In this

connection it is worthy of notice that the stock in London only a month ago is put down at some 6,039 tons against 12,106 in 1890 and 10,454 in 1888. From all this we may see that what proves the rule in all other markets for agricultural produce is reproduced in that for coffee—the superior kinds (superior only by preparation) always command a good price, whilst the lower-qualities produced in large bulk are forced down to a low level. Brazil may produce millions of tons of coffee, but until she prepares it properly the value will never approach that of Ceylon—and we may add Siam too if she follows Ceylon methods. Events prove that we have been correct in our former utterances with regard to the cultivation of coffee in Siam, and we again repeat that from all present indications coffee is far and away the best-paying cultivation of the present day.—*Bangkok Times.*

ARABIAN AND LIBERIAN COFFEE IN THE STRAITS.

Sir,—It may interest your numerous planting readers to hear yet another opinion on soils and prospects of coffee in the Straits. I therefore give mine for what it may be worth. The grounds on which I venture an opinion are that I have seen soils and growth of coffee in all stages and under similar constitutions in both Selangor and Perak. I refer more particularly to Weld's Hill in Selangor; and Kamuning and Waterloo in Perak, the two former being Liberian and the latter Arabian.

It is not my intention to institute comparisons; it would serve no purpose and might be misleading, as I have reason to believe some of the reports made by Ceylon visitors (unintentionally no doubt) are; and in this connection I would take the liberty of remarking that Ceylon visitors looking out for land would do well to abstain in the press from slanging the Native State Governments for supposed illiberal regulations, and go in rather for suggestions for any reasonable desired concessions.

Weld's Hill and Kamuning have equally fine Liberian coffee, and it would be rather bold to say that the soil or the growth of one is better than the other; both to my mind are equally encouraging; the only difference I would remark on is that one is planted closer than the other, perhaps too close considering the luxuriant growth. Comparison of crops there is as yet none; for, though we have the return of "average per acre for 4 years in full bearing" (nearly 9 cwt.) from Weld's Hill, we have none from Kamuning, and all I can therefore say more on this point is that, judging by crop appearances, I shall be much surprised if the average of the latter is lower. Both are at a very low elevation—not over 200 feet—not much difference in distance (30 to 40 miles) from the sea, and both are probably equally protected from the little wind that blows. The future alone can decide which is the best State to plant in. I am confident any opinion now on that point is premature.

So much for Liberian—now for Arabian. Here there is no ground at all for comparison even if it was advisable to make it, as the only coffee of that *jat* to my knowledge, is on Waterloo; there you have nothing else, if a few old Liberian trees (of wonderful growth and laden with crop) at 1,800 feet round the bungalow are excepted. The history of this estate is, in short, that it was opened, planted, and neglected; it is evident, however, by the size of the stumps that the bushes had a vigorous growth; and I am assured it was nothing but neglect that brought about the "shuck" condition the estate was in when the present proprietor took it over. Since then, in response to liberal treatment, it has given good paying crops, and the result of efforts to resuscitate this badly-treated coffee are sufficient to warrant the hope that, without any excessive cost, it can be restored to good health and usefulness.

But it is of the younger coffee, 150 acres between two and three years old, planted by the present owners, that I want particularly to speak of as

evidence of the fitness of the soil and climate at average elevations of 2,500 ft. to grow, not only paying, but really bumper, crops of Arabian. The young coffee in question is in growth most luxuriant; there is hardly a speck of leaf disease on it: and the crop it is carrying is estimated at 3 cwt. per acre after a heavy pruning, by which it is judged some 2 cwt. crop was thrown away. One thing important to be noted in connection with Arabian cropping here is that the harvest does not come on in a heap as in Ceylon; the picking is spread over some nine months at least, making it much easier for the bushes to carry bumper crops without being exhausted. Another thing is that there is never a day without sunshine, and the rainfall which at Waterloo is about the same as in Dimbula is much more evenly distributed over the year than in Ceylon. For instance, this year the rainfall registered on Waterloo has been as follows:—January 6'30, February 5'80, March 10'56, April 7'86; there has been no one week without rain except towards the end of last week. You may indeed say it is, for that estate, the perfection of both growing and ripening weather, and there are many more places like it in Perak for those inclined to search for it carefully; but it can hardly be chosen without going to the trouble of careful examination.

The advice I would give intending selectors is that they should make known some months beforehand to the British Resident their wish for land and desire that suitable blocks be selected within certain elevations, and facilities given in the way of walking-roads or paths to allow the jungle to be thoroughly examined. I have no doubt such a request if properly put forward, would meet with a favourable response. I dare say you are aware that, by the new regulations, land for planting can be got for a premium of 3 dollars per acre and no quit rent.—I am, &c. D. MACKAY.
—Local "Times."

COFFEE.

From the translation of a French work, "Spectacle de la Nature," made in 1736, we reproduce the following account of the coffee tree given in the form of dialogue between the Chevalier and the Prior:—

Coffee, whose good effects are universally esteemed, is the Berry of a small tree, which formerly was known in no country but the kingdom of Yemen in Arabia and as the seeds, which are found in the heart of the fruit, are qualified to clear the head and relieve it from sleepiness, when they have been infused in water; the Arabian monks are said to have been the first who made use of them, that they might be enabled to perform their nocturnal devotions without drowsiness. This artificial drink came easily into repute, among those Nations that frequently invent new liquors to regale them instead of wine, which the Law of Mahommed has prohibited among them. Some Turkish doctors at first opposed the introduction of this liquor, and declared it to be too spirituous, and almost as inebriating as wine itself; but the Musti soon removed this difficulty, and coffee was vindicated from the imputation of any vinous quality, and was allowed to be a lawful liquor. It was then publicly drank in Constantinople and Cairo, from whence it has been transmitted to us, about sixty years ago.

Chevalier. I am surprised that we don't sow this useful and popular seed in our Southern Provinces at least.

Prior. It will not succeed either there, or in any other part of the Kingdom; because it ought to be sown immediately after it has been gathered. It was formerly imagined, and several people are still persuaded, that the Arabians of Mocha drenched the berries in a brine, or some luvivous liquor, before their exportation, to prevent their being sowed with any success, and that they themselves might not be deprived of the profits of this plant, by its propagation in other regions. But since some of the trees have been transported to the isle of Bourbon as well as to Batav and Holland; and likewise from

Holland to France, where they have been cultivated in a successful manner; we have been convinced that the seeds of this plant will never prosper, if their plantation be delayed ever so little. Those that were gathered at Amsterdam, and sent to Paris, were unsuccessful; but all such as were gathered either at Amsterdam, or in the King's Garden, from little trees, which had been planted there, proved very thriving, when care was taken to set them the moment they were gathered.

The Coffee tree may be seen in the Royal Garden, where its height does not exceed five or six feet, and its stem is about an inch in thickness; but it rises to the height of forty feet in Arabia and Batavia, though its thickness seldom exceeds five inches. It is always covered with flowers and fruit. It shoots out, through the whole length of its stem, a growth of branches which are always exactly opposite to each other, and in different pairs, one of which crosses the other. The leaves, which resemble those of the common laurel, are also ranged in couples; at the bottom of these spring the fragrant flower-branches, which have a near similitude to those of the Jasmim, and have five chives in their centre. The berry or fruit, which appears after these, is not much unlike a hard cherry, in its colour and shape. The flesh, which is not disagreeable, serves as a tegument to a couple of shells, each of which contains a seed. One of these is frequently abortive, because its due fecundity is seldom imparted to it in the flower season; the other grows stronger, and receives a better nourishment.

THE USE OF COFFEE.

Some persons infuse all the fruit after it has been dried; others choose the shells; but the best and most usual method is only to infuse the berries, when they have been moderately roasted in a vessel of varnished earth, which is always preferable to one of brass, or iron. The berries are judged to be sufficiently roasted, when they begin to assume a violet-hue, and discharge an oil of a very agreeable scent. The coffee which is newly ground, has always the most virtue; and when it is infused in boiling water it loses fewer of its volatile parts, than when it is immediately poured into cold water. When the heat of the fire raises the powder to the edge of the coffee pot, it is precipitated with a few drops of cold water.

It is the opinion of our best and most experienced physicians, that coffee promotes digestion, and corrects sharp humours, when it is drank at meals. Several persons prefer it, in the morning, for its dissipation of vapours and other disorders of the head, and for imparting a liveliness to the spirits. Every one knows how much the repose of the night is hazarded by the repeated use of this liquor in the same day; and what precautions are taken, to correct the bitter flavour of its salts, with milk, and sugar, and bread. Sugar is a constant ingredient, bread is proper, when the liquor is drank in a morning; and milk is necessary for thin constitutions, which would otherwise be injured by the salts.

Chevalier. Is there any particular choice to be made in the purchase of coffee?

Prior. The small and greenish berries, and especially those which dispense an agreeable scent, and are transmitted to us from Cairo, by the way of Marseilles, are much more esteemed than the large and inodorous species, which is transported to us over the ocean.—*Madras Times.*

THE MAURITIUS VANILLA CROP.

Our little colony of Mauritius, with a history only less turbulent than the hurricanes that periodically ravage its plantations, has had the good fortune to have been chosen by Bernardin de St. Pierre as the scene of one of the most famous romances of the eighteenth century; and again, in our own day and country, under the transparent device of "Palmiste," it has furnished Mr. Besant with part of the setting of two of his most unconventional stories. In these works a Mauritius hurricane is graphically described and to them readers should turn for a vivid im-

* It lies to the East of Madagascar.

pression of the disaster like that which overtook the island on April 29th last, but the news of which (Mauritius nothing yet connected by telegraph with the outer world) reached us only at the end of last week.

On this occasion half the sugar crop is reported to be destroyed, and what that means may be gathered from the fact that sugar, rum, and molasses practically spell the whole means of existence of the population. There is, however, one other industry in the island which though small compared with the culture of the sugar-cane, is of particular interest to the drug trade. That industry is vanilla. Mauritius has for many years been one of the principal vanilla-producing countries, and as nearly all the vanilla grown in the island is consigned to London for sale, any serious damage to the vanilla crop may be expected to react, in the first place, upon the London market. The neighbouring French island of Bourbon, which grows about one-half of all the vanilla in the world, sends its produce to France; while Mexico, the next greatest source, has hitherto shipped most of her crop to the United States, where probably more of the drug is used than in any other country in the world. It would be very interesting to know precisely what damage, if any, the vanilla vines have suffered from the April hurricane; but upon this point no positive information appears to have yet been received. There exist, however, certain factors from which we may form negative conclusions, and these factors seem to warrant the view that, even if the worst fears of injury to the plants should be confirmed, there is no ground for any serious advance in the value of the drug. If we glance at the production of vanilla in these Eastern islands during the last twenty years we find that there have been but few really bad harvests, while, until quite recently, the cultivation must have been a very profitable branch of occupation, judging by the steady increase in the exports from Bourbon, Mauritius, and the Seychelles. Neither in Ceylon, nor in the West Indian Islands, where vanilla was introduced many years ago, does the industry appear to have made any real progress. The reason probably is that vanilla-growing is essentially a painstaking and laborious business well suited to the habits and means of the small French or Franco-Creole cultivator, but quite unadapted to the ways of the Anglo-Indian planter, whose strength lies in the production of heavy staple goods. The vanilla-vine commences to yield fruit in the third year, and continues to bear for fifteen or twenty seasons. Great care is necessary at the flowering period, when the plants must be fructified by hand, and the curing also involves considerable labour and risk. On the other hand, the yield per acre is very considerable, and a small plantation, it is said furnishes enough, in good years, to provide for the entire wants of a small cultivator. One reason for assuming that the Mauritius vanilla plants have suffered less damage from the recent hurricane than other crops is that the principal work of destruction seems to have been done on the North-Western coast of the island. Vanilla, however, is not grown upon the slopes fronting the sea, as it could not withstand the climatic influences prevailing there, but upon the declivities facing inland, where the force of the wind was probably less than in more exposed positions, and where the vine is trained either against huge erections of trellis work or against trees left expressly for its support. The hurricane occurred just at the time when the pods which have grown from the last October blossoms would be approaching maturity. The green pods are gathered in May and June, but they have then to undergo a lengthy process of curing, and in the ordinary course arrive upon the European markets towards the close of the year.

It has been estimated, upon apparently good authority that the world's consumption of vanilla is about 230,000 lb. per annum. The calculation was made a few years ago, since when there has probably been little increase in the requirements, as vanillin, the synthetic product, has usurped the place of the natural drug in many branches of manufacture. But, assuming that the consumption is now 250,000

lb. per annum, the depreciation which vanilla has undergone during the last two or three years appears fully justified by the increased output for the crops of Bourbon, Mauritius, and the Seychelles alone are estimated at about 260,000 lb. in 1891, 200,000 lb. in 1890, 150,000 lb. in 1889, 180,000 lb. in 1888 and 350,000 lb. in 1887. Add to this the Mexican production, which in good years is perhaps 100,000 lb., and it will be seen that there is probably a sufficiency of old stock in the various centres to enable us to do without the 40,000 lb. a year or so which we may expect from Mauritius without any fear of a vanilla famine. It is only about seven years ago since the Seychelles began to produce vanilla in commercial quantities. Seasons and prices have been adverse to the development of the new industry in those islands; yet the 1891 crop is believed to have actually exceeded that of Mauritius in quantity. The appearance of the Seychelles vanilla is generally good, although the pods are somewhat deficient in flavour, and, judging from the quantities which they have poured upon the London market this season, they are likely, if Mauritius failed us, to be able to supply the deficiency without much difficulty. In the early spring of 1879, and again in February 1881, cyclones visited Mauritius, and caused a temporary advance in the price of vanilla, but the earliest reports of destruction upon which these rises were based soon proved greatly exaggerated, and the market ere long went on as if nothing had happened.—*Chemist and Druggist*, June 4th.

CEYLON TEA IN AUSTRALIA.

The Melbourne *Argus* of 30th May reports the sale of 80 chests of Ceylon tea at 7d to 1s. In its issue of 1st June the *Argus* has the following:—

At auction 217 packages Indian teas at 5½d to 8d and 40 chests Ceylon at 8d to 10d were quitted. Private sales include 170 chests Ceylon at 8d to 1s 2d. A heavy clearance of tea, covering about 500,000lb., has been effected at the Customs today, and will reduce the stocks as stated below. Our compilation of tea statistics for the week ended Saturday last, 28th inst., is as follows:—

		Corresponding Week Last Year.
	Lb.	Lb.
Entered for bond	589,472	38,120
Duty paid	Ex ship .. 88,178	3,979
	Ex bond .. 61,339	160,011
Exportation	Ex bond 32,479	36,898
	Under draw-back .. 114,613	34,885

Stated in the ordinary form, the particulars for the week are as follows:—Receipts of tea into bond last week comprised 8 chests, 11,666 half-chests, and 78½ boxes China, and 566 chests and 446 half-chests Indian and Ceylon. Deliveries for home consumption consisted of 196 chests, 771 half-chests, and 890 boxes, against 353 chests, 2,800 half-chests, and 744 boxes for the corresponding week last year. Deliveries for export were 8 chests, 802 half-chests, and 404 boxes, against 32 chests, 863 half-chests, and 119 boxes for the corresponding week last year. The stocks in bond on the 28th inst. will be found stated in packages below. Converted into weight the figures compare with those at same date last year as follows:—

	May 30, 1891.	May 28, 1892.
	Lb.	Lb.
China tea	3,131,452	765,046
Indian and Ceylon tea	953,965	237,125

In stating the stocks for the corresponding date last year allowance is made for the corrections which the Customs found necessary in June last, viz., an understatement of 1,548,000lb. China, and an overstatement of 357,880lb. Indian and Ceylon. The value of the statement as a comparison of stocks is vitiated by the large quantity lately transferred to duty-paid stocks.

In its issue of 2nd June the *Argus* reports the sale of 50 packages of Ceylon tea at 6½d to 9½d; and

quotes the following from Messrs. A. Harvey & Co.'s monthly report:—

Ceylons have arrived in rapidly-increasing quantities, though the extra weight of leaf in the last steamer has checked the ardour of buyers, who had previously been very eager, and had enabled importers to sell at once each shipment as it came forward at prices that should have proved very satisfactory to shippers. The value shown in these teas has necessarily been very good to create the strong demand of the past two months, but the heavy increase in the shipments looks like lower rates, unless the recent strong advance in the Colombo market materially checks supplies. Almost all sales have been effected privately. Dust sold from 4½d to 6d; fannings, 5d to 7d; broken leaf, 6d to 8d; pekoe souchongs, 6½d to 8½d; pekoe, 7d to 9½d; good orange pekoes, 10d to 1s 1d; and choice teas, up to 1s 5d. In its issue of 3rd June the *Argus* reports the sale of 400 packages Ceylon at 6½d to 11d; and in its issue of the 4th it says:—

In tea, the only description in which business is reported is Ceylon, of which about 200 packages have been quitted at various prices.

The *S. A. Register* of Adelaide in its issue of 7th June reports:—

All grades of India and Ceylon tea are firm at an advance of 1d to 2 per lb. on prices ruling a week or two ago. The stocks held in this market have, however, been too small to afford any scope for speculation or large dealing, even had our merchants been inclined to deal extensively, hence sales have been confined to fifty chests of this line and 100 of that, parcels which in the years past were only regarded as retail orders, but in the altered state of things are looked upon as wholesale parcels. No single sale of more than 250 packages has been brought to maturity during the late little spurt, and only a few thousand packages in all have changed hands. It must be remembered, however, that blended teas have almost entirely superseded the consumption of teas from original packages. Nevertheless prices are firmer and sales brisker than for some time. During the fortnight some 1,500 packages in all of India, China, and Ceylon growths have been placed, from low to good. Prices are not given in any case, but from all quarters the record denotes firmness. Coffee is comparatively low in stock, and the strong prices obtaining in Ceylon and Nonnea must have the effect ere long of establishing a substantial advance in local prices. Today there is scarcely a 5-ton parcel that would be quoted for were the enquiry made, and business is carried on in half-ton and ton parcels, 1s 5d per lb. being value of good ship assortments, & p.

THE ELECTRIC-LIGHT IN AGRICULTURE.

In a recent article entitled "Electro-culture," we quoted results of experiments at the Massachusetts Agricultural College, which show that currents of electricity, properly applied, influences plant growth favorably. We also attempted to show that the earth is an exhaustless reservoir of electricity—that it is, in fact, a vast Leyden jar, the dense air at the surface, compressed as it is with the weight of a ton on each square foot, being the non-conductor, the glass, which separates the opposite electricities of the conducting upper strata of this air and of the earth, so that when connection of the upper air and of the earth is made by a conductor, active currents of electricity are obtained, and was shown by Fischer, of Waldheim, who placed sixty lightning rods around each hectare (2½ acres), by which he collected electric currents and increased the crop 50 per cent.

In the present article we quote from Prof. Baily, of the Agricultural Experiment Station of Cornell University, in reference to the effects of the electric light upon plant growth. His experiments in 1890-91 show that—

The electric light promotes assimilation; it often hastens growth and maturity; it often intensifies colors and sometimes increases production. The experiments show that rest and periods of darkness are not necessary to plants, and that the electric light

enables plants to assimilate during the night and must produce plants of great size and precocity.

In 1891 Hervé Mangon found that the electric light produced chlorophyll, or green substance, in the leaves of plants. In 1869 Prillieux found that the electric light enabled plants to decompose water and carbon dioxide. In 1880 Dr. Siemens found that:

With electric light by night and solar light by day melons were remarkable for size and flavor, hbananas were unsurpassed, grapes were of stronger flavor, strawberries fruited early and abundantly, wheat, oats and barley grew so rapidly that they fell of their own weight. In all cases plants exposed to both sources of light showed decided superiority. In all cases growth was hastened.

It is to be observed that in all these experiments it was found necessary to modify the light by using a glass globe.

It appears from the experiments quoted that electric currents give power in the motor which may be used to cultivate plants; that electric currents applied to plants stimulate growth and influence the yield favorably, and that electric currents give light which enables plants to grow night and day.

Electricity is a new science. We are just beginning to learn how intimately it is connected with our work, and how we may turn it to our uses. Sooner or later every discovery has a practical application. The progressive and thoughtful agriculturist treasures up new ideas, even though he may not see their immediate use. As Emeron has said:

Our duty is plainly not to throw oneself across the track; not to block improvement; not to sit still until we are stone, but to watch the uprise of successive mornings, and to conspire with the new works of new days.—*Louisiana Planter and Sugar Manufacturer.*

CARDAMOM-GROWING IN SOUTHERN INDIA.

The *Madras Mail* correspondent in North Travancore writes, under date March 26th, that the cardamom-weighing season is over, and that the superintendent of the cardamom hills, who during the harvest, attends at some central spot in the collecting region for fiscal purposes, has left. The cardamom crop was a large one this year, but owing to rain falling while most of it was exposed on slahrocks to dry, a large amount has been damaged. There are several sirkar depots for weighing cardamoms, the most important being at Sandampars, near Devikulam, and at Oodaman Shols. The way to the former leads from Devikulam through magnificent forests, from which the undergrowth has been cleared and cardamoms planted instead. The owners of those plantations reside mostly in the lowcountry villages, and only come up once a year to cut back the encouraging undergrowth and to pick the crop, which is taken to the nearest weighing depots, and there laid out on large slah-rocks to dry.

Cardamom being a Travancore sirkar monopoly, great precautions are taken to prevent theft and smuggling across the British boundary, but much smuggling goes on nevertheless, a great many gardens being within a few miles of the frontier. At each depot is stationed a detachment of the Nair Brigade, beside numerous peons and guards. The sirkar gives the land to the ryots, without demanding any money payment whatever. As much cardamom seed as is required is also given free. When the crop is picked and dried the Government takes charge of it, and stores it in buildings set apart for the purpose. It is weighed and packed in gunny bags called "chippams," sealed with the sirkar seal all along the stitching, and sent away on bullocks to Kumili, under the guard of a detachment of the Nair Brigade. Here it is packed in carts and sent to Alleppy, where it is sold at public auction. As each bag is weighed, a ticket is put in giving the ryot's name and the total weight and number of bags belonging to him, and the number of each bag, so that each ryot may get his share of the

money the cardamoms fetch. The Government defrays all expenses of transport and sale, and takes three-fifths of the proceeds of sale, paying two-fifths only to the ryots. This may seem very little, but when it is considered that the ryots (except during the first year) do exactly one week's work in the year for it, and make no money payments whatever in the way of purchase of land, seed, taxes, or for watchmen, and transport of their produce to the coast, it appears at once that their two-fifths of the gross proceeds of sale is a comparatively large share.

The sirkar keeps a staff of guards and watchmen at each pass on the hills all along the British boundary, and a preventive and detective staff in the low country, besides a European superintendent and assistant superintendent, with their office establishments, and several zamindars and subordinate officials, the salaries of all of whom are charged to the cardamom department. As a matter of fact, last year, with an exceptionally good crop, the sirkar only made a profit of 50,000 rupees out of the whole monopoly.

The average yield of cardamom gardens, ill-treated and neglected as they are by the ryots, is only one thulam (about 18 lb.) per acre. The price fetched in Alleppey is about 20 rupees a thulam, of which the ryot gets 8 rupees; that is to say, he gets 8 rupees an acre per annum, and I doubt if he spends 1 rupee per acre. The size of a garden averages 20 acres.—*Oil, Paint and Drug Reporter.*

PLANTERS' ADVANCES TO COOLIES.

In another column of today's issue we publish a petition to the Government of India on that much vexed question of planters' advances to coolies, which has been drawn up by the Wynaad Planters' Association. It is based entirely on the expressed opinion of Government servants who have had to deal with that particular District. The petition begins by reciting an unfulfilled promise made to the planters by the Madras Government in 1877. It then cites the opinion of two of the Collectors of Malabar as to the inadequacy of the Act XIII of 1859, which opinion is backed up by a large majority of other Magistrates who were consulted in 1884 and whose opinions are recorded in G. O. 1911, 1884. It then goes on to point out very clearly the grievances under which planters are suffering; but these perhaps are still better illustrated by the actual experience of an individual. In March, 1890, a planter in South Wynaad who had been opening new land to a considerable extent and required an increased supply of labour, advanced the sum of Rs. 100 to nine different contractors in sums varying from Rs. 100 to Rs. 200 each. The contractors (chiefly Tamils from the Coimbatore District) all came with good testimonials. They contracted among them to bring in 295 coolies by the 1st of June. It was a season of great sickness during April and May owing to influenza. By the 1st of June, though labour was then a matter of absolute importance to clearings, no coolies had come in, no maistries had arrived, and no excuses had been sent for their non-appearance. The work had to be done, and contractors from the Malabar Coast were employed at a very much increased rate. By the 1st of July the whole gang, that was ever forthcoming, had arrived, *i.e.*, four for the contracting maistries with twenty-three coolies! The planter was at first loth to prosecute the five defaulters because he hoped that when the worst of the S. W. monsoon was over they would begin to come in. At last in September he went into court and laid a complaint under the Act against the maistries. Although every detail as to the men's parentage, village and taluqs was given, the planter was informed that he must send his own men to identify the defaulters. After considerable trouble he found two Tamil coolies who lived at the same village as one of the defaulters, and who reluctantly agreed to go with the warrant and identify the man. They were given Rs. 10 between them to cover their railway fares and other expenses. At the end of a week they re-

turned saying that they had been robbed of the Rs. 10 on the road to Calicut and asked for a further sum of money. But the planter thought that this method of arrest would soon become too costly and declined to send them again. The warrants were consequently sent to the Magistrate nearest to the defaulter's village, and in the course of fifteen days were returned to the Vayitri Sub-Magistrate unserved.

The Act makes the defaulter's offence criminal, but the warrant of arrest holds good for only the term of contract, although under the Penal Code the warrant for the apprehension of a criminal never expires. As a matter of fact, only one of the defaulting maistries was ever arrested, and he came to his arrest because he felt so secure from punishment that he actually took work on a neighbouring estate. He was brought up before the Vayitri Sub-Magistrate and was ordered by the Court to bring his contract number of coolies on to the estate within ten days, and was warned that unless he did so, he would be given three months hard labour. He was then dismissed to collect his coolies without any sort of security or guarantee as to his re-appearance, and it is needless to say he was never seen again. To sum up; the planter in question lost the bulk of his Rs. 100, had constant rides to and from the Magistrate's Office some 13 miles from his estate, paid fresh fees every time he had the warrant for arrest renewed, and got absolutely no redress. This no doubt is an exceptional instance so far as the amount lost by one planter in one year is concerned; but it is an instance of what is constantly occurring on a smaller scale all over the planting districts. And it is not only the planters themselves who suffer; the contracting maistries suffer to an even greater extent from absconding coolies. The Sub-Magistrates who have to deal with cases under the Act recognise the injustice done to the planter, but confess their inability to assist them owing to the interpretations put on the Act by the High Court. The higher Magistrates, when appealed to, also admit the inefficiency of the Act. The law advisers to Government and the Judges of the High Court, when appealed to, give conflicting opinions as to what may or may not be done under the Act; and in the meantime the planter and the contractor are without any legal protection from defaulters, notwithstanding the promises given by the Madras Government fifteen years ago. We sincerely hope that this petition, signed as it is by all Southern India planting Districts, will stir the Government of India into giving the matter its most serious attention.—*Madras Mail*, June 23.

THE PROSPECTS OF TOBACCO CULTIVATION IN SUMATRA: RUIN AND DISASTER THREATENED.—Says our correspondent in a letter which has only reached us this morning:—"A great calamity is threatening the cultivation of tobacco in Deli, by a peculiar disease in the nursery beds, which painfully reminds one of the fearful ravages of the Phylloxera. Half the estates in Deli and several in Langkat and Serdang are infected, and a failure of the crop may now already be foreseen, unless radical means are immediately found to prevent a further spread of the disease, which is so swift in its ravages that in a very short time the whole country may be totally devastated. The disease made its first appearance a few years ago on a couple of estates, and it has assumed most gigantic strides since last year. It has been found necessary to throw away hundreds of cartloads of the young plants which are totally unfit for transplanting. The effect this visitation will have on the tobacco market in Europe can scarcely be realised." Bad as the outlook thus foreshadowed appears, there is still the hope that the danger may be averted, by the disease being stamped out.—*Straits Independent*, June 11.

TEA AND COFFEE IN BURMA.

We are glad to see that the Government is about to make another attempt to encourage the cultivation of tea and coffee in Burma. Experiments have been made in the Tenasserim division and in other portions of Lower Burma, but the results which have attended them are not so satisfactory as to attract private enterprise to any great extent. On the other hand, however, the coffee plantations near Toungoo have been attended with success sufficient to guarantee the prosperity of more ambitious efforts in the same direction. This time it is the high ground and the hills on the Upper Irrawaddy beyond Bhamo which the Government offers for the cultivation of tea and coffee. The *Burma Gazette* publishes some correspondence which has passed between the Deputy Commissioner of Bhamo and the Deputy Conservator of Forests and the Commissioner of the Northern division on the prospects of the cultivation of tea and coffee in the Bhamo District. The Deputy Conservator, who should be a pretty accurate judge on the subject, is of opinion that the cultivation of both tea and coffee would be successful in portions of the District which he names. The land on the lower ranges of hills between Bhamo and Shwegun and in the Upper Defile is very suitable for the cultivation of tea; and for the cultivation of both tea and coffee the higher banks of the Irrawaddy anywhere above flood-level, and the undulating ground between Fort A. and Shwekyina are very suitable places. The Deputy Conservator further says that tea is grown in nearly all Kachin villages and seems to flourish. The Deputy Commissioner does not venture to offer an opinion as to the success of the experiment, but he suggests that it would be advisable to throw open for cultivation only those tracts which are near lines of communication, three of which he mentions. These tracts are mentioned, also, by the Deputy Conservator. The tracts all lie on the river and are easily accessible by boat or launch: communication by land is impracticable. This is a sensible suggestion. Those who undertake the cultivation of tea and coffee do so for the purpose only of making it a profitable investment to themselves, and however successful plantations may turn out in the direction of the plants flourishing and the crops being abundant, if there are almost insurmountable difficulties in the way of conveying the produce to the markets, and if conveyance is very slow and expensive, it is very improbable that the investment will attract private enterprise. When the cultivation of tea and coffee has been started on an extensive scale, it is probable that easy communication by land will be made as the area of cultivation extends, but for the present at least it certainly would be wise for planters to turn their attention to the tracts which are easily get-at-able by water.

Another consideration is that as provisions must all be imported, there being absolutely nothing to be had on the spot, it is imperative that communication with Bhamo should be easy. The scarcity of labour is another drawback which has to be considered. The Kachins have no love for work, and both the Commissioner and the Deputy Commissioner are of opinion that labour will have to be imported. This, we fear, will be a greater drawback than want of practicable land communications, but it is not insurmountable. The question is, where could labour be imported from? Shan labourers might be induced to emigrate to the Kachin hills, or even labour might be brought from India; but in the latter case the plantations would have to be very successful indeed to make it pay the planters to import Indian coolies. But we do not see why the Kachins should not be trained if some pains are taken with them. They are not unaccustomed to the cultivation of tea—it is grown more or less in every Kachin village—and we are sure that if sufficient inducements are offered by planters, the Kachins will come from even remote parts to work on the tea and coffee estates. In advertising the land for the cultivation of tea and coffee the Commissioner recommends that the Government should be cautious. We do not think that this suggestion is influenced by any belief

that the land may turn out to be unsuitable for the cultivation of tea and coffee, but is a natural precaution, considering, as the Commissioner says, the suitability of the climate and soil has not been established by experimental cultivation,—which the Government must, in its own interests, take to save itself from liability in the event of concessionaires, who have been unsuccessful, claiming damages on the plea that they have been led into the venture by the delusive hopes held out by the Government. The local Government has had one experience at least in this direction in the matter of granting concessions in Upper Burma. It is honest at least for the Government to offer no opinion as to the suitability or otherwise of the soil and climate for cultivation, and intending concessionaires of land will be now on their guard and satisfy themselves on these points first before embarking in the venture. We think the Government, however, might render a great deal of assistance by making the necessary experiments under the auspices of the Forest Department. As we have stated over and over again, there are many places in Burma suitable for the cultivation of tea and coffee, and if it is widely advertised that the Government is willing to make liberal concessions of land, the influx of private enterprise will follow as a matter of course.—*Rangoon Times*, July 2.

At last the Government has passed orders on the scheme of Agricultural Schools and Farms for the Madras Presidency, and indicated the lines on which they should be started. As already stated, five districts will be chosen in which farm-schools will be opened, and in each a plot of ground for an experimental and demonstrational farm will be selected and acquired. The schools will accommodate about 80 scholars each, and will be exclusively reserved for the practical and theoretical teaching of agriculture and veterinary science, on the model of the College of Agriculture, but on a small scale, the necessary knowledge in other subjects being secured by fixing a certain test of general educational qualifications before entrance. The curriculum at the farm-schools will extend to four years. As regards the location of the schools, the Government has selected the three districts of Coimbatore, Godavari, and Bellary, and has asked the Directors of Agriculture and Public Instruction to offer further suggestions regarding the districts and places to be selected for the remaining two schools.—*Indian Agriculturist*, June 11th.

TEA IN FOOCHOW.—Concurrent with the Feast of Dragons we have had, as usual, a freshet on the river, and the surrounding low-lying country flooded, but there has been nothing abnormal in the height to which the water has risen in the immediate neighbourhood. Accounts reach us, however, of a very different state of things higher up the river, where the rains appear to have been very heavy. At Yenping Fu the rise, above highwater mark, is reported to have been as much as thirty feet: A passing courier, carrying official despatches, reports the loss of life and property to have been very great, the extraordinary rising having come upon the people very suddenly and unexpectedly. Two boats laden with tea, containing, it is said, 1,000 half-chests, were smashed to pieces passing through the rapids and the crews drowned. For three days the traffic in the upper part of the river was stopped altogether, and the new tea crop has been checked in arriving in consequence. With all these accounts of heavy rains up country it is gratifying to know that they did not commence until after the first crop tea had been picked and packed, so that our supply, as seen from the musters, is free from any weathery condition, as it is called, complained of in the teas at one of the other tea ports.—*Foochow Echo*, June 4th.

COOLY CONTRACTS IN SOUTHERN INDIA.

The article we extract from the *Madras Mail* (on page 119) indicates the general scope of a petition addressed to the Viceroy of India on the subject of difficulties connected with contracts for coolie labour in the Madras Presidency and the Native States of Mysore, Travancore, Cochin, &c., connected with it. The representation ought to carry much weight, for it is signed by representatives of planting communities scattered over Southern India as follows:—

JOHN F. JOWITT,
Ag. Hon. Secy., S. Wynaad Planters' Association.
A. LAMBERT,
Honorary Secretary, Coorg Planters' Association.
L. D. COLLEDGE,
Hon. Secy., North Mysore Planters' Association.
BROOKE MCKETT,
President, South Mysore Planters' Association.
HENRY M. KNIGHT,
Hon. Secy., South Mysore Planters' Association.
J. S. VALENTINE,
Hon. Secy., Travancore Planters' Association.
W. S. LECHLER,
Hon. Secy., Shevaroy Planters' Association.
F. GRIFFITH,
Hon. Secy., Kotagerry Planters' Association.

We have no more doubt now than we previously entertained, and that was none, that the main reason for labour difficulties amongst the planters of Southern India, incongruous as it may seem, is the nearness of their estates to the home and fields of the labourers. The temptations to desert and attend to their ancestral rice or other culture, instead of the interests of their employers from whom they have received advances, are strong in proportion to the degree of contiguity; and even honest contractors, if such beings exist, suffer equally in loss of advances, if they make them, as the estate owners who primarily advance the money, with the hope of being supplied with an adequate labour force. Warrants, whether issued against fraudulent contractors or coolie deserters, seem to result in no good if issued in British territory, and cannot run in some of the feudatory States, whose processes are executed in British territory, while in regard to Mysore the reverse is the case. The intention of the existing law was that breaches of contract by recruiters and coolies should be treated criminally, but the intention of the law is either not carried out by the Police and the Courts, or the law is so inelastic that defaulting coolies are not allowed to work off advances but compelled to pay them or suffer imprisonment,—that is in the rare cases in which coolies deserting while under advances are captured,—which is rendered the more difficult by the differing British and Native States jurisdictions. The petition is too long for us to give *in extenso*, in addition to the summary and remarks in the *Mail* editorial, but there are some special passages which we must quote. For instance:—

It has been urged by the few Magistrates who were opposed to fresh legislation on this subject that the root of the evil lay in our system of advances. But we assert that our advances have done more than anything else to break down the village slavery that used to exist in our neighbourhood and that, but for our advances coolies would never have been allowed to leave their homes and earn a higher wage.

During the discussions which have taken place between the Associations joining in this petition, it has been brought to our notice that the Act cannot be put in force in the following cases. (a.) Planters or contractors residing in Mysore, cannot obtain warrants against defaulters in British territory, though planters in British territory can obtain warrants against defaulters in Mysore. (b.) Warrants cannot be obtained against defaulters in Cochin

territory; half the European coffee estates on the Nellampatty Hills are in British and half in Cochin territory. In this case, a Tamil coolie from Coimbatore District frequently takes an advance to work in Wynaad and then takes another to go to the Nellampatty Hills; on the arrival of a warrant, he merely has to cross the boundary and arrange to work on the next estate to escape arrest.

It seems to be unfair to the planter that a coolie absenting himself without leave during the period of his contract can practically deduct the time of his absence from the time he has to serve. It also seems to be unfair to the coolie that if on arrest after the expiry of the term of his contract he is willing to work and the planter to accept his service, the Court cannot pass an order to that effect. The Court at present can only order him to repay the advance and imprison him if he refuses or is unable. The planter can only save him from this by withdrawing his complaint, but if he does so, he loses all hold on the coolie if he again absconds.

A clause is wanted to provide that the defaulting maistry should be treated on exactly the same footing as a defaulting bankrupt is treated in the insolvent courts.

The Collector of Malabar, in treating of this subject in 1884, wrote to the Chief Secretary as follows:—

"The maxim *nemo debet per se-ipsam accusare* has been imported into the Criminal law of India as of England. In India some relaxation of the strict interpretation put on it in England has been permitted; but such relaxations still fall far short of such an interpretation of it as would be required to meet the planters' wishes in respect of defaulting maistries."

"Stated broadly their argument is.—We advance our money to a man to be invested in a particular way, the man disappears and when he is brought up on a warrant he is unable to produce the money, and gives a most unsatisfactory account of what he has done with it. Is it not fair to presume that he has misappropriated it? And yet, we are asked to prove how he spent it."

"The hitch lies in the criminal law interpretation of the maxim above quoted. The defaulter gives a plausible account of how he lost the money or was robbed of it or advanced it to coolies who immediately absconded or so forth, his statement being frequently a compound of what is false and what is true. The planter has nothing further to advance than that the money was paid for a certain purpose and that the purpose was not carried out, that here is the man and that he cannot produce the money. Of course the Magistrate asks if there is any evidence for the prosecution to prove either the misappropriation or the falseness of the prisoner's plausible tale; and of course as the scene of the misappropriation or of the real loss or of both, is laid some 200 miles off and in foreign territory, no evidence for the prosecution is forthcoming; the prisoner gets the benefit of the doubt and walks out of court free."

"All that the planter really wants is to be satisfied how his money went. The best and most successful planters are those who do not exact their pound of flesh, who best read the native character and see that, above all things, a native is almost by virtue of necessity loyal to his superiors and who therefore readily forgive a fault, being assured that it will be made up by increased diligence in the future. If the man has really and truly lost the money as he alleges, he is easily forgiven, the matter is amicably arranged. On the other hand if the money has been misappropriated, it is perfectly just that the defaulter should be sent to jail just like his brother the defaulting bankrupt. They have both made away with other people's money, and cannot satisfactorily say what has been done with it."

"What I would therefore propose is that in the case of defaulting maistries the burden of proving that the money was really lost or was properly spent should lie on the maistry and that on failure to prove this, the maistry should be liable to imprisonment extending to three months; and that his contract should still be enforceable under the other provisions of the proposed Act."

We would respectfully point out that we ask for these amendments not only in the interests of the employer but also in the interests of the would-be honest contractor. It is equally unintelligible to him, if he should have given his coolies under advance a respite, and has not applied for a warrant against them until the day on which the term of their contract expires, that he should be refused redress.

Ceylon planters have complained of the laws which govern their relations with their coolies, and no doubt occasional difficulties occur; but, what with our insular position, our unity of Government and jurisdiction, and, strange to say, our greater distance from the sources of our labour than is the case with our South India brethren, our position is on the whole enviably favourable when contrasted with that of most employers of labour, especially that of the South of India planters. We might indeed have added Northern India to Southern.

INDIAN TEA AT CHICAGO.

SILGHAT, June 19.—A meeting was held at Salona, Nowgong, on the 18th inst. in aid of the funds for pushing Indian tea at the Chicago Exhibition. The tea planters present subscribed R480 on the basis of ten per cent on managers' and seven and-a-half per cent on assistants' salaries. A copy of the subscription list and the proceedings was circulated to other planters of the district. Strong opinions were expressed as to the inadequacy of the sum at present expected. An amount equal to the Ceylon Fund was at least necessary. The Calcutta subscriptions were considered unequal to the occasion. Comment was made on the letter of the Indian Tea Districts Association, London, sending plenty of good advice, but promising no financial assistance. It was recommended that the owners and shareholders of Ocean and River Steam Companies and all interested in any way in tea should be pressed to subscribe individually to enable full advantage to be taken of the splendid opportunity to improve the prospects of the tea industry. It was finally considered that the Local Government should give liberal help, as the prosperous condition of the Assam Province was entirely due to the capital invested by the planters.—*Cor., Englishman.*

FIRE INSURANCE RATES ON TEA ESTATE BUILDINGS.

The Secretary of the Planters' Association sends us copy of further correspondence regarding the premium for fire insurance on the buildings on tea estates, as follows:—

Copy.

Ceylon Association in London, 4 Mincing Lane, London, 10th June 1892.

Dear Sir,—I have the pleasure to enclose copy of letter received this morning from Sun Fire Office, London.—I am, yours faithfully,

(Signed) WM. MARTIN LEAKE, Secretary.

A. Philip, Esq., Secretary Planters' Association, Kandy, Ceylon.

Copy.

Sun Insurance Office, Threadneedle Street, London, E. C., 9th June 1892.

The Secretary, Ceylon Association in London, 4, Mincing Lane, E. C.

TEA ESTATES.

Dear Sir,—Referring to our letter of March 24th I have pleasure in stating that we have had under consideration our Inspector's report on his recent visit to Ceylon, and, as a result, we have been able somewhat to reduce the rates we have hitherto charged. I enclose a copy of the rates we have fixed, which you will see are to be taken in con-

junction with the printed tariff, of which you no doubt have a copy.

I trust that this attempt to meet the views of the tea planters will result in an accession of business to us, and that a wider experience will enable us to appreciate still more closely the actual value of the risks. You will see that strong inducements are held out for the construction of a good class of buildings—I am, dear sir, yours faithfully, (Sgd.) E. S. MARWELL, Supt. Foreign Dept.

Copy.

TEA ESTATES, CEYLON.

Isolated building containing steam, engine, boiler and for stove.	1/2	per cent	1/2	per cent
In which both withering and firing are carried on.	1/2	per cent	1	per cent
In which firing alone is carried on.	1/2	per cent	1 1/2	per cent
In which withering alone is carried on.	1/2	per cent	1 1/2	per cent
In which no withering or firing is carried on without engine or stove.	1/2	per cent	1	per cent

A. Buildings of iron, stone or brick with iron or tiled roofs, wooden flooring, rafters and supports allowed...	1/2	per cent
B. Buildings of brick, or stone or iron pillars with weather boarding and for wattle and daub and iron or tile roofs	1	per cent
C. Buildings of brick, stone iron pillars with weather boarding and for wattle and daub and shingle roofs. Also wooden and wattle and daub buildings with iron or tile roofs	1 1/2	per cent
D. Wooden or wattle and daub buildings with shingle roofs	1 1/2	per cent

As in printed tariff.

COTTON has been ginned by electricity at the Agricultural and Mechanical College of Alabama (U. S. A.), thus furnishing an entirely new application of this marvellous form of power. For the purpose of illustrating the transmission of power by electricity, the class in electrical engineering under the direction of their professor, A. F. McKissick, connected the generator at the dynamo room of the college with the motor at the Statum farm by a wire 3,000 feet in length, the distance between the college and the farm. By running the dynamo at the college, the motor at the farm did the work of the ten-horse power engine formerly used. It ground oats and corn for cow feed, and ginned cotton, doing the work in a simple, effective manner with small percentage of loss.—*Indian Agriculturist* June 11th.

THE TEA SEASONS OF INDIA AND CHINA.

A correspondent asks:—"Can you let me know when the Indian and China tea seasons commence and end respectively?" In a recent article we indicated that the tea seasons for India and China ran from 1st June of one year to 31st May of the succeeding year. On that occasion we noticed the figures for total deliveries of tea in London. Deliveries for export were included; and as by far the larger proportion of tea exported from London is China, that country was in total deliveries slightly in advance of Ceylon. When it comes to deliveries for home consumption, however, we find the cases reversed. The figures and the percentages, for India, Ceylon and China, are given in Gow, Wilson & Stanton's circular issued with the *Observer* after the arrival of last mail. The relative positions of the tea from each country consumed in Britain for the twelve months between 1st June 1891 and 31st May 1892 were as follows:—

Indian tea	lb.	105,356,293	51 per cent.
Ceylon	"	58,299,737	28 "
China &c.	"	43,584,433	21 "

In the previous season the percentage of China was 29 against 29 for Ceylon, so that now for the first time in the history of tea consumption in Britain the product of Ceylon has been used more largely than that of China. Ceylon, in truth, is gaining even on India; for whereas the percentage of Indian tea consumed was 53 in 1889-90, it was only 51 in the past two years Ceylon rising in the three years from 16 to 28 per cent, and China going down from 31 per cent to 21. Meantime, increasing proportions of Indian and Ceylon tea are competing with China in the export trade as well, the figures in last season being for Indian tea 4,141,000 lb.; Ceylon 2,998,000 lb. or very nearly 3 millions; China 29,541,000 lb. While China has been stationary in the past two seasons, the increase in Indian has been from 2,327,000 lb. and in Ceylon from 1,426,000 lb., the export in this case having doubled.

Our local tea season is coincident with the calendar year, as we have no such close winter seasons as influence growth in India and China; but it is convenient that the figures for Ceylon tea should be compared with those for Indian and China, not only for the years ending 31st December but for the seasons closing on 31st May.

THE AMSTERDAM CINCHONA AUCTIONS.

Amsterdam, June 9.

Of the Java bark offered at today's auctions 1,753 packages sold at somewhat lower values, the unit not averaging over 6 cents, or 1d to 1 1/16th d. per lb. Manufacturers' stem and branch barks, original and renewed, brought 11 to 82 cents (equal to 2d to 1s 2 1/2d per lb.); ditto root 15 to 43 cents (equal to 2 1/2d to 7 1/2d per lb.); druggists' bark in quills, broken quills and chips 11 to 52 cents (equal to 2 1/2 to 9 1/2d per lb.); and ditto root, 12 to 19 cents (equal to 2d to 3 1/2d per lb.) The largest buyer was the Anerbach factory, then followed Gustav Briegleb and Matthes & Bermeester.—*Chemist and Druggist.*

CONSULAR REPORTS.

HANKOW.

Consular Christopher T. Gardener addresses his report on Hankow trade in 1891 to the Marquis of Salisbury on March 14th. Mr. Gardner reports:—

EXPORTS.

The exports that show an increase over 1890 are native cloth, musk, nut-galls, wood-oil, opium, black tea, brick tea, and sundries. The exports that show

a decrease are coal, fungus, gypsum, hemp, hides, medicines, tea-oil, rice, rhubarb, silk, vegetable tallow, tea-tablets, tea-dust, tobacco, varnish, white wax.

BLACK TEA.—The export of Black Tea shows a slight increase in quantity of 1,181,669 lb. over 1890, and the larger proportionate increase in value of £550,976. The increase is due to an increased consumption of tea in Russia, and to the home markets being more fully stocked at the end of 1891 than at the close of 1890. At home there was undoubtedly a diminished consumption of China tea, owing to the competition of India and Ceylon.

The export of Black Tea during the last six years has been as follows:—

1891.....	68,590,451	1888.....	77,452,441
'90.....	67,342,334	'87.....	84,566,084
'89.....	75,740,133	'86.....	90,232,956

The following table shows the destination of the teas exported from this during the last six years:—

Year.	London.	Odessa.	Chinese Ports for Abroad.
	lb.	lb.	lb.
1891	10,463,466	24,467,000	33,659,985
'90	11,314,300	22,742,241	30,012,603
'89	16,051,022	16,797,177	43,032,792
'88	21,857,360	15,002,057	40,593,012
'87	22,742,233	11,148,487	50,675,030
'86	39,545,472	9,898,887	41,121,585

The prosperity of Russia, which up to this summer had been proceeding by leaps and bounds, led to tea purchasers here competing with great eagerness for the first fine crops of tea for the Russian market. It was further believed that the crops of finest tea were extraordinarily good in quality and also short in quantity. This led to unheard of prices being paid, as much even as Tls. 90 per picul, or about 3s 6d per 1 lb. The high prices paid at the beginning of the season increased the average value of all the tea exported, though the prices ranged very low at the end of the season, owing to the fact that the probability of there being a bad harvest in Russia began to be known, the demand in Russia for tea having in 1891, even more than in previous years, fixed the market selling price. Much of the tea sent to London was for the Russian market, and the fall in value of the paper rouble from 2s 4d in June to 1s 10d in November caused the tea sent later in the season, in spite of their lower price, to be an unfortunate speculation for those who exported them.

It will be noticed that there is a slight increase in 1891 of Black Tea sent to China ports over that in 1890. Part of this increase is accounted for by the fact that much of the tea that used to reach Russian Siberia from this by way of the Han River, Fanch'eng, and Ninghsia, not appearing in the returns of the maritime customs, now goes to its destination by the longer but easier route of Tientsin and Kalgan, to do which it is carried to Tientsin from this in steamers, and is entered in the books of the maritime customs. New fiscal arrangements in Siberia have added to the effect of an easier route to transfer the trade away from that by Fanch'eng to that by Tientsin.

Odessa is becoming more and more the depôt of the Russian tea trade, and a certain quantity of tea that used to reach Russia through Tientsin and Mongolia now finds its way to Russia by Odessa. This will be more and more the case as the internal communications from Odessa are improved. Russian transport vessels carrying the Russian reliefs to Wladiwostok and the time-expired men from Eastern Siberia (Primorsk) to Russia visit Hankow on their way back and fill up their holds with tea; but British vessels have also succeeded in obtaining charters to carry tea from this to Odessa.

The increase in brick tea of 3,000,000 lb. is probably due partly to tea being sent by way of Tientsin (in which case it appears in the returns), instead of by way of Fanch'eng (when it does not appear in the returns), and partly by mere fluctuation of trade.

Log tea, and inferior tea with stalks, packed in the shape of logs, weighing from 8 lb. to 80 lb. each, wrapped in the leaves of the "bambusa latifolia," and

reduced in bulk by binding the log with split bamboo, a new article of commerce, was exported from this last year to Chinese ports to the value of £548.

SUNDRIES.—The increase in sundries is due to three items; beans for the manufacture of soy, £10,000; copper for tribute, over £44,000; and wood poles, £110,000. The last increase is interesting. Wood poles cannot be brought down to this port under transit certificate. The reason for excepting timber from the privilege given by the Chinese Government is that the forest regions are sparsely inhabited, and sufficiently policed for the Chinese Government to be able to ensure adequate protection to persons sent there to purchase timber.

TIMBER.—For many years the high transit duties imposed, amounting often to over 100 per cent., *ad valorem*, checked the trade in timber, which the natural features of the country—steep declines easily formed into timber shoots and swift torrent capable of floating the timber to navigable streams—should have facilitated, and which the very low charge for labour in the forest regions should have made profitable. Lately, however, these inland transit dues have been lightened, and the consequence has been an enormous extension of the timber trade here. Most of the timber goes down river in the form of huge rafts. These rafts, with the butts erected on them for the raftsmen, looking like floating islands, are a remarkable feature of the river landscape of the Yangtze; and the floating timber yards where these rafts are lashed together reach (beginning about four miles above this Consulate) for some six miles along the north bank of the Yangtze. The value of these rafts must be enormous but they do not appear in the trade returns of this port. Owing to the increase of both rafts and foreign shipping at this port, collision between the rafts and foreign vessels at anchor here were at one time frequent, giving rise to acrimonious and troublesome disputes. I accordingly, in the spring of 1890, persuaded the Chinese authorities to make the following four rules for rafts:—

- (1) All rafts must be provided with strong mooring tackle.
- (2) No rafts must get under weigh except early in the morning.
- (3) No rafts are to get under weigh in threatening weather.
- (4) All rafts must float down the south bank of the river, merchant steamers and lorchas here being anchored on the north bank.

These regulations worked well, and there were consequently no collisions from March, 1890, till June, 1891, but in that month, owing to freshest and the raft employes not using sufficiently strong tackle, some rafts broke from their moorings and endangered our shipping. I accordingly invited a deputation of raft owners to meet me, and explained that it was to their interest to force their employes to abide by these rules. They saw the force of my argument, and gave me a written guarantee that they would insist on the raftsmen they employed adhering strictly to the regulations. There has consequently been no collision since.

The poles appearing in the maritime customs returns were sent down to treaty ports lower down the river by British and American lorchas, and by junks chartered for that purpose by British subjects and American citizens, who have the right to charter junks for treaty ports and pay on the charges of such junks dues according to the treaty tariff. The expansion or contraction of this trade will depend as to whether the maritime customs or the native customs give the greater facilities for exporting the timber.

COAL.—There was a very slight decrease in the export of native coal. Coalfields exist in the hills from here to at least Chungking, a distance of over 600 miles. They are probably the largest coalfields in the world, but as yet have produced no fuel suitable for use with machinery such as that at present here. Efforts are being made to search for a more suitable kind, and doubtless machinery will be ultimately adapted to the coal most easily procurable, and the export of this commodity will be a large one. Coal mines in this region are worked in a very primitive method, and as yet only surface coal has come to the market.

TEA OIL is used both for purposes of light and food. The decrease in exports has been progressive, and is probably due to the fact of other illuminants, such as kerosene oil, coming into favour.

The short export of *Tea tablets* was probably due to the famine in Russia. Tea tablets being exported after the leaf-tea season is over, and being consumed by the Russian commercial classes as a luxury the export of them is particularly liable to be affected by the prosperity or otherwise of Russia's commerce.

The decrease in the export of *Tea-dust* of over 60 per cent. is serious. All the tea-dust exported from this went to Great Britain, to flavour Indian teas. The decrease is due to two facts—first, the consuming classes are getting accustomed to the flavour of Indian tea, and consequently the dust is not so much in demand with our grocers for giving it the flavour of Chinese tea; and, secondly, the tea growers of Ceylon have been successful in producing a flavouring tea which, blended with the Indian tea, suits the palates of our consumers.

As early as 1880 I reported to the Foreign Office my opinion that the competition of Indian tea would injuriously affect the export of Chinese tea, but it was not till 1885 that I was sent officially to this Consular district. I at once pointed out to the Viceroy my fears as to the Hankow tea trade, and urged on his Excellency the desirability of fostering the production of other commodities that would make up for the inevitable decay of the tea trade. I pointed out to him that the hopes of Russia's supplying England's place as a tea purchaser were illusive, and recommended to his consideration the three products of rhea fibre, silk and tobacco. With regard to rhea fibre as yet attempts to export it have been unsuccessful, either because Indian competition has been too keen, or because the Chinese have not acquired the art of de-corticating it so as to suit the requirements of our manufacturers.

FOREIGN IMPORTS.

In *Metals* the increase has been all along the line, except in the case of pig-lead, and as most of the pig-lead imported is used for lining the boxes in which tea is exported, the import of lead will naturally decline with the diminution of the export of tea.

The increase in the import of *Window Glass* is also progressive, and will probably continue, as the Chinese find its superiority for window panes to the paper panes generally used in native houses, and as the increase in wealth renders more of the natives able to afford it.

The increase in the import of *Needles* is also progressive, and will probably continue, our needles being far cheaper and handier than the native needles, and though the import in 1891 reached the respectable figure of over 635,000,000, it has not yet reached its limit. There are still places in the interior of the region supplied from here where our needles are unknown, and whence in course of time they will oust the native needles as they have done in other regions of China.

The enormous increase in the import of *Kerosine Oil* is noteworthy. The following are the amounts imported during the last six years:—

	Gallons.
1886	3,715,810
1887	3,202,550
1888	1,674,050
1889	2,241,390
1890	3,045,460
1891	5,753,028

The use of kerosine oil is discouraged by the Chinese authorities from the very praiseworthy motives of preventing fires, yet its cheapness causes a great demand. I think this fact ought to encourage our manufacturers. There is in this Consular district a large possible market for our goods, if only our people would think a little less of what they want to sell, and a little more of what the Chinese want to buy.

WUHU.

Consul Colin M. Ford addresses, on March 11, his report on the trade of Wuhu for the year 1891, which states:—

* * *

GREEN TEA is the only other article of any importance of which the export appears to be growing. In 1890 the quantity exported had risen from 3,244 lb., valued at £172, in 1889, to 47,641 lb., of the value of £1,617, a very notable advance; and in 1891 there was a still further improvement, the export having been 67,261 lb., valued at £2,521. This is still far short of what the export of this article used to be in the early years of foreign trade at this port, but it shows a steady tendency to return to the former level. *Black tea*, on the other hand, continues to decline, the export having fallen to 242,470 lb., valued at £11,363, from 256,412 lb., valued at £13,135 in 1890, in which year there had already been a considerable fall from 310,133 lb. valued at £20,278 in 1889.—*L. and C. Express*, June 3rd.

PLANTING NOTES.

In the *Grocer* Mr. James Llewellyn-Hughes, once a tea planter, and still kindly remembered in the tea districts of India, points out that from an analysis of the accounts of eighty joint stock companies registered in Calcutta, and representing an aggregate invested capital of £2,54,58,150, a total net profit for the year 1891 was made of £1,252,605, or 4·88 per cent. on the capital. "This," he says, "compares with 2·54 per cent., or barely 2½ per cents., paid in 1890 and 4·18 per cent. in 1889." We believe it is no secret that Mr. Llewellyn-Hughes is not enamoured of tea planting as a remunerative occupation and he points out with something like triumph that there were eighteen companies that made an actual loss of from 2 per cent. to 3·62 per cent. Mr. Llewellyn-Hughes, in his reference to the poor return paid by many of these Calcutta companies, omits to mention certain gardens, like the Bargaug Company, Assam, the Nedeem, Western Doon, which have, according to the *Pioneer*, paid steady dividends of 20 per cent., and the Matelli Company, which has paid as much as 40 per cent. to its shareholders. But Mr. Llewellyn-Hughes might with advantage turn his attention to the London Tea Companies for the other side of the picture. A table supplied by Mr. Ernest Tye, giving the results of working in 1891, shows that the fifteen companies who have published their reports, with an aggregate capital of £1,094,057 and a planted area of 22,814 acres of tea have realised net profits which amount to £89,204, or equivalent to a dividend of 8·15 per cent. on the whole capital invested. This indicates conclusively, Mr. Hughes notwithstanding, that, by economy of working and careful manufacture of really good teas, tea planting in India as an industry can hold its own against any country, and is not to be despised as a remunerative investment.

I am glad to see from "Planters'" letter that in South Wynaad tea cultivation is being extended. I did not know that the particular Company referred to had any intention of going in for new clearings. I can only hope that their example may be followed by others more timid, and still doubting. I have also heard that activity in tea cultivation has again commenced in another part of Wynaad. Very glad was I to get this news, as it is hence that I expect to see the facts and figures come, which shall convert Didymus and his following.

During the year 1891 the number of emigrants (coolies almost entirely) from the Madras Presidency was 146,554. This number does not include 5,203 who proceeded from the Ganjam district to Assam. I mention these facts incidentally, in case any should say it is impossible to get labour in Southern India.—"St. Louis" in *Madras Times*.

ANNUAL REVIEW OF INDIAN AND CEYLON TEA.

38, MINCEING LANE, June 1892.

The completion of the twelve months ending 31st May—which custom and convenience have made the limits of the season—affords an opportunity of reviewing the position, and of publishing, with the permission of Proprietors, a tabulated statement of results.

Progress, more or less uniform, marks the record. A larger area under plant: increased productiveness both in India and in Ceylon: a somewhat lowered cost of production: and a marked advance in consumption at home and abroad,—stand on the credit side of the account. On the other side must be set the reduced average of market rates due partly to the fact that heavier crops have only been secured at some cost of quality, and partly to the movement in the direction of lower value which has of late affected so many other kinds of imported produce. Over-production there certainly has not been, as yet; for we carry forward stocks smaller by 18 million lb. than existed 10 years ago, on which to work a business larger by 42 million lb. per annum than it was then; and in none of the world's markets are there supplies in reserve for contingencies.

But while there has been progress, it has not been entirely in one direction: there have been backward movements also,—still, at no time has there been stagnation; and we place on record the growing interest which attaches to Indian and Ceylon tea as a sign of vitality auguring well for the future.

The attention which has been directed to British-grown tea through the public press—whether by the accurate comments of the Chancellor of Exchequer in recent Budget statements; by those who represent the planting community; or by other whose business it is to gauge the public taste and feed it with lavish advertisement—beyond question is a contributory cause of the life and movement in our markets. A more substantial reason, some think, is to be found in the policy adopted by producers of selling with a free hand on arrival, which practically compels those engaged in the trade to fix their attention on the market. At times it is true, this cannot be done without disturbance of price, but in the long run it attracts operators and retains them. The seller's necessity is the buyer's opportunity; and neither capital nor industry will be drawn into a market offering few chances for their profitable employment.

On the other hand, there is a cause operating to divert Dealers' capital, and to lessen the number of those willing to carry stocks. We refer to the gradual gravitation of the trade of the country into the hands of great Co-operative Societies, Packet Companies, and large retail distributors who make a speciality of tea. Their business has been acquired at the expense of the grocer, and therefore of the Wholesale Dealer; but unlike the Dealer they are not, as a rule, stockholders, preferring to follow rather than to anticipate the market. It is obvious that this may eventually have results not yet contemplated: it is, therefore, necessary for those who realize the important function fulfilled by the Dealers as holders of stock, to consider how their position can be strengthened, in order that the buying power of the Trade may be kept up to our requirements. The profit divisible among those engaged in re-selling and distributing is not what it used to be, and it is unequally divided—a very small profit being made by those who strictly confine themselves to wholesale trade, the retailer taking all the rest. This is a result out of proportion to the capital and experience brought into the business by old and wealthy firms; and it is, therefore, not surprising that some are either retiring or ceasing to operate as formerly. One difficulty is that their purchases being ear-marked, so to speak, by the Public Sale record, excessive competition compels them to deal at the barest margin of profit: the remedy would seem to lie in the development of business by private contract as well as in the Sale Room. Some large Importers encourage this, others prefer to keep entirely to Public Sale—it is a subject on which opinions naturally differ—but the volume of supply is now so vast that sellers could create a market outside the Auction Room, and at the same time keep in touch with the new class of buyers who have become such an important element in the Trade.

We pass from considerations which press more directly upon those whose duty it is to safeguard

the interests of sellers here, to the wider question of consumption—its progress in the past and probable expansion in the future.

The total increase of 12½ millions in the Deliveries tells of growth, and we do not think its limit has been reached, though to some extent the heavy clearances may be due, as they have been previously, to low prices.

Going into details, we see that 7½ millions more of Indian, 18½ millions more of Ceylon, and 13½ millions less of China have been taken. The continuous increase in the use of Ceylon tea is the feature of the year: that it has occurred without checking the use of Indian is most satisfactory to all who refuse to regard their respective interests as antagonistic.

We have alluded to low prices as a possible cause of the large Deliveries, but we think that the more general use of Ceylon and Indian combined is so raising the character of the tea supplied to the public that it is becoming a more popular beverage. The average annual consumption per head of the population is 5½ lb., but the average quantity used by an adult tea-drinker is about 12 lb. per annum, and by a household which includes children probably 8 lb. per head—it follows, therefore, that a large portion of the population consume very little at all, so there is still a good margin for increase in the aggregate amount consumed. But while this may be so with regard to tea as a whole, a reference to statistics shows that the proportion of British-grown tea used in the U. K. is still insufficient to absorb all that we are likely to receive. During 1891 the proportion rose from 72 per cent to 80 per cent: and by April of this year it advanced to 84 per cent; but this rate only represents 176 million lb. out of the total of 210 millions which may be used at home during the coming year, leaving a considerable surplus, for which we must hope to find buyers outside the United Kingdom.

The need of fostering trade with other markets becomes, therefore, more pressing than ever, and it is encouraging to find evidence that efforts made in the past—whether individual or associated—are now bearing fruit.

The export of Indian from London has risen to 4½ million lb., and of Ceylon to 3½ million lb. in the season, the United States, Canada, and Constantinople being the principal buyers, with a steadily growing demand, though still too much limited by price. In most parts of the world with which we trade our teas are gaining repute, and although the Australasian buyers have not taken much more than in 1890-1, a trade is being developed with Western Asia through the agency of Bombay houses which will be of great benefit, as it absorbs a class of tea with which our market is often over-supplied. The importance of bringing our tea into notice in other centres of commerce is so manifest, that no opportunity—such as the coming Chicago Exhibition—should be lost; and it would be well if India and Ceylon could act in concert, for however natural it is for individual action to be inspired by individual interest, the facts are that the two Industries have practically become one and that those who buy for trade purposes are unmoved by sentiment, and take whichever growth happens to be the cheaper, provided it be suitable, the source of supply being to them comparatively speaking a matter of indifference. The United States offer the widest field for enterprise; but as only 8 or 10 millions out of the 90 million lb. annually used there are black tea, and as the preference shown for unfermented kinds is almost certainly due to some property of the water, which makes them the more palatable—progress must needs be slow, unless Producers are willing to take the risk of making tea resembling Oolong, to suit the national taste. In course of time, a market would probably be found for a large quantity; the risk would be, that failing buyers in the States, such tea would be difficult to sell elsewhere. Many Proprietors, however, may be willing to make experiments on a small scale, and show that, if called upon, they can meet the demand from all quarters of the world.

From the subject of consumption we pass to consider what class of tea will prove most profitable to produce.

The course of the market seems to justify the opinion we have repeatedly expressed that a gradual, if slow, re-action from the craze for mere "cheapness" is taking place. It is true that very low-priced teas are advertised, but, for obvious reasons, they are not pushed by the countermander by the agent, and we believe are not extensively sold outside London and a few large cities—and there is evidence that consumers are learning that the best tea is the most economical to use. To those who closely watch the operations of the principal retail distributors—usually credited with succeeding by the attractive power of a low quotation—it is instructive to note that they are, notwithstanding, among the largest buyers of good tea, making liquor the criterion of value.

But while we put forward this view with some confidence, we do not suggest that it will rally all growers to shorten their crops in the endeavour to make such teas as now command high prices. A great variety in the character and value of supplies is necessary; and until the average retail price is more generally raised by the drift of public opinion in favour of a good article instead of a "cheap" one, it would be opposed to experience to expect that present prices of fine tea will rule with any considerable increase in their supply. Still, the margin between the value of a good crop and a bad one is now so wide as to represent the difference between a fair profit and none at all—and so long as there is no actual shortness in the total supply (which would at once alter the range of prices) we think market rates will tend in that direction.

We do not advise growers to set themselves the task of making any particular type of tea, for although in recent years a preference has been shown for fully-fermented, deep coloured kinds, of late there has been some re-action in favour of high-flavoured, pungent varieties, of Ceylon as well as of Indian—and we therefore recommended each one to make that kind which experience has taught him his soil, plant and appliances are best fitted to produce.

One point is clear, viz.: that every one who has already made a name for a speciality, or for fine tea, should aim at keeping it, and take no risk by change: the reputation of a mark still counts for much, and buyers pay most attention to those one which they can depend for regularity of quality and character from season to season. This applies with special force to certain estates in Assam and Ceylon, and to many in Darjeeling, of which it may be said—without any disparagement of other gardens or districts which have their own merits—that their finest teas hold an unassailable position.

It is especially desirable that from Ceylon should come more frequently invoices containing finely sorted tea—net of fancy character as specimens of the tea-maker's art, but for the practical purpose of lifting the dead level of market quotations, and of giving the trade something to talk about and work upon. Every year from India comes a fair supply in bulk of "Pekoe," selling from 1s 3d to 2s, and of "Broken Pekoe," selling from 2s to 2s 6d per lb.: their quotation in the public records of business is of great advantage, inasmuch as it imports elasticity to the value of good teas of a lower grade.

The progress of the Ceylon trade is shown by the following statistics, covering four seasons.

Year ending 31st May, 1892	Import	64 million lb.
Do. do. 1891	"	47½ " "
Do. do. 1890	"	34½ " "
Do. do. 1889	"	26½ " "

Total in Auction 790,000 pkgs. Average sale price

(exclusive of reprints)	9½d per lb. (approximate)
" " 605,000 "	" 11d "
" " 450,000 "	" 11d "
" " 351,500 "	" 10½d "

WM. JAS. & HY. THOMPSON, Brokers.

TEA AND COFFEE IN BHAMBO.

In Saturday's *Burma Gazette* there are some papers published relating to tea and coffee plantation in Bhamo. Mr. C. W. Palmer, Deputy Conservator of Forests, reports that he considers all the lower ranges of hills between Bhamo and Shwegu and also in the upper defile most suitable for the cultivation of tea. Tea is grown in nearly all Kachin villages in these hills and seems to flourish. Tea will also, he thinks, do well on the highest bank of the Irrawaddy as well as coffee anywhere above flood-level. Some coffee plants which were put out in the forest compound last rains are doing well. He recommends that a small plantation be started in Bhamo.

Mr. George, the Deputy Commissioner, says that it would be best at first only to throw open for tea and coffee cultivation three tracts, as they are nearer the line of communication than others. These tracts are: (1) The tract between the Tapin and Namtabet and Namsiri chaungs. (2) The hills east of the third defile. (3) The land on either side of the main Irrawaddy anywhere above Shwein.

The Forest Officer says these are good for tea and coffee cultivation. These tracts all lie on the river, by which there is communication either by boat or launch. Communication by land is in most instances impracticable. There are no large villages properly so called anywhere; and if labour in any quantity is required, it would most probably have to be imported. Provisions would have to be got up by river. Except in the case of Tract (1), practically provisions in any quantity are locally unprocurable. The people barely grow enough for their own needs. As to the terms of the proclamation Mr. George thinks it would be sufficient to notify that land said to be suitable for tea and coffee is available and that it would be leased in accordance with special rules made by the Financial Commissioner. Most of the land in the tracts is overgrown with thick jungle, except in the neighbourhood of Bhamo, and it would take some time to clear.—*Rangoon Gazette*, June 24th.

NOTES ON PRODUCE AND FINANCE.

TABLET TEA.—That 493,392 lb. of tablet tea should have been exported from the port of Kiukiang last year is plain indication that this new substitute for brick tea is popular. Unlike brick tea tablet tea is made from the very best quality of tea dust. It is formed, by pressure alone, into small cakes, which are perfectly hard and solid and somewhat resemble chocolate in appearance. The material is not, like brick tea, moistened with steam before being compressed, and the flavour is not in any way impaired by the process of manufacture. As it takes up little space, and is most unlikely to get spoilt or damaged, it is a convenient form of tea for travellers, backwoodsmen, or armies in the field, and the Chinese at present have the control of the market in it.

ENGLISH GROWN TEA AT THE INTERNATIONAL HORTICULTURAL EXHIBITION.—Last Friday H.R.H. the Duke of Connaught visited the Indian tea gardens at Earl's court, and was shown the manufacture of tea in its various stages by Mr. Macgregor, an Indian tea planter. The Duke tasted the tea, which he pronounced to be good. The Exhibition bids fair to eclipse all former Exhibitions held at Earl's Court, and the tea garden and factory are amongst the chief attractions. The small hand-power Jackson's tea roller, especially made by Messrs. Marshall and Sons, Limited, for the Exhibition, is doing its work most satisfactorily.

THE SIZE OF TEA CHESTS.—The efforts that are now being made to push Ceylon growths in Canada, the States, and the Continent would be largely aided by the growers packing their teas in half-chests of about 60 lb. net., says the *Produce Markets' Review*. It cannot be too clearly pointed out that the foreign buyer objects to chests, and will not handle them if he can avoid it, but takes naturally to the smaller packages equal in weight to half-chests of China tea, to which he has always been accustomed.

PRODUCE IN BOND.—According to the "B" Bill of Entry, the bonded stock of tea in the Customs and

Excise warehouses of the United Kingdom on the 31st ult., was 74,098,210 lb., against 79,020,834 lb., on the corresponding date of last year and 85,239,638 lb. in 1890; of cocoa, 12,340,566 lb., against 11,746,084 lb. and 12,584,730 lb.; coffee, 258,477 cwt., against 236,924 cwt. and 377,686 cwt.

LAST WEEK'S TEA MARKET.—Of last week's tea market the *Produce Markets' Review* says:—"The medium grades of Indian especially were in good demand, and enhanced values were in most cases paid, as the stock of these kinds is now reduced to small dimensions. A fairly good business has been transacted in the lower grades, at gradually hardening rates, and, with the probable absence of any imports of importance for some time to come, it is not unlikely that higher prices will be obtainable later on. Hitherto leaf teas have offered such exceptional value, that broken descriptions have been comparatively neglected, but owing to the advanced rates for the former, dealers have been obliged to resort to the use of broken tea in an increased proportion; hence the improved demand, which will no doubt continue."

CINNAMON.—At the quarterly sales of cinnamon held last week 1,800 bales, 18 parcels, and 14 boxes Ceylon were offered, and importers experienced difficulty in disposing of their consignments. The prices were about on a par with those of the Feb. auctions in some instances, but in the majority of cases they were 2d per lb. under former rates. Out of the quantity at sale not more than two-thirds were sold in the room, and a large portion (580 bales) of "unworked" cinnamon, included with the amount of "fourths" brought forward, was realised at such reduced figures as from 4d to 7d per lb. Firsts went at 7d to 10d., superior plantation at 1s 2d to 1s 3d seconds at 6d to 8d finest at 1s 2d thirds at 5½d to 7d a few up to 9d and 10d and fourths at 4½d to 6½d also broken (in boxes) at 4d to 5½d down to 3d and 2½d.—*H. and C. Mail*, June 10th.

S. I. PLANTING DISTRICTS AT CHICAGO.

Our panting correspondent, St. Louis, has already announced that the Indian Tea Association of Calcutta is prepared to arrange for the representation of our tea districts, but that it cannot undertake the representation of coffee and cinchona. Of course, tea is the most important staple to be pushed, and as the Tea Association has little or no interest in either coffee or cinchona, it has no doubt rightly decided not to be hampered with either of these products. A large sum of money will be required to make the exhibit at Chicago a success, and it is hoped that at least \$50,000 will be raised in India, apart from a contribution from the Government of India. All gardens are being invited to subscribe at the rate of 2 annas per acre, but subscriptions will also be required besides from Agents, Brokers and Managers. Several firms in Calcutta have subscribed \$1,000 each, but so far we have not heard of any Madras house following suit. The two principal tea districts in Southern India are the Nilgiris and Travancore, and doubtless if planters there subscribe, firms who are interested will also make donations, and both the Government of Madras and the Travancore Government may be approached on the subject. The Travancore Planters' Association did, we see, request the Ceylon Planters' Association that its district might be included in the Ceylon representation. In his letter, the Chairman, Mr. Knight, writes:—"Travancore might well pay at least about \$8,000, which would be at about the rate of \$1 per acre on the cultivated area, if Ceylon will consent to the combination, and there would be no difficulty in carrying out all arrangements for selection of exhibits on the same lines as Ceylon may determine upon." That island has, however, decided that it must stand alone, so we hope that Travancore will now arrange with Calcutta. \$8,000 is a handsome contribution from so young a district, and we trust it will be supplemented by a substantial subscription from the Government of that State. So far we have heard of no movement on the

Nilgiris, but there is no reason why that district should not follow the example of Travancore, and we hope that there will be no further delay in getting together a small working committee, and calling in subscriptions, etc. Our Simla correspondent announces that Mr. Blechynden, Secretary of the Agri-Horticultural Society of India, has been chosen as the Indian representative at Chicago, and a better choice could not have been made.

We publish in another column some suggestions which were read at a General Meeting of the Indian Tea Districts' Association in London on 22nd March last, many of which have already been followed. The paper containing these suggestions the Calcutta Committee are now distributing amongst planters, in Northern India and so it will be of interest to our planting readers. Here particular stress is laid on the importance of the United States as a market for Indian tea; and the splendid opportunity which the Chicago Exposition offers for making these teas known. It seems to us of great importance that every district should be represented, in order that American dealers may see what a vast range of qualities India is able to export, and to learn that by coming to this country, they can suit the different and varied tastes of consumers. Particular attention should be laid on this great variety of teas, so that if the leaf exported from one district cannot produce a liquor pleasing to the American palate, some other district may be able to do so. We should be surprised if at the present moment one-half of the districts in this country have ever exported tea to the United States.—*M. Times*, June 28.

INDIAN TEA AT CHICAGO.

NAUGONG, ASSAM, June 18.—A meeting was held at Salolah this afternoon in connection with the furtherance of the interests of Indian tea at the Chicago Exhibition, at which the following gentlemen were present—T. Henderson, Salolah Tea Co., Ltd.; S. M. Barry Kellyden Tea Co. Ltd.; R. G. Sis-on, Upper Assam Tea Co. Ltd.; W. H. Lyall, Nonoi Tea Co., Ltd.; M. Ohamey, Haspan, Tea Estate; H. L. Calcraft, Langsu g Tea Estate; C. D. Tennant, Alnkeek Tea Estate; A. D. Macfarlane, Salolah Tea Co. Ltd.; E. F. Prycei Salolah Tea Co., Ltd.; H. A. Peck, Nonoi Tea Co., Ltd., by his Attorney, W. H. Lyall.

Mr. Henderson first read over to the meeting a letter dated 29th May, from the Secretary to the Assam Branch, Indian Tea Association, containing an extract from a letter received by him from Mr. J. N. Stuart, and also some suggestions for obtaining the necessary financial support for the due representation of Indian teas at Chicago Exhibition of 1893 as read at a general meeting of the Indian Tea Districts Association, London, 22nd March, 1892. The question of local subscriptions was then considered, and a proposal that all present should subscribe was unanimously agreed to. The basis of subscription was fixed by general consent at a percentage on salaries—ten per cent. for managers and seven and-a-half per cent for assistants; and a sum of R480 was subscribed on the spot. It is decided to forward a copy of the proceedings and the subscription list to all planters in the District who had been unable to attend the meeting, and little doubt is felt that every one will add his proportion. A general discussion of the whole question and of the papers read by Mr. Henderson then followed; and, though no resolutions were formally passed, the unanimous opinion of the meeting on various points was summarised and recorded. It was generally agreed to that the amount of the Calcutta subscriptions was not equal to the occasion; that all Agents, Brokers, Ocean and River Steam Companies carrying tea, and, in short, everyone in Calcutta in any way interested in tea, should have subscribed liberally before asking managers and poorly paid assistants, whose connection with an interest in tea was often a very fleeting one to help.

The value of the suggestions contained in the letter from the Indian Tea Districts Association was duly appreciated and acknowledged; but sarcastic comment was made on the fact that so much good advice was entirely unaccompanied by any substantial pecuniary aid, or even promise of it, beyond a para, suggesting that "a promise of pecuniary support should be obtained from Companies, Firms, and persons in London concerned in the production of Indian teas." During three months which have elapsed since the date of the letter under comment there has been no word of any sums or amounts subscribed in London at all. The question of the total amount to be raised was considered. Mr. J. N. Stuart's letter hopes for R75,000 to R1,00,000. Assuming that the Assam Districts subscribe two annas per acre for the 240,000 acres under tea, as per last Government return, this would give R30,000; but as it is improbable that every garden will subscribe, the amount from this source was estimated at R25,000. The subscriptions advertised in the *Englishman* of 15th instant are under R30,000. This leaves R20,000 to be raised from managers and assistants to make up the lowest amount suggested by Mr. Stuart. No doubt this amount will be forthcoming; but this will still leave India's resources for the Chicago Exhibition R125,000 short of the amount which Ceylon will have at its disposal. Owners, shareholders, and those interested in tea, other than managers and assistants, should be looked to for personal subscriptions as distinct from subscriptions by Companies, or per acre. It was suggested that the Calcutta Association should address all shareholders individually, and impress on them the importance of raising a large sum of money. If they fail to seize this occasion, they will be showing a lamentable want of interest in their own future, and losing the greatest chance of improving the prospects of the tea industry, which ever has or ever will be open to them.

Finally, the meeting recorded their unanimous opinion that the local Government ought to help the fund with a very substantial subscription, seeing that the prosperous conditions of the province is entirely due to the tea industry, and the amount of capital invested therein by planters. The rate of revenue has been doubled within the memory of planters present at the meeting; the amount of revenue increased enormously. It is a matter of notoriety that the Assam ryot is better off than any other ryot in India while Assam also provides an outlet for the surplus population of famine-stricken and over-populated districts in other parts of India. This latter consideration should induce the Government of India also to give substantial assistance to an effort to improve the prospects of an industry to which not only Assam but the "Labour Districts" owe so much.—*Correspondent of the "Englishman."*

BORELLI TEA COMPANY.—The eighteenth ordinary general meeting of the Borelli Tea Company, Limited, was held yesterday at 138, Leadenhall-street, E. C., Mr. J. A. N. Martin presiding. In moving the adoption of the report, the Chairman said the Board were very sorry not to come before them with a better dividend than the 6 per cent. per annum recommended in the report. They would observe, however, that there had been an increase in the cultivation of 130 acres. Mr. Bennett, one of the directors, had just returned from visiting their gardens, and had reported that the extended ground had been very well planted. The reason for the smallness of the dividend was that their manager had made somewhat medium teas, but the policy of the Board was that the quality should be improved in the coming year. The report stated that a net profit had been realised of £1,456, the crop showing a considerable increase over that of last year, and the average price obtained for it being 10 3/4d per lb. Mr. W. H. Bennett seconded the adoption of the report, which was carried after a brief discussion.—*Financial Times*, June 10.

TAR AND TAR PRODUCTS INDUSTRY.

Although the substances known in trade under the name of tar are, as far as their external appearance goes, much alike, their composition as well as their application, is very diverse. Lignite tar and turf tar are obtained by the dry distillation of light bituminous lignite, particularly near Weissenfels and Zeitz, in the province of Saxony. One hundred and forty kilos of lignite yield 20 kilos of tar. From the dry and fractional distillation of this tar, light oils are extracted, which are employed as illuminants under the names of photogen and solar oil. A substance separating itself when cold from the afterwards over distilled heavy oils, which is of a white, wax-like appearance, is known as paraffine. The brown oil left behind is used as paraffine oil and Vulcan oil for greasing wagons. Carbohc acid is extracted as an accessory product, whilst the residuum remaining in the retorts is made into asphalt.

Wood tar is divided into three sorts, known in trade as pine wood tar, beech wood tar and birch wood tar; they are mainly obtained as accessory products in the extraction of charcoal. From the dry distillation of knotted pine tree roots, pine tree tar is obtained: this tar is used as a rot preventer, for daubing on wood work, for cables and ropes and for caulking. When this tar is again distilled a liquid combustible oil—wood oil—is obtained, and the residuum is cobbler's pitch or ship pitch. The tar extracted from birch wood is largely produced in Russia, and is used in the preparation of Russia leather. From beech wood tar, a peculiar, volatile substance, used in medicine and otherwise, and known as creosote, is produced. It is also present in the smoke of imperfectly burning wood, and it forms the most important agent for smoking meat and other edibles.

The most important tar is that obtained incidentally in the manufacture of gas, and which is known as coal tar. Owing to the many uses to which this tar can be applied, it has almost grown to be the main product, and gas the accessory product. The first important application of coal tar in Germany was for roofing felt, for which purpose the tar has to be liberated from its volatile ingredients. Instead of extracting the latter, the tar was heated in open vessels, and it was only in 1846 that Bronner, of Frankfort on-Main, extracted by distillation a light oil, which still continues to be used under the name of Bronner's scouring drops; it principally consists of benzine.

More or less specifically heavy oils are won in distilling the tar and catching the volatile products. The first distillates are known by the name of light oils, and the heavier and less volatile as heavy oils. The residuum is employed as artificial asphalt for roofing felt, asphalt pavement and in the varnish trade. The most volatile part of the distillate, benzol, benzine or naphtha, serves as scouring water, for lighting, and especially for the production of nitrobenzol, artificial bitter almond oil and aniline. From the heavier distilling oils anthracene and artificial alizarine (which is found in a perfect condition in madder roots) are prepared. The now well known saccharine is also produced from the heavy tar oils. After a complicated chemical treatment aniline dyes were first won from tar oils in 1856. A further tar product is naphthaline used against moths.—*Kuhlow's Review.*

THE USES OF BAMBOO IN JAPAN.

The second meeting of the first Session of the Japan Society was held on the 12th inst., at the Society of Arts, John-street, Adelphi, when a paper was read by Mr. Charles Holme, F.L.S., a member of the Council of the Society, entitled "The Uses of Bamboo in Japan." Mr. F. T. Piggott, vice-chairman of the Society, presided, and there was a crowded attendance. A special feature of the evening was the exhibition of Mr. Holme's varied and comprehensive collection of Japanese articles made of bamboo, to which addi-

tions were made for the evening by Dr. Anderson and Mr. Earkin. This interesting collection which has been exhibited at Warrington, is to be transferred to the museum at Kew. The Chairman, in introducing the lecturer, said that the only surprising thing was that Mr. Holme was the only person who had really touched the subject in the way of collecting utensils made of bamboo, because one's first and last notions of Japan were connected with it. He supposed that in the whole vegetable kingdom no plant was put to so many and varied uses. He should have thought it was easier to say in Japan what was not made of bamboo than to attempt to catalogue the articles which were made of this remarkable plant.

The Lecturer, who was received with applause, said that among the products of nature utilised by man there was perhaps no one that had been so extensively and variously employed as the bamboo. Travellers who had visited those parts of the world where the grass grew had made frequent reference to the multitudinous services it performed as food, medicine, in construction of houses and bridges, weapons of offence and defence. In household and personal requirements, it played a more or less notable part. To enumerate in detail all its many uses in various parts of the world, from Burmah to Madagascar, from China to Brazil, would be well nigh an endless task. Some idea of its great economic value might be gathered from an examination of the purposes to which it has been applied by the Japanese to supply their everyday wants. In prosecuting their inquiries they soon found that in comparison with the Chinese and some of the races of India, the Japanese had almost neglected its use in such important objects as houses, bridges and boats. There was nothing in Japan like the native houses in India and Burmah made from ground to roof entirely of bamboo, or like the elaborate bridges made of stout bamboo which exist in certain portions of China or like the fishing boats at Formosa, where hull, mats, and cordage are all of bamboo. It was not far to seek this comparative neglect on the part of the Japanese. Constructions made of bamboo in India were very cheap. Good roomy houses, for instance, could be built for twelve shillings, but unfortunately they were not very serviceable. Two or three years was the measure of their endurance, and to last even this time they required a good deal of mending and patching up. Bamboo, with all its excellencies, was not suited to structural work in outside exposed situations. Fortunately for Japan, it was not only favoured with bamboo but an abundance of excellent timber, the latter being so much better adapted to all important structural work. Therefore it was naturally preferred for such purposes. Nevertheless, the Japanese house builder used bamboo as an adjunct. In China paper was made of bamboo. In Japan bamboo was not used for paper making, a superior kind of paper being produced from another grass. The Japanese used sheets of bamboo in place of writing paper. In India a white mineral matter drawn from the bamboo was used for medicinal purposes. In Japan, however, it was not so used. It was necessary, he thought, to point out a few of the differences of the use of bamboo in Japan as compared with other neighbouring countries. They were thus able to see that the Japanese by no means slavishly copied their neighbours in the uses to which they put this material, but that they followed their own ideas, and only made it applicable to such uses as were suited to their own purposes and conditions of life. There were many varieties of bamboo indigenous to Japan.

One species only a few inches in height covered the uncultivated portions of the country very much to the detriment of pasturage. Some varieties grew to the height of 30 or 40 feet, with stems six or seven inches in diameter, and there were many species of intermediate growth. The peculiar properties which rendered bamboo especially valuable to man's use were its great strength, flexibility, and lightness, the hollowness and boxlike cavity of its stem, and the ease with which it could be split into long even flexible lengths. It had, moreover, its excellence as an article of food. Collectors of Japanese objects of art know how frequently the labourer was portrayed either digging up the bamboo shoot or carrying it on his back for his wife to cook and prepare for himself and family. Opinions varied greatly on gastronomic subjects, and many dishes favoured by the Japanese required, to say the least, much education on the part of the European palate to appreciate. (Laughter.) But the bamboo shoot, when well boiled, was by no means to be despised by a hungry man, whatever his nationality might be. The uses of bamboo might conveniently be put under three general heads: implements employed in agriculture and the trades; secondly, household utensils; and thirdly, objects for general use. Mr. Holmes then went on to describe in some detail the various implements made of bamboo which were used in the preparation of rice, tea, silk, &c., in weaving and dyeing, in baskets for traders and for fishing. Many of the articles which the lecturer explained were exhibited to the audience. Bamboo was used in a variety of ways—in the kitchens in the service of tea, in the arrangement of flowers, and in general household requirements. Mr. Holmes thought it surprising that with the many ideas which Europe had taken from the East it had not adopted bamboo for tobacco smoking. The tiny Japanese pipes were generally applied with a bamboo stem; the bowls and mouthpieces were usually of metal. Women's pipes—for, said Mr. Holmes, ladies smoke in Japan, and he created a little diversion by adding, "The same as they do here"—have a longer stem, and the cases in which they are kept are artistically made of bamboo. He then went on to speak of the use of bamboo for musical instruments and for toys. Coming to the personal uses of bamboo, he instanced fans, umbrellas and hats as, perhaps, the most important. The Japanese umbrella was the most classical form of a very necessary object. We all knew the appearance in London or Paris of a multitude of black or sombre umbrellas in the streets. It was not in any way gratifying to the aesthetic sense, but in Kioto, where the imported gingham had not yet been introduced, the use of the native umbrella seemed to lighten the highways in pouring rain as with a ray of sunshine. The lecturer then proceeded to give some miscellaneous uses of bamboo in Japan. Amongst other things he described the *nomi tori* which the lecturer caused some amusement by translating "flea catcher." This ubiquitous little insect, he added, was to be found in Japan as elsewhere. He exhibited the article to the audience, and it certainly looked as it appeared to the lecturer the first time he saw one more suited to catch rats and mice than fleas. The little bars of bamboo are half an inch apart, but the lecturer explained that the fleas were caught by smearing the bottom of the trap with bird-lime, and the only object of the bars was to keep the clothes of the susceptible native in whose sleeve it was secreted from touching the bird-lime. In conclusion the lecturer said the Japanese were truly lovers of the bamboo. Their artists never tired of depicting its graceful form, or poets of

praising it, while metallers, lacquer-workers, and potters fashioned their wares in imitation of it.

The Chairman having invited a discussion, Mr. Okoshi, Japanese Consul in London, after complimenting the lecturer upon the interest of his paper, said that one curious thing was that the bamboo could be grown in private gardens. Still more curious to the European, perhaps, was the fact that bamboo was used as a family name in Japan. He could mention about thirty different family names called simply Bamboo. In other cases some adjective from the shape of the bamboo was prefixed, as Mr. Inside Bamboo, Mr. Middle Bamboo, or Mrs. Bamboo Under. (Laughter.) The bamboo was so extensively used in Japan that some of them were even born Mr. Bamboo.

The Rev. S. Coode Hore said that the symbol of the bamboo, according to the Japanese, expressed in English—Just Judgment, Noble Heart, and Devoted Sentiments.

Mr. Jackson, as Curator of the Royal Gardens at Kew, who hoped to have charge in future of this marvellous collection of bamboo products, said he was glad of the opportunity of congratulating Mr. Holme upon his success in collecting such a comprehensive series of bamboo articles. The exhibition of these objects would popularise and make more general the knowledge of this wonderful series of plants of which the bamboo formed apart. He thought the public were to be congratulated upon the acquisition of such a rare collection.

Mr. F. Satow asked the lecturer whether bamboo was used in the schools of Japan in a similar way that a kindred product was used in this country, and whether it had the same stinging qualities. (Laughter.)

Mr. Holme said that he would reply to the question at once. The Japanese were very gentle with their children, and the bamboo was not used in that particular manner. In China, however, the case was different. He believed there the bamboo was used to inflict very great cruelties.

The Rev. S. Coode Hore said that in one of the classical books of China he thought the Shi King there was a reference to the ancient classical birch.

Mr. Larkin said that in the year 1877 he had rather an unpleasant experience of one of the uses of the bamboo, which had not been mentioned by the lecturer. The Japanese Government had remitted the taxes of the laud into a tax of coin—that was to say, the taxes gathered in rice were substituted for a tax in coin. The peasants were unable to furnish the coin to the extent required, and they were very perplexed and rose in rebellion. It happened to be in the neighbourhood at the time, and he noted that their arms consisted of bamboo spears, and most formidable weapons they were. The spear was pointed like a lance, and heated to a degree of hardness that it would go through the bodies of two men with a good thrust. As he ran in his flight to the sea, he saw the Japanese peasants thrusting the bamboo spears into the houses and killing many men.

Mr. A. Diosy, honorary secretary of the Society, said that one use of the bamboo had not been mentioned that evening. It was really of Chinese origin. In the province of Kiushiu, on the island sea, the custom prevailed in summer of having in each house one or several bamboo cylinders made of plaits of bamboo, which people took to bed with them for the sake of coolness. There were no beds in Japan; the people slept on mattresses covered with quilts, and in hot weather these were sometimes inconveniently hot. Two plans were adopted to obviate this—one was to have a cord attached to a quilt, which ran over a small hook in the ceiling, so that the sleeper could raise

the quilt from his body at pleasure; but the mode most frequently adopted was to have this bamboo cylinder under the bed-clothes to keep the quilt off the sleepers. It was about the size of a human being and each person took this to bed with him.

The Chairman, in closing the discussion, said that he thought some attention might be advantageously given in Europe to the use of bamboo for musical instruments, more particularly the organ.

Mr. F. Satow proposed a vote of thanks to the lecturer, which was seconded by Mr. F. T. Edwards, and carried unanimously.

Mr. Holme, in acknowledging the compliment said, with regard to the spear in Japan, it was made of a class of bamboo that was solid throughout. It was common enough in India, but it was very rare in Japan, and only occurred in a small district. That was why he had made no reference to the use of bamboo as a weapon.—*London and China Express.*

SAND-WASHING APPARATUS.

One of the most important, and, at the same time most difficult and expensive, operations in connexion with waterworks practice is that of cleansing the sand used for filtering purposes. The sand must be removed from the filter beds, some of which have an area of several acres, and thoroughly cleansed from its accumulation of impurities before it can be replaced for use, and this is a tedious operation involving a large amount of manual labour. There are various ways of carrying out this operation, but they are all open to the objections stated. Numerous schemes have been tried for improving and cheapening the ordinary process, but they have hitherto proved only partially successful. An important advance, however, has been made by Messrs. Hunter, Fraser, and Goodman, who, being practical engineers, have worked out a system in which the difficulties of sand-washing are entirely overcome. This system has been put in operation at the Kew-bridge Works of the Grand Junction Water Works Company, of which Mr. Frazer is the engineer. The method of washing sand hitherto adopted at those works has been to remove it from the filter bed and throw it into washing-boxes having perforated bottoms, where it was cleansed by an ascending current of water under pressure. This process was at once wasteful, slow, and costly. The new apparatus consists of a receiver which is placed at the level of the filter bed and into which the sand is tipped by the barrowful. From this receiver the sand, mixed with water, is carried up a tube to the first of a series of hoppers on the bank of the filter bed by means of an injector supplied with water under pressure, the injector opening into the ascensional tube. The hoppers are of cast iron and are placed about 7ft. apart. Each hopper is 2ft. 4in. square, and 2ft. 2in. high over all, and is provided with a jet pipe connected with a main carrying water under pressure and regulated by a valve. These hoppers vary in number, according to requirements, the general number being eight, but they need not all be used at the same time. When in operation the water is turned on and issues through each jet forcing water up the delivery pipes into the hopper, the valves being so regulated as to give an uniform overflow at each hopper. The dirty sand is delivered into the first hopper of the series, and, gravitating to the bottom, is carried forward in a mixed stream of water and sand into the next hopper. This process is repeated in each hopper until the last in the series is reached, which discharges the clean sand into a truck on the filter bed for relaying or at any other point where it is wished to deliver it. The dirt is thoroughly separated from the sand and passes away from the hopper with the overflow water. If screening is necessary, it is effected by discharging the sand and water from the first hopper upon an inclined screen of the required mesh, and which is fixed over the second hopper. With a moderate consumption of water two men can wash and screen three cubic yards of sand per hour, no

matter how dirty the sand is. There are two sets of this apparatus at the Kew works, where they have been in satisfactory use for the last six months. One set is at present in operation cleansing the whole of the sand of a filter bed nearly two acres in area, while another set is at work cleaning the surface sand of another filter bed three-quarters of an acre in extent. These operations were witnessed on Friday afternoon by a party of engineers and other gentlemen interested in waterworks practice, and after careful inspection it was the opinion of those present that the claims of efficiency and economy made for the system were fully established. Mr. Fraser stated that under the old system the thorough cleansing of the sand of the larger filter had cost about £2,000, whilst, by the new system, it was more quickly effected for about £1,000.—*London Times, June 6.*

ECHOES OF SCIENCE.

The Sargasso Sea or floating masses of gulf weed in mid-Atlantic which impeded the ships of Columbus four hundred years ago, has been the subject of careful study by Dr. Krümmel, a German mareographer, who takes a different view of its origin from that commonly accepted. He shows, to begin with, that the Sea is much more extensive than Humboldt supposed. The middle or thickest part is elliptical in form, the great axis lying along the tropic of Cancer and the foci at 45deg. and 70deg. west longitude. Around this are other more extensive but thinner accumulations of the weed, which vary with the prevailing winds.

The gulf weed (*Fucus natans*), which, with its little round "berries" is not unlike the mistletoe in form, but of a brownish-yellow colour, has been thought to have lost its property of rooting on rocks, and to have acquired the power of living afloat. It has even been suggested that the sea marks the site of a submerged continent, apparently the lost Atlantis. Dr. Krümmel holds that the weed has simply been drifted to its present position by the Gulf Stream and its affluents from the West Indian Islands and the Gulf of Mexico. It is now proved that the Gulf Stream is not a single narrow "river of the ocean," as Maury poetically described it; but consists of a number of currents, not only from the Mexican Gulf, but the Antilles. The weed, according to Dr. Krümmel, would take fifteen days to float as far north as the latitude of Cape Hatteras, and five-and-a-half months to reach the Azores. In the Sargasso Sea it becomes heavy and sinks; but the supply is kept up by the Gulf Stream. Dr. Krümmel is certainly right in giving the Sargasso Sea a much wider area than Humboldt did and than our maps usually portray. It has been encountered some two or three hundred miles north-east of Barbadoes; but whether the weed is solely carried from the West Indies and the Gulf is perhaps open to doubt.

The latest results of meteorological science concerning the general circulation of the atmosphere are thus summarised by Dr. J. M. Portner in a lecture to the Scientific Club of Berlin. In consequence of the unequal heating of the globe at the poles and the equator winds or air currents are set up. These are easterly in the zone between 35deg. north and 35deg. south latitude; and westerly outside of it. In the northern hemisphere the easterly currents at the earth's surface become more northerly, and in the higher strata of the atmosphere more southerly, in approaching the latitude 35deg. At the equator there is a zone of calms near the surface with ascending currents, and a strong east wind higher up. Again, at latitudes 35deg. north and south there are surface calms, but with descending currents and a wind towards the poles high up. North and south of these belts westerly winds prevail at the surface, and north-westerly or south-westerly trades higher up; all becoming more westerly with increasing latitude.—*Globe.*

FRUIT AS FOOD.

Now, I will tell you what I claim for fruit as food; that is, for fruit as a complement of one's daily diet. 1—That it is exceeding y palatable. 2—That it causes, owing to this very palatableness, an increased flow of saliva. 3—That it thus assists us in digesting other

food, both bread and meat. 4—That fruit is itself easily assimilated by the system. 5—That it keeps the system free and in good working condition. 6—That from its acids, salts and essential oils the blood is purified and disease germs destroyed. 7—That from its saccharine matter the body is nourished and the animal heat kept up.

It would seem like a paradox to say that fruit both warms and cools the body, but such is the case. In summer its acids temper and equalize the heat, in winter its sugars warm. Sugar and acid, in fact, are so equally balanced in this food, formed in the great laboratory of nature, that neither preponderates unduly or to the detriment of the other.

We may take the testimony of birds as to the healthfulness of fruit.* And who so bright, cheerful and happy as they? The blackbird knows well what to treat himself to in sweet summer time, and flutes all day in the groves and the greater part of the night as well; yet in winter, cowering for shelter under the dwarf pine trees, he does not let down his heart. On the contrary, he is content if he can scrape up a few grub worms from among the withered leaves and obtain a hip or a haw to assist in digesting that worm.

The Arabs form a good example of a nation that to a large extent lives on fruit. We are apt to claim courage as characteristic only of the British soldier. This is simply our insular ignorance and arrogance. Who can be more brave than the Arab, or who possess more *elan* or dash?—*Rural Californian*.

FUNGI.

This delicious fungus will often come without being asked, as on old rubbish heap, and amongst cucumbers and melons; but when formally invited, it is capricious, and, at times, somewhat unpolite.

The Mushroom, *Agaricus campestris*, may be studied to advantage as it appears from time to time in the fields. For several years in succession we may search for them in vain, but at last there comes a hot, dry summer, and instantly, on the occurrence of showers the pastures will be covered with mushrooms. Heat promotes the "running," that is, the diffusion of the spawn, and a very moderate amount of moisture suffices to bring up the plant. The cultivation consists in imitating as nearly as possible the conditions that promote the growth of mushrooms in the meadow and by the roadside. The soil must contain a sufficiency of nitrates and phosphates, hence fresh short stable dung and good turfy loam are important aids. Darkness is regarded as essential, but the outdoor mushrooms proclaim that it is not. However, darkness promotes the kind of atmosphere that suits mushrooms, and hence the abundance and fine quality usually of mushrooms grown in dark houses.

Formation of Beds.—To prevent any misunderstanding, it may be well to intimate that all indoor beds whether in an old outhouse or in a first-class mushroom house, are made in precisely the same manner. Usually the beds are made exclusively with horse-droppings; but, apart from economical considerations, a mixture consisting of horse-droppings, short litter, and dry friable loam can be strongly recommended. By adding loam less manure is of necessity required, and the beds continue in bearing longer; and if there is any difference the mushrooms are of finer quality. Maiden loam rather rich in decayed fibrous matter is alone suitable for this purpose, and it should be employed in the proportion of about one-fourth of the entire bulk.

When the droppings are procured from a stable on the place, they should be collected from the manure-heap about twice a week and spread out under cover, to keep them rather dry and prevent their exhaus-

tion by fermentation, shake out all the short stuff and spread it out to dry; for when thrown into a heap in a moist state the fermentation quickly becomes so violent as to rapidly exhaust the manure. It must not, of course, be dust-dry or it will not ferment at all; but in practice it is found that a very small amount of moisture is sufficient to ensure a mild and steady fermentation. A week or so before it is intended to make up the bed throw the manure into a heap to set it fermenting, and by the end of the week it will be quite warm enough for use. Frequent turning at this stage are quite unnecessary, but it is well to turn it over once, and as far as possible to place the outside portion in the middle of the heap.

In the formation of the beds place an inch layer of loam over the bottom, and then proceed to fill in with the manure and loam; the latter must be perfectly dry and a little spread over each layer of manure as the work of filling proceeds, to ensure its being equally distributed throughout the entire depth. As each layer of three or four inches is placed on the bed let it be beaten thoroughly firm, for the spawn then runs more freely and excessive fermentation is prevented. Twelve inches is a good thickness for the bed, independent of a two-inch layer of loam, which should be applied after it has been spawned. The heat will, in all probability, increase rapidly during the first few days, and if it becomes excessively hot a few holes may be bored to allow the heat to escape; but it is much better to have the materials in proper condition, so that there may be no overheat, for with the escape of heat by means of holes referred to much of the ammonia, so essential in the production of mushrooms, will be lost. A careful watch must be kept upon the temperature, which ought not to exceed 80°. Immediately the heat commences to decline, and is about 75°, spawn the bed. Break the "bricks" up into pieces of about the size of a small hen's egg, and by means of a dibber insert them about twelve inches apart and regularly over the bed to a depth of three inches or so. Immediately after a bed has been spawned apply a half-inch covering of loam, or of perfectly dry cow-manure broken up to a powder and loam in equal proportions. In eight or ten days afterwards the spawn will commence to run, and an inch and a-half of either loam or a mixture as above advised should be spread over the surface. This should be rather dry and of the same temperature as the bed, if not a little warmer, as anything like a chill must be carefully guarded against.

Management of Beds.—In the after management of the beds the main points are to maintain them just moist enough for the development of the spawn and no more, and the house at a suitable temperature. Before a bed comes into bearing the temperature may range from 60° to 65°, but afterwards the mean should be 60°, as that temperature is the most conducive to the production of mushrooms of first-class quality; moreover, the beds remain in bearing much longer. As the house will contain beds in different stages—one only newly made up, a second just coming, a third in full bearing, and a fourth in all probability on the point of exhaustion—the temperature last mentioned will be found generally the most suitable. The beds will come into bearing in about five or six weeks from the time of spawning and if made up as advised they will continue in bearing about three months.

Outdoor Beds.—For these a sheltered and out-of-the-way place should be selected. They are formed with the manure in a fresher state than has been recommended for the indoor beds, and precisely the same as it comes from the stable. The sweetening so necessary when intended for hotbeds is not required but to well mix it together and ensure its fermenting steadily, throw it into a heap and turn it over twice. The outdoor beds should be made in the form of ridges, three feet in width across the base and brought to a point at the top, with sides as sharp as they can be conveniently formed. The manure must be beaten firm, and when the heat begins to decline and the temperature of the mass is about 80°, spawn the

* Not always: for instance the fruit of *Strychnos nux vomica* so common in the jungles of the North-Western and North-Central Provinces in Ceylon is eaten by birds; but if human beings followed the example they would find it a deadly poison.—Ed. T. A.

ridges by inserting lumps of spawn in the manure in a similar manner and at the same distance apart as advised for the indoor beds. Then cover with two inches of nice loamy soil, and beat it well, and to make it thoroughly firm sprinkle it with water and then smooth it with the back of the spade. A covering of straw or long stable manure, about nine inches in thickness, must be applied; and to keep this dry lay mats or thatched hurdles over it. Outdoor beds require more attention and labour than those under cover, but the produce obtainable from them will afford adequate remuneration for all the labour that may be expended upon them. The manure will at the end of the season be available for dressing the kitchen garden, but it will not be so rich in nitrogen as manure which has simply been brought from the stable and thrown into a heap, and its value as a fertilizer will consequently be less. The outdoor beds may be made up during the same period as mentioned when speaking of the beds in sheds; and the last one may be assisted as the cold weather comes on by a good covering of warm fermenting materials.

In gathering the Crop it is important to cut them as low down as possible, for when a considerable portion of the stem is left it affords a harbour for maggots. At the same time care must be taken to avoid disturbing the small mushrooms with which those ready for the table are frequently surrounded. If not gathered in the form of buttons they should be gathered immediately they have attained a fair size and before the gills assume a dark colour.—*Amateur's Kitchen Garden.*

THE SOUTH MYSORE PLANTERS.

A not very amicable state of affairs seems to exist between the South Mysore planters and their coolies, judging from the Annual Report, a copy of which has just reached us. There has been an apparently organised campaign against the planters in regard to their agreements, and the orders of Magistrates have been regularly quashed by the High Court without allowing the planter-complainants any chance of satisfying the Court of the justice of their cases. A very bad sign, too, is the fact that offences in Mysore against Europeans have become very numerous. The coolies, who can behave very well so long as they have a master-hand guiding them, but who, on getting the least chance can do much to harass and annoy, no doubt take the treatment their sahibs are now getting in Court as license for their continuing to annoy their employers. The Mysore Planters' Association admits that, from the nature of the people of the country, a hard-and-fast agreement with the labourer is almost impossible; but the planter does not demand regular or constant work, or that the coolie should clear his money straight off without taking any portion of his pay for food and clothing. Yet, with all this, and because he deals leniently with the coolie, we find the planter is now-a-days held to have forfeited all right to assistance from the State should the coolie afterwards neglect to perform his portion of the contract. All this stands in marked contrast to the peace and harmony that exists between the tea planters of Assam and their coolies, which we referred to at the beginning of the present month in commenting on coolie emigration to Assam. There the coolies, who are not overworked, receive good wages, and are contented. Again, the terms of the new agreement between planters and coolies proposed by Government, which we also commented upon, put both parties on a very fair footing to each other; and there was the remedy if either party broke any of the terms of the contract. What the terms of the present form of agreement that exists between Mysore planters and their labourers is, we do not know. If the terms were similar to that method of agreement we referred to the other day, we do not see how the planters could be put to so much trouble as they are at present by the High Court resuming its campaign against them, and by incivility, assault, and insult.

Though the President and Honorary Secretary of the Association remark at the outset, that it is with pleasure they submit their Report, there is much that is unsatisfactory in it, and in which they deserve sympathy. The Mysore planters have gone on for long, hoping for many reforms, but they know how much they have got. And this of Mysore is your model state. The planters have to fight for themselves; and, knowing this, it is with some surprise we read, in reference to the proposal for the Combination of Associations, the words:—"On return of the papers referred to in the last Report, the Honorary Secretary addressed all the Planters' Associations, inviting them to meet in Bangalore in March next. Only three replied; two promising; and one declining to attend. We have therefore been compelled to abandon all hopes of bringing about the union to which so many planters looked forward." The Mysore planter have many grievances, as this Report shows; they are in a state, where, from the High Court, they get scant justice. At least so we would infer from the Report. Therefore there is every reason why combination is necessary. We need only remind them of the old fable of Æsop, in which he tells of a certain King who, lying on his death-bed, called all his sons to him. Into the hands of each in turn he placed a bundle of sticks tightly bound together, and bade the young men break them. Of course they could not, but when the sticks were unbound and placed in their hands separately they snapped them without exertion. "So my sons," said the dying King, "as long as you remain banded together your enemies will never overcome you; but become separated through quarrelling, and you will be broken as easily as those sticks." The Mysore planters should hearken to the moral of this fable,—that "unity is strength," and a combination of associations would be all the more serviceable to them now, remembering where they are, and how they are circumstanced.—*Indian Daily News.*

FIRE INSURANCE ON ESTATE BUILDINGS.

The Secretary of the Planters' Association sends us the following letter received from the Secretary Ceylon Association in London enclosing copy of further correspondence on the subject of a reduced rate of premium on the Buildings on Tea Estates:—*Copy.*

4, Mincing Lane, London, E.C., 17th June 1892.

A. Philip, Esq., Secretary Ceylon Planters' Association, Kandy.

Dear Sir,—I have the pleasure to enclose copy of letter from the Alliance Assurance Co., advising a considerable reduction of rates for Fire risk on Estates. Mr. Rogivue has come over from Moscow hoping to make arrangements for securing financial support for his business in Russia; he speaks in a very sanguine way of the progress made with Ceylon Tea in Russia and considers the business an assured success, but capital is required to work the increasing business. Mr. Rogivue will return to Russia in time for the Nijni fair.—I remain, dear sir, yours faithfully, (Signed) WM. MARTIN LEAKE, Secretary.

Copy.

Alliance Assurance Company, Bartholomew Lane, London, E. C., June 16th, 1892.

William Martin Leake, Esq., The Ceylon Association in London, 4, Mincing Lane, E. C.

Dear Sir,—Referring to our letter of the 23rd March we have now the pleasure to inform you that, as the result of the visit of our chief Secretary to Ceylon, where he was able to inspect several Tea Factories, we have considerably reduced our rates for these risks.

We enclose a copy of the revised rates which will, we have no doubt, be satisfactory to your Association.—I am, dear sir, yours faithfully,

(Sgd.) P. MYERS, Assistant Secty.

CEYLON TEA ESTATES.

In which withering alone is carried on.	per cent	1	1 1/2
In which no withering or firing is carried on and without engine or stove.	per cent	1	1 1/2

A. Buildings constructed throughout of iron, stone or brick with iron or tiled roofs, wooden flooring, rafter and supports allowed
E. Buildings constructed of brick, stone or iron pillars with weather boarding and for wattle and daub, and iron or tile roofs
C. Buildings constructed of brick stone, or iron pillars with weather boarding and for wattle and daub and shingle roofs. Also wooden and wattle and daub buildings with iron or tile roofs
D. Wooden or wattle and daub buildings with shingle roofs

At the Amsterdam auctions last week the richest parcel offered consisted of six bales crushed Ledger (about half a ton in all) representing 13.03 per cent of sulphate of quinine. These sold at 82 cents per half-kilo or 152 2/3d per lb. Of the 3,724 packages offered, over one-half (2,098), representing 6,852 kilos quinine were bought in holders refusing to accept a unit of less than 6 1/2 cents, whereas 6 cents was the highest price obtainable. Of pharmaceutical barks there was a very good selection, but the demand for this variety was very slack, and only a few lots found buyers.

THE TEA SEASON AT HANKOW.

HANKOW, June 3.—The steamer "Moyune" left this port for London on May 28th taking 4,000 tons of the first season's tea at £4 a ton (if home in 35 days). She shut out quite 1,000 tons of tea. At daylight on May 30th the Russian Volunteer steamers "Saratov" and "Petersburg" followed with about 8,000 tons more for Odessa. It will be some days before the "Benlawers" is finished loading as she is putting it in very slowly, in fact only off and on. Taking it on the whole, the first crop this year has certainly not been a bad one, and if the second crop is better still we shall do fairly well considering the bad times. The Russian steamship "Orel" is here loading and the "Nijui Novgorod" also for Odessa and we expect yet two more Russians to visit us this year; there is also a rumour that one Mutual boat and the "Pembrokeshire" are already on their way to this port. The Harbour Master has his hands full just at present in finding berths for all, there being no less than five men-of-war in port, besides quite a number of other large vessels, not counting a fleet of Shangbai and Ichang river steamers. The usual extra officers required for the assistance of the outdoor staff in the tea season are here and at work.—*Mercury*.

TEA IN AUSTRALIA.

The Melbourne Argus of June 14th says:—Business in tea includes 100 quarter-chests S. O. pekoe at 10s, and 200 packages Ceylon at 6s to 9d. The prices obtainable for Ceylons are gradually hardening. The Argus of June 15th says:—Business in tea reported today is confined to Ceylons, which are active. Sales comprise 390 packages common Ceylon at 6s to 7d, 200 packages at 6s to 10s 1/2d, a small line of fine Ceylon and a line of five Ceylon orange pekoe at 1s. In its issue of June 16th, the Argus says:—There has been a better inquiry for China teas, and sales are reported of 900 half-chests (principally heavy-weights) at up 10s 1/2d, including a small line for export; 250 half-chests old season's congou at 7s 1/2d, 50 chests Ceylon at 10s, 30 chests Ceylon orange pekoe at 1s 0s 1/2d, and 15 chests fine Ceylon orange pekoe at 1s 2d.

The same paper in its issue of June 17th says:—

Tea has been more active. Business reported includes 700 half-chests low medium panyong at 7s 1/2d partly for export; 350 half-chests at 8s, 300 packages Ceylon at 6s 1/2d to 8d and 30 packages at 1s 0s 1/2d. The Argus of 18th June says:—

Tea has been quiet, the only sales reported being 100 half-chests panyong at 9d and 50 packages Ceylon at 7d.

From the S. A. Register (Adelaide) of 21st June we quote the following:—

All grades of India and Ceylon tea are firm at an advance of 1d to 2d per lb. on prices ruling a week or two ago. The stocks held in this market have, however, been too small to afford any scope for speculation or large dealing, even had our merchants been inclined to deal extensively, hence sales have been confined to fifty chests of this line and 100 of that, parcels which in the years past were only regarded as retail orders, but in the altered state of things are looked upon as wholesale parcels. No single sale of more than 250 packages has been

BARK AND DRUG REPORT

(From the Chemist and Druggist.)

London, June 16.

CINCIONA.—At Tuesday's auctions an average quantity of bark was offered. It consisted of

	774 of which	Packages	Packages
Ceylon cinchona.....	431	do	431
East Indian cinchona..	315	do	155
South American cinchona	42	do	42
Java cinchona.....	441	do	355
West African cinchona			

Total ... 2,033 do 1,757 do
There was nothing very remarkable about the assortment of bark, which was by no means a good one, 6 1/2d per lb being the highest price paid, while the average value of the bark sold did not exceed 2 1/2d per lb. It is, however, worthy of note that West African bark which until two or three years ago was unknown, constituted 17 per cent of the total supply on Tuesday. Throughout the sales the tone was moderately steady, and prices showed no change, 11-16ths d. to 1 1/2d per lb. being the average unit.

The following are the approximate quantities purchased by the principal buyers:—

	Lb.
Agents for the Mannheim and Amsterdam works	75,533
Agents for the American and Italian works	68,924
Agents for the Auerbach works	65,889
Agents for the Brunswick works	59,599
Agents for the Frankfurt o/M and Stuttgart works	41,924
Agents for French works	7,125
Messrs. Howard & Sons	4,520
Sundry druggists	30,262
Total quantity of bark sold	357,784
Bought in or withdrawn	37,577
Total quantity of bark offered	391,361

brought to maturity during the late little spurt, and only a few thousand packages in all have changed hands. It must be remembered, however, that blended teas have almost entirely superseded the consumption of teas from original packages. Nevertheless prices are firmer and sales early in the month brisker than for some time. During the four weeks some 2,500 packages in all of India, China, and Ceylon growths have been placed, from low to good. Prices are not given in any case, but from all quarters the record denotes firmness. The Fochow market opened on 9th inst., prices ruling lower than last year, and business done for Australasia has been extensive. New musters are expected towards the end of next month.

NOTES ON PRODUCE AND FINANCE.

A DELUSIVE HOPE.—There has been so little for some years to cheer the drooping spirits of importers of Chinese grown tea that it is not to be wondered that they make the most of anything of a hopeful nature they can find. The reference by our Consul at Hankow to the fact that last year showed the first increase in the export of black tea for that port for some years has been eagerly seized upon in some quarters as indicating a reaction in favour of Chinese tea. Unfortunately for the hopes thus raised there is no real indication of anything of the kind. India and Ceylon hold the market at home, and if the planters are wise and enterprising—and they seem to be both—the new markets will also be steadily assailed and held also.

ANOTHER CEYLON TEA COMPANY.—The Caledonian (Ceylon) Tea Plantations, Limited, has just been registered, with a capital of £30,000, in £1 shares. The prospectus was issued on Monday, when 25,000 shares were offered for subscription, of which 10,000 will be allotted to the vendor as fully-paid on account of purchase-money, thus leaving 15,000 shares to be subscribed for by the public.

THE CHICORY QUESTION.—It will be some consolation to coffee planters to learn that the path of the vendor of chicory is not always pleasant, and that occasionally, at least, he is fined. An appeal case which has occasioned some interest in the trade has just been heard before Sir P. H. Edlin, J.C. The appellant in this case, a grocer in an extensive way of business, was a mild offender by comparison with many who are not fined, but he was not so fortunate. The facts were as follow:—A young man was sent by an Inspector under the Sale of Food Act to one of the appellant's shops. He asked for a quarter of a pound of coffee. The assistant thereupon enquired, "Do you mean shilling?" The buyer said "Yes," and was given a $\frac{1}{4}$ lb. packet, for which he was charged 3d, and which bore a label with the words, "This is sold as a mixture of chicory and coffee." He admitted that he saw the label before he paid the money. The mixture, when analysed, was certified to contain 40 per cent. of coffee and 60 per cent. of chicory. In the course of the evidence of the appellant it was explained, however, that the mixture of which the incriminated sample formed part was one of half coffee and half chicory, but that it was impossible to mix the substances so completely and evenly that some packets would not contain more than 50 per cent. of coffee, and some more than 50 per cent. of chicory. The judge affirmed the conviction for all that, so that the vendors of chicory mixtures will have take heed to their ways.—*H. and C. Mail*, June 24th.

UVA GRASS.—The following inquiry comes from a Californian correspondent:—"Will you kindly inform me of the name and habitat of a gigantic grass of which I forward a few sprays? It is not grown here, but is imported and sold in a dry state under the name of Uva plumes. The plume itself is monstrous, being four or five feet long. The sprays droop entirely on one side, reminding one of the fleece of a Cashmere or Angora goat. The people who furnish the plumes

in Europe will not give the name of the grass." I received a similar inquiry from an English correspondent nearly four years ago, and found that the plumes were then offered for sale by London florists under the name of Uva Grass. How they were obtained is not quite clear, some stating that they came from the Congo, others from India. On comparing the plumes at the Kew herbarium it was found to be the male inflorescence of *Gynerium saccharoides*, a gigantic reed which grows on the river-banks of Cumana in Venezuela, and in Brazil. It is one of the most beautiful of all tropical grasses, the stems being twelve feet long, an inch in diameter, with leaves five feet long and one inch in width, the edges serrate and channelled along the midrib. In habit the plant is not unlike *Arundo Donax*. The panicle is terminal, at least four feet long, copiously branched and plume-like, the branches a foot and a half long and clothed with small flowers, which when dried are gray-brown in color. The plumes sold in the English shops are six feet long, including the stalk; they are extremely elegant and feathery, but are sometimes disfigured by dyes of various colours. There is a large plant of this grass in cultivation at Kew. It is grown in the tank which in summer contains the Victoria regia, and is as striking in appearance as some of the Bamboos. No flowers have as yet been produced by this plant. It is probable that the plumes sold in London, and also, apparently, those now sold in America, are imported from Brazil. Some of the plumes were among the exhibits from the island of Dominica at the Colonial and Indian Exhibition held in London in 1885. It is by no means unlikely that this *Gynerium* could be grown in the southern states, particularly Florida. I have never seen or heard of any other plant in cultivation in Europe except that at Kew, which was imported direct from Venezuela about fifteen years ago.—*Garden and Forest*.

[The above is interesting; but we could wish that the origin of the name "Uva," so familiar to us in Ceylon, had been explained.—*Ed. T. A.*]

A SUBSTITUTE FOR COTTON.—The *Fiyu* reports that Mr. Koyama Bukel, of Kumamoto Prefecture, has invented a substitute for cotton. He obtains it from the bark of the mulberry tree. The bark is first sun-dried and afterwards boiled with an acid, being then bleached by washing, and left to dry. Subsequently it is separated by machinery, treated with medicated water, and finally freed of its outer skin, when only soft fibres remain from which cotton is obtained by a specially designed machine. It is claimed for the cotton that it possesses many properties superior to the ordinary staple.—*Japan Weekly Mail*.

FUNGI.—We are asked:—"Do you know of any good cheap illustrated in color work principally dealing with these from their use and value as a food supply? Surely we have all the conditions here for growing these excellent vegetables of the very best in large quantities, but next to none are grown.—*P. W. K.*"

The best works on Fungi we have seen are by a well-known naturalist, Mr. Cook. But we should think that any good work on gardening would contain instructions on the cultivation of the edible mushrooms. When cattle were allowed to graze on the Galle Face Esplanade in Colombo, these valuable fungi used to be gathered in quantities by Malays, who, we believe converted them into cat-sup. If our recollection serves us right, so long ago as 1847, Mr. David Baird Lindsay of Rajawela estate, Valley of Dumbara, contributed to the proceedings of an Agricultural Society which then existed at Kandy a detailed account of his successful production of edible fungi. The process was to sow fragments of the mushrooms sought to be grown over beds of heated cow and horse manure. The first authority available as we are writing is Hibberd's "Amateur's Kitchen Garden," whence we quote a few passages on page 132.

STEADY PROGRESS IN NYASSALAND COFFEE PLANTING, &c.

COMMISSIONER H. H. JOHNSTON'S PROPOSED NEW ROAD.

In pleasant contrast with the unsatisfactory state of things in British East Africa is the steady development of Nyassaland under Mr. Commissioner H. H. Johnston. The "disasters" within this sphere of which we have recently heard were very lamentable, but it is satisfactory to know that they have not seriously interfered with Mr. Johnston's work. It should be recollected that, although several attempts have been made to unite the interests of the African Lakes Company with those of the Chartered South African Company, this amalgamation has not yet been effected. Consequently the agent of the former company in Nyassaland still endeavours to maintain a sort of independence from the rule of her Britannic Majesty's Commissioner, and is apt to show this by not giving in his telegrams a too favourable account of the Commissioner's proceedings. The telegrams received from this quarter should, therefore, always be received with a certain amount of discount.

After the veritable disaster at Makangira's which involved the death of Captain Maguire, Mr. Johnston, having put other matter straight as far as he could, wisely decided that it would be inadvisable to take any further measures against that wily chieftain until the rainy season was over, and until another officer, to replace Captain Maguire, with an additional force of Sikhs, had arrived from India. He therefore returned to the British Residency at Zomba along with Captain Kane, who had come up to assist him from the gunboats on the Zambesi, and left Mr. King in charge of Fort Johnston, which is situated at the exit of the Shiré from the lake, just opposite Mponda's, with orders not to do anything more than to defend the fort if it were attacked. The fort, it may be remarked, has a deep ditch and a parapet all round it, and is perfectly impregnable to any native force when held by Europeans. Unfortunately, after Mr. Johnston's departure a body of about 300 Angonis—a native tribe, who act as our allies—persuaded Mr. King to go out with them to battle, and attack a hostile chief called Seraphi, at his village up in the hills, some three days' march from Fort Johnston. Mr. King, who was accompanied by Dr. Watson and Mr. Inge, quarter-master in the navy, led a small force of Sikhs and Zanzibaris, together with his native allies the Angonis. But none of the white men knew much of the native language or anything about fighting, at least as practised in the African bush, and, as might have been expected, they made a mess of it, and fell into an ambush. Mr. King was severely and Dr. Watson slightly wounded. The Angonis, of course, ran away, leaving the Sikhs and the Zanzibaris, headed by Dr. Watson, to cover the retreat. This they managed to effect with the loss of two of the Sikhs and the baggage. In the confusion a 7-pounder gun, which was taken with them, was also left behind, and is supposed to be in the possession of Seraphi. But Seraphi, being of a prudent disposition, now says that he is tired of fighting, and wishes to make peace. He has been told, of course, that, as evidence of his good disposition, he must first find and send back the 7-pounder gun. It is also said that Makangira has disappeared from his place on the east side of the lake, in consequence of having been attacked by a hostile tribe. At any rate, all the stories about the traffic along the lake being closed are absolutely without foundation, and the route is perfectly open. Captain Sclater, R. E., Mr. Johnston's principal assistant, was down at Chindi, at the mouth of the Zambesi, when the fighting took place, having been sent there to carry on some negotiations with the Portuguese authorities. He has now returned to the Shiré Highlands, and has been placed in command of Fort Johnston until the new captain of the Sikhs shall arrive from India. Captain Sclater has brought with him from the lower river a large boat which was conveyed by one hundred natives overland, across the portage between the Upper and Lower Shiré. This will run between Mpindi, the port of Zomba, and the lake, and be of great use in supplying Fort Johnston with provisions, which are very short in that district.

As regards matters in the Shiré Highlands generally, they seem to be fairly prosperous. Large quantities of land have been lately taken up for coffee-planting, which is likely to be a very profitable business. The brothers Buchanan, who are the pioneers of this cultivation, expect a good crop, and will send home from fifty to sixty tons this year. They also grow and manufacture sugar and tobacco for local consumption. Attempts are being made to introduce cotton and india-rubber, but coffee will undoubtedly be the great crop of the country. Ordinary labour is cheap, but it is difficult to obtain it regularly.

One of Mr. Johnston's first proceedings on his arrival in Nyassaland was to plan a new road from Chiromo, on the Lower Shiré, through the middle of the Shiré Highlands, direct to Zomba, the British Residency, and thence to Makandaui at the south-eastern end of Lake Nyassa. This, when accomplished, will open up the whole country, and must ultimately be the route of a railway to connect Nyassa with the navigable portion of the Shiré. The first portion of this road has already been made by Captain Sclater from Chiromo as far as Zua, on the Ruo, and a further portion of it has been surveyed. It will also have the great advantage of opening up the Milangi Hills, at the sources of the Ruo, one of the finest parts of the country. These hills are stated to rise to nearly 8,000 feet above the sea-level, and to contain many beautiful open spaces covered with grass, and varied by clumps of forest trees, some of which are of large size, being from four to six feet in diameter. A lot of land has been already taken up here, and it is proposed to build a Government station and sanatorium, for which an appropriate site has already been selected. There is abundance of excellent water, and the air is always fresh and invigorating.

The great obstruction to progress in Nyassaland, however, is the irregularity of the communication with Europe. Settlers will not go where they cannot get their letters. The mails, which are sent via Zanzibar, go so far straight enough, but there they stick until a chance opportunity presents itself of a steamer going to Quilimane or Ghindi. The Post Office, as Sir James Fergusson explained to the House of Commons a few nights ago, "cannot afford" the expense of a regular branch mail from Zanzibar to Ghindi. Considering that the new colony is governed and administered by the Chartered Company absolutely without expense to the British Government, this seems to be a little stingy on the part of the Treasury; but we know full well that it is not the only instance of their misplaced economy. On the other hand, the Government has sanctioned the construction of two gunboats for Nyassa, and the Germans are stated to be sending up a vessel to patrol their portion of the littoral of that lake; so that there can be no doubt that traffic will be on the increase, better postal communication must eventually follow.—*Pall Mall Gazette*.

AMATEUR'S WAY OF ROOTING CUTTINGS—A brief note on rooting cuttings in an ordinary tumbler with a wad of cotton batting in the bottom, appeared in an earlier number of *Popular Gardening*. This method proves to be an easy and convenient one for the amateur having only a few cuttings to strike at a time, and not always the necessary conveniences, propagating bench, sand, etc., at command. During April we received some choice tomato plants by mail, which were all broken up, so that only a few of the tips were in good shape. These inserted in cotton batting in a tumbler in same way as geranium and coleus cuttings, etc., are placed in the windows of the sitting-room, and soon emitted healthy, fibrous roots, although left entirely without attention, and no water was applied after the first thorough soaking given to the cotton batting. The plants were set into open ground directly after taken out of the tumbler, and are now as large and thrifty plants as any we can show that were grown from seedlings. It is wonderful how long cotton batting will remain moist after once being soaked full of water. Undoubtedly this method will be found useful by amateurs in many ways.—*Indian Agriculturist*.

Correspondence.

To the Editor.

QUESTION REGARDING AREKANUTS.

Fairieland, Kandy, June 24th.

DEAR SIR,—I notice in the *Observer* of 22nd "25 pks. and 99,906 cwt. R906,963." This would represent less than R10 per cwt. I have sold dried arecanuts to traders at R15 to R17 per cwt. Can you obtain further information with regard to the local market or export for this product; also, as to the best varieties' rate, as opinions differ very much? The "rata" or "hambam puwak" is the most sought after at present, yet I am informed that the smaller "native" kind is more appreciated by the trade.—Yours faithfully,
SHELTON AGAR.

[This is a matter regarding which our personal knowledge is limited. We have a few of the "rata" or exotic kinde growing on Eilandhu, but merely as ornamental trees. Can any correspondent give the information desiderated regarding the narcotic nuts?—ED. T. A.]

EFFECT OF EXCESSIVELY WET WEATHER AND OF PRUNING IN SUCH WEATHER ON TEA.

Central Province, June 27th.

DEAR SIR,—I have with great pleasure read Mr. John Ferguson's letters and also your remarks and notes on them. They are all very much to the point. One thing I do not think enough has been made of—the excessive wet season of 1891, particularly Nov. and Dec. of that year's abnormal rainfall and also of Jan. 1892. There is not the slightest doubt that the heavy wetting and chilling the soil got in 1891 have for the time deteriorated the tea bush and have more or less destroyed all flavour in the teas of those estates that were exposed to this excessive wet. Nov. and Dec. 1891 and Jan. 1892 following on an already wet season, have done the principal part of the damage. Our rainfall here to end of June 1891 was 131.00 in. The highest before, in 1888, was 108.36 in. so the rainfall for 1891 was 22.64 in. above the wettest year previously in 12 years, 44.25 in., and above the average for that time. Another reason for the sudden falling-off in flavour was in 1891 caused by a large number of estates pruning very low, principally because tea was in most places 7 or 8 years from first pruning and of course had to be cut down low to get what is called a new head which must be done every 7 years or so. To make matters worse this was done in an abnormal wet season, and many, I am afraid, pruned lower than there was any occasion for.

One of the first agricultural authorities of the present day says:—"Pruning is always more or less injurious to the life of a tree. In some cultivations it must be done. The more carefully and less often this is done the better. When a tree is cut down the roots die off in proportion to the amount of the cutting down of the tree. The great danger is fungoid growth at the roots." Surely if this is the case our trees must have suffered excessively from pruning in 1891. I cannot agree in the idea of our teas going off in flavour as they get older. I have been making tea here now for 10 years and have not noticed any falling-off in flavour till after May 1891 and on to the present time. Now our teas are gradually recovering flavour, which this dry season has helped on. Our rainfall to 26th inst. is only 45.29 in., and only 4 days more of June to run against a rain-

fall in 1891 of 131.00 in. to end of June. This dry season is quite a Godsend to us tea planters; we have had too much wet and the ground want drying to get rid of the sourness, &c., caused by the excessive heavy rainfall in 1891.

Another cause injurious to the tea bush in wet districts is pruning in the wet months, viz., from May to October. Tea takes longer to recover than, than when pruned in January to March (besides the injury to the roots if the agricultural authority quoted is correct). S.-W. monsoon pruning takes 8 to 9 weeks to recover and sometimes longer. January pruning 5 to 7 weeks and in 3 months your tea is in full flush again; besides the tea flush is riper and not so long recovering the effects of pruning; you will be making as good teas in 3 months from pruning as you will be after S.-W. monsoon pruning be 7 to 9 months and longer. Again, if you want flavour you must not cut your tree down too low. You may get a heavy flush from low pruning but a poor thin flavourless tea. To get flavour you want a big tree, particularly in the wet months in best districts, when the tree wants all its foliage to resist the injury of the damp at its roots. A knife should never go near a tree then, if healthy trees are wanted which will give good flavour teas. Sunshine, of course, is needed, but with all you can get of it you won't get good teas off heavily pruned bushes.—Yours very truly,
X.

TEA PRODUCERS AND TEA BUYERS.

Upcountry, June 28th.

DEAR SIR,—I have read the letter signed "Tropical Rustic" in the *Observer* of the 24th inst. He appears to write altogether from a planter's point of view, this would be very satisfactory if the home buyers would see it in the same light, but what care they how the tea is produced? All the buyer looks to is to get the best value he can for his money; and the planters are vying with each other to give him this, and so long as there is a higher standard to be attained this will continue. Small blame to the man who buys broken pekoe instead of pekoe souchong if he can get better value for his money. The planters have been and are educating the people to drink a higher class of tea; and this will continue so long as a higher class can be attained, and the prices not increased. It is, as "Tropical Rustic" says, a case of the "survival of the fittest"; when the buyer cannot get the class of tea he wants from one shop he will pass on to the next.

Ceylon is drawing too much from the soil, where the supply is limited, instead of drawing more from the atmosphere, where the supply is unlimited.

AN OLD COFFEE STUMP.

Dimbula, July 4th.

SIR,—Re the letter referring to the above in the *Observer*, might I ask "Old Coffee Stump" what reason he has for saying that "Ceylon is drawing too much from the soil, where the supply is limited, instead of drawing more from the atmosphere, where the supply is unlimited"? I suppose that "Coffee Stump," before publishing this conclusion in your paper (from which it will, no doubt, be copied into home papers and serve to gladden the hearts of such people as are interested in Ceylon), went scientifically into the question; and as this is one of the utmost importance to the planting community, it is to be hoped he will favour us with facts and figures in support of his statement.

PRACTICE VERSUS THEORY.

TEA IN THE PAST, THE PRESENT AND THE FUTURE.

Clipston, Northampton, June 7th.

SIR,—Occasionally it is instructive to look back in these days of hurry and attention to the day's doings only, seasoned with the inevitable forecast. In this instance I shall venture to trouble you with the ideas upon China, especially relating to tea, at the date November 14th, 1835; and my authority is the "Penny Magazine." Referring to tea the magazine expresses the opinion that of all its botanical productions "that, which is most completely associated in our ideas with China, is tea." It had been cultivated however at Rio Janeiro, and a Mr. Clarke Abel, an authority quoted several times throughout the length of the article, saw it flourishing in St. Helena. The Cape of Good Hope is mentioned as the most suitable geographical and geological situation for its growth. Allusion is made to the transporting of tea plants from China to St. Helena and Cape of Good Hope. Mr. Clarke Abel was of opinion, that, the difficulties of manufacture could be overcome, and he concluded on the important subject with this extraordinary sentence—the fulfilment of which we all know!—"that if ever it shall suit the policy of this country to derive the tea from our own dependencies, there can be no doubt that we shall cease to be indebted to China for an article that enters so essentially into the comforts of all classes of my countrymen."

Contrasting the times with those of "Queen Bess" when the maids of honour drank ale and ate rounds of beef at breakfast, he mentions that 30,000,000 lb were then annually consumed. He considers, that it is not proved that the use of tea is of comparatively recent origin, and refers to positive evidence as to its use in the eighth and ninth centuries. At that early period an Arabian merchant refers to a tax on tea—the infusion of a herb named "Sah," which is a very near Arabic rendering of the Chinese "Cha." It is not necessary to trace the course of increased consumption, as these figures being so very small compared to our present experiences they sink into insignificance and are as difficult to understand as our millions of today.

The praise of tea, and the method of making it, are celebrated in the language and poetry of China, and the method may be here reproduced:—"Place over a gentle fire a well-seasoned long used vessel filled with the pure water of melted snow. Boil it long enough to turn a lobster red, and then pour upon it the leaves of the choicest tea in a tea-pot of the finest porcelain. When the thick cloud rising from it becomes a thin mist floating on its surface, pour it into the cup and drink it off. This precious liquor will drive away every care. The delicious state of quietude produced by such a beverage must be felt, and cannot be described." The mixing of other plants' leaves are alluded to, and amongst them the "camellia sesanguis" (Ohawa or "flower of tea") the *olea fragrans*, an Arabian jessamine. The preparation of "brick tea" does not commend itself to our Ceylon ideas of cleanliness, the "serum of the blood of the sheep" being the glutinous liquid employed, and the Tartars scrape off some of the tea from this brick and boil it in a saucepan "with butter, flour and milk." O my prophetic soul, my Lipton! Much is said as to the qualities and properties of tea; and it is used to counteract the effects of "the half putrid quality of stagnant water," but very properly something is attributed to the fact of the boiling of the water necessary in the preparation or infusion.

There is something more curious—the use of tea will correct the gross humours engendered in the system by the use of "pork and fat meats"; at the same time the excessive use of tea—the abuse in fact—is deprecated and the corrective to eat abundantly of fat meat! The description of the plant is unnecessary, but a word or two on the preparation of the commercial product may not be unacceptable to your readers. Mr. Abel admitted that black and green tea were produced from either of his specimens, which were lost, and the difference both of colour and quality could be explained "by the different management of heat and in drying the tea." He says there can be little doubt that a leaf dried at a low heat will retain more of its original colour, and more of its peculiar qualities, than one that has suffered a high temperature."

The strongest tea that he tasted called "Yu-tien," and used only on occasions, scarcely coloured the water. These were "the scarcely-expanded buds of the plant," in other words, if I may be so bold, "golden tips"!

The "copper plate drying" business is indignantly set aside as being on chemical grounds quite absurd. Planting is described, and it is asserted that it is not considered advantageous to the plant to pluck from it under three years old and at the height of four feet, which is mentioned as the usual growth for that age.

Now for reasons which will be patent to every experienced planter. ("Conjum vepeny doraili"?) I shall allude to the March or first gathering. "Great precautions are taken in this gathering." What are they? For weeks, the people engaged study diet and habits of personal cleanliness eating only such foods as communicate agreeable odours to the skin and breath and wear gloves in order to prevent any damage to the flavour of the tea! Of course we know better now and are aware that the finest teas ever produced were picked by Tamil coolies! Nevertheless, there is a lesson to be learnt in this, April and June produce the coarser teas and the abundant harvest. The factory procedure is not worth alluding to, for present science has dealt and is dealing with this in a manner hitherto unknown. The preliminary packing in baskets is peculiar, however; and drying again just before the final packing for sale or exportation. "No tea is drunk in China until it has been prepared at least a twelvemonth" sounds very peculiar to nineteenth century notions.

The best tea is said to come from the province of "Kiang-nan": but the greatest quantity of black teas exported to Europe from "Fokien." The overland trade with Russia is alluded to, and the remark is made that a sea voyage does not injuriously affect tea. The quality of the tea obtained for Russia depended more upon "the greater fitness and excellence of the soil, &c., in the districts from which the Russians alone are permitted to draw their teas."

Here then are the thoughts about tea in 1835, and it seems almost incredible that the consumption should now approach six times the quantity then consumed, our population only having doubled! 200,000,000 is an amazing quantity, and with Ceylon contributing nearly half still more so! How literally the idea of the British dependencies furnishing us with our wants has come true. Long may the enterprise flourish in Ceylon! The *Englishman* (Calcutta) has a correspondent who refers to the lamentable want of energy which has distinguished the Indian tea industry in its competition with Ceylon, and says that every device known to the "new advertising" has been employed in popularising the Ceylon

product in the home market" and that the same is being done in Chicago "with a view of securing a practical monopoly of the American market." So much the better! Every effort should be made to raise the average to 1s per lb. The correspondent of the *Englishman* writes that a representative is to be sent to the World's Fair at Chicago "who shall convert the free citizens of the United States from their present faith in the Chinese product to an enlightened taste for 'Mazawattie' (sic)! Surely this is "a confusion of 'Epitaphs'"!

With many apologies for the length of this letter, I remain, yours faithfully,

ARTHUR C. ISHAM.

TEA CULTIVATION AND SCIENCE.

DEAR SIR,—It is quite too delightful to get a bit of true science into the discussions on tea cultivation. It is exactly the thing that is most wanted. But let it not be veiled in ambiguity and buried in verbiage. We are told that the right system is to tap the inexhaustible atmosphere, and not the soil, for flush. That is splendid and true science! Only let us know how to do it—how to compel the trees to turn their attention, more than they do in their own natural way of feeding—to the nectar of the air and less to the "sour" soil. How a plentiful rainfall "sours" the clean soil of our mountain slopes should also be explained scientifically. Then, again, why should trees be pruned *this* way instead of *that* way? WHY in January rather than in June? Why high instead of low, &c.? Also, who has proved that the roots "*die*" in proportion as the tree is pruned? Do they really die and grow again, or is their action the operation of their natural functions, only temporarily suspended or suspended at all? Or, are their functions not actually quickened (according to the *season*), the tree resting, in any case, when it is natural for it to rest, and active, in any case, when it "season" for active life comes round? If the trees has been pruned it naturally expends its power to clothe itself again with foliage (to our advantage) but if it has not been pruned it turns its attention to seed, or to its strength in stem and branch? Almost invisible in its results, at least, I suppose so only we want the Oracles to say.

I am asking questions, not teaching. Should not our chief study be the "seasons," and our cultivation be regulated according to them? Does a farmer at home sow when he should harvest, or expect to harvest in "seed-time"? Are there not well-marked seasons in Ceylon? Uva with its seasons and Kandy with its seasons? Each a separate study. Does, say on the Kandy side, elevation mean anything more than a little earlier or a little later activity than the true mean? Would any system of pruning compel tea to flush as plentifully in January, February and March as it does naturally in April, May and June—or in July, August and September as in October, November and December?

I was a long time in going over my pruning last year. Am I wrong in saying that, notwithstanding that, nearly all the fields are now alike, the earlier pruned lagging and the latter pruned hurrying on the growth?

One of your correspondent says, "the dry season has been a blessing in disguise"! I do not dispute it, but I should like to know "why," apart from sweetening the soil. It has put a fearful lot of flower, bud and seed on the trees, whereas we want so to control the trees' natural forces to produce leaf only. I have no doubt it can be done,

and that your correspondents are on the right track. Only I ask for more reasons, or, in other words, proof, so that we can feel safe in following their lead.

ANOTHER PROPRIETOR.

P. S.—Since writing the above I see in your yesterday's issue another correspondent urging the same question. His short note is headed "Tea Cultivation and Tea Buyers," but it is not very clear where the "Buyers" come in.

CEYLON AT THE CHICAGO SHOW: A GOOD INVESTMENT.

Madukelle, July 8th.

DEAR SIR,—It is now some time since Mr. Grinlinton wired that £20,000 would be needed to thoroughly represent Ceylon at the Chicago Fair, and as yet no one has made any suggestion as to how the extra sum is to be raised. Of ridicule there has been enough and to spare, the latest hailing from Nawalapitiya being a fair specimen of the kind. This talk of low prices for our teas preventing more money being subscribed is the sharpest-edged tool such writers could play with, as it cuts the very vitals out of their argument. The lower the price goes the more need to bestir ourselves. The tea market has now reached the lowest stage it has ever touched. It is not because our teas are bad; for I affirm that the teas made during the last six months in Ceylon have been equal to, if not better than ever before sent to London, better made from better leaf, and from improved machinery. Brokers also find little to condemn in the teas, and yet the prices are heart-breaking. If Ceylon planters could only for one week be transported to America and taken through the vast territories of "Uncle Sam" to see the great cities teeming with activity and population, all of them desirous to get good tea and only waiting to have it put before them in a suitable fashion, they would be the first to acknowledge that not a modest £20,000, but a sum twice as big would be well spent to gain over such a constituency. Yankees and Southerners are fond of show, tall talk and swagger, as long as there are dollars behind. Commissioner Grinlinton without dollars would be no one, "charm he ever so wisely," but backed with plenty of cash, and in the position to blow his trumpet with the loudest of them, Ceylon is bound to profit. Look at Commissioner Ferguson at Melbourne: how out of small beginnings what handsome results have accrued. Do not let the good ship be lost for a pennyworth of pain, but to raise the required sum let superintendents of tea estates come forward and like the Assam planters tax their salaries 10 per cent to make up the deficiency. Do not imagine the crowd who will frequent the Great World's Fair at Chicago will be like a common or garden every-day Cockney throng, the *hoi polloi* who jostle each other at an Earl's Court or a Chelsea Exhibition. The Americans are one and all well educated and as keen as hawks, and although narrow-minded in that they think there is no country like America or people like Uncle Sam's children, they will appreciate good Ceylon tea, as I have seen for myself in hundreds of cases, if it only be put within their reach.

Indian papers have been patting Ceylon planters on the back, more to urge on their own fellows to "go on better" than that we really deserve it. Let us now show that we really mean business and in some way or other raise the sum already subscribed to the £20,000 wanted.

In conclusion I leave better and older men than myself to decide how the money is to be raised. I can only propose that in the event of Government

or other aid being insufficient, that all superintendents of tea estates in receipt of R3,000 per annum or more, should voluntarily tax their salaries as the Assam planters are doing to keep the good cause at Chicago.

The Rev. Sydney Smith is credited with the shortest charity sermon ever preached. "Brethren," he said, "my text is 'He who giveth to the poor lendeth to the Lord;' if you like the security down with the cash." The enthusiasm and the big collection that followed was astounding. In our own case if the Ceylon tea planters trust their Commissioner, let him have a free hand and what money he wants.—Yours faithfully,

T. D., Jr.

P. S.—"Cast thy bread upon the waters and it shall return to thee after many days"—a strange saying but one most applicable to the present case.

THE WASTE OF MANUFACTURING PROCESSES.—Steady progress is being made in the utilization of the offensive waste material of various manufacturing processes, says the *Pall Mall Gazette* :—

The "ammonia water" of the gas works, once considered an entirely waste and obnoxious product, now yields the principal supply of sulphate of ammonia. The distillation of shale for the production of paraffin oil ranks next, and this is followed by the blast-furnace gases of ironworks. In some of the more extensive ironworks, Mr. Fletcher records in his report on the alkali works, as large a capital as £70,000 has been expended in the erection of apparatus for the collection and manipulation of the tar and ammonia derived from the gases. In some cases more of the capital invested in an iron-smelting work is devoted to the treatment and collection of the tar and ammonia than to the production of the iron itself, and more profit is yielded by the former than by the latter, so that the iron may almost be styled the by-product, and ammonia the main product. Mr. Fletcher does not fear that the more extensive collection of ammonia—last year's production was no less than 143,606 tons—will lower the price to an unprofitable extent, considering that its chief use is agricultural. In extracting the sulphur from the tank waste of the alkali works the Chance-Claus process is very successful. Already 80,000 tons have been extracted at a cost which leaves a profit to the manufacturer. The present rate of production is 900 tons a week, and it is fast increasing. The sulphur made is of the purest, and it finds a ready market at home and in the United States and elsewhere abroad. When the sulphur has been extracted, the tank waste is no longer the noxious material that it previously was, and pressure is being brought to bear upon the makers to induce them to desulphurize all their waste. Efforts are being made to utilize the residue in the manufacture of cement. The liquors resulting from the operations of tinsplate manufacture, and of works for galvanizing iron, containing either sulphate or chloride of iron in solution, have till recently been allowed to flow away, causing great pollution of the streams which received them. Now it has been found possible to recover much valuable acid and oxide of iron, and prevent a considerable source of river pollution. It has thus been demonstrated again and again that obnoxious "waste" can be turned into wholesome commodities, to the gain of the manufacturer.

THE ASSAM TEA PLANTERS have been fortunate in more respects than one in securing a new field for recruitment in Ganjam, the northernmost of the districts of the Madras Presidency, as in the labourers they have been getting from there have found the best material for withstanding the unhealthy climate of the Province. The report on emigration from Ganjam to Assam in 1891, is a brief document but by no means unsatisfactory. In that year 5,208 labourers were recruited against 1,247 in the previous year. Of course there were charges of kidnapping,

but none were substantiated, a result which must be considered satisfactory when compared with the number of similar complaints made in connection with emigration from the Bengal districts. "The emigrants," we are told, "proceed to Assam cheerfully, having learnt from returned emigrants the nature of the work and the prospect of profit. After the registration of the emigrants by the several Protectors of Labourers, they are conveyed by the contractors to Gopalpur, and there accommodated in suitable depôts. They are thence shipped by the first available British India Steam Navigation steamer to Calcutta, under the supervision of the Port Officer, Gopalpur, to whom an extract from the register of emigrants is sent by each Protector of Labourers immediately after the registration of each batch." To the Government the emigration from Ganjam must be profitable, for while the receipts amounted to R9,404, the expenditure during the year was only R373.—*Madras Times*, June 20.

THE PROFITS OF TREE PLANTING—A famous admiral used to scatter acorns from his pockets that England might never lack oaks for ship-building. That was the patriotic side of tree-planting; here is the pecuniary. A certain Tommy Walker, of whom we are told by a Yankee journal, when a child planted four walnut-trees by the roadside opposite his father's house, ten miles west of Knoxville. He lives to see four walnut-trees grow to a measure of four feet in diameter, worth, if properly cut and seasoned, at least 400 dols. each. Had he planted 500 walnuts on an adjoining acre of ground, his heirs, when he did, would have been 120,000 dols. better off. Today they would be 200,000 better off. Had he planted 10 acres they would be worth at least 2,000,000. Had he planted a hundred acres, and all the trees had reached an average size of three feet in diameter, and there is no reason why they shouldn't, as the land is fertile and impregnated with lime, his heirs—and there are only three living—would be worth altogether 200,000,000 dols. If like Johnny Appleseed, who planted thousands of apple trees in the North-West, he had planted all the worn-out fields in Tennessee with walnuts, it would be the richest State in the Union by far.—*P. M. Budget*, June 16th.

TEA IN YOKOHAMA.—The *Japan Weekly Mail* of March 26th says.—According to the *Nichi Nichi Shimbun* the quantity of tea sent to Yokohama from all parts of Japan during 1891 was 269,610 parcels of which 24,195,100 catties were sold, 22,986,780 catties being exported. The provinces from which the tea was sent were Enshu, 63,055 parcels; Seishu, 52,019 parcels; Shimoza, 30,145 parcels; Bushu, 15,870 parcels; Mito, 10,107 parcels; Joshu, 6,888; Echigo, 3,312; Chikngo, 2,988; Kuzusa, 1,855; Sanstu, 780; Iga, 673; Izu, 409; Goshu, 386; Yamashiro, 295; Toza, 268; Bizen, 252; Owari, 239; Setzu, 279; Hida, 176; Soshu, 71; Shishu, 43; Shimotsuke, 37; Yamato, 21; Chikuzen, 19; Echuzen, 10; Kozuke, 7; Kishu, 6, and Iwasbirr, 1. The same journal gives the following list of the quantities exported by the various firms in Yokohama:—

	Catties
No. 33, Messrs. Mourilyan, Heima & Co.	4,206,000
No. 178, Messrs. Smith, Baker & Co.	3,411,000
No. 211, Messrs. Hunt & Co.	3,300,000
No. 48, Messrs. Mathon & Co.	2,048,000
No. 143, Messrs. Fraser, Farley & Co.	2,045,800
No. 210, Messrs. Helge & Co.	1,593,000
No. 265, Messrs. C. A. Low & Co.	1,463,500
No. 221, Messrs. Cornes & Co.	1,401,500
No. 1, Messrs. Jardine, Matheson & Co.	1,273,500
No. 22, Messrs. Middleton & Co.	1,129,500
No. 225, Messrs. John Duncan & Co.	9,122,000
No. 198, Messrs. Otto Rönner & Co.	828,500
No. 2, Messrs. Walsh Hall & Co.	345,000
No. 175, Messrs. Faye Boardt.	27,700

THE MOZAMBIQUE TRADE.

The Annual Report of Mr. Vice-Consul Ross on Quilimane, already extracted from, has now reached us in full. Mr. Ross, it may be remembered, paid a visit to Ceylon some time ago, being a son-in-law of the late Mr. Tylor. He affords a great deal of information in a clear fashion on his part. We quote as follows:—

No detailed statistics have been published of the trade of Quilimane since 1887, but the following figures show values of the past two years:—

Year.	Exports.	Imports.	Exports from bond.	Duties.
	£	£	£	£
1890	84,633	116,763	58	22,044
1891	112,708	156,832	9,830	25,046
Increase	28,075	40,069	9,772	3,002

The exports consist—1st, of the following oil-producing seeds: groundnuts, sesame seed, and coprah; 2nd of heeswax, india-rubber, ivory, gold-dust, a small quantity of hides, and orchilla-weed; and when the crops have been good rice and grain of various sorts are sent to other parts of the province, and even to India as ballast of returning dhows. No timber is exported though there are in many parts of the country great tracts of timber-producing forest.

The ivory export this year has fallen-off very much practically none having been brought by caravans from the interior. This has either been bought by the African Lakes Company before reaching the coast, or has gone to places further north in the German territory, seeking a better market. Ivory is always sent by steamers. It is the custom to pack for shipment in bags only the smaller tusks; the larger ones go uncovered. About 30,000 lb. weight of ivory has been exported by Chindé free of duty. The amount of oil-seeds and rubber and ivory exported, and the destinations of the shipments, is shown in the annexed table:—

ANALYSIS OF DESTINATIONS OF PRODUCE EXPORTED IN 1891.

	Groundnuts.	Sesameseed.	India-rubber.	Wax.	Coprah.	Ivory.
Marseilles ...	2,875	122	660	5,000	1,045	...
Lisbon, to order	275	60
Rotterdam ...	1,431	29	6,000	14,800	20	..
London	1,800	1½
Bombay	10
Lisbon	56
Hamburg	580	..	38,000	35,000	115	..

The crop has been an average one. The rice and grain crops have been rather below the average and at the present time native food is somewhat scarce and dear. A good deal of rice will be imported from India to make up the deficiency in the local crops. Coffee has ceased to be an article of export. None is grown in the district, and that from the Shire Highlands is now exported from Chindé.

The native industries are very few, and the articles made only suffice for local demand.

Under European supervision bricks are made and sold at from 1/ to 2/ per 1,000. The quality and shape are very indifferent.

Boats of native wood are built by native workmen under European supervision.

The native industries pure and simple are confined to the making of mats, native earthenware pots, canoes and fishing nets. The principal woods are called luabe, pangira, moesa, kossa umbila, and pan-ferro (iron wood.) They are chiefly heavy hard woods, and are used in the construction of buildings, white wood giving way so soon before the ravages of white ants.

SHIPPING AND NAVIGATION.—There has been a regular monthly service maintained by Deutscher Ost-Afrika Linie via the Canal. The Mala Real (Portu-

tuguese) has maintained a monthly service more or less irregular. This company publishes no timetable. I append a note of the rate of freight by the German and British lines.

Description.	German.		British.	
	£	s. d.	£	s. d.
Coprah Per ton	3	15 0	2	16 0
Sesame seed ..	3	15 0	2	16 0
Groundnuts ..	3	0 0	2	6 10
Rubber	4	10 0	4	10 0
Orchilla weed Per 40 cubic feet	2	15 0	2	10 0
Wax	16 ewt., 40 cubic feet..	..	3 10 0
Ivory	0	0 1½	2	2 ½ cent

In addition to these lines, the Castle and Union lines have occasionally run steamers from Natal, and intend to do so in the future every three weeks. Messrs. Bullard, King and Company, of Durban, have run a steamer monthly between Port Natal and Mozambique, and announce their intention of sending one of their Indian steamers along the coast each month. Steamers of the British India and Clan lines have called here when sufficient inducement offered. Besides steamers, three sailing vessels have loaded at this port, two for Marseilles and one for Rotterdam. Some half-dozen dhows come here every year from Bombay, laden with sundry goods. They trade along the coast till about August, when with the end of the monsoon they returned to India. The British steamers have on several occasions called at Chindé, and landed cargo and passengers there. The crossing of the bar at that place has been accomplished without difficulty by steamers of 900 tons. During most of the year as steamers did not call regularly at Chindé dhows were employed in taking cargo to Chindé. The freight by steamer is 1/ per ton, and by dhow 13s. 6d. The dhows brought return cargoes of Zambesi produce. The duration of voyage from bar to bar is almost the same for a dhow as for a steamer, about 10 hours.

Sailing ships never visit this port except when chartered.

SAILING VESSELS.—The pilot never crosses the bar to bring a vessel in. His work consists in piloting the vessel between the inside of the bar and the town. The fee is 10/ out and in, payable whether the pilot comes on board or not, but one quarter of this is often remitted when his services are made use of only one way. The channel from the bar to the town has recently been well buoyed, and it is intended to erect leading lights to admit of vessels crossing the bar at night.

LANDING AND LOADING.—The landing and loading is performed by lighters of from 5 tons to 20 tons, propelled by oars. There are jetties at which cargo can be landed except at low water spring tide. The anchorage being in the river 12 miles from the bar, shipping operations are seldom interrupted by rough water. The current at spring tides runs very strongly up and down and hinders lighterage considerably. A lighter with crew cost about 2/ per day. The charge for landing cargo is 7s 6d per ton, and for loading 5s.

On the Zambesi there are at present two British cargo steamers, and one Dutch; two British gun-boats, and four Portuguese. The British cargo steamers run between Chindé and Chilomo, and sometimes Port Blantyre. The fuel used is wood; coal only is taken from the Chindé when wood is scarce. Welsh coal costs 3/ 10s, and Natal 2/ 10s per ton. They carry up general cargo and passengers, and bring down coffee and ivory from the shire Highlands and Lake Nyasa, and oil seeds from the Zambesi. They are quite insufficient to cope with the trade.

Transport by the Zambesi to Senna and Tete is by means of lighters, boats, and canoes, all of which run the risk of being capsized by wind and hippopotami. This year one merchant lost 400/ worth of ivory through a lighter being capsized and sunk by one of these animals. During the past year the British South

Africa Company sent several parties from Fort Salisbury, and bought large quantities of goods in Tete, whence they were taken overland. The distance between the two places is about ten days' march. This brings Fort Salisbury within 18 days from the coast, as steamers can run from Chindé to Tete in eight days. A large quantity of oil-seeds is grown on the Zambesi about Senna, but the difficulty and cost of transport is so great that the Oost Afrikaanische Compagnie, the only European firm in that place, has closed its establishment there. The Senna natives transport now on their own account to Muzongoa, a place on the Zambesi, 100 miles from the mouth, where there are both European and Indian trading-houses. From Muzongoa the produce are carried by steamer to Chindé. A well organised flotilla company for the Zambesi and Shiré would pay handsomely now, and would have a good future before it. The vessels employed in the service would require to be carefully built to suit the particular requirements of the river. At Chindé a piece of ground of 10 acres has been leased to Her Majesty's Government whereon to build store-houses, &c., and a township is rapidly springing up there. It is intended to build at once a wooden pier to facilitate the loading and discharging of lighters. The anchorage is about three miles from the bar inside the river, and is well protected, and has deep water and a sandy bottom. The tides run very strong there. The township is on a sand-bank, one side of which is washed by the sea. The port is connected with the main Zambesi by a deep, though narrow and twisting channel, some 14 miles long. The Kongoni bar is no longer used as an entrance to or exit from the Zambesi.

It is intended at an early date to place two small steamers on the Kwa-kwa, and to run them between Quilimane and Magarrumbe, whence there is always a good road to the Zambesi. Nothing more has been heard of the wharf and tramway which were spoken of last year.

SHIPBUILDING.—None is done here, but a number of boats and lighters are built every year by native carpenters of native wood. These craft are rough, heavy and strong, but badly finished, and constantly in want of repair.

COAL.—None is imported here, but a small quantity is imported monthly at Chindé for the use of the river steamers. The Portuguese Government river steamers have used coal dug from the Zambesi bank at Revugve, 20 miles above Tete. The beds run for more than 60 miles along the bank of the river, and the coal could be hewn and brought down river for about 20s per ton, a price that would make it cheaper than would fuel, the supply of which is often very insufficient.

Agriculture on a large scale has not been tried by any person. Each native hoes and cultivates his own little patch of ground. The crops grown are rice, different kinds of beans, maize, millet, peas, serafie seed, ground nuts, and in the cold weather most European vegetables. The fruits produced are mangoes, oranges, limes, lemons, figs, guavas, grapes, pine-apples, pomegranates, custard apples, cachew prickly pear, and a small wild apple not unlike an olive.

Domestic animals are represented by a few horses, donkeys, cattle, goats, sheep, pigs, and poultry. Horses do not thrive, but donkeys and mules do very well. There are not enough cattle, sheep, and goats to maintain a supply of butcher meat, and poultry forms the staple article of diet. Fish of an excellent quality are fish caught near the sea, but only in small quantities.

	Per lb.
Beef	8d.

Water is obtained from wells; it is only moderately good. It can be supplied to ships at 20s per ton.

A vigorous effort to grow sugar-cane has been made by the Companhia do Assucar di Mozambique. The site chosen for the plantation is on the right bank

of the Kwa-kwa, about 70 miles from the coast. At the end of 1890 and the beginning of 1891 some 60 tons or 700 tons of Natal cane tops were imported, of which 75 per cent were spoiled en route. The first planting of 180 acres was made in January, 1891, with Natal and native tops, with the result that the native cane has been discarded as too slow and poor in growth. The soil of the first field has been found unsuitable, and another site is to be tried. It is proposed to try ratooning the canes. The rainfall of 1891 has been much less than usual, amounting to only 35 inches; in 1888 it was 63. Much of the cane was destroyed by drought, some by white ants. In addition to sugar the company proposes to plant mealies, and experimentally, sea island cotton, pepper, vanilla, and Liberian coffee has been tried and found to do fairly well. Sugar machinery of the value of 2,000l has been imported, and is now on the way upcountry. The mill can turn out 20 tons a day. In addition to this a good frame saw has been imported and used to cut planks for building. The experiment is to be made of crushing oil-seeds by a hydraulic oilpress, and exporting the oil. The company has leased the lakes of the Prazo in which it works, and has an ample supply of labour. The adults in the Prazo number 6,000.

The native population of the district is estimated at 1,000,000, that of the town at 10,000, but there are no accurate data to go upon. The European population is about 200, of whom 140 are Portuguese, 25 British, and the others Dutch, French, Swiss German, and Italian. The British Indians number some 200. They are divided into two religions, Hindu and Mohammedan; the latter are by far the more numerous. They are of four sects, Meman, Khatri, Bohra, and Khoja. The Hindus are of four castes, Bhattia and Banyan (merchants,) Vanja (sailors,) and Karna (small shopkeepers and spirit dealers.) The Karnas alone of the Indians sell liquors. The British-Indians come from Kutch, Porbundir, Jamnagar, Batwa, and Lalpore.

The rates of wages are as follows:—

Description.		Amount.			
		s.	d.	s.	d.
Cooks ...	Per month	12	0	20	0
Servants ...	"	6	0	12	0
Carpenters ...	Per day	0	10	1	6
Blacksmiths ...	"	0	10	1	6
Masons ...	"	0	10	1	6
Boatmen ...	"	0	10		
Labourers ...	"	0	10		

At a distance from the town the pay of craftsmen is the same as in the town or a little higher, but that of servants and labourers much less.

There is a military and civil hospital located in a temporary building, under charge of a doctor, and an apothecary who dispenses medicine. The diseases prevalent among Europeans are *brachmia*, *marah*, and bilious fevers. In 1890 influenza attacked many people, and carried off many natives. The natives suffer from fever, lung complaints, leprosy, elephantiasis, and native small-pox. An attempt was made in 1890 to enforce vaccination among natives, but it did not appear to have been persisted in.

Passports for the interior or for any part of the province have been done away with, but they are still demanded of those leaving the province. Permits to live in the country must annually be taken out by foreigners coming into the country. The fee charged for these is 2s 2d.

PUBLIC WORKS.—None of importance carried out during 1890.

TELEGRAPH.—The telegraph line runs from Quilimane to Gwongoe, on the Zambesi, and Chilimo, on the Shiré. There is also a line from Quilimane to the signal-station at the mouth of the Kwa-kwa. A line to Chindé from Vicenti is nearly completed. The service is fairly well carried on considering the nature of the country and the difficulties of transport. The rate to all places is 2d a word and 4d for each message. The telegraph revenue for 1891 was about 500l, a great increase upon last year.

There are no made roads, only tracks through the bush. The streets of the town are of sand.

RAILWAYS AND BRIDGES.—None.

TROOPS.—Are from Angola and India, officered with colonial and Portuguese officers.

During the year there has been a voluntary and involuntary immigration to a considerable extent. Of the former some came from Madeira; the latter were men who had taken part in the disturbances in Oporto. It is said that the immigrants for the most part have prospered but indifferently. This is not to be wondered at, as most of the immigrants were unskilled labourers, for which class there is no demand.

COCONUT FIBRE.—No attempt has been made to prepare this, all that is taken from the coprah-producing nut is discarded. The natives would soon learn to prepare it for export if they had a few lessons from some one who understood the work, and a profitable business could be done.

CUSTOMS DUTIES ON TEA.

The Board of Trade Journal gives the following return embodying the latest modifications in the rates of Customs duties leviable on tea imported into the undermentioned European countries, according to the most recent information in the possession of the Board of Trade:—

INDIAN TEA AND THE CHICAGO EXHIBITION.

It has frequently been alleged against Indian tea planters that they are incapable of united action such as has brought Ceylon tea so prominently to public notice, and many a time and oft has the Indian Press urged upon them the vital necessity of pulling all together, if they do not wish to be left out of the new tea markets that are gradually being opened up in America, Australia, the continent of Europe, etc. The motto which Indian planters, like their Ceylon *confères*, should adopt is "United we stand, divided we fall," the truth of which must be very patent to all but the most obtuse. The opening up of new markets is undoubtedly the only way, as an Indian planting contemporary puts it, to "save from ultimate ruin our decidedly tottering tea industry," and an opportunity to exploit one of the best

markets will shortly present itself and should be taken advantage of, for it will probably never occur again. We refer to the forthcoming Exhibition at Chicago, which will, it is expected, "lick creation" in many ways. We have already reported that an attempt is being made in Northern India, or rather in Calcutta and Assam, to raise sufficient money to enable the Indian planting interest to be adequately represented at the Exhibition, and that Mr. Blechynden, the Secretary of the Agri-Horticultural Society of India, has been selected as the Indian Planting Commissioner, if we may so style him, to the Exhibition. This gentleman—who is reported to have not only strong business capacity, but experience as a practical planter, and is steady, gifted with great tact, and not one to be easily hoodwinked—recently proceeded to Simla to interview the Government of India with a view to obtaining its liberal support, and it is understood that he leaves for America almost immediately. The Tea Committee having selected him as its representative at Chicago, it may be taken for granted that he is the most suitable person for the post. Accordingly it behoves all planters not to hamper him in his action and refuse to support him with the funds necessary for the due attainment of the object which all must desire, viz., the successful introduction of Indian tea into America.

The *Indian Planters' Gazette* states that it has received letters grumbling because a tea expert was not chosen, and hundreds of letters complaining that it is the Agents of the Tea Companies alone who profit by tea planting, the planters and proprietors suffering so that the Agents may thrive! Surely something must be wrong here. It seems to us to stand to reason that the interests of the Agents are bound up with those of the planters, and that whatever tends to adversely affect the latter must in due course have a like effect on the former. One correspondent, referring to the handsome sum subscribed by Ceylon planters, says it will no doubt be asked why their Indian *confères* do not do and do likewise; and he then proceeds to give the answer, which is that "as a rule the Ceylon planter is his own Agent, deals with his Banker and pays no middle charges." Other correspondents have argued that the sum which the Agents in Calcutta have subscribed is out of all proportion to the gains which they derive from the gardens, and to the amount which the Managers and Assistants are individually asked to contribute. This may be so, but the Agents may have to dip their hands again and again into their coffers, as necessity arises, in order to render the venture at Chicago a substantial success. At all events, this is not the time for bickering. A house divided against itself cannot stand, and it is the imperative duty of all desirous of the ultimate benefit of the Indian planting interest to sink animosity, and unite to present a firm front in the Battle of the Teas which is about to be waged. Mr. Griulinton, who is representing Ceylon in America, and who is now exploiting the country, states that £20,000 is the minimum sum required for Ceylon at the Chicago Exhibition, a quarter of which will be recouped by sales. This sum will no doubt be forthcoming, and the question arises, "Is India going to let this grand opportunity pass, and allow Ceylon to flood the American market with her undoubtedly excellent tea to the detriment of India's equally excellent product?" We trust not. We believe, however, that not a third of the sum estimated to be necessary in Ceylon has as yet been promised in India. A venture of this description requires ample funds for its successful accomplishment. Niggardliness now will mean failure in the future. Let the Indian planters, then, be generous; let them give as much as they can, and we may trust to the Agents—if not to the Government—seeing to it that their own contributions are on no less generous and proportionate a scale. The planters of Southern India should be up and doing, and we would counsel their joining the planters of Northern India in the Chicago crusade, for thereby they will probably derive more benefit than by taking action by themselves. We shall have some further remarks to offer on this subject in another issue; meanwhile,

we quote what our contemporary, alluded to above has to say on the subject, and with which we entirely agree:—

"We once more ask our tea planting brethren to realise the fact that they have a big chance in front of them which one and all should combine to back up. We do not hold a brief for the Agency houses, but are purely, as we ever have been, the advocate of planting enterprise. Unity is strength, and disaffection the worst of weakness. What Ceylon has done, surely India can do ten times over. China tea is getting more and more out of favour everywhere. Ceylon, in a very few years, will have to meet the heavy handicap of an overstrained soil, and now or never is the time for us all to unite in advertising and pushing Indian tea, and not to wait till worse times, brought on by our own inaction stop Banks' coffers from flowing, and Agents close advances to all but gardens with monied proprietors behind them. Let all and each connected with the industry put their hands in their pockets, Proprietors, Companies, Agents, Shipping-Companies, Managers, Assistants and all; and while we are about it, do the thing well, and if America can be opened out as a market for Indian tea, let it be no fault of those interested if it be not thoroughly tapped."

The following remarks by the London correspondent of a contemporary—which have an indirect bearing on the matter referred to above—will be read with somewhat mingled feelings:—

"Much surprise has been caused in England at the apparent indifference of the Government of India to the advantage of advertising Indian products at the forthcoming American Exhibition. The matter has been taken up in Parliament by General Goldsborough, the Conservative Member for the Hammer-smith division, who will ask Mr. Curzon for a little information. The gallant Member in the first instance inquires whether India is to be represented at Chicago, and if so, whether the Government of India proposes to give a grant-in-aid. There is a rumor abroad that the Americans themselves rather than leave India out altogether are prepared to vote £20,000 to securing exhibits from our Eastern Empire, but I mention the report under reserve."—*M. Mail*, July 1st.

THE CEYLON TEA INDUSTRY.

A dozen years ago Ceylon appeared to be in a very bad way. Disease had killed the coffee industry, multitudes of the planters were ruined, vast amounts of capital were lost, and land was almost unsaleable. It looked then as if the future of the island would be gloomy one; but the planters were aroused to new endeavour. They substituted tea for coffee, and their success has been one of the most marvellous in recent economic history. So late as 1884 Ceylon sent to the United Kingdom barely $1\frac{1}{2}$ million lb. of tea, out of a total consumption of over 175 million lb. Practically that is to say, Ceylon supplied only about 1 per cent. of the total consumption. Last year Ceylon sent us very nearly 51½ million lb. of tea, out of a total consumption of 202½ million lb.; so that whereas in 1884 we got only about 1 per cent. of our tea from Ceylon, seven years later we got about 25 per cent. Her supplies to us have been in the interval multiplied about thirty-five times. She has made all this extraordinary progress at the cost of China. In 1884 China sent us, in round figures, nearly 111 million lb. of tea; last year she sent us only about 49½ million lb.—that is to say, while in 1884 China sent us about seventy-five times as much tea as Ceylon, last year she actually sent us less. Our purchases from Ceylon in the intervening seven years were multiplied about thirty-five times, while our purchases from China fell off more than 50 per cent. That is a marvellous record of progress. It shows how much may be accomplished by courage, skill, enterprise, and capital and it encourages very great hopes for the future of Ceylon. Of course, tea is ruinously cheap at present. It is not likely that the Chinese would allow themselves to be driven from the British market without a

struggle. They are fighting desperately, and in their competition they have forced prices down ruinously. The Chinese teas, however, have fallen much more than either the Indian or the Ceylon tea. But as the figures cited above show that China has been utterly defeated, and Ceylon is decisively victorious, for the future there can be no doubt at all of the result of the struggle, and there can be equally little doubt that there will be an improvement in prices.

Taking India and Ceylon together, we get now over 70 per cent. of our tea from those two countries, and, as shown above, we get about 25 per cent. from Ceylon alone. China has fallen to quite an unimportant position. But outside of the United Kingdom there is a vast scope for Indian and Ceylon enterprise. It is roughly estimated that the consumption of tea outside of the British Empire is about 250 million lb. per annum; that is to say, the consumption outside of the British Empire is larger than the consumption of the United Kingdom. This vast market has yet to be conquered by India and Ceylon, and there is little reason to doubt that it will be conquered. The Ceylon planters are pushing their trade in Anstrasia, and they have now made up their minds to push it also in the United States. They have secured a good position at the Chicago Exhibition. On the Continent also they are intent upon competing; and as they have so completely won at home there seems no reason to doubt that they will win abroad. Of course it is hardly probable that tea will become as favoured an article of food abroad as it is in this country. But its use may be greatly extended, and even if it is not extended, the displacement of Chinese tea by British-grown would mean an enormous increase in the demand for Ceylon and Indian tea. Therefore the prospect is that the production of tea, both in Ceylon and in India, will be augmented year by year, that the tea plantations will rise in value, and that consequently investment in tea-planting seems a favourable outlet just now. The very depression is itself an advantage. In the first place, the low prices compel the planters to exert themselves to the utmost to make known their wares and to gain a foothold in new markets; and in the second place, the depression in the trade enables the investor to place his money on better terms than he could do if the immediate prospects were brilliant.—*Money*.

THE JAPAN TEA SEASON.—From the commencement of the new tea season up to the 14th inst. 13,106,500 *kin* (one *kin*=13 lb.) of tea arrived in Yokohama from the interior, and 12,575,000 *kin* were sold to foreign merchants. The tea trade returns of the port for the 15th were:—Arrivals, 190,000 *kin*; and sales, 228,900 *kin*.—*Japan Weekly Mail*, June 18.

MALACCA TEA.—There have been submitted some specimens of tea grown in Malacca by Tan Hin Guan, a Chinese cultivator of tapioca and many other products. This Malacca tea is prepared after the Chinese fashion, and has, of course, the flavour that we associate with China tea. It is of good quality, and is wholesome and pure; and might with advantage be put upon the European market in the Straits.—*Straits Times*.

EUCALYPTUS IN CAPE COLONY.—The eucalyptus, which now forms a prominent feature in Cape scenery, was introduced into the Colony by James Backhouse, a Quaker missionary, who paid a visit to the Cape in order to look up the various mission-stations in 1838, and brought with him seed from which the first tree was raised in a garden behind the market-place at Graham's Town, in the Eastern Province. Sir Lowry Cole, during his term of office as Governor of the Cape, brought six or eight young plants from Mauritius, two of which are still standing in the Botanic Gardens. Thus far, eucalyptus oil has not yet been distilled in South Africa for commercial purposes.—*Chemist and Druggist*.

ARABIAN COFFEE.

There is now-a-days no question that Coffee Arabica is of African origin. Its natural habitat seems to be the country of Gallas and Harrar. The plants was introduced into Yemen at the date of the Abyssinian conquest and the downfall of the Hymyarite Empire about a century before the era of the Hegira. The culture of coffee rapidly spread in all the western parts of Arabia Felix—that is to say in the regions subject to tropical rains.

The system of cultivation has not altered for centuries, and the plantations of coffee-shrubs on horizontal terraces, on the mountain sides are today still like those of which Niebühr wrote, more than a century ago. The natural slope of the ground is sometimes very steep, consequently the walls of rough stones which sustain the terraces are built up to a height of from 20 to 26 feet which is equal to, or even more than, the width of the terrace itself. This arrangement ensures perfect drainage which is very salutary for such a plantation. The soil is carefully prepared, and almost always shaded by large trees (Ficus, Tamarindus, Ehretia, Dobera, &c.), planted in a row. Many plantations are irrigated during the dry season by means of reservoirs placed on a level with the highest terrace, and fed by the deviation of a spring or neighbouring stream. The plants are generally supplied from nurseries, and are obtained from seed. The seeds, before being used, receive a certain preparation which consists in the removal of the pulp, and the submission of the seeds to a slight drying in a layer of ashes. They are sown from October to December, in borders of good soil, enriched by cow or sheep dung. The seedlings are shaded from the extreme heat of the sun by a covering of boughs, and are watered at least once a week. At the end of six or seven weeks the young plants are carefully picked out and removed wrapped in mats, to the prepared plateaux. The coffee shrubs are planted in lines about 30 to 40 inches apart, they are watered once a fortnight, and the soil is manured when necessary. From two to four years must elapse before the shrubs begin to bear. In Haraz, some growers consider that plants obtained from natural seed-plots are more vigorous than those germinating from seeds submitted to the process above described.

The natural seed plot is managed thus:—Many of the berries when fully ripe, are attacked by birds which eat the fleshy part of the pericarp (the pulp). The stone covering the seeds is thus laid bare, becomes detached from the plant, and falls to the ground. The cultivator examines the plantations every day, and hastens to lightly cover over these seeds on the place where they have fallen. They do not germinate for two or three months; but the young plants are said to grow to a height of from 12 to 15 inches in the first year, and to continue to develop rapidly. It is known that the pulpy portions of the fruits, dried in the sun and pounded, constitute a material used for the preparation of a stimulating beverage, possessing analogous properties to an infusion of tea. This warm draught has a very pleasant flavour when it is properly prepared. Scented with ginger or some other spice it is, with "Qat" (leaves of *Catha edulis*), a favourite stimulant with the Arabs of Yemen, who do not use coffee as do the Turks and Europeans. Everywhere, in the sandy solitudes of Tehâma as well as on the steep summits in the Gebell district, is raised the "Mikaye," this is a hut made of branches or a shanty of rough stones, often far away from any populated centre, where is sold, in default of any more substantial fare, the decoction of gische, known as "gafal," which is always to be had fresh, earthen jars with long necks and large rounded bases.

The fruits of the coffee trees, dried in the sun, arrive from the interior in their natural condition, in cags of matting. In the centres of exportation, the most important of which is the port of Hodeidah, the gafal is submitted to a process which is intended to separate the seed from the pulp. The operation is conducted by means of mill-stones moved by hand, which is very fatiguing work, and must necessarily be replaced by perfected machinery as soon

as ever hand labour becomes dear. For some time past mortars of English manufacture have been used at Aden. The material thus pounded is estimated to consist of 50 per cent of the seeds proper, 35 per cent of pounded pulp, 12½ per cent. of powder yielded by the stones, and 12½ per cent of waste produce. The commercial value of the prepared seed is at the quay of Hodeidah from about £7 to £8 for 220 lb.—Translated from "Voyage au Yemen" by A. Defflers.—*Gardeners' Chronicle*.

NATIVE PERUVIAN COTTON.

The United States Consular Agent at Payta says, that after five years of drought, the province and State of Payta are naturally depressed in the way of commerce and all kinds of industry. The valley of Chira forms a favourable exception. The production of the valley consists principally of native Peruvian cotton (*Gossypium herbaceum peruvianum*), an article used very extensively in Europe for the manufacture of woollen goods, with which it mixes readily, on account of its rough, strong, and long fibre, is produced abundantly throughout the State after the rainy seasons, which are periodical, and occur generally every seven years, and is cultivated always along the banks of rivers on lowlands irrigated by the overflow of streams. The plant is arborescent and perennial, and after fully developing continues producing cotton for five or six years in succession, provided there be some moisture in the ground, needing, however, very little of it on account of its deep rooting, thus reaching moisture at great depths. The system of cultivation of this plant is quite primitive, the seeds being planted by making holes in the ground with spades, without tilling or manuring the soil. The plant becomes developed and begins to bear cotton in dry and sandy soil about six months after planting, and about nine months in rich and wet land, continuing to yield at short intervals for five or six more years in succession. The plant may be observed in blossom, with pods, buds, and cotton all at the same time, and giving a continual yield for the time above stated. In certain seasons of the year, about every seven years, the rains are incessant for about two months, both in the interior and on the coast, and water descends in such abundance as almost to inundate the country. Large torrents stream down the mountain side, the valley of the Chira is deluged, flat lands within it are turned into morasses, and morasses into lakes; in fact, the lowland becomes submerged, and the accumulated mass of waters rush with great force down the central valley, which forms their only outlet. The valley, however, is wide, and the descent very gradual. The extent of the valley through which the water flows is from three to four miles wide, and although it is nearly 200 miles in extent, the valley for the whole distance is almost level. The rains generally cease in March, but it requires from thirty-five to fifty days for the water to disappear and leave the land dry. As soon as that is effected there springs up, from the whole surface of the ground which has been thus submerged, most luxuriant vegetation. The soil is wonderfully rich, and has been under cultivation by the aborigines from time immemorial, and its fertility is kept up unimpaired by the slime which is abundantly deposited during inundation. The cotton is collected, when the pods open, by women and children, who are paid in proportion to the quantity collected, the prevailing rates being about 1s 8d for every 100 pounds. It is taken from the fields to the ginning house, where it is cleaned and made up into bales of about 175 pounds each. There are five of such establishments in the province of Payta, one in Querecotillo, on the east side of the river, owned by an Englishman; two in Sullana, a city of about 4,000 inhabitants, on the west side of the river, owned by natives; two at La Huaca owned by an Englishman and an Italian. A considerable quantity of cotton is annually exported and seeds are now also exported for oil making, Europe is the market for both products.—*Journal of the Society of Arts*.

TOBACCO CULTIVATION IN FIJI AND SUMATRA.

(By E. J. LANYON.)

Knowing the extent to which Fiji is suffering from the want of payable industries, and the sparse information which prevails on the subject of tobacco culture and preparation—a subject which promises to be of great importance to the welfare of the Colony—I beg to solicit for these notes the earnest attention of those who are sincerely interested in the progress and welfare of the country. It must be obvious to all such, that the introduction of any industry, requiring no great outlay, giving quick returns, free from the risk of hurricanes, and promising a fair remuneration for the investment of either large or small amounts of capital, would prove an incalculable advantage to all classes of the community.

For many years past, several of the settlers in Fiji have grown tobacco on a small scale to supply the local market. It will, I think, be universally acknowledged by them that, where any ordinary care has been bestowed, the results have been sufficiently satisfactory to convince them, that, with a certain and illimitable market for the disposal of the article, and the production of a leaf in any way approaching the value of the Sumatra, Havannah, Brazil or other costly kinds, a golden harvest—or at least a most encouraging issue—might most justifiably be reckoned on. Even the production of a good smoking tobacco for the pipe, would afford a most inviting field for enterprise; and I, still again, further believe that if Fiji tobacco only brought 6d. per lb. in the European market, its cultivation would pay equally as well—if not better than any other product grown in the Colony at the present time. Although the value of tobacco for the pipe is lower than the cigar kinds, yet its yield is correspondingly higher, and its cost of production and preparation much less. It must not be forgotten that our English manufacturers, who are chiefly dependent on foreign sources of supply, are only too solicitous to encourage and foster the production of an article—answering their requirements—in their own British Colonies.

There are good grounds for believing that Fiji possesses the capabilities—even in an eminent degree, desired for the cultivation of marketable tobaccos—especially the higher and more costly classes, suitable for the manufacture of cigars. The tobacco leaf, when grown in countries far apart from each other, varies greatly in character and appearance, and at least in as great a degree as any other vegetable production. This variety and divergence may be partly owing to the selective agency of cultivators; but the sole effect of soil and climate seems, more than any other cause, to impress a certain definite character on the respective growth of each country. For example; certain parts (southern) of the United States, in which tobacco is so largely and successfully grown, can only produce the sorts suitable for smoking in the pipe; and the States, notwithstanding the variety of soil and climate and extent of territory at their command, have to draw their supply of the finer sorts from Cuba, Sumatra and other distant and foreign sources. I venture to point to the obvious conclusion that, the acquisition of a true knowledge of the special class of tobacco, naturally produced in their various localities, and the conditions of soil, climate, mode of cultivation, preparation, &c., are the first of all necessities when considering the establishment of the industry in Fiji. It would be a waste of effort to attempt the growth of any other variety, or to prepare it for a purpose for which it is not adapted, whether for cigars, the pipe or cigarettes. It must also be remembered, that, though tobacco, of a sort, will grow almost anywhere, it is, often only in special limited localities—as is the case in Sumatra—even in the countries that have proved well adapted for its growth, that the superior and

paying classes of each sort can be produced. For instance, in the district of Serdang (Sumatra) the tobacco is of an inferior quality, burning with a black ash—instead of a white—arising from the want of potash in the soil; whereas the tobacco produced in the adjoining district of Deli, only a few miles distant, is of the very finest quality. This points to the necessity of a careful selection of site, a knowledge of the article itself, the constituents of soils and the requirements of the world's markets. It will thus be seen that it remains for the Fiji tobacco grower to discover which of the payable classes is most suited for the conditions of his soil, climate and other surroundings. Although there is a large proportion of land possessing a soil most eminently adapted for the Sumatra, Cuba and other fine varieties, there are localities where the soil will be found better suited for the better classes of the heavier and coarser kinds.

The next matter of importance is the procuring of seed from reliable sources, and the selection of a kind which possesses those points that are of chief consideration to the grower. Various kinds occur in connection with the various classes. Some of these possess distinctive qualities and advantages over others: not only in regard to yield, comparative heaviness of leaf, curing qualities, color, &c., but also maturing and other advantageous peculiarities. As an illustration, I may state that light colored seed produces light coloured tobacco, and as light coloured tobacco finds the readiest sale at the present time, the observance of this point in selection is one of great importance to the grower. Through, it is said, neglect in this direction, a large estate in Sumatra realised for its last season's crop prices that were far below those of other estates that had bestowed the necessary amount of attention to the matter. Then again, there are plants possessing various objectionable peculiarities that render them strictly ineligible for seed raising purposes. It is also imperative that the planter shall change his seed for that of another estate every year, and never grow a crop from his own. The larger the area under cultivation of one class, the better and truer to its type the tobacco will be.

The selection of season for planting demands the most careful consideration, in order not only to ensure a favourable development of the plant and timely maturing of the leaf, and the formation of the essential oils that help to impart the desired aroma, &c., but also to evade the difficulties and drawbacks attendant upon the ripening, harvesting, and curing of the crop during a protracted spell of wet weather. Irrespective of these considerations very much wet weather causes the leaf to become rusty and spotted. I am of opinion that March or April, or perhaps May, would be the best months on Taviuni, and other parts of Fiji, having a similar climate, for the setting out of the plants; but, of course, much depends on locality. If tobacco has once got a fair start, it is astonishing how much dry weather it will endure, which proves that it is, essentially, a sun plant.

That there is little known, and, much to be learnt in Fiji about the cultivation and preparation of the crop, is an irrefragable fact. In connection with the former, one conspicuous feature of the system generally employed in Fiji, as compared with that of other successful growing countries, is the omission of a thorough working of the soil—consisting not only of effective digging, but also a constant loosening and heaping up of the loose soil around the plants—thereby not only nourishing and strengthening those, by placing new soil within reach of their roots or mouths, but also most materially improving the quality of the leaf, through the soil being always mellow, loose and able to absorb excessive moisture. There may be some planters in Fiji who may think that, owing to the good soil they possess this source of labour can be dispensed with; but I can assure them this idea is a downright fallacy; and, if they persist in holding this opinion, they had better leave tobacco growing alone. There are several matters in connection with

topping, priming, degree of ripeness at which the tobacco should be cut, mode of harvesting, &c., that have to be learnt; which although simple in themselves, are of the greatest importance; and, I may add, that the manner in which these are performed, and the objects aimed at, are at total variance with the principles observed in Sumatra &c., and produce totally different results. It is in the curing and preparation of the leaf for the market, that the most enormous mistakes and omissions occur. The whole system as now employed in Fiji, is utterly and wholly opposed to the approved systems practised in Sumatra, the Philippine Islands, Cuba &c.; and it is undoubtedly chiefly to this cause, the produce placed on the local markets owes its demerits, and fails to find any favour in wider commercial circles. Although the different methods employed in regard to cultivation and curing in various countries, embrace principles closely allied, or that are nearly identical with each other; and the various classes of tobacco only demand slight modifications in culture and preparation, yet these ramifications, however simple they may be, produce results that give the tobacco a definite character. It therefore remains for the Fiji planter, after acquiring a knowledge of what these modifications consist, to adopt such as may be applicable to his requirements. Until earnest attention is given to the matters I have referred to, and an improving spirit sets in, I can, with safety, positively and emphatically assert, no improvement in the quality or value of Fiji tobacco can possibly be expected, and it must remain a comparatively useless and valueless article.

I have now a little to say about Sumatra and the tobacco industry there. Deli, that portion of the island in which tobacco is grown, is about 4 degrees north of the equator, long, 98° to 99° east, is composed of three states. Deli, the oldest, is in the centre, and is under a Sultan; Lang Rat to the north is under a Chief; and Serdang, to the south, is under a Sultan. The whole forms part of the Residency of Seak. Beng Ralis further down the coast, is the seat of Government. The Resident for the East Coast, has his quarters here. Locally, the administration is carried on by an Assistant Resident who lives at Medan, which is the principal town on the Deli river. The Assistant Resident is assisted by Controllers, stationed as follows:—one at Binji; one at Clamba (for Upper and Lower Lang Rat); and one at Rante Panjong for Serdang. South of Serdang are the districts Bedagai and Padang, over which the Suzerainty is claimed by both the Sultan of Serdang and the Sultan of Deli. The two last districts have only been opened out during the last 5 or 6 years. The districts I have referred to are the only parts in which tobacco is grown, and for but a very small portion of the island. The other parts are said to be unsuitable for tobacco, whilst even the newer of those that have been opened are far inferior to the older district of Deli I have already referred to the inferiority of Serdang. The tobacco districts are not far from the coast, and in some instances the estates are quite close to the sea—fully enjoying the influence of the sea breeze and air. Luxuriant coconut trees are met with in all the tobacco districts, whilst the characteristics of vegetation—especially in Deli—are in many respects analogous to those of Fiji. Among the vegetable growths I recognised were *vesi*, *vaci*, *vasa*, the weed called *deni orsi* by the Fijians, and many other trees, plants and shrubs that I do not know the Fiji names for. Among the latter were several growths of a soft, quick-growing nature, that, like in Fiji, spring up on abandoned land which has been previously cultivated. In connection with this I may state that this species of growth is far more rapid in Fiji than in Sumatra; but in the case of the more primitive growth the trees are taller and straighter, and show less inclination to lean towards any particular direction which is of course attributable to the absence of strong winds or hurricanes. There are many fine species of timber trees, in some of the other parts of the island. Flowering plants and shrubs

are numerous, and countless parasites garland the forest trees with flowers of every hue. The most curious of these is the *Rafflesia*, which, clinging to the bark of large trees, spreads out the largest known flower, with a calyx 3 feet in diameter and 9 inches deep. The fruits are numerous and very rich, and include the durian, litchee, mango, mangosteen, rumbutan, &c., &c., &c. The elephant, rhinoceros, tiger, leopard, black bear, tiger cat, wild swine, tapirs, antelopes, deer, monkeys, (including the orang-outang), ant-eaters &c., abound; hippopotami and crocodiles frequent the rivers. A large quantity of rice is produced in the island. A small quantity of coffee is grown by the native; also pepper at Acheen. Acheen is situated at the extreme N.W. end of the island. A large body of troops are stationed here: and it is only by the maintenance of these that the Dutch are enabled to levy taxes or exercise any control, and subdue the frequent outbreaks that are constantly occurring. The interior parts of the island are inhabited by a tribe called the Battaks, who, fearing that the Europeans may still further encroach upon their lands, openly show their objection to his presence, or, any protracted sojourn, by hostile intimidation. Thus, the Europeans know but very little about the interior parts. There are a few Battaks who work on the estates. These are generally employed in felling, building sheds, &c.

The Battacks are of the usual Malay type. The Lampongs, who live in the Lampong district, are of middle stature, well formed, of pleasant exterior, mild, but uncivilized and lazy. Polygamy obtains, the wives being bought from their relatives. The horses are all built on posts of iron wood, and several families live under the same roof. The Acheenese are tall, well made, active and intelligent, but cunning, proud, treacherous, and blood-thirsty. They live simply, but are total slaves to opium. Only about a couple of years ago, they captured a mercantile steamer off Acheen, and demanded with threats of violence, ransom for the crew.

Sumatra possesses a soil consisting of a vegetable mould resting on a volcanic base. Although the soil in Sumatra is fairly good, it is undoubtedly far behind that of Fiji. I have samples of Fiji and Sumatra soils with me, and intend submitting them for a comparative analysis. The presence of potash—so essential for tobacco—is not nearly so strongly indicated in the Sumatra soil as in that of Fiji. This is shown by the greater absence of tree ferns, or at least by a very much smaller growth. Then again, maize and other crops, that have much demand on this ingredient, and are easily grown in Fiji, can only be raised in Sumatra on a few exceptionally good soils, and even then with only a small degree of success. The climate is somewhat similar to that of Fiji, somewhat wet. Occasional showers, with more or less heavy rain at times, in the wet season; and moderate spells of dry weather, of uncertain duration, in the dry; a slight increase of temperature takes place from October to March; the minimum being in May. The thermometer ranges from 70° F., at sunrise to 94° at 2 p.m. The monsoons are irregular, and rain falls during all the months, though the quantity in October and December is double that in February and June. Like in all planting communities, the Sumatra planters are generally complaining of either too much rain or too little. The nights are cool but the days are sometimes very warm, although very often they are cloudy and pleasant. Some parts of Sumatra are very unhealthy, and fever very prevalent, especially at Serdang. Deli is not at all unhealthy. With a proper selection of season, I believe Fiji possesses equally as favourable a climate for tobacco cultivation as Sumatra.

I presume it is generally known in Fiji that Sumatra tobacco owes its great value and merits to its superior adaptability for cigar wrappers. What chiefly recommends it for this purpose is its fine, soft, silky, and elastic texture, suitable conformation, glossy appearance, and good burning qualities. These qualities are developed to a very large extent by the mode of culture and manipulation followed

in its preparation for the market. As far as aroma is concerned there is little to recommend it, which may be gleaned from the fact that nobody smokes it in Sumatra. Although devoid of that fine aroma which distinguishes the Havannah tobacco, it is, nevertheless, the most serviceable in the market, and for every pound of Havannah, there are a hundred or more of Sumatra used. The Sumatra planters have repeatedly tried Havannah seed with the view of endeavouring to combine the qualities of the Sumatra tobacco with those of the Havannah, but have not been able to get the Havannah plants to grow successfully, and have therefore been compelled to fall back on their own seed. Had they succeeded in their experiment, the tobacco would have been greatly enhanced in value, and weather and fertility of the soil; but, in general times, it may be said that if the soil is good and season favourable from 7 to 8 cwt. per acre can be reckoned upon, on some fields as much as 9½ cwt. are got, but, on the other hand, there are fields that yield only 5 cwt. or even less according to soil. The highest grades of Sumatra tobacco are worth from 5s. to 7s. per lb. The average value may be said to be (including all grades) 2s. 6d. or 2s. 7d. per lb. Leaf containing 40 per cent of broken and inferior leaf lately realised the average of 2s. 3½d. per lb. I have reason to hope that, with the exercise of proper care, so large a percentage of broken, rusty, worm eaten, rotten, and other inferior leaf will not be found in the Fiji produce. In Sumatra there is an export duty of 14 guilders per bale. Besides the manager's salary, there are also the salaries of clerks, assistants, mandors, tandils, directors, administrators, &c., &c. The freight per German Lloyd from Sumatra to Holland, is 55fr. per last of 800 K. G., or ten bales, or reckoning the dollars (American) at 2fr. 50, 2 dol. 20 cents per bale or £5 14s. per ton. This includes transhipping and expenses at Singapore and insurance.

That the profits attending tobacco cultivation in Sumatra under favourable conditions, are often fabulous, is an undeniable fact. It is no uncommon thing to hear of estates clearing from £10,000 to £20,000 or £30,000—according to extent under cultivation—in one season. It is unnecessary for me to dwell at any great length upon the payable nature of the industry, or to allude to the enormous dividends paid by the companies interested—reaching as high as 160 per cent. and even more; not only have the Deli companies paid these enormous dividends, but they have in addition set aside 15 per cent. of their profits towards a sinking fund for redemption of capital. The present price of the Deli Maatschappij Co.'s 100 guilders share is 680. Such immense profits will perhaps in some instances be sceptically regarded, but in evidence, I can only recommend those who have any doubt in the matter to make more searching enquiries for themselves, the formation of large companies in Holland for the extension of the industry and the great prosperity planters and all classes of the community associated with the industry enjoy—solely from this one source of cultivation. Whilst travelling from Colombo, I heard a Tamil servant who was travelling with his master—a Sumatra tobacco planter—aptly term Deli “the land of gold”; and from what I afterwards saw and learnt about it, I certainly thought the appellation was not an inappropriate one. The evidences of wealth and prosperity are to be seen in every direction, amongst all kinds and conditions of men—from the “tobacco lord” who spends his money with a freedom rarely met with amongst planting communities in the days of low prices and short crops, to the “boy” and native one meets with whilst travelling, drinking cordials and aerated waters, and smoking “Old Judge” and other imported fine cut tobaccos. Everything is most exorbitantly high in price, yet nevertheless everybody appears to have more money than they know what to do with, or, at least, ample means to provide far more than what, in most communities, the same class of people would deem the ordinary necessities of life. Managers draw salaries, which with their commissions, range from £700 to £300 a

year, drive about on the estates in buggies with a footman; and a Fiji planter might, I think, say they do the thing in good style. Estate management and expenditure is of a far more extravagant and lavish description than it would likely be in Fiji among its more hardworking and self-reliant planters. The industries hitherto tried in Fiji have left so small a margin for profit, that Fiji planters have been taught the strict necessity of economy, whereas in Sumatra the contrary has been the case. Another advantage which exists in Fiji, and to which I have not previously referred—reducing cost of production—is Fiji's comparative freedom from destructive worms, insects, &c. that give so much trouble in Sumatra. Worming there forms one of the most tedious and important of all operations. Worms are so bad in Sumatra at times that they become a perfect plague. Another advantage which I think, judging from my own knowledge and observations in connection with tobacco in Sumatra and Fiji, will be found to possess, consists in the fact, that owing to its superiority of soil, the second crop obtained from the suckers, after the stalk has been cut, will, owing to the greater vitality of the stalk, be larger and of a more uniform and desirable quality than it is in Sumatra.

Upon considering the various conditions under which tobacco is grown in Sumatra, and comparing them with those that exist in Fiji, together with the results that have attended the experimental growth of the Sumatra kind—irrespective of the Havannah and American—in spite of the unfavourable conditions in regard to selection of soil, seed, season and imperfect mode of cultivation, with which these experiments have been accompanied—it will, I think, be seen what great inducements exist for furthering the experiment in connection with tobacco growing in Fiji; and as fair inference from the facts adduced also be seen, there is every reason to believe that, with a proper selection of soil, seed, season and mode of cultivation, not only the Sumatra, but Havannah would no doubt have onstripped all others, as it would not only have served for wrappers, but, having the necessary aroma for fillers, would have served for that purpose also. Most Fiji planters are undoubtedly aware that Havannah tobacco grows exceedingly well in Fiji as much so as any other class. This fact indicates to a large extent the superiority of the Fiji soil to that of Sumatra. It is well known that the Cuba (Havannah) soil is of a very fine description; and there is no doubt that the Fiji soil—in many parts of the group—more closely approaches it in character than the Sumatra. This fact should afford no small incentive for the prosecution of the experiments in tobacco growing in Fiji.

The principal old tobacco companies in Sumatra are the Deli company, the Amsterdam Deli, the Batavian Deli, and the Langkat company. Besides these there are several other smaller concerns. The estates are formed on bush land. A crop is taken off, and then the planter is compelled by the Government to allow the natives to grow a crop of rice (dry) on it. After this the land is allowed to remain fallow for six years before another crop of tobacco is planted. In a few exceptional cases in the district of Deli, where the soil has been unusually good another crop has been taken off in the third year. What procedure would be best to follow in Fiji, or what crop would be best to grow as a rotation one, is a matter open for consideration and experiment and the judgment of the planter; but there is no doubt that the Fiji soil will be found to be better able to endure the demands on it than the Sumatra. Owing to the system of cropping I have referred to, the possession of large areas of land are necessary in Sumatra for the prosecution of the industry, especially when large areas are planted every year. It will thus be seen that the available land is becoming fast played out, whilst there is a very narrow scope for selection, all the best land having been taken up. It is unnecessary for me to refer to the advantage Fiji possesses in this respect. In opening an estate the land is divided into blocks of 100 acres that are worked in succession. Each

block is 2,420 yards long and 200 yards wide, and is bounded by drains and good macadamised roads on each side. These blocks are divided into sections 200 yards long and 36 yards wide, consisting of about 1½ acre. A section is allotted to each labourer; and it is the labourer's task to fell, clear, prepare and plant the land, and cultivate and take care of, top, prune, sucker and harvest the crop:—viz., about 10,500 plants, planted 3 feet by 2 feet apart. Road making—an expensive work owing to the scarcity of stones—drawing, cart work, &c., is generally done by Kilings, or Tamils, the other work alluded to is performed by Chinamen. The average total cost of labour is about 1s 6d, (eighteen pence) per diem; and large advances have to be made that often lead to a loss. The labourers are often a troublesome and turbulent lot, and incendiariism is very frequent—setting fire to the tobacco sheds, with the tobacco in them. The drying sheds, fermenting house, and other necessary buildings, form the chief source of expense. The drying sheds are erected at convenient places along the side of the road which divides the block, being opened up from the adjoining one which is to be planted the following year, so that they may serve for two years or plantings. These sheds are made of jungle posts and sticks, and are thatched in the same way as a *tibi tibi* house in Fiji. The only difference is that, instead of sugarcane leaf, a wide bladed, coarse kind of grass, which I have seen growing in Fiji, is used. These sheds are 180 feet long and 66 feet wide. The king posts are 28 or 30 feet high, and the short wall posts 7 or 8 feet high. They have thatched walls with suitable windows, doors, ventilators, &c., and posts for supporting the rails and poles for hanging the tobacco—all of which are of course jungle timber. The cost of thatching a shed of this size is generally about 450 or 500 Mexican dollars (a Mexican dollar is equal to about 3s. 2½d.) The procuring and erection of the timber is done by the estate or other workmen. The thatching is done by contract. A shed of these dimensions suffices for nine labourers' tobacco, or about 14 acres or about 94,500 plants. I was on an estate where there were over 30 of these sheds, besides fermenting shed, &c. The fermenting shed is a permanent, and generally more substantial building although thatched fermenting sheds are often employed on some of the largest estates. This building, is generally erected for the sake of convenience near the manager's bungalow. On an estate of 300 acres the fermenting shed is about 480 feet long and 80 feet wide. The king posts are 30 feet high, and the wall posts 8 or 9 feet high. The building has a verandah on the side most exposed to the beating rain, and the inside suitably fitted up with raised board platforms, floors, &c., to serve for fermenting, sorting, bulking, &c. When the tobacco has sufficiently dried in the drying-shed, it is brought in carts to the fermenting shed to be fermented, assorted and finally packed or baled. The bales contain about 180 lbs. of tobacco. The tobacco is transported by rail or cart to the nearest shipping place, and shipped via Penang, or Singapore to Amsterdam in Holland. Here, tobacco manufacturers, buyers and speculators, flock from London, the other European cities, New York and elsewhere, to join in the keen competition which generally attends the periodical sales. In regard to the yield, it is somewhat difficult to give an estimate, as much depends on the locality, state of the kind also will find most congenial homes in Fiji; and only require a proper preparation of the leaf to win for themselves a favourable position and reputation in the European and other markets.

All new industries in their experimental stage are exposed to risks, difficulties and disappointments, and are often accompanied by much loss of money and time—especially when much outlay has to be incurred in the initiation, and the crop occupies a long time to give returns. In the present instance, where the planter possesses good land lying idle, and is perplexed how to profitably utilise it; stores lying empty of produce and other convenient buildings that can inexpensively be fitted up to serve the purposes of curing and storage; tools, eligible labour and other conveniences, only little outlay

will be incurred in making the experiment; while, from the quick returns the crop gives, should any unforeseen difficulties be encountered and disappointment ensue, no very great loss or misdirection of time will arise. The risk is therefore only small; while, with the exercise of care, chances of success and prospect of substantial reward is comparatively very great. Difficulties may arise at the onset. Sumatra encountered many difficulties and disappointments at the beginning, but with perseverance, care and experience—gained from accumulated experiments—have achieved, there is every reason to believe Fiji can do, and it is my strong conviction that Fiji possesses, in several important respects, unusual inducements and advantages for the prosecution of this important and payable industry. I may remark that this conclusion has not been gained through any narrow, theoretical and careless consideration of the subject, but through the most careful researches, closest study, and careful reflection on all matters having any practical bearing on the question; and through the facilities that have been lately afforded me in Sumatra for acquiring such knowledge as was essential for the purpose—and assisted to no small extent by my long residence in Fiji, and local knowledge of it in its various surroundings. The object of this article is not to teach, but merely to point out a few of the most salient points, associated with an industry in which several Fiji planters have evinced an interest, and to direct attention to and excite and interest in a matter which promises to be of no mean importance to the welfare of the Colony, the prosperity of the planters and all classes of the community. There is no time to be lost in making the experiment, as from the conspicuously payable nature of the industry at the present time; other competitors will soon be in the field. In conclusion, I cannot refrain from remarking that, if Fiji loses this chance without making an effort in the contest, I feel assured it throws away the best chance it has ever had and one it may never have again—and one it can very ill afford to waste so ruthlessly.

P.S.—In the foregoing article, I have omitted to refer to Central Curing Establishments. These Establishments are under European supervision, and are formed for the purpose of fermenting, preparing for market, baling and shipping leaf, grown and dried by natives and other small growers. The leaf is either bought by the establishment, or cured assorted, baled and shipped for a certain charge. In some cases the leaf comprises that which is grown by the natives for taxes in the village Government gardens, in a similar manner as was formerly adopted in Fiji in regard to cotton. In this case, the growers are supplied with selected seed and the site for their operations, and the maintenance and mode of culture, erection of drying sheds, drying, &c. are under the guidance and occasional supervision of an inspector. The number of drying sheds required in each village of course depends upon the number of growers. The tobacco, when sufficiently dry, is taken to the establishment (fermenting-shed)—erected at the most convenient place—and paid for according to quality &c.—*Fiji Times*.

FROM THE METROPOLIS.

LONDON, June 24th, 1892,

THE CALEDONIAN (CEYLON) TEA PLANTATIONS COMPANY.

The *Financial News* this week contains the Prospectus of the "Caledonian (Ceylon) Tea Plantations Company, Limited"—Mr. A. Ross's which I have already allowed to. In case it should not reach you otherwise, I send you copy. Mr. Sinclair is not on the Board; no doubt it is more convenient to have London residents as Directors, and Messrs. Paine and Williams are both strong men. Altogether, the prospect of the Company floating is a very good one with Mr. Ross's guarantee of six per cent for seven years, and I should infer from

the figures given that the Company is likely to earn a good deal more:—

(Financial News, June 21.)

NEW ISSUES.

The Caledonian (Ceylon) Tea Plantations, Limited, has been formed with a capital of £30,000 in £1 shares. The present issue consists of 25,000 shares, of which 10,000 will be allotted to the vendor as fully-paid on account of purchase money, thus leaving 15,000 shares to be subscribed for by the public. The Miriacotta, New Caledonia, Selegama, and Nikakotua tea plantations in Ceylon will be acquired by the company, and the crop for the current year is estimated at 200,000 lb. The price to be paid for the tea estates, together with the machinery, plant, and fixtures, is £22,000, £12,000 being payable in cash and the balance in shares. The vendor has agreed to guarantee a dividend of 6 per cent per annum for a period of seven years.

Interest at the rate of six per cent. Guaranteed for a period of seven years. The Caledonian (Ceylon) Tea Plantations, Limited. Incorporated under the Companies Acts, 1862 to 1890, whereby the liability of the Shareholders is limited to the amount of their subscription. Capital £30,000 divided into 30,000 shares of £1 each. Issue of 25,000 Shares of which 10,000 will be allotted to the Vendor as fully-paid shares on account of purchase money, and 15,000 are now offered for subscription, on which interest at the rate of 6 per cent. per annum is guaranteed by the Vendor for a term of seven years, the balance (5,000 shares) being left in reserve for future working Capital. Payable—5s on application, 5s on allotment, and the balance as required, in calls of not more than 5s. each, with an interval of not less than three months between each call.

Directors:—George W. Paine, Esq. (Chairman Kelani Valley Tea Association, Limited,) Cotswold Lodge, Upper Norwood, Chairman. Bennett Williams, Esq. (Chairman Anglo-Assam Tea Company, Limited) Wildlands, Cottenham Park, Wimbledon. W. Gow, Esq., of Messrs. Gow, Wilson and Stanton, Tea Brokers, 13 Rood Lane. * A. Ross, Esq., Ceylon Planter, St. Kierans, West Norwood, S.E.

Bankers.—The Commercial Bank of Scotland, Limited, 62, Lombard Street. Tea Brokers.—Messrs. Gow, Wilson and Stanton, 13, Rood Lane, E.C.

Solicitors.—Messrs. Jenkins, Baker and Macklin, 134 Fenchurch Street, London, E.O. Secretary (pro tem.)—H. F. Stanley, Esq.,

Auditor.—Henry Richards, Esq., 11, Poultry Chambers, London, E.O. Offices,—11, Old Broad Street, E.O.

PROSPECTUS.

This Company has been formed for the purpose of acquiring and, by the addition of new capital, further developing the following Tea Estates, situate in Ceylon, and known as the Miriacotta, New Caledonia, Selegama, and Nikakotua Tea Plantations.

The Miriacotta and New Caledonia are freehold Plantations, worked as one estate, situate in the Upper Maskeliya district, consisting of 260 acres of tea, 10 acres of grass, and 143 acres of virgia forest, within about 15 miles by Government cart road from the Hatton Station, on the Ceylon Government Railway. There is a large and well-furnished bungalow on the property and ample coolie lines. The tea factory has recently been completed, and is equipped with the most approved machinery, driven by water power of which there is an abundant and constant supply. This property has a most healthy climate, the elevation being from 4,300 ft. to 4,700 ft. above sea level. The rainfall is frequent, though not so heavy or prolonged as in other districts, the annual amount being about 120 in. The lay of land is easy, and the estate is liked by coolies, of whom there is always a sufficient supply.

The Selegama is a freehold estate situate in the Matale West district of Ceylon, 12 miles from the railway station of Matale. The property is on an extensive square slope of the Amboka Peak, at an altitude of about 2,200 ft. to 3,200 ft. above sea level.

* Will join the Board after allotment.

The lay of land is perfect and the property compact. The rainfall is about 100 in. per annum. This estate comprises about 930 acres, including two small and joining properties which are worked with it, and upon which cocoa and cardamoms are grown. At present there are 215 acres under tea, 179 acres virgin forest, and 540 acres chena. There is a bungalow and tea factory upon this estate, also two rollers driven by a water-wheel, there being for the present requirements a sufficient supply of water. More machinery will be required within the next year, as the younger tea comes into fuller bearing and as further extensions are made. There is plenty of coolie labour on the estate, and Sinh less can, if necessary, be had from the surrounding villages.

The Nikakotua is a leasehold estate, held under several long leases, subject to renewal at the option of the Lessee, and is also situate in the Matale district, 1½ mile from the railway station, and is bounded by the Great North and Ratota district cart roads. This estate consists of 197 acres of Chena land, of which 67 acres are now under tea, though not yet in full bearing. The rainfall is well distributed, amounts to 80 in. to 90 in. per annum. The soil is of great strength and richness, and labour is abundant. The tea estates in the immediate vicinity of this property are yielding, according to age of plant, as heavily as any in the island. There is no machinery upon the property at the present time, but as the tea comes into full bearing it is proposed to erect the necessary plant and further to develop the capacities of the estate.

The quantity of tea sold in the London market in 1891 from the above estates amounted in the total to 128,500 lb., at an average price of over 10½d, and as a portion of the tea grown upon these properties is not yet in full bearing it is anticipated that this return without any further extensions by fresh planting will shortly be increased to 210,000 lb. per annum; at the same time the Directors can, if desirable, increase the capacities of these properties by bringing annually a greater number of acres under cultivation.

The following is the total area of the above-named estates, together with the crop of tea which it is anticipated will be produced during the current year:—

	Tea Acres	Forest Acres	Total Acres	Additional Area which can be put under Tea Acres	Crop lb.
Miriacotta, including New Caledonia.....	260	153	413	70	110,000
Selegama.....	215	719	934	400	50,000
Nikakotua.....	67	130	197	130	10,000
	542	1002	1544	600	200,000

The following figures taken from the published list in the supplement of the Ceylon Observer represent the Dividends earned and the present value of the Shares of several Ceylon Tea Companies:—

Name	Capital.	Value of Shs.	Dividend per cent	Present price
The Ceylon Tea Plantations Co., Ltd.....	£200,000	£10	15	£16
Dunkeld Estate Co., Ltd.	R140,000	R500	12	R625
The Scottish Ceylon Tea Co., Ltd.....	£50,000	£10	18	£137/6d
The Yataderia Tea Co., Limited.....	£R190,000	R100	13	R200
The Yataryantota Tea Co., Limited.....	R100,000	R1000	40 paid	57 earned R3000
The Glasgow Estate Co., Limited.....	R200,000	R500	9	R825
The Kelani Valley Tea Association.....	£20,000	£10 (5 pd 10)		R110

The price to be paid to the Vendor for the purchase of the above-named tea estates, with the machinery, plant, fixtures, &c., is £22,000, which is to be satisfied as to £12,000 in cash, and as to £10,000 in fully-paid Shares of the Company.

The Vendor, who will join the Board after allotment, is so satisfied with the value of these estates and the profit to be derived by this Company, that he has agreed to guarantee a dividend of 6 per cent. per annum for a period of seven years.

An estimate, based on the sale by public auction of 200,000 lb. of tea, the anticipated yield for the first year, after making all allowances for expenses in Ceylon and London, should yield a dividend of at least 10 per cent. on the issued capital of the Company which dividend should be materially increased in the course of the next two or three years, as the present area of tea comes into full bearing.

The Directors propose to retain the services of Mr. James Minton, the Managing Agent appointed by Mr. Alexander Ross, who has been in charge of these properties for the past four years.

No promotion money has been or will be paid the Company contracting directly with the present owner of the property, who has agreed to pay all expenses connected with advertising, circulation, and printing this Prospectus. A Contract has been entered into, dated May 16th 1892, and made between Alexander Ross of the one part and a Trustee for and on behalf of the Company of the other part.

All the statements made in this Prospectus are based on information furnished by the Vendor, and it has been agreed that no purchase money shall pass until an independent report has been obtained by the Directors verifying the statements contained in this Prospectus, and as to the validity and soundness of the Vendor's titles. The above Contract and the Memorandum and Articles of Association can be inspected at the Offices of the Company, where all further information can be obtained.

Applications for Shares should be made on the accompanying Form, and forwarded to the Bankers of the Company. Prospectuses and Forms of Application for Shares may be obtained at the Bankers and Offices of the Company. If no allotment is made application money will be returned in full.

Dated May 24th, 1892.

(Financial News, June 21.)

The example set by the directors of the Caledonian (Ceylon) Tea Plantations, Limited, might be followed with advantage in regard to many new companies. The prospectus of the company referred to expressly stipulates that all the statements contained therein shall be duly verified by means of an independent report—which must also testify as to the validity of the vendor's titles—before any part of the purchase-money is handed over.

(Daily Oracle, June 23.)

CEYLON TEA.—The prospectus of the Caledonian (Ceylon) Tea Company, which will be found in our advertising columns, calls attention to the position which Ceylon tea is taking in the markets of the world. One of the most remarkable trade departures of recent years has been the development in the use of Indian and Ceylon tea in the tea-drinking countries of the world. The consumption of tea grown in these parts of the British Empire has had a very serious effect upon the China tea trade, which threatens to develop still further. Year by year the demand for Ceylon tea grows literally by leaps and bounds, and there seems to be no reason why it should not continue to do so. It is expected that the Chicago Exhibition will lend itself to pushing these teas in the United States. The Americans are not tea drinkers to the same extent that the English people are, but still they are very considerable consumers, and there is no reason why they should not be induced to take Ceylon tea much more freely than they do if it be brought before them as it has been brought before the public in this country. With the aid of a grant from Government Ceylon has already subscribed a considerable sum of money towards securing a suitable representation at that exhibition.

CELERY COFFEE is the newest nostrum. It is, according to the prospects—for, of course, its inventor and proprietor wants to form a company—a most pleasant beverage, agreeing with tender

stomachs that reject tea, cocoa, and ordinary coffee. It is also an infallible cure for rheumatism, gout, and other ailments!—*L. and C. Express.*

LABOUR IN BRITISH HONDURAS.—It is not often that Colonial Office reports are brightened up by the faintest glimmer of the personality of the writer. As a rule, they are the merest dry-as-dust collection of statistics, but now and then there is a hint that the weary official who has penned them is after all a man and a brother. The Colonial Secretary for British Honduras has, however, succeeded in imparting a delightful touch of cynicism to one of the questions dealt with in his latest reports on that colony. In British Honduras, as in other tropical and semi-tropical countries, the labour question is both complicated and simplified by the lavish abundance with which nature responded to man's most casual efforts. A handicraftsman in British Honduras can earn something like two dollars for a day's labour, and is not expected to do more than half the work which an English labourer does in the same time. The most efficient bricklayer in Belize, the report states, is an inmate of the lunatic asylum—a fact which moves the Colonial Secretary to make the delightful observation that "no sane day labourer sees any necessity for excessive diligence!"—*Aberdeen Free Press.*

THE TROPICAL AGRICULTURIST MONTHLY.

Vol. XII.

COLOMBO, SEPTEMBER 1ST, 1892.

[No. 3.]

THE LONDON TEA AUCTIONS AND THREE MONTHS' PROMPT.

It is but very few months back that the whole of the London brokers, conjointly with all those other numerous parties who are concerned with the sale of Ceylon tea, bestirred themselves most energetically to secure for the sale of our produce a greater amount of accommodation than had been previously conceded. The attempts then made were successful, and we practically obtained for the sale of Ceylon teas in Mincing Lane twice the time that had hitherto been at our disposal. On this result, we naturally felt, all concerned might well be congratulated. But we are now informed that in practice the advantage anticipated is nullified by a consideration which had not before come into view. This is a somewhat singular one, and certainly one which was scarcely likely to strike outsiders, even if it might have been thought to be probable that it would occur to the minds of those who are daily engaged with the selling and purchase of tea. It appears that owing to the custom of the trade, now a long established one, the date from settlement of accounts is always made to reckon from a Saturday, three months from that day of the week being calculated as the period over which credit is taken. As is known to all, the Ceylon tea sales take place now on every Tuesday and Thursday in each week; and for some reason unknown to us, but presumably because accounts cannot be made up in time, the sales effected on the second of those days are not included in the returns made up on the succeeding Saturday. The consequence is that moneys due for purchases made on the Thursday do not reckon for their three months prompt until the Saturday week; and as the result to this on every sale effected at Thursdays' auctions there is the loss of a week's interest. It would not at first sight seem that this loss would be sufficiently serious in amount to warrant the assumption that Tuesdays are selected in preference to Thursdays for offering teas for sale in consequence of it. And yet it may possibly be that the delay of a week in settlement may be of some considerable importance to sellers who have a large amount of tea in the market. At all events we are assured that this cause is operat-

ing to nullify the advantages of late secured by the multiplication of the days available for the sale of Ceylon teas. Tuesday's lists are still almost overcrowded, while those of Thursday are nearly barren of offerings. The result is that we are almost where we were before the change in system was made, and that time is deficient for the due and proper examination and tasting of the many samples submitted in connection with the sales of Tuesday. It is evident from this fact that some further change of arrangement must be needed in order to enable us to fully reap the advantages to secure which such strenuous efforts were lately successfully made. We have suggested that it seems unlikely that the amount of loss due to a week's delay in settlement could have had such a result. But there is the fact and it cannot be set aside. Something must be done to overcome the difficulty, and we should think it ought not to be insuperable. Surely Friday and Saturday—the latter, however, a short half-day in all business at home—should afford ample time for the registration of claims upon the three months' list. If it is not, some means must be found to simplify existing procedure, and we do not doubt that the subject will receive the fullest consideration by the Tea Committee of the Ceylon Association in London, and that some means of full relief will be suggested and obtained by it.

FROM THE METROPOLIS.

LONDON, July 1st,

A DEPRESSED TEA MARKET

in Mincing Lane is not good news to send to Ceylon. I was in the Lane and round the City on several business calls on Tuesday and heard nothing encouraging about tea prices—brokers had not even got their valuations, and the prospect was a large importation of good China teas at moderate prices. I must leave others to judge how far this increased business in "Chinas" is due to the anticipation so eagerly insisted on both in Ceylon and the City, in certain quarters, that our tea exports for 1892 were only to be a very little in excess of those in 1891. Of course, if such prove to be the case, there is no more to be said than to give credit for sagacity and correct information in the quarters referred to, but if (with the monthly export latterly exceeding 7 million lb.) it proves that the total outturn approaches to (if it does not exceed) 80 million lb., then it will appear to have been a great pity, to say the least, that a cry of "exaggerated estimates" had been raised, encouraging English buyers to go more freely into "Chinas."

Notwithstanding this fact, however, and the 16-

cont banking troubles, there seems to be very ready support extended to our new

TEA PLANTATION COMPANIES.

I was in a Broker's office in Mincing Lane one day this week, when a business man called, who had not long ago a large connection with China tea, to signify rather considerable investments of himself and friends in shares of the "Asiatic Produce Company" and the "Caledonian (Ceylon) Tea Estates Company." Referring to the latter here is an editorial notice from a City journal which shows how well the Company is thought of:—

SOME NEW ISSUES.

During the past ten days there has been a wild rush for a little of that money which the prudent spectator has been hoarding up for use at the first convenient opportunity. It would be difficult to say whether he has merely nibbled at the baits which have been dangled before his eyes, or has gulped them down in a wholesale fashion, but it is not so difficult to conjecture that in one or two instances he will regret having adopted the latter alternative. The ventures that have been offered to him lately have been of a mixed description, and the promising and unpromising have been about equally divided. Some half-dozen concerns have been thrown on the market since last week, and one of the best of them is the Caledonia (Ceylon) Tea Plantations, Limited, whose promoters ask for 30,000*l.* in order that they may acquire certain tea plantations in Ceylon.

There are a good many recommendations possessed by this prospectus that are rarely to be met with. In the first place, the Corporation will acquire something which is of distinct value in itself, and which is even now of an exceedingly remunerative character. Another consideration is that although there is considerable competition in this particular market for tea, yet the planters appear to be able to keep up prices. Of seven Ceylon tea companies that have been in active operation during a considerable period one has paid its shareholders 18 per cent., another 15 per cent., a third 13 per cent., a fourth 12 per cent., and a fifth 10 per cent. If the old adage which tells that the "proof of the pudding is in the eating of it" goes for anything, these figures are full of meaning. The promoters have striven very hard to be fair, and appear to have succeeded to a larger degree than is usually the case with the fraternity. But if anything more were needed to induce the belief that this company is floated under the most favourable auspices, and with every prospect of being successful, it is surely to be found in the desire of the vendor to guarantee a dividend of 6 per cent. for a period of seven years.

I fancy the prospectus of the former (the "Asiatic") Company has already reached you; but to make sure I now send one. You will observe it has been constituted mainly to take over the Rakwana estates—Springwood, Barra and Rennevettenne—of the family of our old friend Mr. Shand, and the leading spirit in this promotion, as in several other very important directions connected with the development of our tea enterprise, is Mr. Hamilton A. Hancock, who, with his brothers constituting the well-known Mincing Lane Firm of Messrs. Hancock Brothers & Co., has had a very long connection and the highest reputation in the China and Indian Tea trade, before taking up Ceylon. Mr. Hancock's connection with several of our Tea Companies of late years, however, has been of very special service, in my opinion, to the colony and our staple enterprise, and I sincerely hope, as I believe, that success may crown the enterprise and business of them all. In Rakwana district I need scarcely say the Lauderdale Company is very closely identified, and if, as is not improbable, there may be an amalgamation here with the "Asiatic," and perhaps further purchases of properties made, the greater part of the

district would be held by the one proprietary Company, and local management so concentrated that efficiency and economy could not fail to be promoted. Besides, Mr. H. A. Hancock—a host in himself (and school-fellow and friend by the way of the Messrs. Fenn, Church Missionaries, so well-known in Madras and Ceylon)—there are on the Board of the "Asiatic," such well-known men as Mr. V. Hugh Smith (of the Bank of England), Mr. R. H. Letchford, and more recently there has joined Mr. Meares, of Meares, Absalom & Co., who have a very extensive tea selling connection throughout the United Kingdom. In connection with the transfer to the Company of Springwood and Barra estates, I understand that Mr. J. A. Maitland, the energetic Manager of Lauderdale, is to be moved and placed in charge of the "Asiatic's" properties; Mr. Low, his competent assistant, probably succeeding Mr. Maitland at Lauderdale.

You have already learned (I see by last *Overland Observer*) about Mr. Hancock's proposal to secure the bulking of

SMALL BREAKS OF CEYLON TEA

at this end, an arrangement which, if carried out, may mean a good deal more money into the pockets of some Ceylon planters and also greater facilities for pushing on teas into the Russian and other new markets. A great objection at present is the difficulty of getting big enough breaks of suitable Ceylon teas to tempt big dealers, and few firms have had the experience, or are likely to have better opportunities of reaching Russia than the Messrs. Hancock.

In this connection I have neglected to refer to what I learned from Mr. Rutherford during a recent call about the new

STEEL PLATE TEA-BOX, THE ACME,

prepared by certain practical Glasgow working mechanics who have started a firm to manufacture them, as an improvement on Mr. Andrews' invention in the same direction. Strangely enough, Mr. Andrews, whose name has so long been connected with this and other work connected with tea, had just died—a sudden illness from exposure. Mr. Rutherford thought so well of this latest tea-box that his Company has given an order for a considerable number (some thousands) to make a full and fair trial, the result of which cannot fail to be looked for with much interest by tea planters generally. The prices, I think, were given at 2s 6d and 3s 3d with the present low exchange: this means a considerable difference on the wooden and lead boxes unless decided advantages are secured by the use of the "Acme." By the way, is there no chance of getting neat and cheap tea boxes from Ohina for use in Ceylon—"John Chinaman" might be pleased to learn that though we mean to cut down his tea, we can offer a market for his boxes!

I was very gratified to learn how fully Mr. Rutherford agreed with the argument, and contents generally of

MY TEA LETTERS

to the *Financial News*. He found fault, as many Ceylon men do, with Mr. T. C. Owen's qualifications. Messrs. Rutherford and Talbot had some very valuable experience in connection with the older estates of their Company,—notably Dunedin, now our 14 years old—in showing that Ceylon tea has not deteriorated, and that in fact younger plantations better planted perhaps and with virgin soil, have never got the prices of the earlier years, simply because of the general fall in tea values. The standard for the general quality of tea tea is now much higher—in fact the taste of the public (as well as of the experts?) has been educated and improved greatly

of late years. Mr. Rutherford mentioned that he has been surprised to find how well the value of the Kalutara District teas has kept up—this district generally, he thinks, beats Kelani Valley in prices.

THE FOOCHOW TEA TRADE.

From Foochow we have the following tea news under date the 11th instant:—The export to Europe is 59,000 lb. against 38,000 lb. at the same date last year. It consists of small quantities, chiefly Paklings sent to Hongkong for transhipment to the mail steamers. The "Nestor" will be leaving tomorrow with $\frac{3}{4}$ of a million of lbs.—Musters of the New Season's crop were first shown on the 26th ultimo and the opening of the market took place on the 6th instant. Some 12,000 boxes Pakling had previously been settled and also Flowery Pekoes to some extent, but the opening is not considered to have taken place until first purchases of the staple of the port have been made, that is, of Panyong district teas: of which a purchase of 1,500 half-chests was made in a line on the 6th instant, at Tls. 19 to 25, the price being about 15 per cent lower than that at the opening of last year.—The quality of the crop, as a whole is not equal to that of last season in point of make or in fineness in the cup, but what is wanting in these respects is fully made up for by improved strength in teas from most of the districts. This applies specially to Paklings, Panyongs, Saryuons and Tong Fong Tongs. Of the Yung Hows, a few of the head chops are as good as last year, but the bulk of the crop is inferior and the same must be said of the Suey Kuts. The Soomos have certainly the merit of being strong and some of the best teas are thick, but there is an absence of quality in them. Kein Yong appears to have ceased to produce tea. The Sou-chong crop is disappointing, and yet a few chops which stand out are distinctly fine. The Flowery Pekoes compare fairly with last year's crop excepting that there are not the chops of extra choicest quality as in 1891—Prices paid for the best chops of Congou are with few exceptions about 15 per cent under last year. If all the medium quality settled does not show this decline this week, it is sure to next. When added to a general decline in the rate price of 10 to 15 per cent, a fall of 3d in exchange is added, it must be admitted that buyers are acting on comparatively favourable terms.—The first crop according to the tea-men's account, will be limited to 190,000 chests.—That would be 30,000 chests less than last year, but, of course, these statements must be listened to with great caution. The arrivals of Congou to date are 120,000 chests against 168,000 chests at the same date last year. The shortness is accounted for by a freshet on the river having detained some of the boats.—The settlements to date 20,000 chests against 18,000 chests last year.—The Stock is 99,000 chests against 149,000 on the same date last year.—Exchange is 2s 11 $\frac{3}{4}$ d for 4 months' sight credits, and Freight £2 per ton of 40 cubic feet.—*N.-C. Herald*, June 24th.

An eye-witness reports a huge crowd of boats, laden with tea, anchored just above the rapid, detained by the freshet on the river. With the fine weather of the past two or three days and the subsidence of the water, the addition to the stock of tea next week will be very considerable.—*Foochow Echo*, June 11th.

Owing to the continuous rain a total failure of the Mooklee crop is reported. If this proves to be correct, the loss will not only be severely felt by the growers, but by the manufacturers of scented tea and the Tientsin snuff men.

We hear that some of the tea-men who suffered heavily from losses on their ventures last year have done so well this that they are retiring from the trade altogether. This is a wise step, no doubt, and they will not be missed. In spite of a clearance last year we understand that there are far too many still left, as shown by a competition upcountry that was quite unexpected.—*Foochow Echo*, June 18th.

THE ASIATIC PRODUCE COMPANY, LIMITED.

CAPITAL, £25,000 IN 5,000 SHARES OF £5 EACH.

DIRECTORS:

Hamilton A. Hancock, of Messrs. Hancock Brothers & Co., 28, Mincing Lane, E.O.

Vivian Hugh Smith, 71, Princes Gate, S. W., and Hay's Wharf, S. E.

Robert H. Letchford, 2, Lime Street Square, E. O., of the late firm of Messrs. Harvey Brothers & Letchford, 21, Mincing Lane, E. O. (Managing Director).

PROSPECTUS.

This Company has, as will be seen from the Memorandum of Association annexed, been formed for the purpose of acquiring Tea and other Estates in Ceylon, and elsewhere, of working the same, and dealing generally in and with Eastern produce.

The Company has entered into a contract for the purchase of three Freehold Estates, Springwood, Barra and Rangweltenne, situate in Rakwana in the Island of Ceylon, within 90 miles of Colombo, and the Directors have agreed to accept conveyances of the several Estates as the titles are proved. The elevation of the Estates varies from 1,500 to 2,800 feet. The total area is 1,557 acres, of which 650 are already planted with Tea. Of the land not under Tea about 500 acres are suitable for planting.

The consideration for the sale of the Estates, as expressed in the above contract, including all buildings, machinery, and implements, is £23,500, payable—as to £15,000, in 5 per cent. Debentures, repayable at par as follows, viz: £5,000 in 10 years, £5,000 in 13 years, £5,000 in 16 years, or previously, at the Company's option; as to £4,000, in Ordinary Shares: and as to £4,500, in cash.

The Titles to two of the estates, namely Springwood and Barra, have been proved to the satisfaction of the Company's Legal Advisers in Ceylon, but the Title to Rangweltenne still remains to be proved. Under these circumstances the Directors have arranged with the Vendors forthwith to complete the purchase and to obtain possession of Springwood and Barra, amounting together to 1,150 acres or thereabouts, on a *pro rata* basis price per acre, leaving the purchase of Rangweltenne for the present in abeyance until the existing difficulties connected with its title have been removed. Upon the purchase, which is now on the eve of completion of the Springwood and Barra Estates, the apportioned sum of £17,500, part of the original purchase money or sum of £23,500 will be payable as follows, that is to say: as to £11,200 in £5 per cent. Debentures (repayable at par as follows, viz: £3,800 in 10 years, £3,700 in 13 years, and £3,700 in 16 years, or previously at the Company's option) as to £3,000 in Ordinary Shares, and as to £3,300 in cash. The balance of the original purchase-money, viz: £6,000 will be retained until the purchase of Rangweltenne can be effected. The Directors hope to arrange with the Vendors for the purchase on reasonable terms from them, of the Green Leaf off the Rangweltenne estate, so that the estimates as to output given in this prospectus, may not be affected by the Company being temporarily unable to acquire the legal possession of this estate.

The Tea Leaf from the three Estates is manufactured at the Factory on Barra. The production for the past year has exceeded 270,000 lb. manufactured Tea; and it is anticipated that 330,000 lb. will be produced when the Tea at present planted is in full bearing.

The estates are provided with machinery and buildings, but it is expected that an outlay of £2,000 will be necessary to render the factory thoroughly efficient and capable of dealing with the entire output, and of improving the quality of the tea made. This expenditure has been allowed for in the present issue of capital.

The foregoing particulars have been furnished by the vendors, and are believed to be accurate, but the terms of purchase provide that the acreage is to be verified by a Surveyor, acting on behalf of both parties and should the area under tea prove be less or more than herein stated the purchase money to be reduced

or increased as the case may be, at the rate of £25 per acre. The cost of the survey will be defrayed by the Vendors and the Company in equal proportion.

The Directors estimate that the output of tea from the three estates should alone yield a gross profit of at least £2,500, and save as to the Managing Director's salary, and a fixed annual fee of £50 for each Director, the Directors have made their remuneration subject to the profits available for dividend on the ordinary shares exceeding 10 per cent. Of any profits in excess of 10 per cent the Directors will be entitled to one-fifth.

In estimating the above profit the Directors have based their calculations on the present production of tea at prices under those now ruling. This production, as already pointed out may be expected to increase very materially. The Directors, moreover, hope shortly to arrange for the acquisition of further estates on advantageous terms.

In the present issue of capital the Directors believe that they have made ample provisions for working expenses and improvements.

The only Contract entered into is one bearing date the 10th March, 1891, but executed after the incorporation of the Company, and made between Charles Shand, Charles Edward Hood Symons and Francis Shand Robertson, and the Company for the sale and purchase of the three above-mentioned Estates. It may be inspected at the Offices of the Company's Solicitors.

Application for Shares must be made in the enclosed form, and where no allotment is made the deposit will be returned in full.

Prospectuses and forms of application for Shares may be obtained at the Registered Offices of the Company, 2, Lime Street Square, E. C.

London, 1st June 1892.

COCOA.

One of the best advertisements that an article of popular consumption can have is a mention in the Budget. Mr. Goschen's reference to cocoa two or three years ago sent the sale of that commodity up by leaps and bounds, and his eulogy of British-grown tea in last year's financial statement, according to a leading firm in Mincing-lane who have just published a review of the tea trade for the year has, had a like effect on the Indian and Ceylon trade. Coupled with the reduction of duty it gave a stimulus to the sales, which is seen in a striking way in the statistics of the year. During the twelve months ending the 31st May there were $7\frac{1}{2}$ million pounds more of Indian, $18\frac{1}{2}$ millions more of Ceylon, and $13\frac{1}{2}$ millions less of Chinese tea imported, while there was a considerable increase in the re-exports abroad, probably due to the same causes. It is hardly to be wondered at, therefore, that the Chancellor of the Exchequer's name stands at the present time very high in Mincing-lane.—*Radical Review*, June 21st.

CEYLON ESTATES INVESTMENT ASSOCIATION.

ANNUAL MEETING.

The eighth ordinary general meeting of the Ceylon Estates Investment Association (Limited) was held within the company's offices, West George Street, today—Mr. J. B. Macbrayne presiding. The chairman, in moving the adoption of the report (which has already been published), mentioned that they had expended £2,431 10s 3d, in addition to the factories and on new machinery. This expenditure was absolutely necessary, on account of the increasing tea crop. They would have liked to show a larger profit; but taking all things into consideration, the result was very satisfactory. The out-turn of tea had been 224,000 lb. or an increase of 20 per cent. over the previous year. Owing, however, to the low state of the

market, the prices realised had been lower than last year. The prospects for the coming year were encouraging, the tea crop being 15,000 lb. over last year's crop. A dividend of $7\frac{1}{2}$ per cent. was proposed.

Mr. H. G. Crum seconded, and the report was adopted.

Rev. Dr. Grant and Mr. Robert King were reappointed directors, and Mr. A. Moore, c. a., was reappointed auditor.

This was all the business.—*Glasgow Evening Mail*.

NOTES ON PRODUCE AND FINANCE.

INDIAN TEA AND THE CHICAGO EXHIBITION.—The sleepiness of the Indian Government in, at the last hour, only consenting to lend official aid to the tea industry, in order that it may be represented at Chicago, is thus commented on in *The Times* of Tuesday. It says:—"The representatives of the Indian tea industry seem to have at length awakened to the necessity of opening out new markets for the enormously increased tea crop of India. Recent telegrams intimate that ten leading Calcutta firms have subscribed a thousand rupees each towards the fund for scouring a proper exhibit of Indian teas at the Chicago Exhibition; that Indian tea plantations with an aggregate area of about 100,000 acres have accepted the proposal of a voluntary cess for the same purpose; and that the Government of India has tardily consented to give some aid. The action of the Government of India in this respect has been alike feeble and dilatory. India is at present the country in the world which is making the most important start in new industries and productions. Yet it is the country in the world, if we exclude uncivilised and self-isolating regions, which will be most poorly represented at the World's Fair in America. It is estimated that the sums officially allocated from various sources by France and Germany to secure an adequate representation of their national industries aggregate £300,000. England has appointed a Royal Commission with a Parliamentary grant of £60,000 for the same end; and even in little colonies like Ceylon the local Government has recognised the importance of the opportunity and is stated to have contributed £60,000 for the exhibits of the island products. The Government of India, with infinitely greater interests at stake, has not only failed to appreciate the opportunity, but it has stolidly refused the offers made to it."

THE SPREAD OF TEA AGENCIES.—One effect of the great increase in the tea-drinking habits of the nation, and the consequent increasing consumption of tea, is to be seen in the extension of tea dealing or "dabbling" in tea. We allude to retail transactions all over the country. Besides the vast number of grocers and tea dealers everywhere, there are a host of tea agents and travellers who are paid to sell some special blend or garden tea, and, in addition to these, there are numerous small agents, postmen and others, who eke out a slender income by taking orders for tea when they can get a chance. Thus a large trade in tea is transacted outside the recognised media, such as the grocer, confectioner, and chemist, and it is to those as well as to the shopkeepers, that the teas of Ceylon especially owe some of their popularity. The spread of tea agencies is a good thing for the tea planter. It makes him less dependent on the grocer. Whether the consumer benefits by the introduction in some instances of unskilled labour, and the connection of blends of tea by others than expert hands, is a matter open to more doubt.

NATAL TEA.—As mentioned last week, some 118 packages of common quality Natal tea in small breaks was offered in Mincing Lane. The Pekoe fetched $5\frac{1}{2}$ d to $6\frac{1}{2}$ d, Broken Pekoe $4\frac{1}{2}$ d, and Pekoe Souchong 4 d to $4\frac{1}{2}$ d. Tea planting has not yet become very popular in Natal, but, should the output increase, the South African demand would, we imagine, be quite sufficient to cover a reasonable production. Natal is not likely to prove a rival to Indian and Ceylon in Mincing Lane so far as tea is concerned.—*H. and C. Mail*, July 1st.

"MIXING" INDIAN TEA.

Adulteration was once called by Mr. John Bright "a form of competition," and a necessary concomitant of English trade. We are familiar with the chicory mixture, which some people prefer to pure coffee; but the articles that are tampered with by the retailer are legion. The adulteration of tea has long been suspected, and in some cases the Inland Revenue analysts have found English sloe-leaves in Indian tea, suggesting a distribution and confusion of plants that would puzzle Linnæus himself. The newest ingredient, however, calls up mixed feelings. England has hitherto got all its tea from abroad; but now, according to a medical contemporary, it is to have native tea. "Some of the Kent people," it declares, "have made up their mind that hops, which make such capital beer, will make equally excellent tea. They are hard at work now elaborating a process of converting hops into fresh tea-leaves. The object of this is not merely to give us an entirely new tea, but to furnish us with an article which will alter both the flavour and the quality of the tea we have now in use. Hop tea alone is not particularly agreeable to the unsophisticated palate, but neither is beer or stout; and yet the majority of English people gradually acquire a very keen relish for well-brewed beer. Why should they not also learn to appreciate the flavour of hop tea? If need alone, the taste of the infusion could easily be modified by the addition of cream, or sugar, or other substance. But the idea of the Kent hop-growers seems to be to use the hop as a qualifier and improver of the common Indian and China teas. A Maidstone correspondent declares that this new outlet for Kentish produce is well-known in the District.

The hops are brought from the farmers, green as they are picked. They are then laid for a few hours to wither, after which they are put under a rolling apparatus, which in half-an-hour makes them look like tea leaves both in shape and colour. Afterwards they are passed through an Indian drying machine. They are then sent to London where they are mixed with Indian and Ceylon teas, and retailed at two-and-sixpence a pound. As the buyers give the farmers from fourpence to sixpence a pound for the green hops the margin of profit is respectable. Hop tea is a novelty that appeals alike to the toper and the teetotaler. Tea, the produce of the Chinese or Indian plant, has been denounced as a beverage by some medical men. It is said to affect the nerves, to injure the digestion, to destroy the coats of the stomach, and to give many men and women sleepless nights. On the other hand, it has formed part of the Laræ and Penates of Englishwomen for many generations. The man who always comes home to tea has been held up to admiration, in striking contrast to the degraded being who preferred his boon companions at the public-house to the pleasant presence of his wife porning out "the cup that cheers, but does not inebriate." Will hop tea suffice to draw the husband to the hearth again? Will he consider it a kind of beer and relish it accordingly? It is said, and we believe with truth, that the makers of all the temperance drinks infuse into them a small percentage of alcohol, just to give them a relish. Hop-leaves are not alcohol, but they will give to the homely cup of tea a quality that has hitherto never belonged to it. Whatever tea is, bad or good, it does not tend to repose. It makes many people over-wakeful, and is taken in gigantic doses by young students reading for examinations. Hops, however, are distinctly narcotic. The soporific effect of a hop-pillow is an article of faith with many persons; it was said to have given George III. sleep when all drugs failed. Now, will the hop tea from Kent be really a soothing beverage? At present no substitute for a cup of tea has been discovered, and its utility for afternoon gatherings has given it a new vogue. Still, doctors object to its after effect on weak nerves, although they admit its relieving and refreshing results for the time. Perhaps the hop tea, or tea made from a mixture of the Kentish

and Indian plants, will combine the refreshment of the one herb with the sleep-giving effect of the other. Perhaps a lady, coming late from the ball, will take her cup of tea as a sleeping draught, and find in it not only refreshment, but repose. It may be said that wearers of the blue ribbon will object to this srtful adulteration, and demand their Oriental beverage pure and free from Kentish admixture. The question of intoxicants, however, is not at all raised. Hops mixed with malt and fermented constitute one of the ingredients of beer; but hop-leaves are in themselves as harmless as grapes, which, before they are made into wine, may be consumed by the strictest teetotaler.

There is, however, one consideration not yet mentioned. Hop tea may, or may not, be an improvement on the Oriental drink, but why should it not be openly sold as such? When we ask for butter we do not like to get margarine. Chicory in our coffee must be proclaimed. Publicans are punished for "craftily qualifying" their spirits and ales. If a thing is sold as all wool or all silk it should not be in part alpaca or cotton. Why then, should Indian or China tea be sold at two-and-sixpence, if it is half made up of Kentish hops purchased at sixpence a pound? Are English tea merchants bent on doing good by stealth—bringing sleep to weary eyelids—and would they blush to find it fame? Perhaps the Inland Revenue will look to it. The Chancellor of the Exchequer levies a duty on tea, but if the merchant sells as tea what is half hops from Kent the revenue will suffer in proportion. It is curious that the revelations on this subject always indicate that the hop-leaves are mixed with the Indian, not with the Chinese, plant. The explanation may be the superior strength of the Indian herb; also that as far as adulteration is concerned, the Chinese are masters of it, and leave nothing to be done by English impostors. Perhaps our medical men will kindly tell us what would be the effect of hop tea largely taken. Would it be a beverage to soothe as well as to refresh? As to information from those engaged in the English trade we cannot expect it. They will all deny the soft impeachment; for though hop-leaves are undoubtedly despatched from Kent to be mixed with Indian tea-leaves in London, their exact destination is a mystery which no detective has yet founl out. Drinkers of Indian tea should probe the mystery, for they mayall be taking hop tea without being any the wiser. Indian tea has had many enemies to contend against, and it will be strange, indeed, if the latest is to be the Kentish farmer.—*Englishman.*

HIGH RANGE, NORTH TRAVANCORE.

(FROM OUR OWN CORRESPONDENT.)

June 23rd, 1892.

The proceedings of the Travancore Planters' Association for the year 1891-92 has only just reached us. It is a record of much useful work done, and contains a great deal of interesting information. The Travancore Government have been liberal in granting money for roads, and R18,000 has been sanctioned for 18 miles of roads connecting different estates with each other, and with the main road. The Sircar is taking steps for getting abandoned estates back into their own hands, by imposing a tax on land, which in case of non-payment will be attached in satisfaction of arrears.

It seems a great pity that the proposals of the South Mysore Association with regard to combination among planters seems to have fallen through altogether. Who was it that refused support? Everyone to whom one talks seems eager to see combination effected, and yet we are told the scheme falls through for want of support. The question of the registration of maistries seems likely to be allowed to slide in the same way. At present, as far as I can gather, we are to wait until we can see the result of a similar measure which is in force in Mysore. At the end of February, there was a balance in hand of R464-6-0, which is better than last year

by nearly 100. I am glad to see some steps taken towards preventing the annihilation of game. The Siroar is to be addressed by the Honorary Secretary on the subject, and let us hope we shall shortly have a good game law for Travancore.

Mr. Fraser put in a very valuable record of Travancore tea averages, the figures being taken mostly from Messrs. Gow, Wilson and Stanton's weekly reports. I gave it in full:—

	lb.	d.
Arnakal	59,200	10
Poonmudi	66,750	9½
Bon Ami	105,850	9¼
Seafeld	59,280	9
Kadwa Kurnam	83,400	9
Nagamallay	61,700	8¾
Isfeld	68,400	8¾
Venture	62,650	8½
Penshurst	53,300	8½
T. P. C.	78,600	8¼

The above have all sent over 50,000 lb. 20,000 to 50,000 lb.

	lb.	d.
Fairfield	28,700	9½
Glen Mary	29,900	9¼
Glen More	20,300	9
Vembeward	35,700	9
Braemore	30,700	9
Glen Brittle	22,700	9
Corrimony	28,200	9
Parvithi	43,300	9
Bon Accord	25,650	8½
Invernettie	35,250	8½
Anamudi	37,350	8¼
Seenikali	35,950	8¼
Linwood	22,850	8
Rockwood	29,200	7¾
Monnt	29,200	7¾

Under 20,000 lb.

Kinmylies	19,650	9½
Comorin	17,750	9¼
B. K. W.	1,650	9¼
Glenrock	6,100	9
Balamore	11,150	9
Great Valley	3,800	9
Home	11,150	8¾
Brighton	12,400	8¾
Hope	8,300	8¼
Moercauld	18,900	8¼
Bison Valley	5,900	8
Beiford	13,300	7¾
Ashley	14,600	7¾
Springfield	1,200	7
Ferrintoria	10,900	6¾
Maimulla	19,950	6¾
T. L.	3,900	6¾

The above shows that, as a rule, estates which send most tea send also the best tea, probably because they also have the best machinery.

The Travancore Agricultural Exhibition for 1892 is to be held at Trivandrum in August. Prizes are offered for Live Stock, Field Produce, Garden Produce, Plantation and Special Produce, Forest Produce, Dairy Produce, Manufactures, Machines, Implements and Tools. The prizes amount altogether to Rs.781.

Two of the estates belonging to the North Travancore Land Planting and Agricultural Society (Ld.) have recently changed hands. One of them is to be converted from cinchona to coffee, the other being too high in elevation for such a change.

Our monsoon has so far, been conspicuous by its absence. Hot sunshine has been the rule for the past fortnight, and unless it quickly changes, we will all suffer. The new clearings are all waiting to be planted, but as the rain holds off, planting has to be postponed. Those who thought we were in for an early monsoon and trusted to the few days' rain we had at the beginning of this month, find that the plants then put out had to be heavily shaded; even the shading, however will not save them unless the ground gets a little moisture into it. In the meantime the price of rice keeps on increasing, and last year's tale of 5 measures for the rupee is quickly coming round again.—*Madras Times*, June 30th.

BARK AND DRUG REPORT.

(From the *Chemist and Druggist*.)

London, June 30.

CINCHONA.—The auctions on Tuesday were neither largely attended nor was the supply of bark quite up to the average, but it is seldom that one sees bidding so brisk and purchases so full as they were then. In consequence, some of the selling brokers exhibited a cheerful tone, and while some reckoned that the unit was a shade better, the general feeling was that it had advanced an eighth of a penny. The maximum touched was a unit of 1¼d. The total quantity of bark offered was 302,078 lb., and of this 283,253 lb. were disposed of publicly, but there were understandings between sellers and bidders regarding the balance of 18,820 lb. The bark originated as follows:—

	838 of which	838 were sold
East Indian cinchona	62	64
Ceylon cinchona	285	220
Cuprea bark	216	206
South American cinchona	65	65
Java cinchona		

Total ... 2,076 do 1,993 do

CINNAMON.—The market is decidedly firmer, and good business has been done this week at the following rates:—Seconds, 6½d; unworked thirds, 6¼d; and fourths, 5¾d. Higher rates are at present ruling at Colombo.

TEA LEAVES.

The above is the title of an interesting illustrated volume, made up of letters and documents relating to the shipment of tea to the America colonies in the year 1773, by the East India Tea Co., now first printed from the original manuscript, with an introduction, notes, and biographical notices of the Boston tea party by Francis S. Drake.

These letters and documents of 1773, relating to the colonial difficulties of this period, having recently been found, give important information on the subject of the East India Tea Co.'s troubles in trying to introduce their tea into America, this portion of the book making 200 broad pages of printed matter. In addition to this, the work contains 100 pages of history and 100 pages of biographical notices or sketches of the tea party, making altogether a volume of about 400 small quarto pages. The book is printed in large, clear type on heavy book paper, and bound in cloth, with an illustrated cover.

The names of 112 of the members of the famous tea party are given; also twenty portraits, thirteen being original and taken from oil paintings never before copied. There are also eight miscellaneous illustrations, several reproducing famous old prints, such as "Lord North forcing tea down the throat of America," "plan of Boston in 1775," "Destruction of tea in Boston harbor."—*American Grocer*.

WHAT IS GOOD TEA?

When Americans go to England they complain that they cannot get a cup of good tea. When Englishmen come here, they make the same complaint. The truth is, the tastes of the two nations have been educated in totally different directions, and there is nothing more tenacious or harder to change than the opinions of our palate.

Certain Ceylon tea planters are just now engaged in informing the people of the United States that China and Japan teas are unfit to drink, and that Ceylon and India teas, produced by English tea planters, are the only truly pure and palatable teas produced.

Some of their advertisements take the palm for unadulterated cheek and gall, not to say downright lying, and they well illustrate the commercial pugnacity of the English nation.

While the public taste in the United States has undergone some changes in its appreciation of tea, notably from China greens to pan and basket-fired Japans, yet it is very far removed from the English idea of what constitutes a good cup of tea.

While persistent advertising and pushing may, in some degree, increase the consumption of Congou or Souchong sorts, Oolongs and Japans are likely to continue the favorites in this country, the romance

of advertising notwithstanding to the contrary. The talk about the "iron in the soil" of Ceylon and India making their teas more wholesome, may deceive John Bull, but Uncle Sam is too wide-awake to swallow such argument, or, indeed, tea which requires such "rot" as this to get people to use it.—*American Grocer.*

[Virulent talk like this is unworthy of the *American Grocer*. Taste which has changed can be changed again; and the chief advertiser of Ceylon teas is an American, Mr. Elwood May. The dealers in China and Japan teas are evidently getting alarmed.—ED. T.d.]

OIL-ENGINES AS MOTORS FOR ELECTRIC LIGHTING.

A great deal of attention is being paid by the power users of the world to the possibilities which lie before petroleum.

Petroleum, it is well-known exists in vast quantities in many parts of the world. The supply in South Russia appears to be inexhaustible, in America and other places there would seem to be stores of it sufficient for all wants for many years. Many people have thought that if at some future date the supply of coal should run short, that it is in petroleum, we should find our most convenient substitute. Owing to the increasing number of applications to which it may be put, the demand in the past few years has increased enormously, and there are now a whole fleet of specially constructed steamers engaged in the trade of carrying it in bulk from one place to another.

These facilities for cheap transport have resulted in the cost of the substance being reduced to about fourpence per gallon, and further reductions are talked about.

A few weeks ago a process was shewn in London, by means of which cheap qualities of the oil may, by the addition of some easily prepared chemical be solidified, and these blocks may be transported about from one place to another like coal, burning with very little ash, and forming a very convenient and cheap form of fuel. It is stated that only about 5 to 7 per cent of the oil is wasted, so that if the process can be as successfully carried out in practice as the experiments already made seem to indicate, it would appear certain that such a fuel would be extensively adopted in many parts where coal is too expensive to be freely used.

But by far the most important of its present uses is that of direct power development in an internal combustion engine.

These have been obtainable for some few years, but it is only lately that they have been perfected and manufactured in sufficient numbers to be recommended for electric lighting work. There seems now, however, to be little doubt that they may be thoroughly relied upon for dynamo-driving, &c., in places where a steam-engine and boiler would be inconvenient, and gas for a gas-engine is unobtainable.

They have also advantages in the question of cost, for we find Sir James Douglass, F.R.S. in a recent discussion at the Institute of Mechanical Engineers stating that, after an experience of over twelve months with a "Priestman" oil-engine, he found that it was cheaper than a gas-engine at the ordinary prices charged for coal-gas in England. He thought that oil certainly was coming to the front.

Messrs. Priestman Bros., Ltd., of Hull, London and Glasgow, have been one of the chief pioneers in the perfecting of petroleum motors. They have spent years in experimental work, and have now succeeded in producing a thoroughly reliable engine, deriving its power from ordinary mineral oil.

As a proof of how important this invention is considered, we may mention that a recent meeting of the Institution of Civil Engineers was occupied with the reading of a paper by Prof. W. C. Unwin, F.R.S., M.I.C.E., describing various experiments he had made, and tests to which he had subjected the "Priestman" oil-engine. He stated that this engine was the only one deriving its power from oil which had stood the

test of practical working in the hands of various users of power. The tests showed that the engine worked with a very high thermo-dynamic efficiency and economy. On all occasions, when he had been using the engine he had been able to start it without any difficulty.

We find that nearly one hundred engines of various sizes from one to twenty-five effective horsepower are already in use for driving dynamos in various parts of the world. Owing to its compactness and the fact that it is perfectly self-contained, and that there is no need to erect steam-boilers or anything of that description, it is especially suitable for isolated installations. There are also several hundreds used for other purposes, such as pumping, sawing, air-compressing, and a large variety of purposes connected with various engineering, manufacturing, and agricultural appliances.

Our illustrations Figs. 1 and 2 show the "Priestman" engine, the first in the field, and the kind manufactured by Messrs. Priestman. Fig. 1 illustrates a three horse-power engine with a dynamo on the same base. The working of the engine is very simple. Inside the foundation there is a reservoir for the oil, which is forced out by an air-pump through a spray-maker. In passing through this device, the oil is broken up into a fine spray. In this form it passes through the vapouriser, when being further mixed with air, it becomes ready for admission into the combustion chamber.

The piston works on the well-known four-cycle movement.

The valves are of the ordinary mushroom pattern, the inlet valve works by the suction of the piston's outstroke, and the exhaust valve is opened by means of a lever from the countershaft, and kept closed by means of a spiral spring. There are no slides whatever in connection with the engine, which are often found to be troublesome in gas-engines.

Like all gas-engines the motive power is obtained by the explosion of a mixture in suitable proportions of vapour of petroleum and air. In the Priestman engine the explosion is caused by a spark from a small primary battery, though where a dynamo is driven by the engine, a small accumulator may be employed for the purpose.

Fig. 2 shows a type of engine which has been adopted by the New South Wales and Victorian Governments for electric-lighting work. It consists of two cylinders and is of 25 horse-power, the working parts being very compactly arranged.

Among the many advantages to be gained by the adoption of these motors may be mentioned the ease of fixing, the absence of all subsidiary buildings, such as boiler-houses, &c., and the fact that petroleum being such an easy thing to move in bulk, the distance of an installation from a coalfield or railway station need not be taken into serious consideration.

They seem to be very easy to manipulate and to require little skilled attention; in many farms where they have been adopted in England, they are left solely in charge of the ordinary farm servants who seem to find no difficulty with them.

The cost of working with these engines, even when the sizes of engines used are so comparatively small, comes out at about one half-penny per brake horsepower per hour, a result which must be felt to be very satisfactory, when all the advantages of the motor are taken into consideration.

The oil is stored in a tank in the body of the engine, and only just the right quantity is admitted at a time into the exhaust chamber from which, when mixed with the proper proportion of air, it is passed into the combustion chamber, which corresponds to the steam cylinder in an ordinary steam-engine.

Another type of oil-engine illustrated in Fig. 3 is manufactured by Messrs. Crossley Brothers of Openshaw, near Manchester.

It is of more recent introduction to the "Priestman," and is really an adaptation of the world-renowned "Otto" gas-engine for using oil. It is constructed on nearly as possible the same lines as the "Otto," the petroleum being vapourised and the oil-gas thus generated is mixed with air in the proper

proportions and exploded in the usual manner. Instead of using an electric spark for the purpose of exploding the mixture as in the "Priestman," a tube kept hot by means of a flame fed from the vapouriser is used with very satisfactory results.

One of the difficulties met with in these engines has been to render them efficient when working at light loads. This is accomplished in the "Otto," the results obtained proving that even when working at half and quarter loads, their cost of working is such as to render its use advisable.

There is a large field open for motive power of this description, and we anticipate that in the course of a few years they will be very generally adopted. Gas-engines require either a gas works to be in immediate proximity or for a gas generating plant to be on the premises with all its attendant inconveniences, while these oil engines only require to be supplied with oil as the reservoir becomes empty. There is little doubt that the experience which has already been gained by the manufacturers of gas-engines, and which is being used in these motors will result in them being still further perfected, and that with the cost of petroleum becoming lower and lower, their economy and convenience will result in many isolated installations of the electric light being put up in places where without them the light would be impracticable owing to its great cost. The electrical engineer will do well to endeavour to make known how simple and economical these motors really are.—*Indian Engineer*, July 2.

EDIBLE WILD PLANTS.

Many of the culicary herbs of former days are no longer in use, simply because they have been superseded by cultivated substitutes of superior quality. Taking some of the more substantial kinds of vegetables of which the wild progenitors are native and abundant in some parts of this country—the carrot and parsnip, for example—we find the roots are exceedingly small and their acrid properties so much more strongly developed as to render them uneatable to the present Briton. As for sea-kale, though the wild plant is not unwholesome, there is not much of it in the whole of the United Kingdom (where it is confined to the coast) and the wild plant is so different from the succulent blanched product of cultivation that one would only eat it as an antiscorbutic in case of extreme necessity. Celery, another native plant, is not merely unwholesome in a wild state, it is absolutely dangerous though formerly occasionally used in very small quantities, according to the herbals, for flavouring soups. Other instances might be given, but our object is to point out that, so long as we can obtain cultivated vegetables, wild produce will not, in a general way, tempt us, because cultivation improves the quality of the vegetable to a remarkable degree. Cultivation relieves the plant from all struggle for existence, and supplies the conditions for quick growth and generous nutrition, so that the cultivated vegetable is almost invariably preferable to the wild. Apart from this it is doubtful whether a large number of vegetables would afford a greater variety for the table than we already possess—greater variety we mean in regard to their flavour and health-giving properties, to say nothing of their nutritive value. Take the cruciferae for example.

When we realise that the turnip, cabbage, cauliflower, kale, radish and cress, in all their manifold varieties, belong to this natural order, and that it also supplies the condiments mustard and horseradish, besides a number of less familiar articles of diet, we can the more readily understand, that, although there are numerous other members of the same order that are equally as wholesome, and might, under cultivation, be equally as toothsome, the chances of a distinct new flavour being added are small. It is good to know, however, in the absence of the cultivated plant that there are many wild plants which might be substituted. How these plants are to be distinguished cannot be conveyed in a short article. Indeed personal teaching is the only safe and trustworthy guide. As a matter of fact, nearly all members are innocuous, if not really

wholesome. Winter cress (*Barbarea vulgaris*), a common plant in hedgerows, furnishes a good salad in early spring, when there is little in the garden except under glass. In Sweden it is boiled and eaten as a vegetable, and it is valuable on account of its extreme hardness. The marsh samphire (*Salicornia herbacea*) is an excellent wild vegetable, and where it is abundant, as on the shores of the Wash, it is collected and sold by itinerant vendors, at a rate that must bring many shillings into their pockets. But of all the wild plants that have a culicary reputation, the common stinging-nettle is the commonest and most generally diffused, growing in waste places and by roadsides in such abundance that a mess of it may easily be procured, though this would not long be the case did all the villagers understand its value as a pot herb. Formerly it was cultivated, and in Scotland, on good authority, "it was the practice to force nettles for early kail." In some districts the practice of eating nettles has survived, and in others it has been revived, but not usually by the poorer people, who are often more fastidious in such matters than their well-to-do neighbours. From actual experience we can strongly recommend the nettle as a wholesome and agreeable vegetable, and we also recommend it because everybody knows what a stinging-nettle is, and there is no risk of mistaking a dangerous plant for it. Dead nettles do not sting, and their colour is strong and disagreeable. For cooking, nettles should be taken while young, or when they are grown up only the tips should be taken, and spring is the best time. Boiled in a small quantity of water until tender, and served with a little butter, pepper, and salt, nettles are at least a good substitute for spinach, if not quite equal in flavour, though some persons aver that they are not inferior in this respect. Equally as good, but not often found in quantity in a wild state, are the shoots of the common hop, when from six inches to a foot out of the ground, or the tips of the elder shoots. But we can only repeat that the supply of wholesome wild vegetables is very limited; whilst uncultivated or badly cultivated land is almost unlimited, and the only remedy we have to suggest for the alleged scarcity of vegetables in the country is the extension of the allotment system and the encouragement of gardening generally.—*British Medical Journal*.

AMERICAN STICKLAC.—According to the *Washington Star*, trees of the stinkwood and acacia variety infested with insects of the same character as those which in Asia produce the sticklac of commerce, have recently been discovered to exist in great profusion in the South-Western States from Utah to Mexico, and from the Colorado Desert to Texas. It is believed that with a proper system of cultivation these "valuable bugs" could be propagated to such an extent as to render America independent of the Old World for her sticklac and shellac supplies.—*Chemist and Druggist*, June 11th.

INSECTICIDES.—The following notes by Dr. J. C. Neal, the entomologist to the State Agricultural College, Florida, U. S. A., will be found of interest:—Nothing has been done in practical entomology that has shown better results than the use of emulsions containing kerosene or insoluble poison held in suspension, and their application to infested plants in a fine spray by various atomisers and spray pumps. With one of these machines, an insecticide can be brought into contact with the insect, and its feeding ground thoroughly impregnated with poison. It is needful that the spray be very fine, and that it be applied with force to reach every infested part or the hiding-places of insects. For cases like infested buildings, as chicken-houses, that are usually very difficult to keep clear of mites and tick fleas, the spray of carbolic white-wash, tobacco, kerosene, oil of tansy, &c., is easily applied.—*Indian Agriculturist*, June 11th.

FROM THE METROPOLIS.

LONDON, July, 1.

MINING AND MINERALS IN CEYLON.

Soon after the reading of my paper before the Royal Colonial Institute, I had a request from the Editor of the *Mining Journal* (one of the leading metropolitan authorities in its department, whose head office is in Finch Lane close to the Royal Exchange) asking me for more detailed information about the mineral resources of the colony, and if I would consent to be "interviewed" and to give a photograph for engraving to accompany the letterpress. There could not well be a refusal, especially as the editor, a namesake from the Lothians, had been accustomed, when connected with another journal, to review our Ceylon Handbooks and Manuals. The result appeared in the *Mining Journal* of last Saturday, June 25th; but owing to the exigencies of space, the reporter's notes of my remarks on our minerals had to be much compressed, so making them appear rather deficient and disconnected. The editor has done his part in a flattering way giving all the personal details which he insisted on learning, but, alas! when he says the engraving is a good likeness, he is the reverse of flattering, for it is rather a smudge. On the other hand a sketch of a gem-digger's hut and working-place by our friend, Mr. John Dent Young, which I found among my papers—intended with others some day for the *Graphic*, has been rather well done. I have ordered blocks of the engravings to be forwarded to you, for which perhaps you may with the letterpress (now sent) be able to find a place in one of your Supplements—the *Literary or Household Register*.

In this connection I had the opportunity this week, during a call at the residence of Mr. E. T. Delmege, of learning from that gentleman the disgust with which he regarded the inadequate operations, feeble enterprize and final collapse of the

RAKWANA GEM-DIGGING COMPANY

which he originally promoted, but from which he retired when he saw a full use was not to be made of machinery and other resources. Mr. Delmege said that at the time the Company gave up, there was in his opinion ample encouragement with a further call of capital to prosecute both gem and plumbago digging and a trade also in mica sheets, and, if I understand aright, there was machinery on the spot or on the way out, which had not been applied. In proof of the soundness of his judgment, there was the fact, contained in a letter just received from Ceylon, that the lessees of the Everton diggings (from the Company?) were getting handsome returns every month. It is a great pity that this opportunity of doing justice to our gemming industry by the application of European machinery and the most recent improvements was lost. Nothing is heard at present of the Syndicate for which Mr. Barrington-Brown reported. And yet, as Mr. Delmege rather bitterly remarked, even in the most depressed times, many money is found in London for gold mines in strange lands where there is no gold—as for ruby mines in out-of-the-way uncertain regions—while for the development of an established industry in one of our best-known and most accessible colonies, every shilling is grudged by the British capitalist.

I learned here of the present great depression in

COCONUT-OIL,

the price of which has fallen to less than one-half that which prevailed thirty or twenty years ago, and with no immediate prospect of retrieval. Mr. Delmege is rather proud though,

and with some reason, of what the Company he is connected with—

"THE CEYLON TEA GROWERS, LD."

("Kangani Brand"), managed by Mr. Hutchinson—has done to promote the consumption of pure Ceylon Tea. All such Companies and Firms like Messrs. Shand & Haldane, the Ceylon Pure Produce Company of which I have already written, deserve specially well of the Ceylon tea planters, as contrasted with Lipton's, Mazawattee or other concerns which deal chiefly in "blends." The "O. T. G. Co." had first got up a very neat price list in French for guaranteed pure Ceylon tea and cocoa with prices stated, which ought clearly to tempt French hotels and households. Mr. Delmege is so well acquainted with the South of France, Nice, Cannes, &c., that he has been able to make our teas and coccas well-known there. That the Company gives a good article at the minimum of profit is shown by the fact that its satisfactory dividend last year was earned through an average profit over all the tea sold of only $\frac{1}{7}$ ths of a penny per lb. May all such Tea Growers and Pure Produce Companies and Firms go on growing and prospering, will be the hearty wish I feel sure of every Ceylon planter.

MR. T. CHRISTY

of Drugs and New Products fame—who, by the way, belongs to a family closely connected with, as he himself is a member of the "Society of Friends"—I learned some curious facts about the raw product used by the great chemists for the manufacture of

"CAFFEINE."

This is chiefly tea, the sweepings and refuse apparently, for it is bought at about £2 a ton and the Messrs. Howard alone are supposed to use about 9 tons a week; the Messrs. Böhringer and others no doubt get as much more. Now, where does all this tea come from? The "Caffeine" is sold at about 7s a lb. Asked about its use, Mr. Christy mentions it is becoming very valuable to Dentists: it is an absorbent, a nerve tonic and a sedative almost approaching to an anæsthetic. It has the property of rapidly hardening the gum, and is much less of an irritant than cocaine. Mr. Christy also mentioned that a large demand for

KOLANUT

in various forms was springing up on the Continent—he sends to Germany as much as 6 or 7 tons a week, I think he said. Some experiments recently made among the military in Vienna in doing without ordinary rations for 24 or more hours are believed to be explained by the use of kolanut, and if so may develop an extraordinary demand. Ceylon planters, in search of a new and paying product, ought once again to turn attention to kolanut.

MR. JOHN HUGHES ON SHODDY AS A MANURE.

The Secretary of the Planters' Association sends us the following letter from Mr. John Hughes, London, Consulting Chemist to the Planters' Association of Ceylon, transmitting a pamphlet on the Agricultural Value of Shoddy:—

Copy. Analytical Laboratory, 79 Mark Lane, London, E.C., June 8th, 1892.

Alexander Philip, Esq., Kandy, Ceylon.
Dear Sir,—I send you a few copies of my paper on the Agricultural value of Shoddy which if you will kindly bring to the notice of the members of your Association, some of them may be glad to have a

copy for reference. The paper was originally published in the *Field* for the special notice of Hop growers in Kent, Sussex and Worcester. It was republished however in the *Ceylon Observer*, and judging from the letters of inquiry I have received seems to have attracted some interest, indeed already a trial shipment has been sent out by the "Clan McIntyre" which I see arrived at Colombo in the 6th inst.—Believe me, yours faithfully,

(Signed) JOHN HUGHES.

SOUTH WYNAAD NOTES.

(FROM OUR OWN CORRESPONDENT.)

At last the monsoon has condescended to look us up, but quite in the most lady-like manner. No bluster or fuss, just a gentle drip, drip, from morning till night, and again from night till morning. Perfect planting weather. There is a very brisk demand for plants, Liberian, Ledgers, and tea, and great energy in putting them out. All last month we had lovely weather speaking from a personal comfort view, and no end of good work was done in weeding, pruning, and manuring. We had little or no rain all through June, and therefore obtained the full benefit of any amount of Cherma labour, so that the estates pretty generally look wonderfully clean and tidy for the time of year. Leaf disease is beginning to show up, I regret to say, even with the small rainfall we have had, and there will probably be a sharp attack on before this month is over. But we are thankful for the respite we have enjoyed and which we may hope will help the trees to mature their crop. The show of new wood is splendid, stronger and healthier in appearance than I have seen it for some years. The berries, too, are far more developed than they were this time last year.

Our Canarese are taking it easy, and drifting in as slowly as they possibly can. They like to arrive after all the had weather, just in time for the light pleasant picking work, utterly regardless, of course, of contracts and advances. The Chermas flock down to the coast for one of their feasts next week, and we shall see them no more for another fortnight at least. As it happens, they will have timed their departure well, as in all probability our "big burst" is not far off, and while that lasts, next to no work can be done.

It seems a pity that all the lovely weather we have had lately, has not been more utilised to repair and generally do up the fine imperial road which has been hestowed upon us. The side drains are only partially cleared, the hedge rows rampant in unchecked luxuriance of lantana; undeniable cart ruts are to be met with, and the grass has encroached so much that our Imperial road looks more like a Devonshire lane! And this is all the more visible in contrast with the magnificence of our new bridges, which really are quite too splendid!

St. Louis asks me a question anent tea cultivation in Wynaad, which I find it not too easy to answer. "Why have the companies, hinted at some six months or so ago, come to nothing?" Well, as far as I can judge, not being personally concerned, I should say it was a case of Mr. Muchafraid wandering about the gardens of Giant Despair. The promoters of the proposed companies were probably sanguine enough, knowing the exceptional advantages which Wynaad offered for tea enterprise. But, the gentle public, not to say "the city," loved not the name of Wynaad. Said they (and not unnaturally), "It is there, it is there, my child," that we dropped our money on oreless gold mines and cropless Arabica; we do not care to hurn our fingers yet again in that speculative sculdron."

Then Ceylon stood in our way: Ceylon with its unlimited talent for swamping every market, Ceylon backed up by a Midas of its own, smashing itself with Arabica, to pick itself up again with cinchona, down again with that, never mind, plenty more money where the rest came from, and cardamoms and tea follow. Then arises the cry, Ceylon will swamp the tea market, what is the use of forming new companies in India? And so the "much afraids" gave it up. I do not myself think that we need be discouraged by this.

As you know, tea is being planted in Wynaad on a rapidly increasing scale; there is nothing which succeeds like success, and I have not the least doubt that when a few years hence it is proved by sound practical experiment tea of the best quality can be made to pay here, that fresh companies will be formed, and capital introduced, which will restore the prosperity of Wynaad, I do not think that those who are now planting are likely to fall into the lamentable error of employing any but the very best machinery for the manufacture of their tea. This mistake has been made formerly, and the result of it has been that whilst the tea, fresh from the factory, was delicious, it would not keep, owing to insufficient drying. It is well known that the tea here is far more full of sap than that grown at a higher altitude, and therefore exceptional care is required in having the leaf thoroughly dried. This, even with exceptional care, is next to impossible if the machinery is inefficient, so that it is really bad economy to hesitate on the subject. I know that nothing but the best *jats* are now being planted. There is no fear that our soil will fail them. Tea here grows most luxuriantly, and does not seem to be troubled by diseases of blights. Given, therefore, that the raw material is excellent, the machinery perfect, and the manipulation thoroughly skilled, we are surely bound to place in the market such an article as will obtain favourable notice, both for itself and for the district in which it has been grown. Later on I propose sending you an outline of the available land suitable for tea in this and neighbouring districts, with any notes of interest, which I may gather about them.

In another of St. Louis' notes there is a query from "Bones and I," on the subject of Bone and Poonac, to which I venture a reply. It seems to me that the reason why "Bone and Poonac" has been abused by some, and is said to do more harm than good, is because its use has not been *continued*. Poonac, the active part of it, is "nitrogenous," and as such, forces the coffee tree or stimulates it into an increased life and production of branch and leaf. The bone provides many of the constituents of the berry, and the tree only takes up just as much as is necessary for the development of the berries, which the other manure has brought to birth. Anything over will remain in the soil. But under a tropical climate the force of the poonac manure is soon spent, and if the dose is not repeated, a vast mass of rootlets and corresponding branches are brought to life, only to find themselves turned out into a hard cold world, with no delicate foot left to keep them going; so they dwindle away and die, and the last state of those trees is worse than their first. No, the dose must be repeated every year, and well dug in and mixed with the soil, so that the roots may not find it all at once and so reap the fruit of greediness; let them feel about for it and spread themselves and get other nourishment, by the way, and a good hold of the oil. Two parts of poonac to one of bone (and not half and half which is simply a waste of bone) is the usual mixture, and a lb. of this is quite sufficient for each tree. But remember that it must be well dug in and thoroughly mixed. In South Wynaad, poonac and bone can be brought up from the coast, and applied to the trees for about R70 a ton, which will do an acre and a third, and will give much more than its worth in crop, but the application must be annual, and I fancy from what "Bones and I" wrote on the subject, that herein he failed and so blamed the manure, unfairly. I give my opinion from many years' experience, and trust that it may be found satisfactory.

An association meeting was held at Mappandy yesterday, and a very fair number of members assembled considering the state of the weather. There was a long discussion about the "Planting member of Council" question. There were several other subjects entered upon, and it is evident that we and our Oorg brethren cannot quite agree upon the registration of Canarese Maistries. The reason of which is, perhaps not difficult to understand!—*Madras Times*, July 13th,

LIBERIAN COFFEE IN SINGAPORE AND JOHORE.

When I heard that circumstances had caused the Loochoo coffee estate in Johore to be thrown on the market, I thought "for sure" that some one interested in planting and having the pen of a ready writer would have come forward, either with a sort of review of the planting enterprise in these parts, or to try to prove extenuating circumstances in the case of Loochoo. "Condemn it all, sir, if it is as fine a place as you make out, why the Hades is it thrown on the market like this?" Well, just now I do not propose to discuss the Loochoo question, but to take as it were, a back look over the planting enterprise in these parts since the first run on coffee took place in Johore, some eleven years ago, there or thereby. The original men undoubtedly went into the thing with too sanguine views and of all things in the world they overlooked the—in planting matters—almighty considerations of Labour. Land, Land, Land. Once the Land was secured where lay the difficulty? Aye, there was the *crux*. They were too cock-sure of securing there all supply of coolies from Ceylon and South India. There two things occurred. First Rama Swamy, who had salaamed to master, and promised to follow him all over the world, did not see it in the same light when he was asked to redeem his promise and follow. Secondly Madras says "No, no. We expect a famine. We must keep our *ryots* here to begin with. Though I have had but little trouble with labour myself, I must say that I feel very strongly on the labour question. The attitude of the Madras Government (which has been described by a person in Singapore as "the most effete administration in the East,") is to me incomprehensible. I honestly believe that a Madras official would rather report 20,000 deaths from famine in India than 20 from fever in Johore.* Of course officials would deny the soft impeachment with a bland and smiling face; but past history tells a tale "which nobody can deny." It is not strange that hitherto no signal success has been scored in planting at this end of the Peninsula. With new land and new labour the first planters could but look for pioneer's luck. They got it, and we now are wise in the light of past events. With two exceptions, the writer knows every coffee estate in Singapore and Johore; at the present time one and all are looking well. Most have a first-class crop on them this year; and all have had splendid blossoms for 1892. All the plantations have improved of late; and three which he has recently had occasion to visit after a considerable lapse of time have come forward in a way that is absolutely marvellous.

The future of this part of the world is an agricultural one, and Coffee is the cult.

W. T. M'K.

—S. F. Press.

TEA IN CHINA.

Foochow, June 25th.

We have it on the best authority that the second crop of tea will be astonishingly small this season, and the information is confirmed as regards supplies from the Paklum and Panyong districts, the heavy rains having interfered with the picking. At the same time shortness, from a variety of causes, is reported all round, especially of tea above common. Taken altogether, the news from the country seems to point to a small and poor second crop.

We have often referred to the abuse practised by the *likin* runners in collecting this tax on tea up-country. There appears to be no limit to their extortion. From an extra impost, or squeeze, of fifty per cent. levied last year over the tariff, we know of

* It is such wild, inconsiderate, utterly incorrect statements which are calculated to prejudice officials against planters. It is the sacred duty of the Madras Government and officials to secure just and kind treatment for their people; and that assured they favour emigration.—Ed. T.A.

sixty per cent. extra having been demanded this year. We have the fact from one of the sufferers, whose name we would mention but for the certainty that he and his family would suffer from the consequences. There is apparently no redress.

If the squeeze is objected to, the boats are simply detained at the *likin* barrier, and, as all the teamen are anxious to get their first crop teas down to market as quickly as possible, there is no other course open to them than to submit. Some day, however, it will be resisted just as the squeeze on salt duty at Tek Hwa was resisted last year, and there will be a repetition of the rioting which took place there, if these illegal imposts are persisted in.

Particular enquiries are being made, we understand, by unknown men as to the results of the teamen's ventures this season. It is generally supposed that those enquiries are being made for the information of the authorities, who it is known have to furnish Peking with the local reasons if any, of the decline of the trade.

The steamer "Taiyuan" leaves tomorrow morning (3rd July) for Melbourne and the "Menmuir" on Tuesday morning for Sydney with the first of the new season's tea. We had heard casually that tea was cheap and we were wondering how this came about in the face of a lessened supply and a larger demand. Native teamen of our acquaintance have explained it to us in the following words:—"Too muchee talkee talkee sellum that tea that Australian man just now; too muchee talkee talkee." It is all very well, they added, for them to be cautious and buy carefully, but the pressure all buyers have brought to bear this season, and especially the Australian buyers, to keep prices down is remarkable and contrary to all precedent; the consequence is we have not done nearly so well as we might have done. This charge of illiberality on the part of buyers leads us to hope that what we heard about the cheapness of tea is really true, and that shippers will reap the full advantage of it.—*Echo*.

HANKOW.—The *Hupao* says:—The tea business at Hankow has been very discouraging this year and merchants dealing in this article have all suffered losses. Formerly a dozen or more large steamers called at that port for tea, but there have only been five or six this season that were loaded with this cargo. The falling off of this trade is attributed to the strong competition of Ceylon tea.

The following are the Hankow Tea Statistics at date, compared with the corresponding number of days from the opening of last season, viz., 46 days; 20th June, 1892:—

	1892.	1891.
Hankow Tea	½-Chests.	½-Chests.
Settlements..	444,070	477,060
Shipments to Shanghai on		
Native account	...	139
Stock	46,500	53,780
Arrivals	490,570	530,979

	1892.	1891.
Kiukiang Tea	½-Chests.	½-Chests.
Settlements...	202,250	308,296
Shipments to Shanghai on		
Native account	...	—
Stock	28,800	18,960
Arrivals	232,110	327,258

The entire business to date as compared with the same number of days last year is as under:—

	1892.	1891.
For London and America...	½-Chests.	½-Chests.
For Russia..	278,000	254,000
	360,320	531,356
	647,320	785,356

COFFEE NOTES.

The coffee of Nicaragua is greatly improving in quality. It is far superior to Brazilian coffee. In the department of Matagalpa there are 2,000,000 acres which will soon annually produce ten million pounds of superior coffee.—*American Agriculturist*.

An employé of the East India Company in 1607, Mr. William Keeling, is believed to be the first among English navigators to mention coffee. He first met with it in the island of "Sootora," and thus describes it: "The people here for entertainment a thing called 'Cobo,' which is a black, bitter drink they make from a berry brought from 'Mecca'; this they sup very hot, and it is reckoned good for the head and stomach."—*Rio News*.

JOKAI TEA COMPANY.

SATISFACTORY RESULTS IN A YEAR OF DIFFICULTY—
THE ESTIMATES.

The twelfth ordinary general meeting of the Jokai (Assam) Tea Company, Limited, was held yesterday, at the offices, 14, St. Mary-axe, under the presidency of Mr. J. Berry White (the chairman of the company).

The Secretary (Mr. Henry Earnshaw) read the notice convening the meeting. The report and accounts were taken as read.

The CHAIRMAN said: Gentlemen, before making any remarks on the figures in the report, I wish to explain that the delay in issuing it and the date of this meeting have been caused by our resolution to sell every ounce of the crop annually before making up the accounts so that none of the figures need be based on estimate. Last year I told you, with truth, that the report they submitted was not only a record of the best year's transactions we ever had, but was, I believe, taking it all in all, the most favourable account ever made by any Indian tea company. Well, gentlemen, there are fat years and lean years, and the year just past had belonged to the lean variety, although we have a fairly satisfactory record to place before you. We have throughout the year been attended by a series of misfortunes. First of all, the produce we held over from last year, and which was most cautiously valued—so cautiously, indeed, that I fully expected it would realise more than £1,000 over the valuation—resulted in a loss of £1,657 13s 9d. No one can be blamed for this, as the produce consisted chiefly of fine teas, and within an interval of a few days an unexpected drop took place in the value of this class of tea. We were not the only sufferers. The most experienced and astute wholesale dealers in Mincing-lane, who are supposed to be even more closely in touch with the market than we are, were far heavier sufferers than ourselves. We then sustained a considerable loss by the wreck of a river vessel in which was a quantity of our most valuable teas, which were insured at the average value of our whole crop, and which in this particular shipment was fully 33 per cent below the real value. We then met with the culminating disaster in the destruction by fire of the factory at Tippuk. If you will look at the profits made by Tippuk in the previous year you will perceive that the loss could have been very little under £5,000. We must hope that, as we have hitherto been exceptionally fortunate, no fresh disaster may occur for many years to come. Coming now to the most important figures in the body of the report, you will see that the out-turn was under the estimate by nearly 100,000 lb., the exact figures being 2,382,000 lb., against 2,480,000 lb. The deficient rainfall in the autumn months was quite sufficient to account for this, and, with the exception of some gardens in the Surma Valley, I believe there was no tea concern in India which did not suffer as much from the same cause. It is satisfactory, however, to know that in a year of such exceptional drought as prevailed in India last year it was so very little felt in the Province of Assam. My own conviction is that we never shall have a really serious drought in that province, owing to the physical conformation of the country. If our out-turn was under the estimates in a small degree, the expenditure was still smaller being

only £81,000, against £89,000 estimated for. Our gross income is nearly £106,000, our tea having sold for a little over 10³d per lb., being 1'83d. under last year's average. We should have maintained last year's average easily had it not been for the low prices fetched by the Jamira, Joyhing, and Subsiri divisions teas. The demand for the various classes of tea varies very much, not only from season to season, but really from month to month, and we have hitherto found it to be the wisest course not to confine our output to one quality only. While we give a very free hand to the managers, who, being on the spot, are best able to judge what sort of produce they can turn out best, we have in general terms instructed some managers to go in for quantity and other managers to pay regard to quality alone, independent of quantity, and, as I have just remarked, this is the most prudent course. But it now appears to us that the time is come for some modification of this policy. The large quantities of medium and common teas produced in several of the other tea districts, which are apparently incapable in turning out really fine tea, lead us to believe that in the future fine teas will pay best in Upper Assam. We will, of course, watch the market attentively week by week, and if any marked change occur we will advise our managers by cable of the necessity of making an alteration in their style of plucking and manufacture.

The gross profit on the working of the season amounts to £25,444 10s 9d, and, after deducting commissions and income-tax, it leaves a net amount available for distribution of £21,586 17s, from which we recommend that the usual dividend of 10 per cent for the year should be paid. We have already paid an interim dividend of 5 per cent. in December last and, if you approve it, we will pay the remaining 5 per cent. now, and we will have a carry-over of nearly £1,600. The reserve fund will remain at the amount it was made up to last year, namely £30,000; but, although it does not come into this year's account, we have already added to it by the premium on the new issue of capital lately made. The estimates of out-turn and expenditure you will find in the usual place in the report. They are for 2,750,000 lb. costing £100,000 to produce being an average of about 8³d per lb. for all charges up to the time of sale in London. Taking into consideration the increased plucking area, the estimated quantity may be considered small, and there is no doubt that we could turn out considerably over 3,000,000 lb. were it not for the reason I have already told you, that we have instructed our managers to pay more regard to quality than to quantity. You will perceive that we have made very considerable extensions this year—over 365 acres in all—the chief clearance being at Panitola, a division which has, with the exception of one year, always given us handsome profits. This extension and the purchase of two small gardens towards the close of the year, brought our capital account up to some £9,000 over the amount fully paid up. This account has been adjusted by the issue of 1,000 additional shares in April last, which with the issue in payment of the Wilton shares, shows our paid-up capital at the present moment to be £231,000. These new extensions will, I believe, in the future, prove to be the most valuable portion of the company's estates. Next cold season we propose extending at Hnkan-Pukri. This garden, which for some years past has produced the finest tea, not only in the company, but in all Assam, is at present under 300 acres. The existing fixed establishment, both European and native, could work 500 acres without any increase in their numbers. We have at last got the Bokel Sawmills into nearly full work. Everything moves very slowly in Assam, and the erection of these mills has taken nearly two years longer than even I had anticipated. We have, however, made a good start by turning out nothing but first-class work. Larger profits could have been shown had less attention been paid to fineness and nicety of work in the boxes, but the reputation we have gained for the best work in Assam will in the long run prove more profit-

able. The Hukan-Pukri mill, like everything else at that factory, has done well. You will be glad to see that we continue to devote the utmost care to the maintenance of the health and general welfare of our native labourers. We have spared no expense in the construction of improved and permanent houses for them, in getting a thoroughly reliable supply of pure water laid down to all the factories, and in other works for their comfort and advantage. The expenditure on these improvements has been very costly—indeed, had it not been for this outlay, we might have doubled our reserve fund during the last three years; but all this has now nearly come to an end and the diminution will be shown in our new year's accounts. The next paragraph in the report refers to the prices ruling during the past year for Indian teas, and their consumption. All teas brought fairly remunerative rates until the end of October, when a change came over the market. Fine teas—that is, teas bringing from 1s 3d to 2s 6d per lb.—maintained their value, while medium and inferior class teas fell quite 25 per cent. lower than had ever been known before. In other words, Pekoe and Pekoe Souchong, which in ordinary times averaged from 10d. to 13d., fell to a point varying from 4½d. to 8d. As these medium teas formed the great bulk of the produce of the majority of our divisions, it naturally affected our gross receipts very considerably. Our Jamira division barely covered expenditure, and the Subansiri division actually showed a considerable loss. Even allowing for a normal fall in prices such unsatisfactory results were, I am sorry to say, due to other causes, which are remediable, and we will take measures to prevent their recurrence.

The figures of the home consumption are for each year from January 1 to December 31, and for 1891 do not appear to be very satisfactory for Indian teas, and show a slight falling off in consumption; but since then, for the five months ended May 31, a great increase in consumption, amounting to 7,000,000 lb. has occurred. The consumption of China teas show the usual steady decrease. As I led you to expect in my address last year, we have continued our policy of annexation. The two small gardens we have acquired on the North Bank are not of much account, and were so much neglected that they will require expensive reclamation. Their acquisition was desirable from this point of view—that they were on the border of our gardens, and evidently worked by their native owners in a manner that would prove, and had proved, a considerable nuisance and some loss to us. These people have no capital, have no regular establishment of imported coolies, and worked these small patches of tea with discontented or worthless coolies from our gardens. The settling down of bad characters almost in the midst of our own people was a bad example, and tended to unsettle those in our employ. After some little judicious outlay, these gardens, I have no doubt, will prove as remunerative as the adjoining cultivation. The acquisition of the estates of the Wilton Company is a different matter altogether. These estates comprise nearly 1,000 acres—996 acres is the actual figure—of tea. About 500 acres of these are acres nearly as good as any of our own properties, although not in such a high state of cultivation; 200 acres are fairly good, but require reclaiming—that is, filling up numerous vacancies and carrying out a proper system of drainage; 200 acres are quite young, and in three or four years' time will be about the best portion of the estates; 100 acres are of a very poor, low China plant, the abandonment of which I have advised, but have left to the decision of the superintendent to do so or not when he has had further experience of this year's working. The chief value of the property, in my eyes, was that it contained 8,243 acres of freehold land in the immediate vicinity of the railway. Now, I consider that this land alone is worth the price we paid for the entire property. As no more fee-simple land will be granted by Government, I hold that this is quite worth £3 an acre, and the whole property has only cost us £21,000. Although the tea on it is not up to our own standard of cultivation, it will with the more liberal

treatment that we will give it, yield a good profit from the outset, nearly equal per acre to the other divisions of the company. Although the season has not been a bumper one, we have had the prudence of our policy practically demonstrated. By judicious extensions and acquisitions, our interests are spread over such a wide area that the fire at Tippuk or the loss in working at Jamira and Subansiri has had only a trifling effect on the general result of the year. A new factory has been erected at Tippuk and is now being used. Our position is exceptionally strong. We hold our cultivation at the very low average of £55 per acre, and this includes two sawmills and 23 miles of light railway,* and over 22,000 acres of freehold land.

The Chairman concluded by moving the adoption of the report and accounts. (Applause.)

Mr. William Halford seconded the motion.

Mr. Rostron remarked that last year reference was made to two articles which they had on their estate—indiarubber and rhea. He should like to know if the difficult problem of discovering machinery suitable to turn them into marketable articles had made any progress during the year. He trusted that in the extensions to their property that might be made every effort would be made to get estates as cheaply as possible. He should also like to know how the company stood in reference to the competition of the Ceylon tea trade.

Mr. Seaton said he noticed that the estimates of cost was a little higher this year, and that at a comparatively low rate of exchange. No doubt, the estimate was a pretty full one, but, the heavy expenditure on machinery having come to an end, he should have expected to see a reduction in the estimated cost. He complimented the board on the satisfactory state of affairs disclosed.

The Chairman said, in reference to the rhea and indiarubber, although no machinery had proved actually successful, he thought they were getting to it very closely. He was himself interested in two syndicates, and thought they had very nearly found out the proper machine. They had 50 or 60 acres of rhea under cultivation; but it would not be worth while to put it on the market until there was a larger area. They had very good accounts of the indiarubber; but before it could be tapped the trees they were planting out now must have six or seven years growth. As to not being too extravagant in the rate they gave for gardens, he thought their last transaction showed they were not likely to err in that respect. He thought the land for which they had paid £3 an acre would be extremely valuable before long. Ceylon teas had affected them, and brought down the price for medium and low-class teas; but Ceylon tea was really taking the place of China tea. They could not turn out the fine liquoring tea, and if Indian tea-growers gave up making the coarser teas they knew that no other part of the world could compete with them; therefore, with the change of policy, he did not think they need apprehend that Ceylon would interfere with them. Ceylon, as he said, was taking the place of China, and they would always want a certain proportion of Indian tea to give strength and backbone to their tea, as the Chinese did before. (Hear, hear.) Replying to a shareholder as to the rate of exchange, the Chairman said it was estimated at 1s 4d this year, and he had no doubt it would not exceed that. The estimated cost was not lower than the last, because they were allowing for making a much finer article. They hoped that the tea which came home this year would average 1s per lb. which would give them a return of 16 per cent., and he did not think anyone need grumble at that. (Applause.)

Mr. Thomas Carritt confirmed the opinion expressed by the chairman as to the relative positions of Indian and Ceylon teas, and said, as far as he could see, the quality of the latter was falling off every year. In the past year the Ceylon people said they were going to pluck more finely, but the quality was poorer, whilst the quantity was not so large as they expected.

* N.B.—Have any Decauville or other railways been formed on Ceylon estates?—ED. T.A.

The motion was then put and carried unanimously.

The Chairman proposed: "That out of the amount of £21,595 4s. 7d at the credit of profit and loss account, the payment of an ad interim dividend of 5 per cent. on December 10 last by the directors be confirmed, that a final dividend of 5 per cent. per annum, free of income-tax, be now declared, payable on, and after June 24th, and that the balance of £1595 4s. 7d be carried forward to next year's account."

Mr. John M. Holl seconded the motion, which was agreed to.

The Chairman moved and Mr. Alexander Lawrie seconded the re-election of the retiring directors (Messrs. Holl and Halford.)

The motion was carried.

Colonel Nowell proposed and Mr. E. Tye seconded the reappointment of Mr. J. F. Kane McGwire as the auditor, and this also was passed.

On the motion of Mr. Tye, seconded by Mr. Smith Harvey, the thanks of the shareholders were voted to the chairman and directors and the superintendents in Assam for their efficient conduct of the company's business during the year.

A vote of thanks to the Chairman terminated the proceedings.—*Financial News*, June 24.

TEA AND TEA PLANTS.

BY DIGAMMA.

Sreekonah, Cachar, February 16th, 1892.

This is a pleasant place on the little river Ghogra just below the falls, and close up to the military road leading from Sylhet to Silchar. There is no lonely European dwellers here, there being no European at all—only myself for the time being. The resident in chief at Sreekonah is a Bahoo, which means a "native gentleman"—the Bahoo Sonat Knmar Dass. I referred to this Bahoo in a former Budget, saying that he and I had been on terms of intimacy for a number of years. This is true. We are good friends. He does his best to entertain me. Of course I may not sleep under the same roof with him, nor eat from the same dish, because in his eyes I am unclean, he being a very religious and high caste Hindoo who never eats the flesh of mammal except goat offered in sacrifice, and of birds only pigeons. He is a man who bathes at least twice a day, who rubs his teeth at least three times a day with a stick, who would rather out off the forefinger of his left hand than touch his dinner with it, who believes in ghosts and witches and who is in every way devoted to the service of his gods. He has very many gods. In addition, he is a man of much cultivation, great intelligence, thoughtful, and spiritually minded. But the Bahoo is not intolerant according to his lights, and I have the use of his covered verandah, which is a room good enough for my purpose. Then, though he abjures all alcoholic drinks on his own account, he has provided beer for my regalement, and many other good things. He is singularly free, too, in conversation, and is always ready to inform me in detail about the manners and religion of his people.

Tea grows wild in the jungle of Sreekonah. It is not that the plant had been brought from a distance for cultivation and allowed to run wild like cherries at Gibside. It is the indigenous plant—the native tree, Southern as well as northern Assam, the valley of the Soorma-Barak as well as that of the Brahmaputra, is the natural home of the tea plant. Tea is not found growing wild in China; and it is alleged that, when left to itself there the plant never attains the dimensions of a tree. The cultivated tea plant in a plantation, perforce of constant pruning, is a shrubby bush, having the dimensions of an average black currant bush, and ranging from three to four feet in height. But the tea plant is not naturally bushy. On the contrary it is a tree growing up to 30ft. high,* and having not unfrequently, at the

thickest part of its trunk, a girth of two feet. It throws outwards and upwards strong woody branches, and it has leaves large, leathery, lanceolate, flat, saw-edged and succulent. This morning I plucked from a tea-tree a leaf which lacks only the sixteenth of an inch to be a foot long and is full four inches wide. I am thinking of sending it to Mr. Stewart, tea dealer in Newcastle, for curiosity's sake. Also, I am assured that still larger leaves are met with.* It was in 1855 that tea was found growing wild in Cachar, one year before its discovery in Sylhet, but about 30 years after its alleged discovery in Upper Assam. I have seen it growing wild on the Kuttal estate and in other places, but nowhere to the same perfection as in this Sreekonah jungle, where the leaves have repeatedly been plucked and manufactured. The Cookies and Cacharies have been wont to gather the seed of wild tea (a tea seed is very much like a hazel nut, but its kernel is intensely bitter), and to sell it to the planters. The product of this seed is the highly priced indigenous plant as distinguished from the China and Hybrid varieties.

It is told of a certain director at the meeting of an Assam tea company in London how he made a motion to this effect—that Orange Pekoe only should be cultivated in the garden of the company, seeing that this kind of tea brings a so much greater price in the market than any other kind. His motion, if he ever made it, was the result of what is a very popular error; namely, that the teas classified in the markets as "flowery pekoe," "orange pekoe," "pekoe," "souchong," "pekoe-souchong," "Congou," and so forth are not only different qualities of tea, but different species of tea, produced by different plants and mayhap in different places. It is not so, however. All the teas mentioned are produced by the same bush; nor is there anywhere a tea plant which may not produce every one of them. As different parts of the hide of the same beast vary in length and firmness, so vary also the different leaves on the same tea plant. As the outer and inner leaves of a cabbage differ in tenderness and in sweetness, so likewise differ in strength and in aroma the leaves of the same tea shoot, according to their age and position. Only the young succulent leaves on the new shoots can be manufactured into tea which the grocer sells; and the younger the leaf—the higher up its place on the shoot—the finer is the quality of the tea which is made of it. The two top leaves have been called the flowery and orange pekoes—the pale yellow "pekoe tips" of the careful manufacturer. Thereafter comes the pekoe leaf, and the one below it and older than it the souchong. It stands to reason that, though the same bush yields all the teas in the foregoing classification, all the bushes in all the gardens do not yield them of the same quality; for one pekoe may differ from another pekoe and one souchong from another souchong according as there is a difference in the character of the seed from which they spring, in the quality of their respective soils, and in their climatic conditions. There is another error about tea from which certain text-books of Botany have not yet shaken themselves clear. Notwithstanding the proved identity in species of all the teas sent to the markets of Europe to be sold for consumption as a beverage, they are still frequently spoken of as belonging to three distinct species of plants—the *Thea viridis* of Linnaeus, the *Thea Bohea* (both of China), and the *Thea assamica*. But the botanists of authority are agreed to consider these three as, at the utmost, only varieties of one species, classifying it under the name of *Camellia Thea*. For the camellia and the tea are identical in genus; and he who has seen a camellia has seen what is likeliest the tea plant—its very first-cousin. There was a time, also, when green tea was supposed to be made from a different species of plant from that yielding black tea. It has not to be said that green tea differs from black tea only in the method of manufacture, and that any tea leaf may be turned out either green

* It grows to 45 feet. There are seed-bearers on Abbottsford estate, Dimbula, fully 35 feet high.—Ed. T.A.

*Leaves exceeding 1 foot in length and broad in proportion have been grown in Ceylon.—Ed. T.A.

or black. The difference is in the degree of fermentation.

He who takes tea for breakfast swallows what is brought about by fermentation as much as the man who drinks beer to his tiffin or red wine when he sups. Tea is a manufactured article; and, before the leaves are capable of yielding a potable draught, they have to be subjected to four main processes—the withering, the rolling, the fermenting and the firing. The most important by far of these is the fermenting; the two first being in preparation for it, and the last being to check it. Certainly, it is not alcoholic fermentation to which the tea leaf is subjected, nor am I able to say by the action of what special ferment it is brought about. I am not aware that anybody can yet tell this. But fermentation is beyond question—fermentation of the putrefactive sort,* whereby vital changes are produced in the constitution of the leaf, its color altered, new powers induced, and essences created that were not in it before. Mayhap it is akin to the fermentation that takes place when grass is made into *silage*. Anyhow, it is this manufacturing process towards an efficient fermentation, neither too little nor too much, which in recent times has altered the whole tea industry as regards the making of the marketable commodity. Handrolling and all other direct manipulation by hands and arms will soon be altogether a thing of the past; and already a factory is by far the most important and expensive part of a tea plantation. The multiplication of machinery, and of expensive machinery too, is steadily on the increase, and the time is not far distant when none will have the chance of starting life as a tea planter unless he be a trained mechanic.

Another word about the tea-plant, which is one of the hardest members of the vegetable kingdom, and which endures an annual slaughter by the pruning knife and a weekly plunder by the nimble-fingered collic picker, which I doubt may be paralleled in the whole range of cultivated plant-life. Provided that the necessary conditions of climate are present, will the tea-plant grow on any soil? One might almost say so. I have seen the tea-plant growing among the boulders on the rugged mountain sides of Ceylon—growing where the coffee grew till it was blasted, and where no coffee would at any time grow. I have seen it spreading its green heads over the far-reaching plains of Assam on land as flat as the open palm of a lady's hand. I have seen it thriving astonishingly in the dried up fens of Sylhet, nothing better than drained peat-bogs. And here I see it in Cachar, where for a generation it has clothed the *teelaks* or little hills that are set as thick in the land as the manure heaps carted out for the top-dressing of an English meadow. Now it is a fair question to ask; Will tea continue long to thrive equally well on soils so diversified, so varied in their aspects, and so different in their composition? Even outsiders are permitted to have an opinion; and it is mine that it will not. Already the Cachar planters see the soil of the *teelaks* in an advanced stage of exhaustion. Its substance is being sapped by the evergreen perennial which fills our tea-cups, and which is rendered doubly greedy of nutriment by the treatment to which it is subjected. And the soil itself, so often loosened by the cadally or great hoe, is being gradually washed down into the valleys by the tropical downpourings in the wet season. In consequence, the ultimate abandonment of the *teelaks* is now the talk of Cachar, and they are thought happy who have *bheel* or fen land for the extension of tea cultivation—that is, land in the hollows sufficiently raised for the preservation of the plants from floods. Will not what is taking place in Cachar sooner or later come to pass in Ceylon—in Ceylon where the tea plant gets practically no rest, where the plucking goes on the round of the year, where I have seen pruning and plucking going on at the same time on the same estate, where the soil on the

mountain slopes is a skin of the thinnest,* and where the tropical downpourings are not more merciful than in Cachar? Will the tea plants lately set upon the hills of Ceylon endure for a long time upon next to nothing? It is more improbable that they will. Ceylon has many advantages over other tea-growing regions in facilities for getting its tea to the ships, in nearness to the great markets, in cheapness of labor, in the greater number of flushings, and in the advertising enterprise of its proprietors. It lacks nothing in the temperature and moisture which the tea plant requires. But it lacks the matchless soil of the Valley of Assam—the sandy loam, rich in vegetable mould, with the lighter sub-strata. Hence it is that the uniform high qualities of the teas of Sibsagar and Lakhimpoor have never yet been possible in Ceylon. When the flood comes down upon the tea-growing levels of Assam, instead of carrying away substance, it leaves a fresh deposit; because the Brabmapootra does in a measure for the great Valley of the North-East what the Nile does for the Delta. As it is the native country of the tea-plant, so it promises to remain the foremost country for tea in all time to come. The future of Ceylon as a tea producing country is most uncertain. And Cachar, barring its *bheel* lands, is also uncertain. The fens of Sylhet promise always to produce abundantly their coarser kind.—*Newcastle Daily Chronicle*.

OUR LABOUR QUESTION.

(FROM OUR SOUTH WYNAAD CORRESPONDENT.)

Time has been in which sundry small Joves shook their thunderbolts at the very name of tea in Wynaad. Fortunately for us, progressionists, all but a very few of these deities have unscrewed their conductors and packed away their thunderbolts, but the one which is still occasionally held aloft is that called "labour." How, say these objectors, do you propose to arrange about labour? What will you do when your Canarese insist on going to their country during the hot months? and when your Chermas leave you in the lurch to attend their innumerable feasts? Tea, you know very well, requires labour all the year round; how is such a difficulty to be met? It is absurd to suppose it possible in Wynaad, and so on. To prove the possibility seems to me a question of such nice and even vital interest in our present crisis, as to be worthy of some serious consideration. It is perfectly true that the Canarese leave us in the hot months, and that the Chermas and his feast are not to be separated. But there are others beside, and we may at least look these over, and see if material for our requirements are not obtainable by thought and patience. We have, for instance, Canarese, Chermas, Coimbatore Tamils and Moplahs; as outsiders, locally, there are Orrumbas, Moopers and Panniahs. I propose taking each of these classes in rotation and considering their several capabilities for meeting our difficulties.

CANARESE.—Formerly our estates were almost entirely worked by Canarese, I think the famine of 1877 was the first cause of the thinning in their gangs. Then came the gold mania, the abandonment of estates, and consequent less demand for labour; so many of the Canarese went off to other districts. However, fresh openings being made, more coolies were required, and here the Chermas stepped in, and in spite of further abandonments on account of horer and leaf, the Chermas has steadily made his way, and the Canarese finds himself considerably out of it. But the Canarese bring up their women. Women pick deftly and are marvellously cheap labour. There can be no doubt that with the inducement of plenty of work we should with little difficulty coax our Canarese.

CHERMAS.—Chermas, perhaps, are the pleasantest labour we have: always patient, cheery, willing, and hard-working, and by no means slow to learn. They do an honest day's work for their four annas, which alas! cannot always be said of the Canarese. They

* Is this certain? Oxygenation is a better term for the chemical change undergone by rolled tea leaves.—*Ed. T.A.*

* Not generally true.—*Ed. T.A.*

would be perfect as labourers if we could induce them to live up here; but this is impossible. Chermas are the absolute slaves of the Nairs and Brahmans of Malabar. They are allowed, as a great favour, by their masters, to work in Wynaad when not required on the rice fields. They receive no pay except their food and one cloth a year, and they are bound to leave the estates at the least beck of their tyrants. They are not allowed to bring up their women, who are kept below as hostages for their return. Of course, the Cherma is only too thankful for his lately acquired privilege of earning money, to murmur against his master's will, besides which centuries of servitude have broken his spirit too much for resistance. Caste prejudice is probably more felt in its effects on progression in Malabar than in any other part of India. The intense conservatism of the ruling classes is not to be overcome by a mere order from Government, and nothing but the gradual influence of education can bring about anything like equality amongst the castes. Not that absolute equality can be possible or even desirable anywhere. I was very much amused once to hear an energetic despoiser of caste discourse. "Rubbish," said he, "This caste nonsense should be put down with a strough hand. Take a Nair and a Cherma and rub them up together, that's what I should do!" I smiled to myself and thought, "I wonder if you were told to take the Duke of Westminster and a Whitechapel coster and rub them up together, whether it would seem to you the best thing to do." But this is a matter for wiser judgments than mine, and moreover, is irrelevant to the subject which I have in hand. As with the Canarese, so with the Chermas, demand would increase supply; and it is very probable that many Chermas could be persuaded to give up a feast, if a pressing flush was on, for they are exceedingly bidable folk when rightly managed.

To keep in Malabar, I will next mention the *Moplahs*. These are good workmen, almost too powerful, as a rule, for such quiet work as picking; but for pitting, weeding and so on, they do very well. But they prefer contract work, and, by reason of their independence and temper, are not so easy to deal with as some of the others. But I could not help thinking during my late travel, that working material might be raised in the poverty-stricken, woe-begone Moplah villages round about the neighbourhood of Mallapuram. These are supposed to be the rebellious, trouble-giving districts, and one is struck by the sullen, hopeless look of the men and the worn, utterly miserable appearance of the women thereabouts. Poor wretches, they are literally ground down by the iron heel of oppression. Their Nair landlords wring the very food from their mouths, and it is hopeless for them to attempt to rise above their state of degradation under the present circumstances. But supposing these men could be shown the advantage of earning their living as the Chermas have done? It is a mere suggestion, of course, and probably we could get quite enough labour without venturing on a perhaps somewhat dangerous experiment. I am only bringing forward every possibility.

COIMBATORE TAMILS.—Tamil are already in by thousands, and as many more as we would want are ready to come. They are rapidly taking the place of the lost Canarese. And a great advantage connected with this class of labour is that while they can be taught to pick well and cheaply, they will come for comparatively small advance. Advance, in the case of Canarese, has become an almost insupportable burden, and a constant incentive to broken contracts: The pity of the Tamil is his unutterable dirtiness. One can't help thinking that tea manipulated by the unsavoury Tamil would probably, like Pnnch's oyster, "have a higher flavour than the rest." But after all, who are we, to be too particular? Think of the mysteries of our cook rooms, and let us not carp at custom. This brings me to our locals.

CURRUMBERS and MOOPERS are much of a kind. They will work by fits, but they are far too lordly and independent to do anything regularly, and for ordinary work, picking at least, I should doubt their efficiency. But as wood-men they are invaluable, and we always employ them for all opening and felling. The Moopers

object to their women working, in fact so timid are these ladies, that if a European comes upon them unawares they raise a terrified yell and scuttle off like so many rabbits to their burrows. But many of the men are fine fellows, and I don't see why on emergency they might not be made useful.

The PUNNIANS are another slave tribe. At present they are rapidly converting themselves into a dangerous class. The last taxing arrangements have obliged numberless Moplahs and Nair proprietors to throw up their cultivations. In consequence, the Punnians have no work, and no food, and have to exist upon roots and berries like the veriest savages. Naturally this leads to robbery, and they are mere tools in the hands of unscrupulous coffee receivers. But they are hard-working and teachable, and might, I venture to say, be made exceedingly useful for tea work. The great secret of it all is good treatment and strict justice. When coolies know that good work means good pay, and *vice versa*, and that they will be decently housed and cared for in sickness, they will come when they are wanted, and I cannot think that the labour question would trouble us long if it came to be known that Wynaad was once more to be extensively opened up. At any rate, no one can deny the fact that the material is available if we only find out the best method of securing it.

It is worth remarking also that the Wynaad climate is now very different from what it was in the old days. The real old jungle fever can now only be found on the Mysore frontier or in Nellumbur. What we get at present is a sort of low fever which is common to all parts of India. The heavy tea work, *i.e.*, pruning could be finished by March, and unless an unusual amount of rain fell, there would be little to do during the "fever months" of April, May, and early June.

Tamil coolies will generally come to Wynaad, especially for those months, if a small inducement, such as train fare, is offered. By giving the Ceylon rates of 6 annas for men and 4 for women we could always get as many people as required. But I hope it will be a long time before prices are run up to that. Probably the best way to encourage good pickers would be to give a small fixed wage of 2 annas and so much per lb. for good leaf brought in say 1 pie per lb. Thus a woman who could bring in 24 lb. would get four annas. But she would have to be a quick hand to earn it.—*Madras Times*.

GINGER-GROWING IN JAMAICA.—The average yield of dried and cured ginger, fit for the market, in Jamaica, is from 1,000 to 1,500 lb. per acre. A good crop may yield even 2,000 lb. As long as the ginger, when dug up, is kept from the sun, it need not be peeled for two or three days. After peeling for the day the roots should be put to soak in plenty of water over night; in the morning washed, cleaned, and weighed; then put on mats and turned over carefully at midday for six or eight days until cured. It takes 3 lb. of green ginger to make 1 lb. of dry root.—*Chemist and Druggist*, June 11th.

COFFEE IN JAVA.—The *Surabaya Courant* notes the fact that the growing scarcity of land fit for coffee cultivation in Java, has led planters there to fix the gaze upon the outlying parts of Netherlands India. Several of them have left East Java to try pioneering in Palembang where the uplands are reported to be adapted for this line of cultivation in soil and climate. Another recommendation is the cheapness of land in that quarter. The same journal has no doubt that coffee has a good future before it. The falling off in the Government coffee yield in Java and the increasing political troubles in Brazil all point to diminution in the large crops of the berry hitherto turned out in these two countries.—*Straits Times*, Aug. 2.

THE TEA ENTERPRISE IN ASSAM IN 1891.

The abstract of the Assam Government report on the position and progress of the Tea Enterprises in that Province, which we take over from the *Indian Agriculturist*, is a suggestive document. Although, as a whole, there has been progress in acreage cultivated and yield of tea, yet such advance has been confined to the districts most favoured in regard to soil, climate and supplies of labour. In less favoured districts, the processes of the struggle for existence and the survival of the fittest have been at work in a severe fashion,—with varying effects,—the general result being that a net decrease of 35 estates is reported. Adverse weather has been adduced as one cause of unfavourable crop returns, especially in Kamrup, where a planter has denounced the season as the worst he has known for 17 years. A general advance in area of cultivation (notwithstanding abandonment of estates) and in yield of tea is qualified by prices low beyond precedent, and the competition of Ceylon is adduced as a main cause. Our Indian friends are no doubt correct in their conclusion, although the facts we have stated in regard to abandoned estates show that the Assam planters are competing with each other. If it is any consolation to the Indian tea planters that their Ceylon competitors are at least equal sufferers from prices low beyond parallel, they may take it, and we fear the time is not distant when we shall have to take account of abandoned estates in Ceylon, if the opening of new markets does not arrest the downward course of values. The total area of land held by planters in Assam is about one million acres; but of course all this area is not suitable for tea culture; the coolies, indeed, being allowed to cultivate rice on some of it. Out of the million of acres, a little more than 20 per cent—208,407 acres—are under cultivation with mature tea, that is with bushes over four years old, while there are 33,416 acres additional under immature plants. In India, however, the age of plants is not, as in Ceylon, counted from the time of putting out the seedling into the field but from the period of sowing seed in the nursery, so that the four years old plants of Assam would be reckoned as only three years old in Ceylon. The total area under cultivation in 1891 was 241,823 acres, a good deal short of 25 per cent of the area held. But this proportion will be reached and exceeded if the increase in 1892 over 1891, equals the increase of 10.785 per cent which 1891 showed over 1890. But we should think the low prices unhappily prevailing for tea, will arrest the process of increase in the shape of new land opened as separate estates or as 'extensions' to existing "gardens;" that being the Indian term, varied by the use of the less poetical description "tea concerns." The district of Lakhimpore seems to be, beyond compare, the best for tea production in India, perhaps in the world, taking the district with its 130 estates and 37,626 acres as a whole. The average yield of North Lakhimpore in 1891 was 572 lb. per acre. It is notable that the best yielding district was the readiest to supply returns asked for by the officials and necessary for a correct report. Cachar compares most unfavourably with most other districts in this respect, and justifies the belief that the enterprise in that valley is not such as those interested could desire. Blight was not added to bad weather in Assam in 1891; but it will be observed that considerable damage accrued from a cause, so rare in Ceylon and so slight in its effect when it does occur as not to be worth taking into

account:—*Hailstorms*. The much greater distance of the Assam and Northern India estates generally from the equator is adverse to them in regard to this meteorological phenomenon.—Apart from the competition of Ceylon, Assam has gone ahead in extensions during the past six years at a rate which might alone account for low prices. The area under cultivation in 1886 was only 203,993 acres. In 1891 the acreage was 241,823, an increase of nearly 38,000 acres, the greater portion of the increase having occurred in the past three years. In Ceylon as well as India, planters will do well, we should say, to hold their hands, for a time at least, in regard to extended cultivation.

TEA CULTURE IN ASSAM.

The Assam Government has issued its report on tea culture for 1891. Following the practice of previous years figures are given separately for each subdivision in addition to the totals for each district. Cachar still heads the list with the largest number of gardens (138), Lakhimpore sadr comes next (130), the former also shows the largest area under tea and the largest outturn. In the Brahmaputra Valley, North Lakhimpore shows the highest proportional yield of 572 pounds per acre, while in the Surma Valley Habigunge heads the list with 449 pounds per acre.

The total number of gardens borne on the registers at the close of 1891 was 828, against 867 at the close of 1890, and thus showed a net decrease of 39. There was a decrease of 43 in Kamrup, as against an increase of ten in Sibsagar, and fourteen in the other districts.

The apparent increase of ten gardens in Sibsagar is due to the inclusion, in this report of nine small gardens in Jorbat, which were excluded from the previous year's reports, owing to the managers not having supplied the necessary statistics in those years. The decrease is largest in Kamrup where 28 abandoned gardens have been struck off the register this year. Besides these 13 gardens in this district which were not worked owing to depression of trade and were hitherto shown under head 'Estimated' have been excluded from the present report in accordance with a suggestion made by the Commissioner of the Assam Valley Districts. Assuming that the above 13 gardens were included among the 22 shown as unworked in paragraph 5 of the preceding year's report, and excluding the nine gardens in Sibsagar included for the first time in the report and referred to above, the actual reduction in the number of gardens in the whole province would amount to 35.

The large increase in Cachar is attributed by the Deputy Commissioner to an attempt made to include in the tea register the areas that have been newly taken up annually by tea planters. In the Brahmaputra Valley, Kamrup shows a considerable decrease in the area held by tea planters, which is due to 41 gardens having been removed from the register during the year (13 unworked and 28 abandoned). The decrease in Darrang is accounted for by the four gardens closed, and that in Nowgong is due to the re-adjustment of the boundaries of the waste land grants by the cadastral survey, no new land having been taken up during the year. The increase in Sibsagar has not been explained, while that in Lakhimpore is attributed to the new gardens opened during the year.

It is satisfactory to notice that there has been considerable improvement in the furnishing of information by the agents or managers during the year under report. The figures for 752 gardens have been furnished by the agents or managers, and for 76 (against 126 in the previous year) estimates have been framed based on the preceding year's returns. The gardens for which the figures had to be estimated are distributed as follows: Cachar 36, Nowgong 5, Kamrup 3, Sibsagar 15, Sylhet 6, and Darrang 11. It is unfortunate that in the case of Cachar, the most important tea district in the province, estimates had to be made for 36 gardens (19 in the sadar and 17

in Hailakandi). All the gardens in Lakhimpore have furnished returns this year, while in 1890 eight gardens had to be estimated for.

The Chief Commissioner's thanks are due to those planters and agents who have helped Deputy Commissioners by furnishing statistics on which this report is based.

The statement below gives for the last six years the areas under mature and immature tea plants, and the total area held by tea planters:—

Year.	Under mature plants.	Under im- mature plants.	Total area of land held by tea planters. Acres.
1886 ...	170,138	33,855	934,134
1887 ..	177,900	33,179	950,171
1888 ...	188,329	28,347	955,499
1889 ..	196,689	30,560	1,000,665
1890 ...	200,658	30,380	994,497
1891 ..	208,407	33,416	996,746

The above shows an increase under all the heads; that in area under mature plants being a steady one. The increase in area under mature plants, which has been general in the Surma Valley, and in the upper districts of the Brahmaputra Valley is due to 'immature' plants passing to the category of 'mature' after their fourth year of growth. Silchar, Habiganje, Ganhati, Nowgong, Sibsagar, and Golaghat, show a decrease in area under immature plants, which is partly due to the above reason, and partly to extensions not keeping pace with the progress of plants from immature to the mature stage.

In the statement below, figures are given showing the total area under cultivation for the last two years:—

District.	Total area under mature and im- mature plants.		Increase or decrease. Acres.
	1890. Acres.	1891. Acres.	
Cachar ...	56,562	58,793	plus 2,231
Sylhet ...	43,196	46,428	,, 3,232
Khasi and Jaintia Hills ...	30	30	...
Goalpara ...	397	425	,, 28
Kamrup ...	6,361	5,131	— 1,230
Darrang ...	21,327	23,134	plus 1,807
Nowgong ...	11,868	11,886	,, 18
Sibsagar ...	54,940	58,370	,, 3,430
Lakhimpore ...	36,357	37,626	,, 1,269
Total ...	231,038	241,823	plus 10,785

The increase in Cachar, Sibsagar and Lakhimpore is due to recent extensions. The Deputy Commissioner of Sylhet attributes the large increase in his district to the extensive areas put under tea year by year in all subdivisions, which have now come under the category of mature. No reason has been given for the increase in Darrang, except that the figures are only approximate, estimates having to be made for 11 gardens some of which have not furnished returns for many years. The variations in other districts have not been sufficiently accounted for. The total outturn of tea in 1891 is reported as 90,399,362 lb. being an increase of 8,280,110 lb. or 10.08 per cent over the previous year's figures.

The following table compares with the figures furnished by the Indian Tea Association, and the Trade Returns with those reported by the Deputy Commissioners:—

Outturn according to Indian Tea Association 1890: Brahmaputra Valley 45,416,721 lb., Surma Valley 31,472,703 lb. total 76,889,424; 1891: Brahmaputra Valley 50,967,373 lb. Surma Valley 38,696,664 lb. total 89,664,037 lb.

Outturn according to trade returns, 1890: Brahmaputra Valley 46,703,973 lb. Surma Valley, 32,016,795 lb. total 78,720,768 lb.; 1891: Brahmaputra Valley 46,418,277 lb. Surma Valley 34,563,950 lb. total 80,982,227 lb.

Outturn according to Annual Tea Report, 1890: Brahmaputra Valley 48,144,401 lb., Surma Valley

33,974,851 lb., total 82,119,252 lb.; 1891: Brahmaputra Valley 50,643,374 lb. Surma Valley 39,755,988 lb., total 90,399,362 lb.

The Trade Return figures are, as usual, the lowest, and those furnished by the district officers the highest. The difference between the latter and the Indian Association figures is not, however, so large this year, being only 735,325 lb., as against 5,229,828 lb., in 1890. All the three sets of figures point to a growth in production which, moreover, has been continuous for some years.

Thus, the yield in all districts, except the Khasi and Jaintia Hills, Kamrup, and Nowgong, has increased. Darrang, which showed a slight falling off in 1890, has much improved this year, while the decrease in Kamrup, which is attributed to short rainfall and want of labour, still continues. The same reason is given for the decrease in Nowgong. The large increase in Goalpara, viz., 29.43 per cent against 1.40 per cent in 1890, is rather curiously explained. For instance, while one manager puts it down to the "peculiarity of the season," and "uneven distribution of rainfall," another says, "the season has been an exceptionally good one and has increased the yield." The Deputy Commissioner adds as his own opinion:—

I believe the season was a very bad one for want of sufficient rain throughout the year. The increase in the yield may have been caused by the increase in the number of mature plants.

The explanations given in the preceding page go to show that the state of things varies considerably in different parts of the same district. This statement is horn out by two other conflicting remarks quoted below.

With reference to the outturn for his district, the Deputy Commissioner of Darrang writes:—

In spite of the dry season many of the gardens near the hills did fairly well. Many of these are new gardens, on which young bushes come under the fingers of the plucker in increased numbers year by year.

One of the leading planters in the district, however, says:—

The tea season of 1891, as far as southern Mangaldai is concerned, has been the worst on record for many years as far as yield, and many without doubt he put down to the scanty rainfall right through the season.

The Deputy Commissioner of Kamrup quotes a manager, whose account, too, of the past tea season is very desponding, from which the following is an extract:—

I may mention that on account of an unusual drought, this season has been, for yield and quality of teas, the worst experienced by me during seventeen years. * * *

In the case of Sylhet the reason given in paragraph 6 above for the increase in area under mature and immature plants, applies also as an explanation of the increased yield.

The Deputy Commissioner of Cachar attributes the increase in his district to the new extensions lately made on richer lands now beginning to yield.

On the whole, the year under report does not appear to have been favourable for the growth of tea throughout the province. Blight was not prevalent to any great extent, but hailstorms did considerable damage to some gardens in Cachar, and Lakhimpore. The rainfall was most unevenly distributed, and caused the season to close.

Few of the district reports give any correct information under the head of prices, a result which is chiefly owing to the fact that in many gardens much of the tea was unsold when the reports were submitted.

The figures kindly furnished by the Secretary, Indian Tea Association, are:—

Assam Valley teas ... As. 7 per lb.

Surma Valley teas ... As. 6 to As. 4 per lb.

These prices are somewhat lower than those for the previous which were—

Assam Valley teas ... As. 7.5 per lb.

Surma Valley teas ... As. 6.8 to As. 6.9 per lb.

The complaint is almost general that the tea market

is very dull, prices having in some cases gone down as much as 4 annas per pound.

The following remarks by one of the leading planters of Lakhimpore may be quoted:

Prices, however, have been very disappointing. The market opened well, but almost immediately prices gave away, and the tendency has been steadily downwards until now, when ordinary teas are selling at abnormally low rates.

The Superintendent of Jokai Assam Tea Company, Limited, a very large concern in Lakhimpore, writes:

Prices have touched the lowest point ever known; some say ordinary teas are fetching 2 annas per pound less than Indian tea of the same quality has ever sold for.

The competition of Ceylon tea is supposed to be one of the principal causes of the depression in the market.—*Indian Agriculturist*, June 4.

DARJEELING LETTER.

The recent prices at the Calcutta sales of tea have been more reassuring, and there seems to be a tolerably steady demand for good liquoring teas with flavor: a great many gardens in this district are behind last year and in the Terai leaf is particularly short just at present so that demand for good strong teas is likely to last throughout July though beyond that period it is speculative to prophesy what will happen. Nearly every portion of this district has been more or less affected by green fly blight and there is no doubt some grand teas have been made lately, by all accounts some fine liquoring teas have gone straight home from Assam and it is certain that the quality of the teas made to date is superior to those made to the same date last year taken all round. It was pointed out very strongly at the commencement of the season to all managers the vital importance of keeping the Indian brand above the standard of Ceylon and China poor liquoring teas and not without effect. If managers would only stick to plucking two leaves and a bud and going round their gardens steadily in six days when labour allows it, we should not see so much Indian Pekoe Souchong on the market at four annas. Labour is more plentiful than it was last year, partly owing to scarcity in Nepal, but the Indian corn crop promises to be a bumper one, so the scarcity of corn ought not to last much longer and this will affect also the price of rice which is now dearer than usual. The Terai is keeping up its reputation as usual by an outbreak of cholera, which has now spread over a tolerably large area. Rainfall has been rather light for the last week in some parts of the district, and very short near Silliguri, all the hills have been heavily clouded and sunshine is at a premium.—*Indian Planters' Gazette*.

INDIAN TEA AT THE CHICAGO EXPOSITION.

TO THE EDITOR OF THE "INDIAN PLANTERS' GAZETTE."

SIR,—With reference to the intemperate letter from a Tea Planter so ably commented on in your last week's issue the following figures taken from audited accounts speak for themselves. They relate to the working in 1891 of the whole of the public Tea Companies under our Agency (good, bad and indifferent) with the exception of one where manufacturing has not yet commenced.

Agents' allowance	Managers' pay,
and for Commission	and Commission
R63,676	R1,10,722

The first amount represents the total amount of allowance and for Commission of any sort whatever bar interest, earned by us as Agents. The second refers to Managers only, and does not include Assistants.

Out of the first sum, European Assistants, Baboos, Sircars, Durwars, Taxes (other than but including Income) numerous subscriptions, Office rent, private residences, stable and various other expenses unknown to tea planters have to be provided. The manner in which applications for subscriptions have been met by certain planters can only be due to misapprehension of the real facts of the case. No Agency business gives such a poor return as tea in comparison with the amount of work involved. Take for example, a Jute Mill of 500 Looms, such an Agency—entailing one quarter the work—will give as good a commission as a dozen Tea Gardens turning out 5000 maunds each. Let all interested in tea for once in a way, if such a thing be possible, sink petty jealousy and cordially support, to the best of their respective abilities, the movement to introduce Indian tea into America. A better man than Mr. Blechynden for promoting the object in view could not possibly have been secured. "CALCUTTA AGENTS."

—*Indian Planters' Gazette*, July 2.

USES OF THE BANANA.

Editor, *Sugar Journal*.

I don't think that the health-giving properties of the banana are appreciated by the people of our large towns where the fruit is so cheap. They merely look upon it as a cheap edible when other fruits are scarce or out of season, but in slices the banana makes an excellent salad served with any kind of dressing; cured it is far more palatable than meat; boiled as a vegetable while green in the skin for one hour and peeled before sending it to the table it will be found excellent, and would make Paddy smile and think he was in old Ireland again. It also makes an extremely delicious pudding for children served with sweet milk and some sugar, and baked for one hour in a moderately quick oven. Many people in different parts of the world can with truth say in regard to the banana "This is what I live on." A very good breakfast dish is to be made by frying slices of bacon and then slices of banana in the hot bacon fat with plenty of pepper, and serving together as one does a dish of bacon and eggs. These are a few of the many ways of utilising this most accessible fruit for both rich and poor, which are well-known to most people living on the coast of North Queensland, but perhaps not so well-known further South where the *Sugar Journal* and *Tropical Culture* circulates.

WILLIAM KEYNOLDS,
Daintree River, North Queensland.

THE COFFEE TRADE.

[In copying the following article from the *American Grocer*, we attract attention to the regrettable facts that in the United States the consumption of coffee and tea is not advancing, while the use of beer is increasing.—Ed. T.A.]

The deliveries of coffee for the eleven months of the trade year ending May 31st were 237,693 tons, against 231,172 tons for the corresponding period of the preceding year. This increase is not as large as we have a right to expect, considering the growth and prosperity of the country. Under favourable conditions consumption should advance about 8 per cent annually. That it does not is surprising, in view of the prices being so much lower for Brazil sorts than at this time last year. The decline is fully 4½ cent per pound on Brazil grades. Mild sorts rule higher, particularly Padang and fine Maracaibo. It is generally conceded by the trade that there is a growing scarcity of fine old coffee, and also that the average grade of the imports is not as high as it was years ago. The substitution of steamers for sailing vessels, the hurrying of the crop to market, less care in the preparation of the bean, new methods of curing, the introduction of machinery, have combined to reduce the proportion of fine or fancy grades of coffee until there is an absolute scarcity of what the trade for

merly designated fine Golden Rio, Brown Old Government Java and fancy marks of Central American and Venezuelan coffee. Another cause for the change is the growth of the business in roasted coffee. There is not as much attention paid to style as in the days when the West and South insisted on buying coffee in the raw bean. This condition can only result in one thing, viz., a steady appreciation in the price of fine grades, until it becomes so marked that planters will regard it as a premium sufficiently large to warrant greater care being given to methods of cultivation and preparation for market.

While there has been no increase in the consumption of tea, which is not as great a favorite or as universal a beverage as coffee, there has been a marked increase in the consumption of beer and cocoa, particularly beer. It seems to be the strongest competitor that coffee has to encounter. The cost of a gallon of beer at retail is 35 at 50 cents while the cost of a gallon of strong coffee is from 15 to 20 cents. It requires no care nor fuel to prepare beer,* which is a cool and stimulating beverage, and hence in high favour with the masses, particularly those of foreign birth or descent.

Without attempt at explanation, we call attention to the fact that the per capita consumption of beer increases in a greater ratio than any other beverage.

AN EX-CYLON PLANTER IN AUSTRALIA.

MILDURA SCHEME—THE BEST WAY TO DEVELOP THE MUSCLES—A DISORDERED LIVER—ANGLO-INDIAN SETTLEMENT IN SOUTH AUSTRALIA.

The Barrier, N. S. W., June 22nd.

I enclose two cuttings which refer to Mildura, and I leave your readers to draw their own conclusions. It is evident that things must be arranged on a sound and satisfactory basis before sufficient inducement can be held out in order to attract new settlers. An influential settler like Lord Ranfurley, who has such a large stake in the scheme, must be of great assistance to the more humble members of the community. I sent you cuttings about Mildura lately, and I shall be on the outlook for the latest news regarding the settlement.

A greenness is gradually appearing everywhere, where formerly there existed nothing but barren earth. Frost is keeping off in a wonderful way, so the "feed" will soon come on now. This climate and life is truly a contrast to Ceylon. A "go" with the axe at the wood-heap in the early morning in the keen cold and then a shower-bath of cold water that makes one gasp and gurgle:—what better appetizer could be found? There is nothing like axe-work to develop the muscles.† What a contrast to the biliousness of morning muster in a tropical climate. The liverish planter is as cross as a bear with a sore head, till the sun gets up. The smoky toast and bazaar egg, and the hasty scribbling in Abram Saibo's pass-book: "7 lb. beef, 2 loaves, 4 lb. sugar (don't send any more of the beastly stuff you sent last,) 1 bottle table salt, 3 lb. onions," &c., and then a note at the foot, "I'll try and send you a cheque next beef-day." Poor patient Abram Saibo! Here we have fresh mutton chops, delicious butter, fresh scones, sometimes an egg, and sometimes porridge. The worst of porridge is that it is too suddenly satisfying and doesn't last. One's appetite disappears too quickly with a plate of porridge and then returns with redoubled vigour far too soon to be pleasant. Then with a pipe in full blast one feels ready to tackle the day's work. No liver here. No feverish inertness or that peculiar feeling at the knees which the Kelani Valley men know so well.

Have you heard anything of the new settlement of Anglo-Indians in South Australia? A Mr. Christie has been prospecting and is very much satisfied with

the result.* A number of civilians with each a certain amount of savings intend to take up a piece of land and cultivate *fruit*. The great danger of so doing is the evil of inexperienced men risking their savings late in life on a project that depends on their own efforts and knowledge. Now Mildura furnishes a better field, as settlers can gain by the experience of those around them. I still believe in Mildura, but evidently there is a good deal to be done to thoroughly establish that colony on a satisfactory footing. Mr. Playford, the S. A. Premier, has returned from India highly pleased with the idea of importing Indian coolies—Tamils especially. The day is coming. Sir Samuel Griffith in Queensland and Mr. Playford in S. A. are both in favour of black labour for tropical latitudes. Then will be the chance for the tropical planter when the selfish white labourer is told to mind his own business.

ABERDONENSIS.

[But the latest accounts are unfavourable to Mr. Playford's scheme.—En. T. A.]

CUSTOMS WEIGHTS OF TEA.—Most of our readers are aware of the mode of ascertaining the tare of China packages, which are made of thin wood and the weight of a parcel is regular; but in the case of Indian and Ceylon teas, the weight of the wood generally varies so much that it is necessary to have each chest tared separately. When teas are weighed on importation, representatives of the Customs authorities, the importers, and the warehouse proprietors are present; but there is no one to represent the unfortunate buyer and as the Customs and the importer gain by the tare being as light as possible, there is the natural inference that the buyer's interest will sometimes suffer. In the case of average weight it is the practice to select a few packages, and if the weight of the tea does not vary more than two pounds, then the weight of the majority of the selected chests is accepted as that of the whole parcel. This possibly is fair as regards the seller and buyer of the whole parcel; but teas are sent to grocers in consignments of single or few packages, and upon the tea being turned out it is often found that the weight of the wood and lead exceeds the tare allowed on the difference between the gross weight and the average net weight fixed by the Customs. This is manifestly unjust, and should not be tolerated any longer. When the duty and price of tea were higher there might have been some reason for ascertaining the tare to almost a fraction of a pound; but now there can be no reason to weigh so finely, much less to have a system in operation which leads to a grocer paying duty on tea which he does not receive, and which was never imported into this country. There was an attempt to alter this system two or three years ago, and some care was exercised to prevent buyers being subjected to unnecessary loss; but now sufficient time has been given to thoroughly test the system, and it has been tried and found wanting. Every package in a parcel should be weighed separately, except in cases where the tares of the selected chests are absolutely uniform. Every buyer should insist upon getting his full weight. He should not rest satisfied until the mode of ascertaining the weights is so arranged that the buyer of a single packages of tea is never called upon to pay for common wood and lead at the price he paid for the tea, and the duty thereon.—*Truth*.

* A most misleading sentence. Of course what is meant is that beer, requiring much care and fuel to brew, is ready for use as drawn from cask, or emptied from bottle.—Ed. T. A.

† Vide the experience of "the Grand Old Man."—Ed. T. A.

* Yes: we had a long and interesting interview with Mr. Christie on his return from Australia. Our good friend Major John Adam Fergusson seems to have impressed him in favour of South Australia, dry as the climate is.—Ed. T. A.

MILDURA IRRIGATION COMPANY.

We learn from the *Argus* that the half-yearly meeting of the irrigation Company was held at Mildura last week, Mr. W. M. Paterson presiding. The new large institute hall was packed with shareholders, and a good deal of excitement was shown. A long progress report was read from the lately-appointed committee, in which some surprising statements appeared as to the company's position and the administration of its affairs. It was stated that if the outstanding rates were collected, there would be sufficient to pay all the arrears of wages accounts and to meet the working expenses to the 30th June. The report recommended the shareholders to pay up the rates, which must be done in any case, and that the wages be the first charge; also, that, in view of the extreme confusion in which all the arrangements in connection with the Company appear to be, and the desirability of having authoritatively defined the rights and duties of Chaffey Brothers, Limited, under the Crown grant, and the rights and duties of the settlers, Chaffey Brothers, Limited, be asked to join the settlers in approaching Parliament to have defined and effectually secured the rights of all parties, and that, failing Chaffey Brothers, consent within 14 days, the committee immediately prepare a petition asking Parliament to appoint a select committee, or otherwise to make a full inquiry to secure the foregoing object. It also recommended the removal of the registered office of the company to Mildura, and that pending the decision of the shareholders on the points raised the directors be requested to abstain from doing anything but routine business. All the business of the meeting including the consideration of the balance sheet and the election of directors, was deferred. The committee's report is, in the meantime, to be printed and circulated amongst the shareholders. Before the close of the meeting Mr. W. B. Chaffey read a letter from Mr. George Chaffey, regretting that important business would prevent his attending the meeting, and stating that he would be only too delighted to accede to any reasonable suggestions made by the meeting. The Earl of Ranfurly afterwards presided at a settlers' meeting, at which the committee was enthusiastically supported, and he opened a subscription-list to defray the expenses wish £20, £100 being promised in the room.

THE DISPUTE AT MILDURA.

For some time considerable friction has existed between the shareholders in the Mildura Irrigation Company Limited and Chaffey Bros. Limited. Each purchaser of land from Chaffey Bros., Limited, becomes a shareholder in the Irrigation Company, and acquires thereby rights to sufficient water as a perpetual easement to his property as well as a liability to be rated for their maintenance. The members of Chaffey Bros., Limited, are also members of the Irrigation Company, and have a controlling influence in the management of its business. A meeting of shareholders of the Irrigation Company appointed a committee to confer with the directors, with power to inquire into the constitution, finance, general management, and affairs of the company. The committee reported at a recent meeting, and brought forward a number of allegations tending to show that the control of the two companies being in the same hands, and the interests being at times antagonistic, the interests of the shareholders in the Irrigation Company had suffered. It was suggested that Chaffey Bros., Limited, be requested to join the Irrigation Company in carrying an appeal to Parliament to have the rights and duties of the settlers on the one hand and of Chaffey Bros., Limited, on the other authoritatively defined. Failing the consent of the Chaffey Bros. the appeal to be made by the settlers alone. It was also suggested that the registered office of the company be removed to Mildura. The meeting was adjourned to give time to consider the report. Messrs. Chaffey Bros. allege that a number of the irregularities complained of took place before there were any settlers, when it was necessary to keep the Irrigation Company alive.

They further state that up to July, 1890, the irrigation had not cost the Irrigation Company one penny. One of the most serious charges, as to the Chaffey Bros., as directors of the Irrigation Company, having charged the settlers jointly and severally with a contingent liability of £50,000 to the Crown, has been publicly withdrawn as being quite misleading. Since the adjourned meeting informal demands of a modified character have been submitted to Chaffey Bros., Limited, which they state they are quite prepared to agree to. These include the election of two local directors of the Irrigation Company, the subsequent increase of the board from five to nine members whereby the settlers may obtain full representation, and an inquiry by the reconstituted board into the alleged grievances of the settlers, with a view to redress. These modified proposals have been submitted through the mediation of Lord Ranfurly. Mr. George Chaffey will go to Mildura this week. He expresses the belief that the dispute will be amicably settled with very little trouble, for both Chaffey Bros., Limited, and the settlers are equally bound up in the success of the settlements, and their interests are not antagonistic, but identical. —*Australasian*.

THE ANNUAL REPORT OF THE ROYAL BOTANIC GARDENS, CALCUTTA, FOR THE YEAR 1891-92.

The Resolution of the Government of India on Dr. King's report is as follows:—

The report shows that the year has been one of great activity as regards outdoor operations, and that much has been done to improve the condition of the driving roads in the garden, which were referred to in last year's report as requiring attention. The season was abnormally dry; and though in the conservatories but little damage was done, it is to be regretted that out of doors, despite the exertions of the garden staff, many casualties occurred especially among the finer and rarer palms. Valuable additions were made to the Herbarium, among which may be mentioned a rich collection of plants from Kew, a beautiful collection of Australian plants from Baron Von Müller, and collections from the north-west Himalayas, Jaunsar-Bihar, Dehra Dun, the Malay Peninsula, North Canara, Sindh, Chota Nagpur, Khasia Hills and Manipur, Upper Burma and Assam, the Duars, Independent Sikkim and Laccadive Archipelago. To the contributors of these specimens, Messrs. Lace, Gamble, Ridley, Peal, Heawood, Talbot, General Sir H. Collett, Captain Fulton, and Drs. Waddell, Cooke, Wood and Alcock, the thanks of Government are due. Dr. Prain visited the Andaman Islands, Parasnath, and the Khasia-Jaintia Hills; and his botanical explorations, as well as those of Collectors employed by the Calcutta garden, have added some valuable collections. During the year the third volume of the garden annals was issued, and the bulk of the material for the fourth volume, containing a monograph by Dr. King on the important family of *Anonaceae* was prepared. Both Dr. King and Dr. Prain continued to contribute valuable papers on botanical subjects to the *Journal of the Asiatic Society of Bengal*. The Lloyd Botanic Garden in Darjeeling was visited in July last by flights of locusts, which caused at the time considerable damage to the plants. The mischief was, however, speedily repaired and the garden is now reported to be in excellent order.

From the detailed report we quote as follows:—

Botanical Collection.—During the year full advantage was taken of the various opportunities offered for the botanical exploration of the provinces allotted to the Superintendent of the Royal Botanic Garden, Colonel T. Cadell, v.c., Chief Commissioner of the Andamans, whose assistance has already had so often to be acknowledged, having invited Dr. Prain to revisit Port Blair in connection with the botanical exploration of his province, and Dr. King having permitted the visit, Dr. Prain proceeded to Port Blair in March 1891. The station steamer, Her Majesty's Indian Marine steamer "Nancowry," having been

placed at his disposal by Colonel Cadell. Dr. Prain was enabled to visit and investigate the flora of Narcondam, Barren Island, Little Andaman, Car-Nicobar, and Batti Malv—all these, save Car-Nicobar, being places never before botanically investigated. Mr. E. H. Man has again most kindly superintended the collection of specimens in the neighbourhood of Port Blair by Burmese convicts. In November 1891, Dr. Prain visited Mount Parasnath and made a botanical tour in Chota Nagpur, while in March 1892 he was directed to make a botanical tour in the Khasia, and more particularly the Jaintea Hills. This tour was in connection with the botanical survey of Assam and Burma, towards which the Government of India and the local Governments of Burma and Assam give annual grants. In connection with this survey also Mr. Proudlock, Curator of the garden, was sent in February 1892 on a collecting tour to Tenasserim, Tavoy, and Mergui. In Assam two native collectors were at work in the Naga Hills for the greater part of the year; latterly they collected on the Lushai frontier; the recent troubles in this region have unfortunately as yet prevented Mr. McCabe from taking the men into the interior of the Lushai country, and personally supervising their work, as he has most kindly volunteered to do. From Burma, besides the Tenasserim and Mergui collections, other collections have been received from the garden collector, Abdul Hok, who has been at work in the Shan Hills and the Ruby Mine districts; some specimens have also been received from frontier stations under the arrangement mentioned in last year's report as having been kindly made by Dr. Leslie.

Library.—Some new books have been purchased; others have been presented to the Library; a good number of old ones have been rebound. Perhaps the most interesting occurrence in connection with the Library has been the acquisition of a portrait of Colonel Robert Kyd. Learning that a portrait of this distinguished soldier was in the possession of the Agri-Horticultural Society, the Curator of the Herbarium, with Dr. King's permission, asked the Society to be allowed to have it copied for the Library of the Royal Botanic Garden. The President and Council having very cordially granted this request, a copy of the original, carefully executed in the Government School of Art, has now been completed, and a portrait of the gentleman who in June 1786 suggested to the Honourable the Board of Directors "the propriety of establishing a Botanic Garden," and who performed the duties of Honorary Superintendent here from August 1786, when the undertaking was commenced, till his death in 1793—an officer described by the Honourable the Court of Directors in the letter in which, in 1787, they sanctioned the action of the Honourable Board in the previous year, as one "who, by the attention he has shown to a matter which may one day prove of the greatest benefit to his constituents and to his country, stands most deservedly high in our esteem and favour,"—at length hangs in the museum of the institution with which his name is so intimately associated.

THREE WAYS OF COOKING CUCUMBERS.

The possibilities of the cucumber, except for pickling or salads, are little understood. It is excellent soup, says an exchange, as well as fried, stewed, stuffed, and many other ways.

Cucumber Soup.—Cut one large or two medium sized cucumbers into thin slices, strew salt over them and place between two plates to drain. Put them into a saucepan, with a quart and half a pint of some white stock, either chicken or veal, and simmer gently, without reducing the quantity, for forty minutes. Season with salt and a little cayenne; thicken with ground rice or arrowroot, wet with milk, and, as soon as it has boiled up, draw to the side of the fire; add half a pint of hot milk and the beaten yolks of two eggs. Serve at once. The safest way to add eggs to any hot liquid is to turn a little of the latter slowly into the bowl containing the yolks, beating the while. When the bowl

is full turn it all into the vessel containing the rest, still beating, and when thoroughly hot pour into the tureen.

Stuffed Cucumbers.—There are several ways of preparing these. Peel two large ones, and with a sharp knife cut out a neat piece from the side. With a small teaspoon remove the seeds, and fill with nice forcemeat of any kind; replace the piece, and tie securely with stout white thread. Line the bottom of a saucepan with thin slices of bacon and veal, lay on the cucumbers, then another layer of veal and bacon, three new carrots, scraped; three small onions and as many turnips; cover with stock or water, and simmer until all are tender. Thicken the gravy and pour it around the meat and vegetables after they are neatly dished. Season, when about half done, with salt and pepper. Another way is to cut them in halves, take out the seeds, and fill with a forcemeat made of equal parts of bread crumbs and chopped marrow, well seasoned with salt and pepper. Tie the halves together, lay on a baking dish, nearly cover with meat gravy, and bake until tender. A good substitute for meat gravy is a brown drawn butter.

Cucumbers Stewed.—Peel and cut into quarters lengthwise, dredge with flour, season and fry lightly in hot butter; put them in a saucepan, with some good brown gravy, and stew slowly until tender. Add the least trifle of sugar and a teaspoonful of vinegar to the sauce; thicken slightly and pour around the cucumbers. Sometimes an equal number of small button onions are stewed with the quarters of cucumbers.—*Florida Agriculturist.*

THE BULKING TOGETHER OF SMALL BREAKS OF CEYLON TEA.

The receipt of the following letter has, we confess, taken us utterly by surprise. So far as we can see no means are to be taken to consult the wishes of the owners of the respective small breaks of tea.

Secretary, Customs, No. 14,918,—1892.

Custom House, London, 4th July 1892.

Gentlemen,—In reply to your letter of the 14th of May last, seeking the permission of the Board of Customs for the bulking together in Bond of small breaks of Ceylon teas, even although they may have arrived by different ships and from various gardens, in view of the difficulties under existing Regulations in the way of disposing of such small breaks at their proper market value.

I am directed to acquaint you that, the subject having been fully considered, arrangements have now been made by which your wishes in this matter will be met, and that the necessary general directions will shortly be issued accordingly.—I am, gentlemen, your obedient servant,

R. T. PROWSE.

Messrs. Hancock, Brothers & Company, 28, Mining Lane, E.C.

TRAVELS IN PERU AND THE UPPER VALLEYS OF THE AMAZON.

BY ARTHUR SINCLAIR.

[The first part of Mr. Sinclair's paper, which we quote from the *Victorian Magazine* for June, is illustrated by a beautiful scene of ferns, palms and other tropical vegetation, entitled "Jamaica: a pretty peep by the wayside."—*ED. T.A.*]

There are three routes available from Europe to Peru, the most direct—after crossing the Atlantic—being up the Amazon: the most comfortable, by the Straits of Magellan; and the quickest, viâ the Isthmus of Panama.

To save time, let us choose the last. One advantage of this route is, that it gives us a peep in passing, at the islands of Barbadoes and Jamaica, the two oldest and most valuable of our West Indian possessions. Barbadoes is only 166 square miles in ex-

tent, but every acre is cultivated, chiefly in sugarcane, and altogether the best cultivated little tropical colony I have come across; densely populated, chiefly negroes, who look much happier and better off than the "poor whites." The English language only is spoken, spoken with a terrific fluency and an unmistakable Irish brogue. Readers of Carlyle's "Cromwell" will not be at a loss to account for this, remembering how Oliver sent so many of his refractory Irishmen there. "Terrible Protector!" exclaims the sage. "Can take your estate—your head off, if he likes. He dislikes shedding blood, but is very apt to Barbadoes an unruly man; has sent, and sends up in hundreds to Barbadoes, so that we have made an active verb of it—Barbadoes you."

Again, in one of the Protector's characteristic epistles, we read that 1,000 Irish girls were sent; "and, as to the rogue and vagabond species in Scotland, we can help you at any time to a few hundreds of these!" An Irish fellow-passenger hearing his own language so well accented, enquired of a Barbadoes negro working at Jamaica, "How long have you been here?" "Noine years," was the reply. "Be jabbers" said my friend, "if you've got black like that in noine years, it's high time I were off home again."

Jamaica has a magnificent harbour, from which superb views of the grand old Blue Mountains are to be seen. Kingston, the capital, is spread out on the rich flat land lying between, sweltering under a blazing sun, from which even the laughing negro is glad to take shelter below the umbrageous trees. The climate and vegetation strikingly remind one of Ceylon, but alas! the abandoned hill-sides testify to the greater labour difficulties of the poor planter here. A few days more, and we heave in sight of the Isthmus of Panama. Generally speaking, the first land seen is Porto Bella, in the Gulf of Darien, which reminds us of a chapter in Scottish history we would fain forget if we could. Here, about 300 years ago, some of the very cream of our countrymen were landed, and sacrificed to the contemptible jealousies of our neighbours. Terrible was the loss to so poor a country, and heroic was the struggle, but it was of no avail against such fearful odds; and now the only really useful lesson we can learn from the disaster is, that even Scotchmen are not equal to manual labour in the tropics; and whatever inducements selfish individuals, or soulless companies may hold out, it may be accepted as a general rule that Europeans are unfitted for field labour in purely tropical temperatures. It may be all very well for overseers who live in luxurious bungalows, and view their fields from under the shade of ample umbrellas, but it means death to the exposed pick-and-shovel man. No; Europeans or men from temperate regions do not readily acclimatise to the tropics, and for that matter, as far as my experience goes, the same rule holds good in the vegetable kingdom: for, although nearly all our most cherished plants come to us from near the Equator, we cannot, as a rule, induce our native trees to take root there.

Colon, our first landing port, apart from its luxurious vegetation, is a very wretched spot. It is only in a Spanish Republic where the existence of such a pestiferous place is possible. It is not merely the disreputable appearance of its degenerate people, nor the frequent squabbles, dignified by the name of revolutions, we have to fear, but the ever present *filth*, which is much more dangerous to life. Fortunately, a fire has recently burned down and purified a large portion of the town of Colon, rendering it, for the time, less dangerous to sojourners. A statue to Columbus stands at the entrance of that now abandoned project, the Canal. Poor Lesseps! would that he had been content with his success at Suez! This gigantic failure—a failure so tremendous that the very ruins may be said to be stupendous—must for many years to come form a melancholy subject of comment, as passengers ride along the margin of the unsightly ditch. What a sad sacrifice of human life and carefully accumulated wealth this unfinished ditch and surrounding *débris* represent! There is little hope of the work ever being finished by Frenchmen now; indeed, we are told that by agreements

the Columbian Republic can next year lay claim to the works as they stand, and mean to do so.

The railway on which we cross the Isthmus belongs to an American Company, and Jonathan knows well how to make the most of it. No such exorbitant charges would be tolerated in any civilised country, and beyond the mere cost of ticket and transport of baggage, the amount of palm-oil one has to expend on officials in order to get along at all, is simply iniquitous. "Ah! but," says Jonathan, "you little know how costly this railway has been. Every sleeper it rests upon cost a life." It takes about four hours to get over the forty-five miles of comparatively flat land dividing the Pacific and Atlantic Oceans, and such is the condition of the first-class American carriages, that a shower of rain renders the use of an umbrella absolutely necessary, unless one is desirous of a shower-bath.

The outlook from the carriage windows is not exactly inviting: deserted villages, palatial bungalows abandoned, ponderous machines rusting among the malarious jungle, flit past in slow succession, while at the various stations a few poor ghostly whites, and hundreds of dark and hungry-looking old Canal labourers, scramble to make a penny out of the sympathetic passengers. The luxuriant vegetation is the only relief to the eye, and it is impossible to believe that these beautiful shrubs, trees and creepers, could not be turned to some useful purpose. There is not an acre of real cultivation; we simply pass between living walls of natural greenery—the beautiful banana leaf, the graceful bamboo, and curious mangrove, the glossy mangoe tree and feathery palms, all mixed up with ferns, orchids and creeping flowers of every possible form and hue. By those who have never left a temperate region, the astonishing variety of plants near to the Equator can scarcely be realised.

A more beautiful situation for a city than that of Panama, it would be difficult to find in the world. The noble and ever tranquil bay is dotted over with the most exquisitely arranged islands—from one to a hundred-and-fifty acres in extent—closely clothed with evergreen trees, glossy shrubs, and flowering creepers down to the water's edge; the little hills around the city are covered with rich and varied vegetation; while the valleys teem with giant trees, amongst the most useful and beautiful in the vegetable world.

Of the city itself I have little to say. There is the usual plethora of Roman Catholic churches and American bars, while Lesseps has added one substantial building in the shape of a handsome range of now tenanted offices, but the streets are atrociously rough, and the sanitary condition indescribably bad. This, I feel sure, has more to do with the unhealthiness of the place than anything else. The climate is humid and warm, but so are many places in India and elsewhere in the tropics, and it would be absurd to think that a mere strip of land lying between the Pacific and the Atlantic would continue to be specially unhealthy if cleared, drained and cultivated like any other civilised country. As it is at present, the cemeteries tell their own sad tale—an ample acreage, but filled to overflowing. On the one hand, as we drive along into the suburbs, lie the remains of the common herd, little wooden crosses being deemed sufficient to mark their resting-place. On the other side, a smaller enclosure evidently contains tombs of a more select kind, the marble and Aberdeen granite head-stones testifying to the goodness, greatness or powers of the departed.

Historically, Panama is chiefly interesting to us as the quondam headquarters of the Spaniards during the years they were spying out, with envious eyes, that great land of promise Peru. 'Twas from here, 360 years ago, that the bastard but ambitious swine-herd, Pizarro, set sail with his cruel and greedy adventurers. Let us follow him. Afar off as it is, we can imagine with what impatience the months and years were spent in sailing to and fro, while reconnoitring his prey; but it seems ridiculous to either credit or altogether blame Pizarro for the so-called conquest of Peru: a man who could not read a line in his own mother tongue, whose signature was a clumsy cross, whose only redeeming

quality was a certain amount of animal courage, was not the man to carry out great schemes. The inception, indeed, was that of a priest, who furnished the funds for the expedition; and the real instigator of the treacherous murder of the too-confiding Inca Monarch was the wily priest who accompanied the gang of butchers. The hardships, too, and terrific tempests encountered in the Pacific must have been rather over-rated by Prescott, as the Pacific does not so frequently belie its name as the eminent historian would lead us to suppose. My own experience, at least, during several voyages, at the same season of the year as Pizarro's was in the very reverse of tempestuous seas, while the temperature was simply perfection, and the air a positive luxury to breathe, after the moist atmosphere of the Carribean Sea; and old salts I consulted on the subject, declared that this had been their general experience during the past thirty years. Pizarro took six weeks to accomplish the distance we covered comfortably in one afternoon, namely, to Point Pinas, where he turned into the river *Biru*—which some suppose to be the origin of the name *Peru*. After sailing up this stream for a few miles, he came to anchor, and proceeded to explore the surrounding swamps. Here we must leave him for a time. Pity it was he ever came out of them!

Peru, in Pizarro's time the magnificent, prosperous and wisely governed land of the ancient Inca, extended along the coast for 3,000 miles, including what is now Columbia, Ecuador, Chili and Bolivia. Since then it has been considerably curtailed, divided and subdivided into little Republics, each more corrupt than its neighbour.

Nowadays, our first port of call from Panama is Guayaquil, the commercial capital of Ecuador, sixty miles inland, beautifully situated on the Guay, the finest river flowing into the Pacific. The island of Puna, at the entrance, may be noted as the frequent rendezvous of Pizarro and his crew. Ecuador is a rich and lovely country, owned, however, by one of the rottenest little Republics in South America, and this is saying a great deal.

The descendants of Europeans living near the Equator seem to degenerate more rapidly and thoroughly than they do at a safe distance. The descendant of the Spaniard here is a very different type from the Chilean, for instance, who with all his faults is a brave, active and industrious man. I would recommend the traveller who wishes to retain a pleasant recollection of Guayaquil not to land: the city looks so much better from a distance: but the country around is a vegetable paradise, such as Britain, with all her tropical colonies, can scarcely lay claim to, supplying spontaneously the very finest varieties of tropical products and fruits, such as cocoa, coffee, pine-apple, plantain and chirimoya, etc., the latter, beyond all comparison, the most delicious fruit I ever tasted, so unlike anything else that it cannot well be described. Mr. Clements Markham, the illustrious traveller, speaks of it as "spiritualised strawberries," but I do not know that this description conveys very much. The tree, usually about fifteen to twenty feet high, is a native of Peru, and belongs to the natural order called Anonad, extensively represented in India and Ceylon by a relative known as the *Sour Sop*, a rather refreshing fruit in a hot climate, but coarse compared with this master-work of nature.

Of commercial products cocoa is the chief, and yet there cannot be said to be any cultivation.

"At what distance apart do you plant your cocoa trees?" I asked an old planter I chanced to meet. "Plant?" he repeated reflectively, "why, the donkeys plant all our cocoa." "The donkeys!" I exclaimed with unfeigned surprise. "Yes, yes," he hastened to explain, "the human-being-like animal you English call donkeys." It dawned upon me that the man meant "monkeys." And it turned out that, being fond of the fruit, they occasionally made inroads upon the ripe cocoa, which they carried to a distance, enjoying the luscious pulp, but dropping the seeds, and thus extending the plantation.

In scenery, I do not know that we have anything, in what we call our old world, to quite compare

with the bold surroundings as witnessed from the Guay. What can we show equal to Chimborazo, when the curtain of mist is obliging withdrawn, exhibiting a perfect pyramid, about 21,000 feet in height, with its green base in everlasting summer, its pure white summit in eternal winter, and the still bolder and more rugged Peruvian Andes to the South, "like mountains piled on mountains to the skies?" The first impressions such scenes have upon ordinary mortals, are so overwhelming, that the most, or the least we can do, is to calmly sit down and exclaim with the Turk—"God is great."

BANANAS FOR BREAKFAST.—We are sure your readers will greatly enjoy a breakfast of bananas especially on a warm morning this summer. I prepare my bananas the night before I wish them for breakfast. I remove the skins, say of six bananas (number, of course, depending upon size of the family), slice and place them in the dish they are to be served in. Sprinkle over them three tablespoonfuls of sugar, and squeeze the juice of one lemon, adding about a tablespoonful of cold water. Then place in the refrigerator if you have one. For a change I often add a cup of milk or some rich custard, or let all get cold, and it makes a delightful breakfast dish.—*Florida Agriculturist*.

SWEET POTATO JOHNNYCAKE.—Take one pint of best meal, salt to taste (half a teaspoonful is the ordinary seasoning), rub into the meal a large tablespoonful of lard, next add to it one pint of smoothly mashed sweet potatoes. If the potatoes are not very sweet, add a tablespoonful of sugar; mix thoroughly to a rather soft dough, but not too soft to handle; have the middle stave of a barrel head washed clean, rinse it, leaving it wet, and on this evenly spread the dough, not quite out to the edges of the board; dip a knife blade into cold water, and with its smooth over the surface of the johnnycake, and stick with a fork as you would biscuit; set it before the fire with a brick or flat iron to support it; let it brown nicely, then loosen it from the board by means of a coarse thread passed between the johnnycake and the board, close to the latter; do not cook it in the oven, but before the fire.—*American Grocer*.

THE CHINA TEA TRADE.—We have received the following advices from Foochow under date of 9th July, concerning the tea market:—The export to Europe is $7\frac{3}{4}$ million lb. against 7 millions at the same date last year the shipments during the fortnight having been $3\frac{1}{2}$ millions lb. in the calling steamers "Glamorgan-shire," "Glenorchy," "Diomed," "Ningchow" and "Benalder." The settlements during the fortnight are reported at 48,000 chests Congou and 7,700 chests Souchong. The figures show a great falling of as compared with the previous fortnight's and would have been smaller still but for the temptation offered by a drop in the rate of freight to 15s. per ton. Included in these settlements is a good deal of tea for the Australian and American markets. The second crop has commenced to arrive but, being poor in quality, has attracted but little attention so far. On comparing prices with those ruling a fortnight ago a general advance of about £1. 1 per picul is noticeable on all grades on Congou. Souchongs on the contrary have gradually become cheaper. The supply of first crop Congou is complete at 195,000 chests, which is 25,000 chests less than last year. It is estimated that the second crop will show fully as large a deficiency, if not large. The arrivals of Congou to date are 204,000 chests against 224,000 chests last year, and 306,000 chests in 1890. The settlements of Congou to date are 149,000 chests, against 127,000 chests last year. The stock is 55,000 chests, against 97,000 chests at the same date last year. Exchange during the fortnight has fluctuated between 2.11½ for 4 months sight credits and 2/10½, at which it closes. Freight to London fell as low as 15s. per ton, but is now at 30s. again.—*N.-C. Daily News*.

THE CEYLON TEA COMPANY.

GENERAL MEETING.

Minutes of proceedings at the first ordinary general meeting of the Ceylon Tea Company, Limited, under the patronage of the Planters' Association of Ceylon within the registered office No. 42, King Street, Kandy, on Monday, 25th July, at 3 o'clock in the afternoon.

Present:—Messrs. L. Stuart, Aranayaka; A. L. Cross, Nuwara Eliya; D. Kerr, Watawala; Edward Webb, Kandy, J. H. Renton, Colombo; J. Munton, Kandy; Harry Whitham, Dolosbage; W. D. Gibbon, Kandy; A. Philip, Kandy.

The notice calling the meeting was read. The minutes of proceedings of a meeting of the promoters of the Company held at Kandy on Friday, the 19th June 1891, were read and were confirmed.

In the absence of the Hon. Mr. L. H. Kelly, Chairman of the Board of Directors, Mr. W. D. Gibbon took the chair.

The CHAIRMAN having made a few opening observations, the Directors' Report was read, and the statement of the income and expenditure and a balance sheet to 30th June 1892 was laid on the table as follows:—

REPORT OF THE DIRECTORS OF THE CEYLON TEA COMPANY, LIMITED,

(Under the patronage of the Planters' Association of Ceylon), to be presented to the Shareholders, at the first ordinary annual general meeting of the Company, to be held within the registered office of the Company No. 42, King Street, Kandy, on Monday, the 25th day of July 1892, at 3 o'clock in the afternoon.

The Ceylon Tea Company, Limited, was successfully inaugurated under the patronage of the Planters' Association of Ceylon at a meeting held within the United Service Library, Kandy, on Friday, the 19th June 1891, and it was duly incorporated as a joint stock company under the public seal of the island on the 25th day of July 1891.

Preliminary arrangements occupied a good deal of time, so that practically it may be said that the business of the Company did not commence until January 1892. The Directors at this, the first ordinary general meeting, now lay before the shareholders the accompanying statement of the income and expenditure and a balance sheet containing a summary of the property and liabilities of the Company made up to the 30th June 1892.

The Directors regret to say that owing to the Company's Bankers, the New Oriental Bank Corporation, having suspended payment, it was necessary to make a call on the shareholders.

All the first Directors retire today, but they are eligible for re-election; it will further be the duty of the shareholders to fix the remuneration of the Directors for their services. The accounts of the Company have been examined and the correctness of the balance-sheet has been ascertained by Mr. John Guthrie whom the Directors appointed auditor, and they would recommend to the shareholders his re-appointment at a fee of R100. As in the opinion of the Board the results of running the Tea Kiosk at Colombo are insufficient to justify the present heavy expenditure on the staff there, the services of the Manager have been dispensed with and fresh arrangements are being made.

By Order of the Board,
A. PHILIP, Secretary.

BALANCE SHEET OF THE CEYLON TEA COMPANY, LTD., UNDER THE PATRONAGE OF THE PLANTERS' ASSOCIATION OF CEYLON, MADE UP TO 20TH JUNE 1892.

Capital and Liabilities.

(Signed) J. Munton, Harry Whitham, J. H. Renton, W. D. Gibbon, Directors.

The shareholders having discussed various points in connection with the operations of the Company,

the CHAIRMAN moved that the statement of the income and expenditure and the balance sheet to 30th June 1892 together with the Directors' Report be adopted. On being put to the meeting, the motion was unanimously carried.

On the motion of the CHAIRMAN the following Directors were unanimously elected:—Mr. C. J. Donald, Mr. E. Hamlin, Mr. J. H. Renton, Mr. Giles F. Walker, Hon. L. H. Kelly, Mr. W. H. G. Duncan, Lient. E. de Frisch, Mr. Harry Whitham, Mr. G. E. Osborne, Mr. T. C. Owen, Mr. W. D. Gibbon, Mr. J. Munton.

On the motion of Mr. EDWARD WEBB, seconded by Mr. A. L. Cross, it was unanimously resolved:—"That as a remuneration for their services the Directors shall be entitled to appropriate annually a sum not exceeding R1,500 to be divided among them in such manner as they may determine."

On the motion of the CHAIRMAN it was unanimously resolved:—"That Mr. John Gutbrie be appointed Auditor."

With a vote of thanks to the Chairman the meeting dispersed.

A. PHILIP,
Secretary to the Ceylon Tea Company, Limited.

FRUIT CULTURE IN INDIA.

A telegram which we publish today announces that the Fruit Culture Committee which has been deliberating at Simla has recommended the appointment of an Inspector of Orchards, and there can be no doubt that the services of some such official as this will be essential to the success of any project that may be devised for extending the industry that has been engaging its attention. In India fruit and tree planting has hitherto been too much neglected. As far as Anglo-Indians are concerned the majority are apt to think that their stay in any station is too short to make it worth their while to beautify their gardens very much. But there are house owners who might certainly turn their attention more than they do at present to the matter of tree planting, whether for use or ornament. It would certainly bring its own reward. A single graft mango tree is often leased annually on the West Coast for over a hundred rupees, and at some stations R50 is quite an ordinary price for the fruit of one tree. Even a common mango tree gives from R5 to R10 a year, and a plantation of trees that would improve the look of many a bare treeless compound would often pay the rent in the case of tenants, or double it in that of house owners. There is a particular caste in India that make a point of planting from ten to a hundred *sapan* trees when a daughter is born. The trees take about nine or ten years to reach maturity, and it is about that time that the betrothal ceremonies of the girl take place. The trees are then cut down and the money realised furnishes the expenses of the marriage and provides the bride with the jewels always given as a dowry on her marriage. One of the wise provisions made by the United States Government is to have one day in each year, called "Arbour Day," set apart as a holiday for the planting of trees; and on that day every man, woman and child, rich or poor, is required to plant a tree of some kind. This was commenced in the State of Nebraska; and already portions of the United States that had become completely deforested are covered with a wealth of shady trees, pines and oaks, walnut, maple, elm, linden and others. If the Government could only institute an Arbour Day in India, and people would enter with interest and sympathy into the movement, the country would be greatly benefited in years to come. The supply of custard apples, mangoes, jack fruit, cachu nut trees, oranges, pumaloes, guavas, strawberry guavas, and many other less well-known fruits would increase, and take the places of the useless dusty trees that form the principal adornment of many Indian gardens. One of the fruit trees that flourishes well on the Indian plains is the bread fruit with its broad handsome leaves. Natives have an aversion to planting it as they believe it to be an unlucky tree, bringing misfortune to the owner; but all the same the fruit if well cooked makes a delicious vegetable. The coconut

is one of the most profitable trees for cultivation. The natives of the West Coast calculate that a tree will have cost one rupee by the time it comes to maturity, when it will give a rupee a year for the next seventy or eighty years; but this is rather too favourable an estimate, R2 for the initial expenses and half a rupee a year clear profit being a safer sum to calculate upon, though in good and suitable soil and when well cared for trees often give considerably over a rupee a year. Some of the plantations of Ceylon which are under European management are most successfully worked.

Whenever fruit culture be attempted it does not do to begin by being too sanguine. A fortune will not be made by a small fruit farmer; but a very fair return for capital can certainly be obtained, taking the good seasons with the bad ones, which in all cultivation must certainly be expected. Lord Derby in an interesting speech on fruit-growing at a Conference recently held in the Town Hall of Manchester remarked that he had heard opinions expressed from which it would seem that the writers or speakers were agreed that fruit could be grown by anybody anywhere; and that one had only to get five or ten acres, no matter what the soil, stick in the trees or plants, and make a fortune in watching them grow. Anyone, he said, who started with that expectation would find himself greatly deceived. The story of the old gardener who when dying told his sons that there was a fortune buried at the root of one of the apple trees is well known. To find the gold they dreamed of the sons turned up the earth thoroughly round the roots of each apple tree; and though they found no gold they reaped a rich harvest in the plentiful crop of fruit borne by the trees in consequence of the turning up of the earth round their roots. Lord Derby in the speech referred to spoke seriously on the subject of the large amount of land lying waste, which no longer could be farmed at a profit, but which could be made to grow fruit very advantageously. Some of the statistics given by him are interesting and instructive. In the United Kingdom strawberries are taken as giving a gross return of £27 per acre and a net return after all expenses are paid of £6 or £7 an acre. Raspberries cost £21 an acre, giving a net profit of £7. Currants £30 gross and over £11 net. Apples, plums and cherries £25 an acre, but the net profit only £5. The profits on apples, however, vary much in the estimates given of them. In the year 1883 "an apple Congress" was held at Chiswick in the gardens of the Royal Agricultural Society, when between 1,500 and 1,600 different sorts of apples were exhibited, all of which had been grown in the United Kingdom. By the way, much valuable information as to the best modes of grafting the cultivating apples has been collected by the British Fruit-growers Association, which endeavours to "promulgate the knowledge of improved principles in fruit-growing"; and that and other Societies offer large sums in prizes for the best managed fruit farms. In the year 1889 the then Lord Mayor of London established a fund of £5,000, the interest of which was to provide prizes for this purpose. According to some of these authorities, a bush apple tree has been proved from experience, and taking good years with bad, to yield fruit to the net value of 1s 6d annually. This appears very small, but when it is remembered that a hush tree only occupies a square yard, and an acre so planted means £40 a year, the profits will be seen to be very considerable. In planting an orchard or garden care has to be taken to select some quick-growing fruit trees as well as those that take a longer time to give a return, such as apples in England or mangoes and coconuts in India, all of which take from four to six years to come to maturity. There is an old proverb, "He that plants pears plants for his heirs;" but in planting for his heirs a man very often plants for his own benefit too.

Over an elevation of 3,000 feet a really good garden may with a little care be easily formed in India for growing peaches, apples, pears, loquats, mangosteens, etc. Seeds can be procured with little trouble from Australia which suit an Indian Hill station well. If plants are to be procured direct, the

best time to get them is in the Australian winter months, June and July, so that they arrive in August, a good time for planting in Hill stations which come under the influence of the South-West Monsoon, such as the Nilgiris, where the hardier of the English fruits flourish well. An interesting paper on fruit growing in Australia has recently appeared in the *Pioneer*. The statistics of fruit culture in South Australia are there given very fully; and the study of the article may be recommended to any one who really wishes to enter into the calculation of profits and losses and cost of fruit planting in the irrigation colonies of Australia. It should, however, be remembered that the fruit grower in India has merely to superintend the planting of his orchard, making his coolies do the hard work; whereas in Australia where labour is scarce and dear, he must work with his own hands, which is not an alluring prospect to an Anglo-Indian who has always had a large establishment at his beck and call. The cultivation of English fruit in the neighbourhood of Simla is about to be tried on a very extensive scale. During the next seven years the Punjab Government is prepared to carry out a scheme for its careful cultivation, the annual cost being estimated at Rs.2,000. Large gardens are also being planted near Naini Tal, Almorah, Raniket, and many parts of the Himalayas. Kashmir has always been celebrated for its delicious fruits, its apples, pears, grapes, apricots and walnuts. The fruit grows there in such profusion that frequently in riding through the orchards the fruit is crushed in quantities under the feet of the ponies. On the Nilgiris also most of these fruits flourish. At Ootacamund, Coonoor, and Kotagiri, may be found examples of carefully kept gardens where, in that perfect climate surrounded by lovely masses of English flowers, English fruits flourish luxuriantly. Even the wild fruits of England, such as blackberries and white raspberries grow in quantities on the hill sides and among the bracken; and wild strawberries are also to be found there.

It is not probable that except in the case of coco and other nuts, fruit grown in India would be profitable for export, as the distance from European markets precludes fresh fruit being exported except at too great a cost to make it possible to compete with fruit grown in the West Indies and other tropical countries nearer at hand, such as Florida and California. In these parts of America as well as in Jamaica, and indeed all over the civilised world, the culture of fruit has of late years increased enormously. In Jamaica the value of the fruit has arisen in fourteen years from £15,000 to £344,000, oranges, plantains and pineapples being the fruits chiefly grown there. Oranges flourish much in Brazil, and the exportation amounts to several millions annually. The trees are said to bear from 200 to 1,000 oranges yearly when in full bearing, and to last for thirty years. An experiment has been lately tried in the Western Doors of planting oranges and lemons. The elevation there is about 2,300 feet, and the fruit grows well; but it is not likely that fruit culture for local demands alone will ever prove paying there to Europeans. Fruit grown in places where means of communication are difficult might often, however, be made into preserves. It is said that about a hundred different preserves can be made from the judicious blending of the fruits of the East and West Indies. A delicious desert dish can be made of mangoes preserved whole; and mango jam and jelly are not as well known as they ought to be. Besides the mango there are the pineapple, guava, and others that can be preserved in a lasting manner and can rival the preserves made of any English fruit; and there is ample scope for their being made very profitable if the manufacture is carried on a sufficiently large scale.—*Madras Mail*, July 18.

FRUIT CULTURE IN THE HILLS ABOUT SIMLA.

The following interesting notes on this important subject have been furnished to the Deputy Commissioner of Simla by the Rev. M. M. Carleton;—

Result of experiments made in horticulture at Ani, a village at 4,500ft. in Kulu sub-division, 65 miles from Simla.

I.—First experiment in apple cultivation. After ten years the whole experiment has proved well-nigh failure. American apple trees, as well as English, are not prolific in this climate at 4,500 ft. A few apples were obtained and the growth of the trees has been all that could be desired, but apples brought from England or Scotland, or from the Northern part of the United States and Canada will not be profitable below 6,000 ft. As an example of one variety, I introduced the Porter apple tree from New England a standard apple for the last 50 years, both in Canada and New England. The trees grow finely, they are the finest in my orchard. They are now 8 years old, but they have never produced even a blossom. This result is the same when trees from New England and Canada are transferred to the Southern States, especially Florida; they grow well, but never produce fruit.

II.—Experiment No. 2 with Cashmere apricots has proved a remarkable success. The native apricot in this warm valley was not prolific, and, from analogy we concluded that the place was too warm for the Cashmere or English variety. We, however, introduced ten trees from the Government garden at Lahore. They grew very vigorously and began to bear fruit the fourth year. They are even more prolific than the native variety in Kulu valley. The fruit ripens about the 15th or 20th of June. I should advise the extensive cultivation of the Cashmere and English apricot in all the lower hills. The successful introduction of the famous Cashmere American fruit drying machines into Simla would enable enterprising persons to establish a very profitable industry in preparing dried apricots for the Indian markets.

III.—Experiment No. 3 with American grapes has proved an unqualified success. My first experiment, made 15 years ago, was with grapes from the Government Gardens of Lahore. The variety was called the Black Hamburg. After 12 years' experiment they proved an utter failure, scarcely a single cluster of grapes in the 12 years. About 9 years ago I sent to America for a variety of hardy prolific grape grown on the northern limit of grape cultivation, where the spring opens in May and frost comes in September. I held the opinion that such a variety would ripen in July before the heavy rain, because the spring open, the last of February or the 1st of March. My experiment proved that the American grape in these lower hills is a great success. Only one vine lived of those I first received, that is about 8 years old, and now, today (May 7) there are about 70 lb of green grapes on the vine. A few such vines around the houses of intelligent zemindars in the Simla district would give a handsome return, especially in the Simla market, in the month of July.

IV.—Experiment No. 4 with the common Himalayan walnut is also a success. Very fine large trees in 20 years, and very fruitful.

In 35 years a grand change in the use of the walnut has taken place. In former times in Cashmere, Chnmba and Kulu, the only use of the fruit was the production of oil to adulterate *yhee*. But now the demand for walnuts in the plains is greater than the supply. On account of the valuable timber the cultivation of the walnut should belong to the Department of Forestry. But in California the horticulturist has captured the species, on account of its valuable fruit. They have introduced the celebrated Persian walnut, and find it one of the most profitable fruit trees. We are surprised that the Department of Forestry have done little or nothing with the walnut in the Simla district.

V.—Experiment No. 5 with the European orange, has proved that the variety commonly called the Maltese orange can be grown in the lower hills, as high up as 4,500 ft. In California orange cultivation is extending up the rich valleys of the Pacific slopes, and I see no reason why in these lower hills, orange cultivation should not be a success. This year from one tree 8 years old, we gathered 220 orange. They were

of the crop of 1891, but they were taken from the tree, February 25th. We follow the custom in California and Florida, and keep the fruit on the trees till the new leaves appear, the last week in February. We have noticed one remarkable fact in this connection. In the winter of 1890-91 we had two snowstorms: the snow began to fall in the night, and it remained on the orange leaves till 8 A.M. next morning. I could not discover that the fruit was in the least injured, through after the snowstorm the leaves most exposed were somewhat injured. The crop of oranges should be gathered about 1st of March, and kept in a dry, suitable place till the season opens in Siam. I learn that orange sold from the Government Garden in Gujuranwalla, and other gardens usually fetch from 5 to 8 rupees per hundred, and it is quite certain that Maltese oranges sent to the Simla market in April, when there is little fruit for sale, would fetch 8, and perhaps 10 rupees per hundred. An orange tree 8 years old that gives an annual crop of over 200 oranges could give the owner at profit of 16 rupees, and that on only 10ft. square of ground.—*Indian Agriculturist.*

NUTMEGS.

An erroneous impression has gained ground in Jamaica that nutmegs will not flourish higher than 1,000 feet above sea-level. This is in consequence of a statement in Dr. Nicboll's "Text Book of Tropical Agriculture," that, "as the nutmeg is essentially a lowland plant, its cultivation is not likely to prove successful at a higher elevation than 1,000 feet above the sea."

Mr. John Davidson writes:—"Mine are all doing splendidly at Bellevue at an elevation of 1,500 feet."

The Hon. H. R. Pilon Schooles writes from Grenada, "Nutmegs in my experience thrive and bear as well at 1,500 feet as at 1,000 feet;—beyond the former elevation I know nothing from our experience here."

The following letter give similar testimony:—

Kingston, April 23th, 1892.

My Dear Mr. Fawcett,—In reply to your note of the 26th received today, my nutmegs are growing at between 1,800 and 2,000 feet above sea-level. When I last saw them 10 weeks ago there was no sign of blight, and I have not heard of any since. Only some 6 or 8 are fruiting, but they are nearly all growing so healthily that I am going on planting them.

One tree I have has an enormous amount of fruit on, the boughs being all bent down under the weight, it is a really fine sight and makes the tree look quite golden.—Yours, &c.,

W. ELOIN SANT.

—*Jamaica Bulletin.*

COCONUT DISEASE AT MONTEGO BAY.

In Bulletin No. 23 for September, 1891, a report was published on this disease. The following correspondence shows that the simple remedy of burning the leaves in the early stages, has proved successful:—

Montego Bay, 4th May, 1892.

W. Fawcett, Esq., Gordon Town P.O.

Dear Sir,—Your letter of date 28th ultimo I duly received, the subject of which I communicated to M. Doull and attach the correspondence for your information. I entirely agree with Mr. Doull that the disease is spreading, and no one, so far as I am able to ascertain has tried the other remedies you suggested.

The disease is steadily thinning the coconut trees in and around the town and its progress appears more rapid in the dry weather than in the rainy seasons.—I have, &c.,

J. W. GRUBER.

Montego Bay, 30th April 1892.

Dear Sir,—Mr. Fawcett would be glad to know whether you tried the remedies suggested to check the coconut disease, and if so with what result.

Are the trees recovering naturally and without the application of a remedy, or is the disease spreading?—Yours, &c.,

J. W. GRUBER.

Alex. Doull, Esq., Catherine Hall Estate, Montego Bay.

Reply,—I have not as yet tried the Sulphate of Iron remedy. I have continued the application of Salt and have kept to the firing of the trees and as far as I can judge at present I consider the last named remedy good—if the trees are not too far gone when fired. A good number that were fired last year are now bearing fruit. The trees do not recover naturally and the disease is certainly spreading.

Catherine Hall Estate, 2.5.92.

A. D.

—*Jamaica Bulletin.*

FROM THE METROPOLIS.

LONDON, July 8th, 1892.

THE CALEDONIAN (CEYLON) TEA PLANTATIONS LIMITED.

IF THE PUBLIC NIBBLE.

The capital of this venture is £30,000 in £1 shares, of which at present only 25,000 are to be issued. It has been formed for the purpose of "acquiring, and by the addition of new capital, further developing the following tea estates, situate in Ceylon and known as the Miracotta, New Caledonia, Selegama, and Nikakotua Tea Plantations." The purchase price to be paid to the Vendor is £22,000 of which £12,000 is to be in cash and the rest in fully paid shares of the Company. The fortunate man who is to receive this nice little sum, of course providing the public nibble, rejoices in the familiar name of Alexander Ross. It appears that this gentleman "is so satisfied with the value of these estates, and the profit to be derived by this Company that he has agreed to guarantee a dividend of 6 per cent. per annum for a period of seven years." Of course, if he goes bankrupt before the expiration of that scriptural period, his guarantee would be a very valuable asset. We do not say that he is likely to go bankrupt for we know nothing about his financial affairs, but the misfortune in question is a contingency to which every business man is liable. And again if Mr. Ross is so confident that 6 per cent can be made out of his property why does he sell more than half his interest in it? Six per cent is not to be made every day—or rather every year. Six per cent is not all the profit expected to result from the working of the tea estates concerned. "An estimate based on the sale by public auction of 200,000 bales of tea, the anticipated yield for the first year, after making all allowances for expenses in Ceylon and London, should yield a dividend of at least 10 per cent on the issued capital of the Company, which dividend should be materially increased in the course of the next two or three years as the present area of tea comes into full bearing. But supposing the yield is not so favourable as it is anticipated to be such an event is by no means improbable, judging by the way in which the anticipations in the prospectus of the average limited company are fulfilled, or rather unfulfilled.

A somewhat lengthy list of the present value of shares in, and dividends earned by several Ceylon tea companies is given. Why, we know not, unless to fill up the prospectus. The profits made by an established tea planting company have no more bearing upon the prospects of the floatation under notice, than have the losses made by other established tea-growing concerns. If the promoters of the Caledonian Tea Plantations have no more sound arguments to advance in favour of their nursing—and we cannot find that they have—we do not think the prospects of the enterprise are very brilliant. The capital asked for is very small and if there were any chance of making the remunerative dividends mentioned, we think that no difficulty would be experienced in getting the necessary money subscribed in Mincing Lane. As we have frequently pointed out the Tea Trade has been very much out of late years, and no favourable opportunity of employing their capital would be allowed to pass by the members of the "Lane," who mostly know how many beans make five. By the way, we do not notice that the promoters of the Caledonian Tea make any mention of

the unhealthy state of the Tea Trade to which we have just referred. They give only the bright side of the picture. We do not think the present scheme at all a good investment.

TEA.

The *Financial World* of the 2nd inst. has the following editorial note on tea:—

The competition of Ceylon is playing havoc not only with the Chi tea trade, but with that of Assam. At the meeting of the Assam Company on Monday the Chairman had to announce that the greater part of the profit had been swept away by the fall in the price of such tea as they had been in the habit of producing. Had the prices been obtained that they reached last year, the differences to them would have meant a very large sum indeed. That was the cause of the unfortunate result; and although there was some blame to those who prepared the tea, the real matter was that tea had fallen all round owing to the competition on the part of Ceylon and other places which had come with a sudden hurst upon the market. The chairman hoped for an improvement next year, but omitted to say how that improvement was to be effected.

It would be a good thing if the news of still further TEA PLANTING in Ceylon put a stop to the extension of operations both in India and Java; and certainly the tea planters of the latter dependency might be asked by our Association to bestir themselves a little, after Ceylon and Indian fashion, to get their teas better known in the Continent of Europe, so as to increase consumption and prevent the necessity for any Java tea coming to the London market.

THE BRITISH NORTH BORNEO CO.

has been holding its half-yearly meeting when Sir Alfred Dent had not a very satisfactory account to render. One passage I quote in case it should escape prominent attention:—

(From the *Financial News*, July 6.)

The crash in the tobacco trade, brought about by the McKinley Tariff Bill, had been so sharp and decisive that it was impossible that the planting interests in Borneo could escape the consequences. He regretted to say that during the year there had been almost a cessation of land sales. The actual sales of land had been £841, as against £39,942 in 1890. The closing of estates had thrown a large number of coolies out of employment, many of whom had to be sent out of the country at the Company's expense. Referring to the discussion on the British North Borneo Company in the House of Lords, he said that the gist of Lord Brassey's remarks was that the time had come when the British Government should assume the administration of that country and similar protected States. No doubt, after a time, their country would be absorbed, like the East India Company, and when that time came it would be the duty of the directors to protect the interests of the shareholders. The trade and revenue of the country for the last five years showed that the progress had been steady, especially as regarded the receipts from revenue proper, the deficit for the past year being entirely due to the cessation of land sales and the depression that had been felt all over the East.

Mr. J. L. Shadd gave an account of his visit—a full report, I hope, may reach you; he spoke of telegraphic communication as the chief present want.

PLANTERS IN JAMAICA.

The Duke of St. Albans (brother of Lady Blake) has a paper in one of July's monthlies on "Jamaica Resurgens" which the *Spectator* describes as very poor and thin, though the following paragraph is quoted as instructive:—

"A young man prepared to exert himself, live carefully, and with small capital, can do better here than in most parts of the world. He can turn his attention to the cultivation of coffee, chocolate, nutmegs, coconuts, bananas, tomatoes, spices, sugar, dye-woods, tobacco, which is an increasing and paying crop, while

the development of railways, and better communication with the United States, is likely to make growing early vegetables and fruit a remunerative industry. If the investor prefers it, the breeding of cattle and horses can be successfully carried on. . . . Estates are pointed out which have repaid the purchase-money in the first year, and others paying 15, even 30, per cent., and, considering the generally healthy climate, the productiveness of the country, the low taxation and security of a settled government, land purchased with a knowledge of tropical agriculture, and selected with ordinary care and judgment, should prove to the energetic settler a remunerative investment."

OIL PROSPECTS.

In my last I referred to the very poor prices offering for coconut oil, and now I see distress prevails near at hand owing to depression in oil industries. Here is a paragraph from the *Daily Graphic*:—

SCOTTISH OIL COMPANIES.—A large amount of capital has been invested in the Scottish oil companies, but of late years the returns have not been satisfactory. In their monthly circular Messrs. J. D. Walker and Watson, of Edinburgh, report during June the shares of these companies have been depressed. "In the duel of the giants—America and Russia—the poor little Scottish shale-oil industry is, the circular states, fairing badly, the announcement during the month of a reduction of 30s. per ton in lubricating oils being another disastrous blow. There is no choice but to follow the 'cut' or be left with the stuff to keep. The outlook for this sorely-ried industry is certainly anything but encouraging, the only redeeming feature being the reduction in working costs. Some consolation may perhaps be drawn from the belief that under present conditions the oil industry can hardly be profitable to the American and Russian producers either, and that therefore some improvement may be looked for when the present struggle between them comes to an end."

Mr. Gladstone in his electioneering tour in Midlothian found himself in the heart of one of the shale-oil districts, but while alluding very sympathetically to the distress prevalent, he pointed out the folly of looking to Protection Customs Duties for relief. If we put a tax on foreign oils, why not on "corn," he said, and then you would have dearer food to injure you.

NOTES ON PRODUCE AND FINANCE.

THE SAME OLD STORY.—The Chinese Consular reports all tell the same tale of losses by Chinese tea growers, and of their inability to compete with Indian and Ceylon planters. Mr. Westall, in a review of the Foochow tea trade, says:—In consequence of orders from Peking, recommendations were posted in the various tea countries by the local authorities to improve the quality of the teas this season, as a means towards the resuscitation of the trade. Some of the teamen in the Peking, Paklum, and Panyong did their best to further this end, and to a certain extent succeeded; but, on the other hand, judging by results, no other conclusion could be arrived at than that those making teas in all other districts had disregarded the recommendation. The former were buoyed up with hope at the opening of the market, when they obtained for a few of their best chops prices 20 per cent higher than the highest price paid last seasons, that they were going to make their fortunes, and congratulated themselves on having followed the guidance of the Manarins. Their satisfaction was, however, shortlived, as the demand for fine tea—at any rate, high-priced fine tea—fell away, and as they persistently refused throughout the season to meet buyers in the matter of price, they were left at the close of the year with the bulk of these teas on hand. There were exceptions to this rule, but, as far as foreigners were concerned, whether they bought of these men at the high price or of others who submitted to a reduction, they lost money on their ventures,

The prices paid for medium teas at the opening of the market, although not higher than last year, were thought by many to be dangerously high considering the low values ruling in the London market, and the telegraphed sales towards the end of July proved that they were so; indeed, the losses made on shipments up to that time were, on the average, heavy. Then, as a natural consequence, prices declined and remained low, though not low enough, as it turned out, for the well-being of those who shipped, as the forced sales of the increased supply of Ceylon and Indian teas in Mincing Lane further depressed prices in that market, and if losses were comparatively light on these autumn shipments, there were, none the less, on the balance, losses. As regards common tea, it was scarcely to be expected that it would touch a very low point here after the "boom" which took place through speculation in London in January last; nevertheless, what is known as "Type" standard was brought in August to lay down at 53d per lb., at which price it remained until the middle of October, when it rose to 6d on account of scarcity. Such of these teas as have already been sold have not brought back the money paid for them, as far as is known at present; therefore the season has not been a profitable one for shippers. As, however, there are still five months wherein to realise the season's export, now virtually complete, it may be considering the exceptionally favourable statistical position of China tea in London, that the result of the year's trading will not turn out to be so unfortunate as was at one time expected. To the natives the season has again been one of severe losses. The little profit made on common tea went no way to make good a tithe of the money they lost on the better kinds. Those of them who have been engaged in the particular branch of the trade of making tea and bringing it down to their market appear never to have heard of the competition of India and Ceylon, or, if they cannot bring themselves to believe that tea can be produced in any country other than their own.

VERY MUCH ALIVE TO IT NOW.—Whatever may have been the case, the Chinese are now alive to the facts. The report we have referred to says:—"They are at length alive to the true state of the case, and are combining to face the difficulty. From what is known of the cost of preparing tea and bringing it to their market the ingenuity of these Chinese will be taxed severely. The cost of growing may be a bagatelle, and labour we know is cheap enough, but the lekin and petty exactions of the officials, as the tea is in transit, will, as matters stand, make it a very difficult thing for them to compete with India and Ceylon. The only chance of success lies in these exactions being reduced. Then there is the export duty. However fair it may have been at the time the last treaty was signed, it is galling for those interested in the trade, both the Chinese and the foreigner, to know that 25 to 30 per cent. on the average value of tea has to be paid. Again, the supply of Congou shows a serious falling off. The deficiency is 50,000 chests, or 13 per cent., the figures being 345,000 chests, against 395,000 chests last season, and (to show how rapid the decline of the trade is) 850,000 chests in 1880. Of other kinds Sou-chong and Pekoe have been in supply about the same as last year, while Oolong and Scented tea show an increase. But Congou is the backbone of the trade, the total yield of the four last-named descriptions being only 90,000 chests. A noticeable feature is the larger business done this year in the manufacture of brick tea by the Russian houses. But a small proportion of the tea used for this purpose is included in the above figures of Congou supply, the remainder being brought down to these firms under contract in bags."—*H. and C. Mail*, July 8.

MUSHROOM CULTURE.

Mushrooms are healthful and find a ready sale in all markets, and yet their cultivation is almost entirely neglected in the United States. They can be readily

grown in the cellars of farm houses, and with little more trouble in the cellars of ordinary dwellings, or for that matter, in the store cellar. A market gardener on Long Island sells from 1,700 to 2,500 pounds of mushrooms a year from his two cellars. Every summer he cleans out his cellars and lime washes them all over. He ascribes his success to thorough cleaning. The microscopist of the Department of Agriculture, has made an admirable report on the edible mushrooms of the United States, which has been handsomely illustrated. We take from a report furnished by Dr. Taylor, the following, relative to mushroom culture:—

The cellar of a dwelling house is a capital place for mushroom beds, and can be used in whole or in part for this purpose. In the case of private families who wish to grow only a few mushrooms for their own use it is not necessary to use the whole cellar; it will be sufficient to partition off a part of it with boards and make the beds in this, or to make a bed alongside of the wall anywhere and box it in to protect it from cold draughts and from mice and rats. Shelves may be placed above the bed for domestic purposes, just as in any other part of the cellar. Bear in mind that mushrooms thrive best in an atmospheric temperature of from 50 deg. to 60 deg., and if you can give them this in your house cellar you ought to get plenty of good mushrooms. But if such a high temperature cannot be maintained without impairing the usefulness of the cellar for other purposes, box up the bed tightly and from the heat of the bed itself when thus confined there usually will be warmth enough for the mushrooms, but if there is not, spread a piece of old carpet or matting over the boxing.

The beds may be made upon the floor, and flat or ridged or banked against the wall 10 or 12 inches deep in a warm cellar, and 15 to 20 inches or more deep in a cool cellar, and about 3 feet wide and any length to suit. The boxing may consist of any kind of boards for sides and ends, and be built about 6 or 10 inches higher than the top of the beds, so as to give the mushrooms plenty of head room. The top of the boxing may be lid hung on hinges or straps, or otherwise arranged to admit of being easily raised or removed at will, and made of light lumber, say of half-inch boards. In this way, by opening the lid the mushrooms are under observation and can be gathered without any trouble. When the lid is shut they are secure from cold and vermin. Thus protected, the cellars can be ventilated without interfering with the welfare of the mushrooms. A light wooden frame covered with calico or oiled paper would also make a good top for the boxing, but would not be proof against much cold or against rats or mice. If desirable, shelf beds could be built in warm cellars above the floor beds, but in cool airy cellars this would not be advisable.

Manure beds in the dwelling-house cellar may seem highly improper to many people, but when rightly handled these beds emit no bad odor. The manure should be prepared away from the house, and when ready for making into beds should be spread out thin, so as to become perfectly cool and free from steam. When it has lain for two days in this condition it may be brought into the cellar and made into beds. Having been well sweetened by previous preparation, it is now cool and free from steam, and almost odorless. After a few days it will warm up a little and may then be spawned and earthed over at once. Do not bury the spawn in the manure; merely set it in the surface of the manure. This method prevents the spawn from being destroyed by too great heat, should the bed become unduly warm. If the manure has been well prepared, however, this is not likely to occur. The coating of loam prevents the escape of any further steam or odor from the manure.—*American Grocer*.

THE CULTIVATION OF WOOD FOR TEA BOXES.

Dr. Heinrich Mayr, Lecturer in Forest Botany at the University of Munich, writes to the *Indian Forester*:—"I have been travelling for more than two months through the northern part of India in order to study forest vegetation from the point of view of

a forester and botanist. On my way through the Terai, and the hill forest of Darjeeling, I have been told that the scarcity of a timber wood fit for tea boxes is getting more and more felt, owing to the waste of the various timber trees on private ground. It seems to me a suggestion worth considering, would he to propose that the Government should try to cultivate on a large scale a wood for the above-mentioned purpose.

To do that in the quickest, cheapest and surest way, I would recommend the Japanese suji (*Cryptomeria*), or as I will name that tree, the *Sequoia japonica* for the hills around Darjeeling, and the *Paulownia imperialis*, or the Japanese kiri, for the plains and lower hills of the N.W. Provinces and Punjab.

In Japan, the "suji," or Japanese cedar, is largely cultivated all over the whole empire, but the localities where this tree is found growing wild, are but few, scattered over the main island "Honshin" and those places are rarely seen by any European. There is a mountain north-west of the lake Biwa in the centre of Honshin covered with large suji trees, evidently wild. There is a broad belt of beautiful forests near Akita, about a fortnight's drive from Tokio beneath the 40th degree of North Latitude, the winter climate of which country is marked by deep snow for four months, and a temperature which several times in this season falls to 10° below freezing point. There the suji forms a splendid mass of forests, partly to the exclusion of every other tree, partly together with *Quercus crispula*, *glandulifera serrata*, *grossiserrata*, *Fagus sylvatica*, *Magnolia hypoleuca*, *Esculus turbinata*, and many other trees; but never is the suji found growing together with another conifer, unless one be planted with it. In such places the suji attains a height of 150 feet and a girth of 6 feet and more. The tree is also said to be a native of China, and from that country the first seed was brought to Darjeeling by Mr Fortune who was sent by the Indian Government to bring supplies of the best kind of the Chinese tea plant. In both Japan and China the tree is usually planted around Buddhist temples, where the finest specimens towering up to a height of 250 feet (Koyasao), may be seen.

A few years ago some travelling botanists suggested that the suji is no Japanese tree at all, being brought from China by Buddhist monks together with *Ginkgo biloba*, *Sciadopitys verticillata*, *Pinus koraiensis*, *Cunninghamia sinensis*, *Podocarpus Nagi*, *macrophylla* and many others; but a careful examination of the Japanese forests from the 35th degree to the 42nd degree, a trip which will take about six months, will show, that only *Ginkgo* and *Cunninghamia* can be traced back to China.

The economic value of the suji in Japan is very great; growing there in all situations and soils, in deep damp valleys as well as on high mountain slopes; it is one of the commonest and also one of the most useful of Japanese timber trees.

The sapwood is whitish-yellow, from 2 to 3 inches broad, and is when beams or boards are wanted, generally not removed from the dark reddish, sometimes black-huish striped heart wood. The wood is very light and soft, and is used for all kinds of carpentry amongst the less comfortably situated people; the slight resinous smell of the fresh wood soon disappears.

Owing to the frequent occurrence of earthquakes and disastrous fires, which often lay waste a town with 3,000 houses in a few hours, the Japanese use quantities of wood in house-building.

For that purpose, the cheapest timber in the shortest time is produced by the suji, which is profusely planted all over the empire, and at the age of scarcely 25 years, the trees are cut down and shipped to the market.

The almost exclusive method of propagation, used in Japan is, from a forester's and botanist's point of view very interesting and important, all plantations being made by cuttings. That is not at all surprising, if we bear in mind that the American "big trees" are *Sequoias* too, and coppice as freely as the Japanese one, if cut in an early age and in healthy condition. I remember even a great number of *Sequoia semper-*

virens stumps: more than 700 years old, perfectly covered with young and very rapidly growing shoots. Close by Kioto, the ancient capital of Japan, is a small forest of suji entirely worked as coppice, with a rotation of 2½ to 25 years.

For propagation of the suji the terminal piece of every branch is used, 1½ to 2 feet long. The plantation in the ground must be made immediately before or at the beginning of the rainy season. The Japanese usually put the cuttings 3 to 5 inches deep in the soil, forming a narrow hole of this depth by a wooden stick of about the same thickness as the cuttings; the young plants grow very rapidly after having made plentiful new roots during the rain. This method is preferred to sowing, the young suji seedlings being tender and easily killed by excessive heat or frost. The suji yields a wood that seems to me very well suitable for tea boxes. I am confirmed in this view after having seen tea boxes made of this wood in Darjeeling itself. Such a box was shown to me in the office of Mr. Home, Conservator of Forests for Bengal. Besides that, I am inclined to encourage the plantation of the suji, because this tree apparently grows well in all different kinds of soils and exposures, from the Terai up to the region of the silver fir.

It would be quite easy to grow within a period of from 30 to 50 years wood of the quality and dimensions required for tea boxes, the manipulation of planting this tree being very cheap and sure, if made in the way and at the season above pointed out. In case these lines may induce some experiments, I will add, the young trees must be planted rather close together, scarcely 4 feet apart; for only in a dense growth does the suji soon lose its branches and produce a clean, straight and valuable pole.

The other tree, which I have in mind as a timber-yielding tree for boxes is a broad leaved tree, *Paulownia imperialis*, called "kiri" in Japanese, which produces a wood still lighter and more quickly growing than the suji, but, as Dr. G. King, Director of the Royal Botanical Garden near Calcutta tells me, this tree does not grow well in the wet climate of the Eastern Himalaya, though possibly the north-western plains and hills might suit it.

The wood of *Paulownia* is largely used in Japan, for boxes of every kind, for furniture amongst the better situated classes, and especially for clogs, which are in common use throughout Japan and which the ladies use varnished and dressed after the newest fashion.

This tree is planted in the villages together with mume (*Prunus Mume*), nanten (*Nandina domestica*), kaki (*Diospyros kaki*), &c as a shelter for the kitchen garden or in other accessible places. When the seedlings are two years old, they are cut off close to the ground, and the new shoots grow straight up to a height of 10 feet and more, without a branch in a single year.

In favourable conditions (deep soil,) the tree easily attains a girth of 3 to 4 feet within 10 years: these dimensions seem to be sufficient for making tea boxes. In Japan, the tree is sawn off every 8 or 10 years, very close to the ground, and the stool is cleanly cut with a sharp knife. The shoots of the following year grown rapidly and attain even larger dimensions than those mentioned.

As far as I can judge from comparison the drier climate of the N.W. Provinces and Punjab with an average rainfall of from 20 to 50 inches per annum may prove suitable to this useful tree, which can stand even a good deal of frost. It would be a pleasure to me to provide the Forest Department with seeds from Japan if my suggestions seem worthy of being considered and proved.

CEYLON V. CHINESE TEAS.

Referring to the article, "The nation slowly poisoned," in our issue of the 28th ult., there are many who endorse Sir Andrew Clark's view of the situation; while many, on the other hand, maintain that Ceylon tea will hold its own in the market, despite the adverse criticism to which it has been subjected.

A gentleman, who has shown a lively interest in this journal, has sent us the following communication, which is so pertinent and to the point that we give it *in extenso* :—

AN INTERVIEW ON THE TEA QUESTION WITH THE
OLDEST FIRM IN THE TRADE.

Having read an article in the *Magazine-Journal* last week, entitled "The Nation Slowly Poisoned," to the effect that this undesirable state of things was being brought about by the extensive consumption of Indian and Ceylon teas, I wended my way Citywards, and at No. 57, Fenchurch-street, was introduced to the head of the firm of Davison, Newman & Co., who, I was given to understand, is one of the highest authorities on this important domestic question.

Whether the busy gentleman who acceded to my request was Mr. Davison, Mr. Newman, or the "Co.," did not transpire. He was "the head of the firm," and I should say, from a phrenological point of view, a very good head too. Plunging in *medias res* as to whether or no the statements contained in the article referred to were not, like many of the teas we drink, somewhat "highly coloured," my informant replied, "I think so." He then proceeded to say that Sir Andrew Clark had summed up the situation in a sentence in his lecture to the students at the London Hospital: "If you want to have, either for yourselves or for your patients, tea which will not injure and which will refresh, get black China tea."

"But," I interrupted, "I understand there is no good China tea in the market."

"In the market—no. It is all bought up by firms like our own when it arrives at the commencement of the season. We have plenty, and many other merchants are possibly well stocked, but unfortunately the British public has become so accustomed to the cheap and——"

"Nasty," I suggested.

"No, I cannot say that. We will say so wedded to cheap and strong qualities of Indian and Ceylon that they do not relish the more delicate importations from China. Neither do they relish paying the higher price of really fine China Souchoong."

It was not an original remark, I know, but I Bumbled out, "The British public's a bass."

"I fear so," acquiesced "the head," for if only half the allegations be true against the much advertised low priced teas, the public will pay very dearly for its imaginary economy."

"I presume," I put in, "these severe strictures do not apply to the better qualities from India and Ceylon."

"Oh dear, no," replied my informant, "but I should never recommend the choicest products of those places in preference to those of China."

"And now, sir," I asked (for I was, and am still, in the dark as to his being Davison, Newman, or the "Co."), "am I right in stating that your firm is the oldest established house in the trade?"

"I think so. The house was founded in 1650 by Mr. Daniel Rawlinson, who was succeeded by Sir Thomas Rawlinson (the Lord Mayor of 1706), and in 1763 it became Rawlinson, Davison, and Newman, which title was altered some fourteen years after to that of its present appellation, Davison, Newman & Co. For 240 years, that is, from 1650 to 1890 the house of which I have the honour to be the head ("No more on that head," I was about to remark, but didn't) occupied the same premises a few doors off, but in 1890 we were obliged to make a change, for the old building was pulled down."

"I believe I am not the first scribe who has had the pleasure of referring to your 'historic house.'"

"Oh dear, no. You will find the firm referred to more than once by Samuel Pepys in his diary, for Dan Rawlinson, the founder, was an intimate friend of the great diarist, and the house is also alluded to as a very old established grocery business in 'The History of Signboards.'"

Commenting on the foregoing, we cannot refrain from observing that although the remarks made by one who is evidently conversant with the tea trade *au fond* partly

traverses the statements made by the eminent medico, we cannot quarrel with those remarks, as they are evidently based on an experience almost unique in any trade. Mr. Samuel Pepys, the immortal diarist, was a great lover of a dish of good tea, and he bought, or rather his hearty and youthful wife brought, her chest regularly of this firm. In those days it was not known that tea could be cultivated with any hope of success in India, but the probability is that had the East India Company known that it could be done, they would have initiated a business which has only come into vogue during the present generation. In this case the growth would have been mellowed down by the long and gradual process of two hundred seasons' refining. This is where the Chinese tea has advantage over our Indian growths, but in any case the contribution which Messrs. Davison, Newman and Co. have made in this issue to tea literature is distinctly a feature, and well worth the reading.—*Magazine-Journal*, June 18th.

[The representative of a firm dealing in China tea naturally endorsed Sir Andrew Clark's view.—*Ed. T. A.*]

A PARCEL OF BURMESE TEA SEED (says the *Rangoon Gazette*) sent by Mr. Oliver, Conservator of Forests, Burma, to the Superintendent of the Royal Botanic Gardens, Calcutta, has been identified as genuine *Camellia theifera*, the Assam wild tea. The general appearance differs very considerably from that of China tea or of the hybrids generally cultivated, and it is interesting to find a form in cultivation which does not differ, at any rate perceptibly, from the wild tea. The specimens were collected in the Mansi sub-division, Katha, but the original plants are said to have been brought from the forest on the Maingthon hills, where they grow wild. The tea is used for eating only. The young leaves are placed for a short time in boiling water, then slightly rolled and packed tightly into bamboo baskets. The baskets with the tea in them are then kept under water or buried in the ground until the tea is sent to market.

IMPROVED CULTURE OF LAND.—The *Pioneer* in an article on "A Department of Agricultural Engineering," writes:—If by scratching the ground, and cropping it twice a year, we can obtain the same output as by the scientific cultivation of a fraction of the area, why should we not choose the simpler plan? In the face of a growing population, this argument in favour of agriculture by faith without works is obviously unsound. The more capital and labour we can put into the soil, provided we obtain an adequate return, the more valuable a property we possess in it. If, as Sir Arthur Cotton says he has done, we can, by systematic deep cultivation, obtain sevenfold crops at a better rate of profit than that usually obtained, it is certainly, in view of the increasing demand for land, to our advantage to do likewise. This agricultural feat is said to be performed simply by the aeration of the subsoil by very deep cultivation. But there is deep cultivation, and deep cultivation. The deep ploughing that turns over the soil in heavy masses, is of little use, and in this respect the country plough is in its action superior to the English one. The process by which the happiest results are said to have been obtained is briefly as follows. The upper three or four inches of mould, which is as a rule all that is capable of nourishing the young plants, is stripped off the ground. The subsoil is dug up to a depth of two or three feet and thoroughly pulverized, no clod being left unbroken. The vegetable mould is then replaced. This costly process need only be repeated at many years' interval, so that practically only the interest on the initial outlay is chargeable against the value of the produce. Lord Tweeddale, who has carried out this system to a considerable extent, mixed up two inches additional every year with the old worked soil, till he was ploughing sixteen inches deep in one furrow.

SPECIAL MACHINERY FOR FIBRE TREATING.

There is a teeming abundance of good fibre plants in Ceylon, indigenous and introduced, which might be made sources of profitable industry, were but machinery available, or modes of chemical treatment known, effectual and cheap enough to secure profitable outturns of decorticated, clean and yet strong fibre. Prominent amongst the introduced plants in Ceylon,—introduced so long ago by the Portuguese from South America that it has become naturalized,—is the pineapple. Cultivated, or rather grown as the natives grow the plants, in hedges and under the dense shade of umbrageous trees, a large number of lengthy leaves are produced, calculated to yield the maximum of long and fine fibres. These fibres are superior to those of the green and grey aloes, so common, especially the green (*Fourcroya gigantea*), as fence plants, and we should say far easier of treatment than the stems of rhea or ramie. The one desideratum is effective crushing, decortivating and cleansing machinery; for leaves enough could be gathered in and around the native villages to afford a supply for decisive experiment; and if such experiment were successful a large plantation or plantations of pineapples could be formed under forest from which only the undergrowth need be cleared away. Although the main object would be the production of fibre, the sale of the fruit produced ought to yield substantial returns. Through the Kew Gardens Bulletin and other sources we have received details of promising machinery and modes of preparation with hot water and chemicals; and from Mexico and Mauritius we have heard of machinery in action. Death's machine is still a claimant for public approval, but many years ago a trial of it in Ceylon, applied to the green aloe, was a failure as to paying results. French engineers and chemists have put forward machines, or combined machine and chemical treatment as successful even in the case of the hard stems of rhea, but as yet nothing effectual and at the same time cheap has reached Ceylon or been invented within its bounds. We have, therefore, read with interest a circular on "Special machinery for fibre treating" by Mr. Ernest Lehman, Engineer and Contractor, Manchester. Notices of the various machines are prefaced by "General Remarks" to the following effect:—

During the last few years great improvements have been effected in the construction of Machines for treating Fibrous Plants, completely doing away with the tedious and expensive methods practised by the natives of Fibre-growing countries, which operations are totally unsuited to the conditions attendant upon extensive production. Many noted persons have been long engaged in endeavouring to solve the problem of the preparation of Fibres on a thorough commercial scale, and the Machines enumerated and described in this list combine all the most recent improvements for Treating and working the various Fibres of Commerce. From an insufficiency of knowledge many thousands of tons of Fibre are annually destroyed or thrown on the waste heap in the East, South America, the Pacific Isles, and other countries, whereas a judicious knowledge of such material would prove a small mine of wealth to the countries in question. Planters, small capitalists and others in the above-mentioned countries have opportunities of enriching themselves by an application of modern ideas and modern machinery to the manufacture of various descriptions of goods from Fibres. Ropes, Twines, Nets, Sacking, Bagging, Carpetings, and Cloths, for a large variety of purposes can be produced from these fibres, and at a comparative small cost, taking into account the vast trouble and necessary expense incumbent on purchasing such goods from other countries.

The circular then proceeds to notice a machine—Specially constructed for Extracting the Fibre from all descriptions of Fibre-producing Leaves and Stems in their green state and freshly cut, under which heading the following may be mentioned:—

Aloe Leaves, Pita, Henequen, Sisal, Manilla Hemp, Istle, Mexican Fibre, Jute, Sida Indica, Banana, Pine Apple Fibre, Rhea, Sansevieria, Asclepias Syriaca (Syrian Fibre), Tucum (Brazil), Bahia Piassava (Brazil), Assam Fibre, Maoutia Puya (Northern India), Bombax Ceiba (Guiana and West Indies), Eleoecarpus Americana (Majagua or Poa Tree), Palmyra Palm (Borassus Flabelliformis), Yercum or Mudar (India), Caludovica Palmata (Panama, Columbia, and Ecuador), Pulu Fibre (Sandwich Isles), New Zealand Fibre, and Phormium Tenax.

Premising that we do not understand the distinction between "New Zealand fibre and *phormium tenax*," for the New Zealand fibre *par excellence* is that of *phormium tenax*, "New Zealand Flax," which grows well on our hills,—we should say, but for what, follows as to subsidiary machines, that this is just the machine required in Ceylon, where appliances of a special character, improved by the experience of many manufacturers during a long series of years is already applied to the extraction of coir fibre from the husks of the coconut. To neither natives nor Europeans has this interesting branch of our manufactures and commerce yielded very appreciable profits, but the fact that it is continued from year to year, shews that it must at least pay the labour of the natives, and give fair returns on the capital employed in the pursuit. It is truly stated in the circular, regarding Coir, the fibres of which differ much in strength, fineness and colour, that

This fibre is extensively used for Cordage purposes, and for making Matting, Stair Carpets, Matting, and Mats of various descriptions are largely made from this fibre, as it easily takes colours in dyeing. A further use for Coir Fibre is for substituting it for bristles in the manufacture of Brushes, Brooms, &c., and when cleaned, dyed, and curled, it is used by upholsterers for stuffing mattresses, cushions, saddles, &c.

The quantity of fibre contained in a husk varies very much, according to climate, seasons, &c. In Ceylon 40 Coconuts will yield about 4 lb. of Coir Fibre. On an average it may be assumed that 1,000 nuts will yield 90 lb. of fibre.

We suppose the figures are correct. The coir may be said to be a "by-product" of the coconut, the really valuable portion of which is the kernel, which is eaten fresh as food (amongst the Sinhalese it is an invariable ingredient in curries), desiccated for export for the use of the confectioner and very largely dried into "copra," out of which oil is expressed, extensively used in soapmaking, the solid residuum, "ponac," being valuable as an oil-cake.—In case experiments should be tried in Ceylon, with pineapple leaves, or similar substances, we quote instructions as to "sorting" of leaves, stalks, &c., which may prove useful:—

Whether in leaves or stalks the material should be regularly sorted, and must be as uniform as possible when operated upon. In the case of Rhea or China Grass the stalks should be cut an equal length. With Pineapple, Agave, Aloes, &c., the leaves should be distinctly sorted, and each description separately treated. Wherever there is found to be any material difference in the quality of the fibre between the inner and outer leaves, each quality should be kept separate.

Before baling the fibre has to undergo a certain treatment. After extracting, the fibre must be allowed to dry thoroughly, and then it is subjected to a brushing action, either being beaten against a post by hand or being brushed in a Brushing Machine, described below. It is strongly to be recommended that planters should adopt the Brushing Machine, as carefully brushed fibre realizes a much higher price. An increase of £1 to £4 per ton can thus be obtained. One Brushing Machine will suffice for eight

Extracting Machines, and an engine of eight-horse power will drive such a set.

After brushing, the fibre should be made into small bundles of about three or four in. in diameter, secured by a strand of the fibre. These bundles are then pressed into Bales of two or three cwt. each. Care should be taken to cover the Bales, as the iron hoops are apt to injure the fibre. When strong rope or fibre bands are used instead of iron hoops, the bales can be exported without being covered, except in case of white fibre, when it should have a slight covering to protect it from the dirt.

'There seems to be common sense in all this. The description of the machine ("Extractor No. A") likely to be most useful in Ceylon is as follows:—

This Machine is furnished with strong framing feeding arrangement, drum with brass knives, iron cover over drum, pullies, and special apparatus for the description of Fibre to be treated. When ordering I particularly request my clients to state the description of fibre they intend to treat. Water connecting apparatus to supply the necessary water to the machine. This Machine will produce about 2½ cwt. of Fibre per 12 working hours. Gross weight 21 cwt. Price, £65 0s 0d.

Some of our mercantile or engineering readers who have had experience of fibres and their values will be able to say if 2½ cwt. of clean fibre say, of pineapple, in 12 hours (nearly 22 lb. per hour) is likely to be profitable in a commercial sense. The machine, when landed in Ceylon, would cost not less than R1,000, and a preliminary machine seems to be deemed necessary which will almost double this sum. This machine is described as follows:—

Leaf Squeezing Machine, for squeezing and crushing the leaves previous to extracting the fibre; consisting of cast-iron framing, with heavy iron rollers running in strong bearings, apparatus for adjusting rolls, arrangement for water supply, gearing, fast and loose pullies. Gross weight 2½ tons. Power required 2-horse. Price, £55 0s 0d.

Then the brushing machine, the use of which is so strongly recommended, is thus described and priced:—

Brushing machine, for Flax, Hemp, and other fibres, with iron framing, drum, door, pullies, &c. Gross weight, 1 ton. Power required, 1½ H.P. Price, £70, 0s, 0d.

And finally there is a—

Softening Machine, for softening the fibre and for breaking it. With strong iron framing, three pairs of fluted iron rollers, rotatory motion, feed and delivery tables. This machine is especially to be recommended for all descriptions of Fibres, and is of invaluable use in all Fibre Factories. The action of the rollers, in the case of Flax and Hemp, breaks the straw without injuring the fibre, and delivers the material ready for scutching. Gross weight, 1¾ tons. Power required, 1¾ H.P. Price, £65 0s 0d.

This is pretty well, if the sale of machines is the object in view, but we seem as far off as ever from one simple and cheap fibre-cleaning machine, unless "Extractor No. A" should really answer all purposes, save the cleansing of the fibre in water, preparatory to drying. We need not quote the descriptions of "Extractor No. B" for coir fibre, £40; or the bark (of trees) crusher and extractor, £80; or the machine for "willowing" coir fibre, £65; or the coconut husk crusher, £40; or the seeding machine, for flax, &c., £35-10; or the scutching machine £54; or of hydraulic presses and pumps at £210. But it is well to know that

All prices include packing, cases and delivery in Liverpool.

Although it is giving an advertisement gratis, we quote the concluding portion of Mr. Leman's very comprehensive circular, embracing, as it does, machinery for the heavy work of crushing tree bark and coconut husk, and for the much lighter

task of the cleansing of cotton, wool, and feathers:—

Spinning and weaving machinery, consisting of Hackles, Spinning Machines, Doubling Machines, Opncing Machines, Cop Winding Machines, Warping Machines, Power Looms, Cutting Machines, Calenders, Shearing Machines, Plating Machines, Sewing Machines.

Special power looms for coir matting and manilla carpeting.

Self-contained rope making machines, to strand and close in one operation, to make Ropes up to 12 inches in circumference.

Horse Hair, Flock, Oakum, and Waste Machinery. Cotton gins. Wool cleaning machines. Feather cleaning machinery. Special attention given to the equipment of Factories for producing sacking, ropes, twines, &c., from all descriptions of fibres, fibrous wastes, &c. Improved steam engines and fibre burning boilers combined. For hilly countries and transport on mule backs, I construct all above machines for packing in small cases. Cattle gears, turbines, and water wheels, all constructed to save weight and bulk. All information relating to the treatment of the various fibres, full technical particulars, plans, &c., given gratis to my foreign and colonial clients.

AGRICULTURAL EXHIBITION AT QUILON.

To the Dewan of Travancore we are indebted for a copy of a report on an exhibition held in February last. From this document we take some interesting extracts:—

"Under class V. the coconuts exhibited were far superior to those in former years. One bunch had 153 nuts and was much admired, the number required in the Prize List being only 40 nuts per bunch. The next largest bunch had 95 nuts in it. But the nuts were larger in size. The largest peeled coconut measured one foot in circumference, and was found R63 in weight. The largest coconut in husk was only 20 inches in circumference and weighed R168 being a little less than the largest exhibited on the last occasion.

"It is often said that we are a poor people, that capital is wanting in Travancore for any large undertaking. This is true to some extent. But considering the fact that large farming is nearly unknown and that this is a country of small farms the want of capital is only an excuse, the want of enterprise is the reality. Enterprise by itself can do much. I was pleased to find that a humble copyist in one of our taluqs drawing a pittance of R8 as monthly pay turned a piece of waste-ground into a beautiful garden by his own manual labour unaided by capital. Some years ago he took up an acre of waste-land and planted it himself, putting up a small shed in it as a residence for his wife and children. I am informed that nearly the whole of the planting, the digging, the enclosing and the building was done by himself, I mean, by his own hands, devoted to this honest labour all the spare time which his humble office afforded. The result is that this little garden holds 102 coconut trees, 11 jack trees, 46 arecanut trees, 14 mango trees, 4 cashew-nut trees, 3 marotti trees and 6 anjili trees, with the valuable pepper vines clasping to the last mentioned. The little property which, when he took it up was worth nothing, is now worth R600. For such devotion he ought to be looked upon as an example to his lazier neighbours. He has thus earned more by his spade than by his pen.

"Under yams, the exhibits have particularly been good. The tapioca exhibited was 10 ft. long and was tremendously big at its root. The removing of it from the ground must have been done with great care for the roots had grown in all directions. The biggest chena which got a prize was 3 ft. 5 inches, in circumference and weighed R1,890.

"Under the head of vegetables, the ash-pumpkin and keerathandu from the Shenkottah Taluq were admired. The pumpkin was 15 inches long and 36 inches in circumference, and weighed R2,016. The keerathandu had grown to a tremendous height

being 5½ ft. long. The mathankai or pumpkin which secured a prize was 4 ft. in circumference and weighed 24 lb. or R1,008."

Paper.—The paper manufactured by the Travancore Paper Mills Company at Poonalore was awarded a prize. The exhibits show that the Company have made considerable improvement since they started the manufacture a year ago.

His Highness the Maha Rajah's Government have liberally sanctioned a special honorarium to be given to a lecture in Malayalam, on some agricultural subject. We have on this occasion hit upon a respectable ryot and a member of a well-known family in Quilon, owning several thousands of coconut trees, to read a lecture on coconut cultivation, the staple product of Travancore. This is meant as an inducement to the tiller of the soil to cultivate the art of committing his experiences to writing, and thus communicate them to his fellow-ryots. I shall expect next year that a humbler ryot than a member of the Kottur family, actually engaged in digging and ploughing, will come forward as our next lecturer. Though, as ryots, I dare say you know more or less the details of cultivation and the capabilities of your lands, I wish to tell you what I learnt from an able Civilian of Madras, a gentleman looked upon as a great authority on agricultural questions 'that land in India, if properly cultivated, will yield six times as much as it does at present.' This is a most important point deserving of your careful consideration. Those of you that belong to the interior Taluqs of this Division ought to know the fact that you are potentially much richer than the inhabitants of the sea-board Taluqs. Nature is particularly kind to you. An abundance of wealth lies just under the surface awaiting the tiller's touch. Much capital is not required either. Nature gives it almost for the asking. Take for instance the plantain cultivation for which the interior Taluqs of Travancore are so well adapted. In one of my circuits to Shencottah, I made the following note for information furnished by some of the plantain ryots. Every acre of a hill-slope will cost R250 for clearing the jungle, planting and growing a plantain tope. This tope will last for 10 years. Deducting the expenses of cultivation, each acre of a plantain plantation yields a clear profit of R10 a month or R120 a year. In about 10 years, before which the plantation does not die out, the ryot makes a small fortune of R1,000 upon every acre brought under cultivation. This looks almost fabulous; but I am satisfied that this is the actual condition of things in the Arienkavu valley.

RUDYARD KIPLING ON RICE CULTIVATION, &c. IN JAPAN.

From a contribution by Mr. Kipling to the *London Times*, we quote as follows:—

If one knew Japanese, one could colloquy with that gentleman in the straw-hat and the blue loincloth who is chopping within a sixteenth of an inch of his naked toes with the father and mother of all weed-spuds. His version of local taxation might be inaccurate, but it would be sure to be picturesque. Failing his evidence, be pleased to accept two or three things that may or may not be facts of general application. They differ in a measure from statements in the books. The present land tax is nominally two and a-half per cent. payable in cash on a three, or as some say a five yearly settlement. But, according to certain officials, there has been no settlement since 1875. Land lying fallow for a season pays the same tax as land in cultivation, unless it is unproductive through flood or calamity (read earthquake here.) The Government tax is calculated on the capital value of the land, taking a measure of about 11,000 square feet or a quarter of an acre as the unit.

Now, one of the ways of getting at the capital value of the land is to see what the railways have paid for it. The very best rice land, taking the Japanese dollar at three shillings, is about £65 10s per acre. Unirrigated land for vegetable growing is

something over £9 12s, and forest £2 11s. As these are railway rates, they may be fairly held to cover large areas. In private sales the prices may reasonably be higher.

It is to be remembered that some of the very best rice land will bear two crops in the year. Most soil will bear two crops, the first being millet, rape, vegetables, and so on, sown on dry soil and ripening at the end of May. Then the ground is at once prepared for the wet crop, to be harvested in October or thereabouts. Land-tax is payable in two instalments. Rice land pays between the 1st of November and the middle of December and the 1st of January and the last of February. Other land pays between July and August and September and December. Let us see what the average yield is. The gentleman in the sun-hat and the loincloth would shriek at the figures, but they are approximately accurate. Rice naturally fluctuates a good deal, but it may be taken in the rough at five Japanese dollars (fifteen shillings) per *koku* of 330 lb. Wheat and maize of the first spring crop is worth about eleven shillings per *koku*. The first crop gives nearly 1½ *koku* per *tau* (the quarter acre unit of measurement aforesaid), of eighteen shillings per quarter acre, or £3 12s. per acre. The rice crop at two *koku* or £1 10s. the quarter acre gives £6 an acre. Total, £9 12s. This is not altogether bad if you reflect that the land in question is not the very best rice land, but ordinary No. 1, at £25 16s. per acre capital value.

A son has the right to inherit his father's land on the father's assessment, so long as its term runs, or, when the term has expired, has a prior claim or even money as against any one else. Part of the taxes, it is said, lies by in the local prefecture's office as a reserve fund against inundations. Yet, and this seems a little confusing, there are between five and seven other local, provincial, and municipal taxes which can reasonably be applied to the same ends. No one of these taxes exceeds a half of the land-tax, unless it be the local prefecture tax of 2½ per cent.

In the old days the people were taxed, or perhaps squeezed would be the better word, to about one-half on the produce of the land. There are those who say that the present system is not as advantageous as it looks. Beforetime the farmers, it is true, paid heavily, but only on their nominal holdings. They could, and often did, hold more land than they were assessed on. Today a rigid bureau survey every foot of their farms, and upon every foot they have to pay. Somewhat similar complaints are made still by the simple peasantry of India, for if there is one thing that the Oriental detests more than another, it is the damnable Western vice of accuracy. That leads to doing things by rule. Still, by the look of those terraced fields, where the water is led so cunningly from level to level the Japanese cultivator must enjoy at least one excitement. If the villages up the valley tamper with the water supply, there must surely be excitement down the valley—argument, protest, and the breaking of heads.

PLANTING NOTES FROM COORG.

(From our own Correspondent.)

THE LOSS FROM BORER.

COORG, July 19.—The largest loss from borer I have heard of this season is 6,000 trees off a young clearing under 20 acres and 8,000 old trees off a field of 25 acres. Fortunately these heavy losses are usually confined to poor pieces, the rich paying ones being left practically intact. Sometimes, however, borer unaccountably gets into good pieces which have usually enjoyed an immunity from the pest; and it is then that it makes itself most keenly felt. Borer is generally severe after a heavy crop, the pumped condition of the trees probably rendering them more easily liable to succumb to an attack. Judging from the past, however, the large losses in some instances this season, which have made parts of estates assume the appearance of newly planted clearings, will not affect

the general prosperity of the coffee industry provided the labour supply be as plentiful in the future as it has been during the past year, and seasons are favourable.

THE WHOLE TRUTH AS REGARDS BORER

appears to be as far from solution as it ever was. The good old way of removing the trees and burning them, although it may not make a big hole in the ranks of the enemy, has at least the recommendation that the unsound trees are got rid of; and it appears to keep the evil within bounds. If they were left alone some perhaps would recover, but the majority of those that did not die out would carry on a precarious existence doing no good whatsoever; and in process of time whole estates would be reduced to a similar condition. Borer is less severe in forest than in low-lying bamboo lands. Is the warmer climate of the latter or the bamboo accountable for this? New clearings sometimes suffer very badly three and four years after being opened. The burn probably drives the insects out of the place, and they do not return to it till they find no further danger is to be apprehended. They have been found to lodge in decayed wood, and I once found one in a dried twig of a jungle tree. Native proprietors, except the few who work on European lines, do not, as a rule, remove borers; hence

A NATIVE NEIGHBOUR IS MOST OBJECTIONABLE.

His place soon becomes a breeding nursery for borers when they migrate in swarms, carrying destruction in their path. This is one reason why the average yield of native gardeus is so much poorer than that of European estates. Much has been said about the coffee industry being eventually entirely left in the hands of native cultivators, owing to their being content with small profits and consequently not adopting a forcing and exhaustive system of cultivation. On the other hand, I am afraid their system of cultivation, which consists in taking all they can get out of the land without making any adequate return in the shape of manure, is calculated to bring about its destruction as speedily as possible. A Coorg, who owns a small place near Santikoppa, told me that he got a 6,000 rupees crop off it last season and spent only half that sum in the working! Native cultivators are heavily handicapped by the high rates of interest demanded by Sowcars for loans. 18 and 24 per cent. are the ruling rates, and they have to hypothecate their crops to secure the loans and sometimes are induced to allow the lenders to take them at a lower valuation than the ruling market rates! The individual above referred to considers himself fortunate in being able to borrow at 12 per cent! There are of course several native proprietors, and all honour to them, who

DO THINGS IN THE RIGHT WAY.

Mr. Thimiah, who has recently become famous through H. I. M. the Queen Empress conferring the title of Rai Bahadur on him, is one of them. He owns, I believe three fine places, one in South Coorg and two in North Coorg and has been successful with all of them. The one near here possesses a good soil and aspect and has invariably, I hear, done well. It has a fair supply of Palghat Wodnr labourers and work is fairly well forward. Mr. Nanjappah, the advocate and brother of Dr. Apiah of Bangalore, owns a nice young place near Mr. Thimiah's. It unfortunately appeared to be short handed a while ago. One is quite struck with the enterprise shown by the owner in fencing in the places with barbed wire. He did not stick at the expense. It proves to be very good economy in the long run. Barbed wire fences promise to become quite an institution in the country in the near future, several estates hereabouts having gone in for them.

THE MUCH-MALIGNED CHARCOAL OR BENDER TREES.

has also been charged with causing borer. I do not know how this is maintained. Many of us are of opinion that it is the planter's best friend, as it springs up spontaneously and soon covers a young clearing, affording protection to the coffee and the durable kinds of shade plants planted out with it. It is undeniably a source of danger if left beyond a certain limit of time, as if it dies of itself the coffee for several feet

around it dies out with it. If on the other hand it is killed by a ring being cut into the stem near the ground no harm is done. I confess to have been considerably nonplussed in this connection by being met with the query "Supposing something goes wrong in the soil which kills both the charcoal and the coffee?" It may be so, but why should a detrimental change of this nature take place only at the spots occupied by the trees in question? Matters being as above related,

THE USUAL PRACTICE

is to gradually get rid of the trees as the permanent ones make sufficient growth to take their places. The limit beyond which none of them should be retained is a matter of opinion. It has been put at 5, 7 and 9 years, but they are sometimes left beyond that. I have noticed them dying in fields of 11 and 12 years, causing much damage. I recently noticed the death of an old jungle tree causing similar damage. The decaying stump of the jungle nutmeg does the same. Hull thus refers to it:—"The stump of a certain class of tree causes, when beginning to decay, the death of all the coffee trees in its immediate vicinity. The remedy for this only lies in the removal of the stump in question." This form of blight was, I believe common down the ghats, where it was pointed out to Mr. Hull when on a short visit to Coorg.

FLOGGING A COOLY TO DEATH.

A Coorg ryot was a short time ago fined R500 and imprisoned for 6 months for chastising a cooly lad of his so severely as to cause his death. The boy's offence was that he had absconded. The ryot had some time previously a breach of contract case in the Subedar's Court against a man and his two wives, who had taken employment on a European place. They pleaded in defence low payments, oppression, and that their marks had been affixed to the contract bond under compulsion. As, however, they could produce no witnesses to bear out their statements, they were ordered to go back and work on their contracts. The conviction of the ryot lends a guise of truth to their story; but I don't suppose this can help them. There have been some early arrivals of labour from Pnthur way. These have been able to complete their paddy field work as their fields are supplied with water from streams. The great bulk of coolies cannot be expected for some time to come as the long break in the weather has retarded cultivation generally.

WAYLAYING COOLIES.

Some landholders here are, I believe, in the habit of waylaying these coolies on the Mangalore road as they come in and impressing them into their service, thus preventing them from fulfilling their legitimate contracts. I know it for a fact that some coolies belonging to a European estate were impressed in this way and the offender got into a blue funk and begged off when the gentleman concerned looked in on him about the matter. Something ought to be done to prevent this sort of thing. The coolies are too ignorant and frightened usually to do anything for themselves.

THE WEATHER DURING JUNE

was abnormally light, the break reported in my notes of the 16th ultimo continuing up to the 16th instant, and the total fall of rain for the month amounting to only 9 inches 32 cents at Mercara and 5 inches 58 cents on an estate near Santikoppa. The rainfall registered for the same month last year amounted to 12 inches 83 cents at the former place, and 6 inches 56 cents at the latter. As this was something under the average, it will be seen the fall this year has been exceptionally small. 9.78 were however registered at Mercara in May as compared with 6.59 the previous year. This will have made up in a measure for the short fall in June. On the whole, from the 1st of January, 1892, to the end of June the deficiency amounts to about 3 inches. This does not appear very alarming, but it was apprehended in some quarters that great harm would result to

coffee from it. As, however, no one appeared to have experienced a similar condition of things, the anticipated harm must be regarded as purely conjectural and based on the assumption that as the monsoon had begun light it would continue so. In the meantime coffee everywhere is looking as well as could be wished. These fears must have completely subsided on the setting in of the next burst on the 5th inst., since when the monsoon seems bent on making up for lost time. The heaviest fall was 4.64 on the 8th inst. and over 3 inches here. It had worked up to this from 1.1 on the 5th. From the 14th to the 17th inclusive there has been light weather with appreciable bursts of sunshine but it has begun to pour very heavily again since yesterday. Tamils do not find this sort of weather congenial, and many of them cause much inconvenience and annoyance by absconding, in spite of all the inducements held out to them to stay. Mercara presents a most dismal appearance at this time of year. It is almost always enshrouded in a pall of mist, and rain descends incessantly, but it is very healthy. The mist sometimes lifts disclosing grand scenery in all its verdant beauty. The effect each time is like that of a new view bursting upon one.

SUPPLYING, HANDLING, WEEDING AND DIGGING

are now in hand, but the weeds are being got under but slowly even on places fairly well off as regards labour. More coolies are required and it is to be hoped they will soon be coming in. Where clean mamoty digging has been done considerable wash has been caused by the recent heavy rains. "Agricola" once writing to the *Madras Mail* characterised mamoty digging as robbing Peter to pay Paul, but I am afraid Paul is also eventually robbed to the benefit of our neighbours the paddy field owners down in the valleys. The mamoty shovels whole spadefuls of earth down the slopes and the rain does the rest. The clearings in the bamboo fared rather badly during the long break in June, I hear, but I daresay the rain has been in time to save most if not all of the plants. Some plants put out early last year looked very sick during a break of about fortnight and as if they would all go; but they were saved and look very well now. It is satisfactory to hear that improvements are to be made in the mail arrangements with Coorg. It is most inconvenient to have to wait days and days for parcels after the letters advising their despatch have been received. And these parcels often contain medicines which may be urgently needed.—*Madras Mail*, July 22.

THE TEA TRADE.

"MAZAWATTEE" ENTERPRISE.

Few departments of commerce have displayed greater activity or more marked development during recent years than the tea trade. There are instances no doubt where it has been marred by unscrupulous traders and speculative advertisers who have taken advantage of a successful epoch, and foisted cheap and inferior teas on the public to the detriment of the legitimate merchant; nevertheless many instances could be given of the great strides which have marked this branch of commerce, notably in the Ceylon tea trade, and where the enterprise of some of the principal firms have had a material effect in bringing the productions of this colony under the notice of the public. Perhaps Messrs. Densham and Sons, the proprietors of the well-known Mazawattee packet tea, have done more than any other firm to popularise this article; certainly they are one of the largest firms of tea merchants in the Kingdom, and have developed a trade in Ceylon tea which is little short of phenomenal. This firm have recently taken new offices at Ceylon House, East-cheap, and it was in the course of a visit to these, that we gathered a few particulars of the extraordinary growth of the Ceylon tea trade, and the important part which the Mazawattee Tea Company in particular has played in its development. They were among the first to

recognise the deterioration in China teas, when China was formerly the great emporium of the world's supply—a deterioration which was probably largely due to the proverbial cunning and trickery of the Chinaman, who cultivated the art of "doctoring" teas, with the result that a temporary gain has almost ruined the tea trade of that country. Various districts of India, and Ceylon in particular, provided teas which were in every respect equal to the teas of China in their most flourishing days of half-a-century ago. It was this accurate gauging of the state of affairs, and the splendid system which they put in operation with regard to the manipulation of these teas, that gave the business of Messrs. Densham and Sons its great impetus; and it is by the rigid way in which they have always kept their teas up to each particular standard, both in quality and flavour, that they now control a trade of such magnitude and importance. The new offices in Eastcheap, entered in March last, were taken to meet the increasing requirements of the business. They have a fine and commanding frontage from Eastcheap, but even this conveys a very inadequate idea of the interior which extends back and spreads out to a considerable distance. They are fitted with every modern improvement as regards light and general facilities for the transaction of the business. A visit to these will convey some idea of the magnitude of the trade controlled, for we may say that, in addition to the gigantic business done in Mazawattee tea, Messrs. Densham and Sons carry on a trade as general tea blenders for grocers second to none in the City.

The front part of the premises on the ground floor is utilized for the various offices. There are the private rooms of the different members of the firm, the advertising and correspondence department, with numerous type-writers, shorthand clerks, etc. Proceeding, the invoicing and clearing department is reached, where there are quite an army of clerks engaged at their different duties. Then there is the ledger-room, which presents another scene of activity, twenty-two ledgers being kept for Mazawattee tea alone, independently of the other branches of the business. Adjoining the offices are the sale-rooms. One large space is devoted to blending for grocers' own canisters. This, as we have previously remarked, is a special feature of Messrs. Densham and Son's business, and a department in which they stand *facile princeps*. Grocers entrusting their teas to this house may always have certain blends matched, and rely upon the standard being maintained. The most perfect methods are adopted for ensuring this; a sample and register (with remarks) of every parcel of tea sent out being kept for future reference. Upwards of 15,000 samples of different teas sent out are held in the offices, so that at any time afterwards a particular blend can be referred to at a moment's notice. Another important department is the buying of India and Ceylon teas, and during the morning a large number of experts may be seen tasting and sampling the teas to be sold at the Mincing-lane public sale-rooms. The whole place is a scene of business activity, a visit to which gives a good idea of the perfection of their trading system. No firm has made a greater study of the tea trade in all its different bearings. Even the water of the different districts in all parts of the kingdom is noted, for in many instances this has different effects on teas, and has to be taken into account, so that teas may be blended to suit requirements.

These offices, important as they are, convey all but little idea of the trade done in bulk in Mazawattee and blended teas. That can only be appreciated by a visit to the immense warehouses on Tower-hill, which, with their commanding sky-sign, are well-known to visitors to the metropolis. Space, however, forbids us entering into any description of these.

We may say, in conclusion, that the new offices furnish another instance of that high spirit of enterprise which has so eminently characterised this firm's career, and placed them in the front rank of the tea trade of Great Britain.—*British Journal of Commerce*,

FROM THE METROPOLIS.

July 15th, 1892.

THE DULL SEASON IN TEA IN THE LANE,

generally synchronous with the middle of the year, is well-nigh over now and prices are expected to improve. But owing to this expectation, a good deal of tea has been kept back and it is just possible that considerably increased off-rings may have an effect for a time. I learned, however, during a call this week on Messrs. Geo. White & Co., that the figures for the consumption of Ceylon tea continue specially favourable and that in China tea, in correspondence, is steadily dropping out of demand. The new China teas are by no means well spoken of, and much interest has been stirred by a comparison instituted between typical samples of Ceylon and China teas, as explained in the following letter which accompanied those sent to me:—

13, Rood Lane, London, E. C., July 8th, 1892.

J. Ferguson, Esq.

Dear Sir,—We are sending herewith a sample of the New China Teas (1892-3 crop) which have just arrived per s.s. "Moyune," and we also send a sample of fair ordinary Ceylon tea now selling on the market.

As many persons interested in the tea trade had for some time been hoping for a revival in the China Department owing to an anticipated improvement in the manufacture, and as such a revival would doubtless have done harm to the Ceylon tea trade, we think you will be interested in comparing these two growths of tea.

When you notice that the China tea was actually sold in London at 11½d per lb. and the Ceylon is a tea on the market at about 8½d per lb. you will at once observe how much cheaper and more serviceable the Ceylon tea is of the two. This must sooner or later be also observed by the country at large, and we hope foreign markets.—We are, dear sir, yours faithfully,

GEO. WILSON & STANTON.

The general opinion, I believe, is that the Ceylon tea at 8½d is quite as good value as the China at 11½d, if not better. This fact and the very general appreciation throughout the country of the trade opinion that much better value is got in Ceylon teas than in China, augurs well for the steadily continuous displacement of the latter from the London market.

Among other good services done by MESSRS. GEO. WHITE & CO.

to the tea planters is the preparation and publication of the following clear *résumé* of

USEFUL HINTS.

Some of them will no doubt read familiar enough; but it is quite astonishing how readily all concerned—the planters especially—are to forget even the elementary rules herewith indicated. A copy of this paper pasted up in every Factory and if regularly consulted, cannot fail to lead to economical results:—

NOTES FOR THE TEA FACTORY.

31, Fenchurch Street, July 1892.

SIZE OF BREAKS.—Parcels consisting of less than 12 chests, 18 half-chests, and 30 boxes, are classed as small breaks, sold in London after the regular auctions, and do not, as a rule, command so much competition as full sized ones; they should therefore be avoided. Where circumstances do not admit of large breaks of Broken Pekoe, Pekoe, and Pekoe Souchong being made, it would be better to bulk the fine leaf together and ship it as one parcel, taking out only the coarse Souchong and Dust.

ASSORTMENT.—On estates in full bearing the following assortment will generally be found to answer, although it may be varied according to circumstances, viz.:—A first-class Broken Pekoe; a Fine Pekoe; the bold leaf often sent with Pekoe to be left in the Pekoe Souchong; the Rough Souchong to be equalized and mixed with the Fannings, the whole of which could

be called Broken Tea, thus making in all four kinds-Parcels containing Dust are not readily saleable, therefore this should be sifted out and shipped separately.

PACKAGES AND BULKING.—Full chests are ordinarily suitable to the home trade, though half chests are liked by many buyers both for export and home use, especially in the case of pekoes and fine descriptions. Leafy kinds for drinking alone, often sell well in boxes, but these packages should be under 28 lb. gross so as to avoid the 1 lb. draft allowed on those over this weight.

Factory-bulked teas are preferred by most houses, and if this operation can be done effectually at the factory, the expense attending it in the London Warehouse will not be incurred. Unless, however, the rates of each break are regular, (i.e., do not vary more than 2 lb.), every package has to be turned out here, so that the advantage of Factory bulking is thus partially lost. Besides this, the cost of taring separately is heavier than when an average can be struck by testing 10 per cent of the packages.

MARKING.—Name of garden, description of tea and chest number is all that is required on the package. Weight and tare are superfluous, only lead to confusion, and can always be checked from the garden invoice.

LONDON WAREHOUSE CHARGES.—Economy in all charges must be studied, and if the packing is regulated in accordance with the following scale, a considerable amount may be saved in the course of a season.

PER PACKAGE WEIGHING GROSS. (SUBJECT TO A DISCOUNT OF 10 PER CENT.)		60 lb.		45 lb.		35 lb.		17 lb.		Not exceeding 16 lb.	
		s.	d.	s.	d.	s.	d.	s.	d.	s.	d.
Landing and Housing Rate.....	2 3	1 10	1 6	1 3	1 5	1 0	1 4	0 10	0 6	0 7	0 3
Management Rate.....	2 9	2 3	1 10	1 8	1 2	1 0	1 3	1 0	0 7	0 4	0 4
Bulking and Taring.....	2 0	1 8	1 5	1 3	1 2	0 11	0 8	0 6	0 6	0 4	0 4
Bulking or Taring separately.....	1 6	1 3	1 0	0 11	0 10	0 8	0 6	0 5	0 5	0 3	0 3
Reit per week.....	0 1	0 0½	0 0½	0 0½	0 0½	0 0½	0 0½	0 0½	0 0½	0 0½	0 0½

N.B.—For determining the Class under which a Break is chargeable, the average gross weight must be ascertained. When the fraction of the average is half a pound or more, the higher rate will apply. Thus the average of a Break being 89½ lb. gross, the whole Break will be rated at 90/129 lb.; but the average being less than 89½ lb. the whole Break will be rated at 80/89 lb.

GEO. WHITE & CO., Tea Brokers.

It was very pleasant to learn of Mr. Geo. White's thorough enjoyment of his visit to the Ceylon and Indian Tea Districts, but especially of his month in your island. He has returned all the better for the trip and change of scene, and his only regret is that time and circumstances did not permit of his seeing more—indeed of carrying out a great deal of the program which he had laid down for himself.

Talking of the need of

ECONOMY IN RESPECT OF TEA

reminds me of a subject started in the course of a varied, interesting conversation with Mr. Stretch (of Messrs. Darley & Butler), namely, the strong reason now existing for a movement to secure a reduction in the present

DOCK CHARGES ON TEA.

The subject has been lately mooted by a City man with very large tea interests, and this led Mr. Stretch to go into figures which show that these charges are equal to from 8 to 10 per cent on the value of the teas. Of course, the general fall in prices of late years has increased the percentage and indeed is the cause of a claim for reduction. It is evident that lower values are bad all round—for the planter, merchant and broker and tea distributor as well as for the Dock Companies. And the worst of the matter is that the latter are far from prosperous. To start an independent (co-operative) Warehouse for Ceylon planters' tea, might be one way out of the difficulty. Some of the large Indian tea firms have their own wharves or warehouses and a not uncommon answer from them to brokers, seeking business, is to suggest that some of the teas of constituents should be sent to their warehouses as a *quid pro quo*. The whole question of Dock Charges and the room and need for reduction is likely to come before the Tea Committee shortly.

Of another product,

COTTON,

once of special importance to Colombo merchants through their close connection with Tinnevely—Mr. Stretch had not a very brilliant account to give, though the relative position of the South of India product is very much better than I can remember it to have been. To those of us who go back to the time when the present managing head of this London house and your mercantile representative in Council were among the most assiduous, if not boldest riders in and around Colombo, it is of interest to learn of a younger generation making a mark for physical vigour. In the *Field* of the 9th inst. you will find, in a report of the

TEA IMPORTS AND DELIVERIES.

Recurring to the statistics just published by Messrs. Geo. White & Co., of which I send you a copy, it is very striking to note the progressive advance of Ceylon in correspondence with the fall-off in China. The year is here counted from 1st July to 30th June, and here at a glance is the comparison I refer to in respect of imports:—

Imports.

	Ceylon.	China and Japan.	Difference.
	lbs.	lbs.	lbs.
1891-92...	63,768,000	60,214,000	= Excess Ceylon 3,554,000
1890-91...	50,191,000	69,742,000	= " China 19,551,000
1889-90...	34,290,000	90,050,000	= " 55,760,000
Then in regard to consumption:—			
	<i>Deliveries.</i>		
1891-92...	61,366,000	66,494,000	...
1890-91...	44,482,000	81,305,000	...
1889-90...	32,893,000	87,836,000	...

We may be sure that the "difference" at the close of the current year will be against China in "deliveries," as it is already in respect of imports; and indeed for the first half of 1892 by itself, the comparison is as follows:—

Deliveries of	lb.
"Ceylon," January to June 1892	=31,101,000
Do. "China" do. do.	=29,603,000

Excess of Ceylon ... 1,498,000

CINCHONA BARK AND "RUBBER."

A very interesting call to me was one on Mr. Meier, once a leader in the cinchona bark trade with very extensive dealings in South America as well as in the East. For a long period Mr. Meier took special interest in the Ceylon industry; but, alas! the trade has gone—disappeared—for as Mr. Meier remarked who could have supposed at the time that contracts were made at 48 cents for 2 per cent bark that it would be selling at 1d per lb. or who could have deemed advances up to £75,000 in a single year for South American bark, from one house, as risky before Ceylon exports took their extraordinary and unexpected sweep upwards.

No more about bark—for even Ceylon is not done yet, while Java is coming on with increasing quantities—said Mr. Meier; but what about your Rubber and Guttapercha? I had no news to give of any value, and it certainly made one feel that in respect of Rubber (as Liberian Coffee, Kola-nut and other new products) the Ceylon planters have too hastily turned aside, when I learned that the single Province of Pará is now exporting as much as 20,000 tons per annum of Rubber worth £300 per ton or £6,000,000!—so said Mr. Meier, and still the demand grows and outstrips the production. The Pará rubber is got by tapping and the trees are taken special care of, now.

ANCIENT MORTAR.

In a recent number of the *London Builder*, our friend, Mr. John Hughes, had an interesting paper on the composition of ancient mortar as used in the construction of our old castles, abbeys and churches. The article includes full analyses of the specimens, also illustrations from microscopic slides of the sand used in the mortar. One of the specimens analysed was from the "Giant's Tank," Ceylon, having been given by you to Mr. Hughes on the occasion of his last visit to Ceylon in 1888. Mr. Hughes is continuing his investigation into the character of the mortar in some of the Northern castles and abbeys, and I am glad to say he has received considerable encouragement from those interested in the matter. The practical result so far appears to be that pure limestones do not make the best lime for building purposes, and that if about 25 per cent of clay were calcined in the kiln together with the limestone the resulting lime would be more hydraulic in character, more like Portland cement, and in general character greatly improved for building purposes.

PERU, & C.—THE WEST INDIAN CURING OF "COCOA."

Mr. Arthur Sinclair's papers on his trip Westward and Southward and impressions of Peru in the *Victorian Magazine* are likely to finish in the September number—the concluding two chapters being the most important. A separate paper will probably be given on the visit to the West Indian islands, Mr. Sinclair being particularly anxious to show up what he considers to be the disgusting West Indian mode of curing "cocoa." This, in the form sent from Trinidad, he does not consider fit for human food, led alone "the gods"! When

these papers are concluded Mr. Sinclair may possibly add a few chapters on "Ceylon," "Tasmania," &c., and republish the whole with illustrations in a handy, attractive volume—"a wee bit buckie" is his modest idea with some such title as "Travels in Sunny Lands in Search of a Home." It would certainly be interesting reading from his happy pen and should take with the public in Great, as well as Greater, Britain—indeed with many from Peru to Lanka and Hobart!

Something must be done about,

TEA ESTATE MARKS

to prevent too close assimilation of marks or even of names of plantations. I have heard of a case where a well known Bogawantalawa estate has got the credit with many of continuous sales of lowcountry tea grown somewhere in the Galle district, in a garden which it seems has exactly the same name (unless a "y" be changed to an "i.") This Galle garden appears to have been in existence for some years, but certainly I never heard of its existence or got particulars for the Directory. Even where the native name justified the adoption of a well-known title, surely to prevent confusion, it would be well to vary the garden's name. In the coffee days we had certainly duplicates and triplicates of one name; but the matter was not of so much importance as in the case of tea.

ROOTS AS INDICATORS OF THE SOIL.—The researches of A. Henrich show that the proportion of nutrififying matter present in the roots of plants indicates the amount in the soil. A. Von Dikow has recently made some experiments to verify this statement. He used barley which was grown in the same soil, but fortified with varying proportions of artificial fertilizers. He finds that the roots of plants show what kind of fertilising materials they stand in need of; but nevertheless, the quantity found does not indicate the amount of fertilising matter in the soil which is capable of assimilation. And also that where the roots contain the maximum of nutrients, it is no indication that the soil is as rich in fertilizing materials as it can be.—*Chemical Trade Journal.*

PINEAPPLES IN FLORIDA.—Pineapples are propagated in three ways—from the "crowns," "suckers," or "slips." They are planted as thickly as cabbages, and at a little distance resemble them. From a five-acre plantation another plantation several times larger can be planted in one season. This rapid method of propagating the plants makes the industry comparatively easy of extension. Nearly all the planters put out new fields every year, provided they have the land at hand. From 10,000 to 15,000 pineapples can be planted to the acre, and in from 18 months to two years after planting the slips the plants will produce fruit. The plants need little cultivation after the suckers have once set, but the top soil requires a little stirring in order to prevent too rapid evaporation of the moisture. Every sucker, slip or crown if properly matured will produce one fine pineapple and each grower expects to realize five cents apiece for the fruit after transportation rates, cost of package, and commissions have been deducted. This means \$500 per acre, but some of the choicest varieties sell for much higher prices, so that from \$700 to \$1,000 is realised. The suckers are planted in rows three feet apart either way during the rainy season in August and during June and July the crops are harvested. The pineapples are cut off close to the main stalk with a sharp knife and the thick pointed leaves are trimmed so that the fruits can be packed easily.—*Indian Agriculturist.*

TEA AS A CORPSE PRESERVATIVE!—A striking fact about Chinese use of tea, which is told on the authority of a Chinese officer, is that it is employed for preserving the bodies of the dead. A corpse placed the centre of a box of tea, he says, will "keep" for years. He further asserts that tea, which has been employed in this capacity, is often exported for foreign consumption, the boxes being marked in a way known only to the natives. This may account for the superior aroma which Chinese tea is claimed to possess!—*Asian.* [This idea is really too bad.—*Ed T. A.*]

FRUIT CULTIVATION AT THE CAPE.—An earnest of the intentions of those interested in the Cape fruit trade, to develop it to the utmost, is given in the publication of elaborate suggestions with regard to the packing of the fruit for the voyage to Great Britain. The instructions refer to grapes, apricots, plums and gages, peaches, nectarines, figs, pears, apples, quinces, melons and pomegranates. The hints given to Cape growers are based upon the experiences of the Syndicate which undertook the recent experiments to ascertain whether the fruit trade between the Cape and Great Britain could be made a commercial success. Among the few kinds of fruit which the Cape growers are not encouraged to send are pineapples and oranges. The ordinary Natal pine, they are told, is not suitable to the English market; and as for oranges they, it seems, would carry well, but would not pay for two reasons. Their price is higher at the Cape than in England, and they would arrive in the latter country when abundance of European fruit is in the market. Orange groves must be established and developed near Capetown before this branch can pay. A trade in fresh peas, beans, and early potatoes is likely, we gather, to be developed owing to the success in carrying fresh fruits in the refrigerators of Sir Donald Currie Company's steamers.—*Indian Agriculturist.*

JAPAN TEA IN AMERICA.—After the meeting of the Central Tea Merchants Association, held in February last, Mr. Tagome Hachiro was sent to America to ascertain the business condition there, and we published, says the *Nichi Nichi*, his report, stating that the Government of the United States had hitherto charged no import duty on Japanese tea, but that lately there was a rumour as to the probable imposition of a duty of \$10 per 100 cattie of tea imported from Japan. We now hear of a despatch from the Japanese Consulate in New York to the effect that the rumour was started by some tea merchants in the hope of stopping the importation of inferior tea into the States. Stated accurately, the story was that a heavy duty would be imposed on imported tea under the provisions of the McKinley Tariff. According to that tariff, sugar, honey, coffee, tea, and leather may be imported free of duty, but the President, if he considers that the circumstances of the case warrant such a step, may annul that provision, and impose any tax he thinks proper. Hence it was asserted that the President contemplated imposing a duty on tea from the 1st January. But the rumour was unfounded. According to statistics, the total amount of tea imported into the United States during 1890 was over 30,414,700 cattie, the total price being \$5,323,370. If the Government imposed an import duty of 10 cents per catty, the sum collected would amount to over \$3,000,000. Such a heavy tax could not be paid by the consumers. Moreover, if the President proposed to exercise his fiscal discretion in such a manner, he would be obliged, in the first place, to negotiate with certain Powers. At present, however, there is no sign of any duty being imposed on tea imported from Japan.—*Japan Weekly Mail*, April 23rd.

GROWING WOODS FOR TEA BOXES AND OTHER PURPOSES.

We commend to the attention of our readers the remarks on wood for tea boxes communicated by Dr. Mayr of Munich to the *Indian Forester*. It will be seen that he advises the cultivation on a large scale of *Cryptomeria*, or as he suggests it should be called *Sequoia japonica*, a tree which FORTUNE, the well-known traveller in China, introduced into Darjeeling half a century ago, and which is now being somewhat extensively tried in and around Nuwara Eliya. It is stated that it grows in all kinds of soil, but of course the nature of the soil must affect its growth; and, as a matter of fact, there is a great difference of appearance between the generally dwarfed specimens on the poor peaty grass land of the Plain and the luxuriant growth of those planted in forest soil. On a piece of such ground near the bund of Lake Gregory the *cryptomerias* are only second in height to the *toons* amidst which they grow: any deficiency in altitude being compensated for by the dense lateral growth of branches in the case of the pines. These branches ought when pruned away to be valuable for firewood. One of the great merits of this tree is that it freely coppices; and as it grows much more freely in our forcing climate than in Japan and China, the period in which the timber can be utilized (original growth and successive coppicings) may probably be 15 years instead of the 25 years period in Japan. The tree grows readily from seed in Ceylon; and so far as our own experience goes this mode of propagation seems preferable to that by large cuttings, such as Dr. Mayr describes. The cuttings tried on Abbotsford were not, perhaps, so large in size as those he describes, and for the first year or two after being put into the ground the tendency was towards horizontal growth along the surface. Just as the plants were about to be removed as unsatisfactory they began to send up good central shoots; and the lateral growth, in some cases one mass of cones, was cut away. Our readers will see that the Japanese name of this *Cryptomeria* or *Sequoia* (and it deserves to be ranked with the *sequoias* from the enormous dimensions to which it attains) is *suji*, while the Japan wood chiefly introduced into Ceylon for tea boxes is *moni*. This is recommended as being free from the cedar-like odour which is deemed objectionable in the *suji*; but it will be observed that Dr. Mayr describes the odour as quite evanescent, so that if perfectly fresh timber is not used all objection on the score of odour disappears. It is curious that Dr. Mayr says nothing of the *moni* and does not mention the existence of the American saw-mills, whence so many tea estates in Ceylon and India are furnished with tea boxes in convenient shooks. Even apart from conversion into tea boxes, *Cryptomeria japonica* is well worth cultivating for the fuel derived from its branches and the useful timber purposes to which its tall straight stem can be put. It is, moreover, a very handsome ornamental tree; and FORTUNE went into raptures over one which he found near a Buddhist monastery in China. No wonder if he deemed the tree an acquisition to the hill regions of India, considering the words he wrote now fifty years ago:—

The province of Kiang-see had been shut out and left behind us, and our view now opened on Fokien. Never in my life had I seen such a view as this, so grand, so sublime. High ranges of mountains were towering on my right and on my left, while before me, as far as the eye could reach, the whole country seemed broken up into mountains and hills of all heights, with peaks of every form.

While gazing with wonder and admiration on the scene, my attention was arrested by a solitary pine-tree of great size, standing about a hundred yards from the gateway. No other trees of any size were near it. Its solitary position near the pass, and its great height and beautiful symmetry, made it appear a most striking object. "What could it be? was it new, or did we already possess it in England?" I must confess that for a few seconds I had eyes for nothing else. Chairs, coolies, and mountains were all forgotten, and I believe, had the guard of Celestials attempted to prevent me from going into Fokien, the only boon I should have asked at their hands would have been to be allowed to go and inspect this noble pine.

The Chinese guard, however, had not the slightest intention of interfering with my movements, and, as the tree was on the roadside, I soon came up to it, and found it to be the Japan cedar (*Cryptomeria japonica*), a tree which I had already introduced into England, and which, even in a young state, had been greatly admired there. I had never before seen such a noble specimen, and although I would rather it had been something new, I yet felt proud of having been the means of introducing into Europe a tree of such size, symmetry, and beauty. It was at least one hundred and twenty feet in height,—it might be much more,—as straight as a larch, and had its lower branches drooping to the ground. It had not been "lopped" like other Chinese trees, and was evidently preserved with great care. My Chinamen looked upon it with great admiration, and informed me it was the only specimen of the kind in this part of the country, and that it had been planted by some former emperor when he crossed the mountains.

There are many other passages in which Fortune expresses his admiration of "the beautiful cryptomeria." He estimated the height of the old specimen he so enthusiastically describes at 120 feet; but our readers will see that Dr. Mayr describes the tree as actually attaining 250 feet in height, with breadth of stem in proportion. This tree is surely worthy of special attention by our Forest Department, as well as by planters.—Dr. Mayr mentions another tree which ought also to be tried in Ceylon. It grows at lower altitudes than those suitable for *Cryptomeria*, comes to maturity much sooner (attaining a girth of 3 to 4 feet in ten years!), and coppices so readily that the more it is cut the better it seems to grow. If this tree could be successfully introduced into our Ceylon tea districts, it would certainly be a great acquisition; and it will be observed that Dr. Mayr offers to send seed from Japan. The botanical name of this wonderful tree for rapid growth is *Paulownia imperialis*, and we find from the Dictionary of Botany that it has the habit of *catalpa* and was classed by Thunberg as a *Bignonia*, but it has much more the character of *Scrophulariaceae*, of which it is now considered as forming a distinct genus. It bears handsome flowers. Apart from the Australian *Eucalypti* and *Acacias*, which have not been considered as yielding wood suited for tea boxes, the only exotic tree growing in Ceylon which rivals *Paulownia imperialis* in rapidity of growth (and we should think it would coppice readily) is *Albizia moluccana*, the light wood of which, we should think, would be suitable for tea boxes. Specimens of this tree, not quite 12 years from the nursery, are simply gigantic. The foliage is so like that of *Poinciana regia* (the flambeau or flame tree) that our *Albizias* have been frequently mistaken for the grander but not more beautiful flowering tree: the blossoms of the *Albizia* being snow-white.—Amongst the trees mentioned by Dr. Mayr as associated with the *Cryptomeria* is *Quercus serrata*, which has been found in Darjeeling to yield good fuel at an early age. It abounds in Assam,

NOTES ON PRODUCE AND FINANCE.

THEY MEAN BUSINESS.—The papers received from Calcutta by the recently-arrived mail show that the Indian tea planters feel very strongly upon the subject of their due representation at Chicago. At a meeting held at Silhat, and reported in the *Englishman*, the Calcutta subscriptions were considered unequal to the occasion, and comment was made on the letter of the Indian Tea Districts' Association, London, which letter was said to contain a great deal of good advice, but no financial assistance. The meeting was evidently in the mood for stirring things up. It recommended not only that the owners and shareholders of ocean and river steam companies and all interested in any way in tea should be pressed to subscribe individually to enable full advantage to be taken of the splendid opportunity to improve the prospects of the tea industry, but it was finally considered that the local government should give liberal help, as the prosperous condition of the Assam province was entirely due to the capital invested by the planters. This last phase in the discussion was very much to the point, and we hope it was not without its effect on the Government of Assam.

THE NEW SEASON'S CHINA TEAS.—The quality of the new crop, as far as can be judged at present, is for the most part fairly good, although the liquors of some parcels are rather thin. Prices on the whole opened considerably lower than last year, only a few breaks of very distinctive quality having fetched comparatively high rates. With respect to the supplies of the first-crop teas for the ensuing season, says the *Grocer*, they are said to be 100,000 half-chests short of those in the preceding year, and the market will thus be relieved of any glut that would otherwise be experienced; but as a drawback to this conclusion it must not be forgotten that Russian operators, contrary to their usual custom, have bought 100,000 half-chests (or an equivalent to the above) less than in 1891, and by that means the shortage in the supply has been negated by a falling off in the demand. The late rye famine in Russia, independent of other unpropitious circumstances, has been one of the chief causes of a more parsimonious system of buying on the part of the Muscovite population and a leading caterer of theirs is reported to have taken only about 30,000 half-chests of Monings as his year's supply, in place of over 70,000 half-chests as in 1891; but it is also said, by way of explanation that orders for the fulfilment of contracts not executed on the opening of the market at Hankow will probably be completed in London later on instead, and if so, such a departure from an old-established practice may prove to be a great advantage to the export branch of the trade here.—*H. and C. Mail* July 15.

THE DOUBLE COCONUT OF THE SEYCHELLES ISLANDS.

The history of the Seychelles coconut (*Lodoicea Sechellarum*, Labill.) is most curious. There is not a botanist who has not read about it over and over again, not a traveller to Madagascar, Reunion, or Mauritius, who has not viewed with astonishment its enormous, black, two-lobed fruit, a character that has given rise to names as strange as they are French. Ordinarily it is called "Coco de mer," because it is carried away by tidal currents and deposited on distant shores where it occasionally germinates and grows well; it is also called, "Maldivé coconut," as it is found in those islands, transported thither undoubtedly by some current; "Solomon's coconut," "double coconut," are also names by which it is known, besides others; Rumphius mentions it in his *Herbarium Amboinense* as *Cocos maldiveus*, and alludes to the more or less fabulous stories about the supposed virtues—in one place it was used as an antidote to poison; in another, it was a wonderful specific against colic, apoplexy, paralysis, &c.

Without giving too much credence to the probability of these properties, it appears certain that the fruit of this palm tree fetched a high price. Travellers who were

able to get it, paid £6 to £12 for a single fruit, while the largest specimens went for as high a figure as £18.

Precious vessels or cups were made out of the shell, and were used to hold tobacco, or betelnut. In the Maldives, the king made it a royal property, in order to present it to his favourites, and the theft of one of these coconuts was a capital crime.

Vague ideas prevailed for a long time concerning the appearance of this tree in its native country, its size, leaves, stem, &c. But the discovery of the Seychelles islands in 1743 put an end to these doubts. People soon found out that it was indigenous on the islands of Praslin, Curieuse and Ronde. Sonnerat described it botanically in his *Voyage to New-Guinea*, and brought it with him to Réunion. Commerson continued the observation; and then Labillardère, who gave it its present name, and then Queen de Quincy, Governor of the Seychelles; but it was not until Messrs. Harrison and Telfair were enabled to send flowers and fruit preserved in spirits to Sir W. M. Hooker at Kew, that the complete botanical study of this curious plant could be undertaken.

The *Lodoicea* is found on the mountainous parts of the three islands mentioned above, where it grows on rocky soil in company with *Cocos nucifera*. Its majestic stem, 50 to 70 feet high as a rule, sometimes reaches twice this height crowned with a magnificent head of leaves, sixteen feet long and more. Travellers describe its appearance as noble, but somewhat melancholy. The young leaves, while still undeveloped and rolled up at the top of the stem, are edible, like those of the *Areca oleracea*; they are also pickled when fully grown, the broad, handsome leaves frequently numbering more than a hundred on a single tree are used in roofing, hat making, and even for thin walls. The midrib is made into brooms and baskets; the felt-like down, which covers the young leaves, is much valued for making pillows and mattresses.

The stem is made into pipes for irrigation, or furnishes building wood, or planks for boxes.

The fruit is not merely an object of superstition or curiosity; many useful and durable articles are made out of the nut such as dishes, plates, bowls, and cups. It is frequently used for storing, drinking water, each shell holding about three quarts.

When ripe, one of these enormous nuts weigh as much as 40 lb., and measures 50 inches round and 15 inches long. At first it was thought that they ripened annually, but more recent observations have established the fact that they take many years, probably nine or ten, to ripen.

When the ripe fruit is subjected to a temperature resembling that of the Seychelles, it germinates readily and grows quickly. During the first few years, the young plant does not in the least resemble the adult tree; it is more like some of the *Prichardias* of the Pacific.

As soon as the stem is fairly formed, its base is rounded and fits into a natural bowl or socket, which is pierced by numerous small oval holes, with hollow tubes corresponding on the outside. The roots pass through these holes and tubes, and penetrate the ground but they never become attached to the bowl, thus having a free play and allowing the tree to sway about in the wind, a very necessary provision against violent gales. The stem forms a splendid column, perfectly straight like an iron pillar, and covered with the old leaf scars. The leaves are covered with a thick down before they unfold, and when fully expanded are fan-shaped, ten feet long by five feet wide, though sometimes they attain a length of 20 feet and a breadth of 10.

The colour of the leaves is shining light green, and when they fade, they bend and hang downwards along the stem before falling. The crown of foliage generally contains twenty leaves, but this number may run up to a hundred according to certain travellers, and then the whole tree forms the most splendid object it is possible to behold.

The tree is dioecious. At the age of thirty years, it first puts forth its blossoms, the males forming enormous catkins, three feet long and three inches in diameter, while the females are set on a strong zigzag stalk, covered with large reddish brown scales.

The fruit externally is covered with a thick fibrous husk like the ordinary coconut. The inside, before the fruit is ripe, is formed of a kind of firm trans-

parent jelly. Each fruit contains usually one, sometimes two or three nuts with hard black shells, and divided at the top into two or more deep lobes.

The fruit of the *Lodoicea* has germinated more than once in hot houses. The first time at Glasgow, but the young plant did not survive. Quite recently germination has been successful in the museum of Paris, and the young plants are doing well up to date; it remains to be seen how they will fare subsequently. It would be most interesting to be able to cultivate this remarkable palm in our colony.—*Revue Agricole*.

The Editor of the *Indian Forester* writes:—In putting before our readers the above translation of an article from a magazine which is by no means the least interesting of our exchanges, we wish to mention that it does not seem to be generally known what large numbers of these nuts must be brought to India. In travelling last year and this, in the neighbourhood of Hurdwar and Rikihesh, both great pilgrim places on the Ganges, we noticed that all the better class of the 'fakirs,' who frequent the banks of the holy river and live on the offerings of the pilgrims, carried habitually with them a black curiously shaped bowl with a handle in which they drew from the river the moderate supply of water for their day's use. We made enquiries and at last through the kindness of a brother officer procured one of these bowls for the Forest School Museum. It proved to be the half of one of the nuts of the 'double cocount.' Judging by the numbers we have seen, the trade must be considerable and the numbers of the nuts brought to India for sale great, for we can hardly suppose that even all those we have seen were originally washed up by the sea on the coast of Ceylon or Malabar. The only reference we can find in books to this use of the nuts is a very short one in Dr. Watt's Dictionary, where it is also said that the nuts are procurable in Bombay, at R1 to R2 each. Seemann, in his "Popular History of Palms" says, that the Chinese considered that water kept in the shell would preserve those who drank it from every complaint; but adds by the East Indian as by 'Europeans' "it is probable that they are now only sought as a matter of curiosity or for domestic purposes." We hope some of our readers may be able to add some further information on this interesting subject. [The extraordinary fact ought to be added that a period of ten years is occupied from blossom to mature nut. We have never heard of any of these nuts being washed up on the coast of Ceylon.—Ed. T.A.]

THE AMSTERDAM CINCHONA AUCTIONS.

Amsterdam, July 14.

At today's cinchona auction over 3,000 packages Java bark were offered, but half of this was bought in, the remainder (viz., 1,567 packages) selling at the low unit of 6½ cents per half-kilo (equal to 1 1-16ths d. per lb.) This price shows hardly any advance upon the last sale-rates. The following prices were paid:—Manufacturing bark in chips and quills, 5 to 53 cents (equal to 1d to 9½d per lb.); ditto root 14 to 36 cents (equal to 2½d to 6½d per lb.); druggists' bark in quills and chips 10 to 39 cents (equal 1½d to 7d per lb.) The principal buyers were Mr. Gustav Briegleb, of Amsterdam, the Brunswick quinine works, the Frankfort works, and the Amsterdam factory.—*Chemist and Druggist*.

UYA COFFEE COMPANY, LIMITED.

Capital £100,000, in 10,000 shares of £10 each.

DIRECTORS.—John Brown, Esq., Managing Director, H. H. Potts Esq., L. Pamin, Esq., Edward Conder, Esq.

REPORT to be presented to the Twenty-ninth Ordinary General Meeting of the Company, to be held at No. 5 Dowgate Hill, London, on Thursday, the 28th day of July, 1892, at 12-30 o'clock p.m.

The following Annual Accounts are now presented to Shareholders, viz.:—Profit and Loss Account for Crop 1890-91, Balance Sheet made up to 31st May, 1892.

CROP 1890-1.

In the Directors' last Report the coffee crop of the above season was estimated at 2,500 cwt., and it will be seen that the actual weight sold in London amounted to 2,791 cwt., 0 qrs. 27 lb.

The proceeds, inclusive of a small quantity sold in Ceylon, amounted to £13,875 5s 2d., giving an average of 97s 10d per cwt., against an average of 102s 5d obtained for the previous crop.

The crop of tea was estimated at 280,000 lb. and the actual weight sold from the Company's own estates was 286,346 lb. Besides this 225,800 lb. of tea manufactured from leaf hought from neighbouring estates were sold.

The value of all tea sold was £22,816s 10s, 1d or an average of 10½d. per lb. compared with 10½d for the previous season.

The weight of Cinchona Bark sold was 32,650 lb. and the value £424 15s. 10d., or 3d. per lb., against the former year's average of 3½d. per lb.

Cocoa weighing 52 cwt. 2 qrs. 0 lb., realized £252 14s. 8d., the average selling price being 97s. 2d. per cwt. against 88s. 3d. for the former year's Crop.

It will thus be seen that the total value of all produce sold amounted to £37,369 5s. 9d.

The total Expenditure for the year in Ceylon and London, after allowing for Profit on Exchange, amounted to £33,833 8s. 2d., and deducting this from the value of the Produce, a Profit is shown on the season's working of £3,535 17s. 7d. To this has to be added the balance of £52 7s. 11d., brought forward from last year, giving a total of £3,588 5s. 6d. at the credit of Profit and Loss Account.

An interim dividend of 1½ per cent. on the capital of the Company was paid on 14th January last, which absorbed £1,500 of the above-named sum, and the Directors now recommended that £2,000 be applied to the payment of a further dividend of 2 per cent., making 3½ per cent. for the year, and leaving £88 5s. 6d. to be carried forward to next Account.

The above season has proved an important and fortunate one for the Company, as during the year works of much value have been carried out on the Estates, and at the same time the Directors have been able to maintain a fair rate of Dividend. This was almost entirely due to the increased Coffee Crop, and had it not been for the larger returns secured from this product, it would have been necessary either to curtail the Dividend or to have indefinitely postponed, to the great detriment of the property, works which have now been successfully accomplished.

During the season 258 acres of Tea were planted up and nurseries and other preparations were made for planting up a further 109 acres, and this additional area has now been completed.

Very considerable outlay was also incurred during the season on improved appliances for manufacturing tea, two large Withering Houses have been erected, besides additional Machinery for dealing with the increased quantity of leaf. It is impossible to over rate the value of having ample appliances for manufacturing tea, and especially is this true with regard to Withering accommodation, and the high place which the Company's Teas now hold in the London Market, is in a great measure due to the efficient way in which they are now treated during the process of manufacture. The completion of the Company's Factories has made it possible to carry out the purchase of leaf, and the manufacture of tea for adjoining estates to the satisfaction of the proprietors and to the advantage of the company. The total weight of tea manufactured at the Company's Factories during season 1890-91 was 596,767 lb. Any leaf purchased is bought on a sliding scale, so that the Company's profit as regards hought leaf, is not affected by the fluctuations of the market.

Following the strict line of the policy they have laid down, the Board have debited the whole cost of the above works to the season in which they were carried out so that all expenditure of whatever sort has been written off, and nothing held up in suspense. By adopting this course the Board feel confident that Shareholders will reap the benefit of a gradually improving property, as it will be seen from the table

of the tea area that out of a total of 1409 acres and only 1,000 are at present yielding leaf; there are thus upwards of 400 acres involving considerable cost for up-keep from which no return is at present being secured. All this tea is growing well and in a year or two should show good results.

It will be seen that there are 914 acres still under coffee; it is difficult to express any decided opinion as to this product, but in the meantime not more than 70 acres of it is being planted up in tea. The crop of coffee for 1891-92 will be small, but from the appearance of the trees it is hoped that a fair crop may be secured for the following season. Should it be found necessary to plant up further areas of coffee with tea, it is thought that it will be a very gradual process, entailing no undue strain on any particular season.

CROP 1891-2.

The coffee crop of this season will not, it is thought, total quite one-half that of the previous year. The Tea, however is yielding well, and it is estimated that 340,000 lb. will be secured from the Company's estates. All important outlay on Factories being now completed, it is therefore hoped that a fair Dividend will be earned. The market for tea just now is abnormally low, but statistics point to a recovery at no distant date.

At the last Annual Meeting, Shareholders were advised of the probable purchase of Ledgerwatte estate, and the Board have now pleasure to report that this has been completed at £3,150. This property forms a valuable accessory to Narangalla estate, and ensures an ample supply of leaf to keep the Factory on that property fully at work irrespective of bought leaf. The area now under Tea is as follows:—

TEA.		
Over 5 years old	...	912 acres.
Planted Nov., Dec.	...	1888 87 "
"	...	1889 18 "
"	...	1890 283 "
"	...	1891 109 "

Total area under tea ... 1,409 acres.
Total area under coffee ... 914 acres.

The Board consider that great credit is due to the Manager and his Assistant on the estates, whose willing services have enabled them to transfer so large an area from coffee into tea, and to thoroughly equip three large Tea Manufacturing Establishments without calling on the Shareholders to provide any extra funds.

Mr. L. Famin, a member of the Board, retires on this occasion, and, being eligible, offers himself for re-election.

Messrs. Deloitte, Dever, Griffiths & Co., the Auditors, also offer themselves for re-election.

By order, J. ALEC ROBERTS, Secretary.

July 20th, 1892.

BALANCE SHEET FOR 31ST MAY 1892.

Dr.	£	s	d
To Capital authorized:—10,000 shares of £10 each issued and fully paid	100,000	0	0
To Reserve Fund	4,600	0	0
To Sundry Creditors	2,176	7	8
To Bills payable	10,798	5	9
To Sales of produce account crops 1891-92	13,215	15	0
To Profit and Loss account balance £3,588 5 6			
Loss Dividend paid 14th July, 1892	1,500	0	0
	132,278	13	11
Cr.	£	s	d
By Estates as per last account	£100,000	0	0
By purchase of Ledgerwatte est.	3,150	0	0
By Sundry Debtors	103,150	0	0
By Office Furniture	2,449	7	8
By Machinery, as per last account	£1,214	9	10
Less written 29th off July 1891	614	9	1
By Ceylon and London Expenditure chargeable to crop 1891-92	4,681	10	6
By Cash at Bankers	2,367	15	9
	132,278	13	11

We have examined and found correct—the books and vouchers of the Company in London, with which have been incorporated the accounts from the estates, and aud we certify that the above Balance Sheet correctly represents the position of the Company as shown by such Books and Accounts.

THE POSITION OF TRADE AND MINING INTERESTS.

The present is a time which naturally lends itself to a consideration of the position of the metallurgical branches of trade, and of its probable effect upon the mining industry in the immediate future. As merchants and traders find it to their advantage to carry on stock taking at each natural division of the year, so the investors in mining scrip, and others who have an interest in the prosperity of mining, are accustomed to estimate the possibilities of the future by a consideration of what they have gone through in the past. They are further led to do this by the temporary suspension of business which is resulting from the general elections, a suspension which gives them ample time to look carefully into their affairs. Fortunately, this period of business inactivity will be, for the time being, very short, though manufacturers are somewhat apprehensive as to whether it will not eventually result in further appeals to the country. This, however, is the only disturbing element in the trade position. In every other respect the second half of the year opens with more encouraging prospects than the first. The period through which we have passed has been in the nature of a crisis. The failure of the Oriental Bank was a practical evidence of low financial tide in the East, and this was, in a great measure, brought about by an exceptionally heavy speculation in landed property. The trade of Great Britain with the East bent its head to the blow like a healthy reed, and this contrasted curiously

with the crippled state of Argentine trade after the Baring collapse. Another crisis was threatened to British trade by the imposition of the "prohibitive" continental tariffs. The five months that have elapsed since these new duties were imposed have afforded a convincing answer to those people who had looked up the fiscal policy of France as directly menacing British interests. Some branches of industry have undoubtedly been affected by the new duties, but taking trade as a whole it has benefited considerably. The imports into France have been increasing by leaps and bounds, and, what is more, the greater part of them are composed of manufactured goods. Upon the other hand, the exports have undergone considerable restriction, except in raw material, which has been sent away in greater quantities. This state of affairs, which is so diametrically opposed to all the fundamental tenets of protectionism, is not to be easily explained; but the fact remains that nothing in the past twenty years has inflicted such a heavy blow upon the foreign trade of France than the measure by which it was hoped to improve it. Yet another evil factor against which the mining interest has had to contend in the past is the unsettled state of labour, and the strike of miners in Durham helped in no small way to bring about the quietude which has characterised trade and industry during the greater part of the quarter. But as out of evil comes good, so we may look forward to a better understanding between capital and labour as the result of the conviction that there is nothing to be gained and everything to be lost in a conflict between the two necessary factors of production.

In the face of these great hindrances to trade development it is encouraging to find that there has been no abnormal recession in any branch; in the mining industries, indeed, there has been a distinct advance, brought about entirely by an adjustment of the conditions of supply and demand. The investing public have begun to display more interest in mining enterprise; they are beginning to conceive a more intelligent idea of the characteristics of mining, and instead of allowing themselves to be swayed unduly by the artificial fluctuations of the market they are holding their scrip with the conviction that by showing confidence themselves they are laying the foundation of prosperity to the industry. This feeling has been especially noticeable with respect to home mines. It is quite evident, however, that foreign mining investments are rapidly regaining some of the confidence that they then lost, and the favourable reports of numerous mining companies abroad will do much towards attracting capital. Moreover, it cannot be said that money is scarce except in a limited sense, and however scarce money may be there will always be found sufficient when the possessors of capital are convinced that they may, with fair security, hope to have good returns. Mining is such an essentially British industry that it should be among the first to attract the patronage of capital, and if only an impetus were given, such as that which seemed to be afforded by the rise in tin, the public would be no longer chary of their support to mining enterprises. The natural spirit of mining investment exists as much now as it ever did before, but private capitalists have been deterred from rash speculation by the glimpses which they have caught of the inner workings of some dishonest concerns and they are not likely to place their money with so much freedom as they have done in the past unless they have some sort of guarantee that they are not putting it into the pockets of unscrupulous company promoters.

Now that we are entering on the second half of the year with a more hopeful conviction than was possible in the first, it becomes imperative that we should enquire into the means whereby the favourable elements now discernible can be developed into a trade improvement. This question was fully discussed at the meetings of the Congress of Chambers of Commerce, when the various proposals for bringing about a more perfect form of commercial unity between Great Britain and the colonies were considered. It cannot be said that the Pan-British meeting has advanced us in any appreciable degree

towards the end which everyone interested in the commercial and industrial prosperity of the country would like to see attained. The only possible solution was approved by the meeting, a solution which has been before the country for some years. By adopting a policy of free trade themselves, the colonies would bring about the union which they are trying vainly to effect by inducing the British Government to impose onerous and burdensome duties on its own products. Nevertheless, the meeting gave an official stamp to the proposal which may have the desired effect upon the colonial Governments concerned. At the same time, they discussed various other matters that are of vital moment to the industries of this country as well as to those of the colonies. The proposal to settle all labour disputes by arbitration is one of the first importance. A twelvemonth ago such a proposal was scarcely feasible, as the miners were too much wrapped up in the apparent invincibility of their own organisation to listen to any offer of conciliation. But the solitary lesson that was recently taught to the Durham miners is not likely to be soon forgotten, and they may be prepared now to accept some proposal of arbitration that may in the future prevent any such disastrous conflicts as those that struck a very serious blow at all branches of British industry. If the present encouraging tone in mining is to further develop it is very essential that capitalists should have the perfect co-operation of the miner. Unless this is forthcoming we cannot hope to see any considerable activity in mining enterprise. The labour question has become so important a factor in all cases of industrial development, that it has to be taken into serious account when an undertaking of any magnitude is contemplated. It depends in no small measure upon the miners themselves whether sufficient capital is to be invested to afford them plenty of remunerative work. Any appearance of hostility will infallibly result in the withdrawal of this capital to the permanent detriment of the labouring population. If only the mining industry can be allowed to naturally develop, there is every reason to believe that in the ensuing six months it will experience an activity that is already foreshadowed by an upward movement in some of its chief branches. This is still more likely in view of the many millions of money that are to be spent upon undertakings in London, and of the revival that seems imminent in the trade of the colonies as well as in the finances of South America. All this must have an immediately beneficial effect upon the mining industry. It will open up new sources of consumption, and will render fresh capital available for mining undertakings. The attention that is being paid to the colonies should also result in a further investment of British money, and, unless some unexpected crisis should arise, the mining industry should before long undergo a distinct and encouraging revival.—*Mining Journal*, July 9 h.

NOTES ON PRODUCE AND FINANCE.

TEA AT THE WORLD'S FAIR.—It is quite certain from the letters received in Ceylon from Mr. Griblinton that plenty of energy is being brought to bear upon the work of pushing Ceylon tea at Chicago. A banquet to the officials of the exhibition has been given in honour of Ceylon tea, and the campaign has been opened with strategy and enterprise. Money is, however, the requisite just now. In a letter written from Chicago by Mr. Griblinton to Mr. Mitchell the Ceylon Commissioner says *inter alia*:—"The sum spoken of in the Colony will go nowhere in placing Ceylon where she ought to be at this great Exposition. Our tea industry is everything to the Colony, and unless we are in a position to come out strongly, we shall be nowhere in the race with Japan, which is spending £50,000 or more, with a promise of leaving an important feature in their exhibits to the people of Chicago. My work is now only beginning. I can say nothing as yet as to the future. I can say only hope and try to persuade the directors to grant what I ask." It is evident from this that if Indian planters are to achieve anything like success

in America, an ample supply of funds must be found or the attempt to make a market for India will be useless. As an instance of the *modus operandi* adopted by the Ceylon representatives, we have received a New York paper, the whole of the back page of which is taken up and advertisement of Ceylon tea, with testimonials from leading Americans and their wives who have tried it. Mr. Elwood May is evidently on the war path.

TEA IN GERMANY.—The movement for popularising Indian tea in Germany, which we have referred to from time to time, is gaining strength. Tea is winning favour both in North and South Germany, and there is every prospect that before long Germany will become a large consumer of tea. On the other hand, the official report on the trade of Germany shows that owing to the annually diminishing production of coffee in Ceylon, the business between England and Germany has greatly decreased, and a substitute for such finer descriptions of coffee has had to be sought for elsewhere. The market has discovered this substitute in some kinds of Java coffee, and in some Central American growths—those from Salvador and Guatemala, countries that are greatly improving their crops in point of quality. As regards these last-named descriptions for which London was formerly also the chief market, business has now been transferred elsewhere. Part of the German demand is at present supplied *via* Havre and Hamburg, from which ports exports to Central America have increased considerably, and part is covered by direct purchases in the coffee-producing countries, so that the coffee trade between Germany and England, in comparison to former times, has become reduced to a minimum.

THE CEYLON TEA INDUSTRY.—A correspondent, signing himself "Tropical Rustic," contributes a long letter to the *Financial News*, in continuation of the controversy on the subject of Ceylon tea. He says, in the course of his comments: "Mr. John Ferguson's letter to you of May 19 has put the matter fairly before you; he has grasped the subject with great clearness. I venture now to make a few comments, because there is not a little, but a very great, misconception of the matter of tea growing and its manufacture existing in London, and I, and a good many other planters, have suffered from the position of knowledge wrongly assumed by non-practical men at home, who invariably cry for quality, quality, without in the least knowing how this speciality is attained on the majority of estates. In the first place, it is no doubt, a well-established fact that the Ceylon climate is the best known for the vigorous growth of the tea bush and consequent flushing. Rain falls in every month of the year; the soil never becomes parched, and bushes in many districts are ready for tipping from seven to eight weeks after pruning. Compare this condition with Indian seasons, where they have two months drought, and the plucking is done in about six months of the year. So much for our climate; a few words now about the soil. None of your correspondents appear to have laid stress on the fact that the great majority of estates are not opened out on virgin soil, but on coffee estates from twenty to fifty years of age. This fact must influence the quality according to the circumstances of each estate, its particular district, and the lay of the land and the number of years the land has been exposed to the sun and washed by heavy storms. How often has it been noticed that estates, after getting strength and a little flavour, go off into medium and common teas directly the bushes approach the full-bearing stage! Brokers at once compare the quality with the earlier shipment, and the proprietors and others assume it is the fault of the manager who does not give the close attention with which he was credited at first; the novelty of manufacture has evidently worn off! Then follows trouble, because the brokers and the proprietors have steadily opposed his plea of quantity. Now, suppose a manager has strict orders to produce quality from old coffee land—at, say 3,000 ft. elevation—only the finest plucking can possibly give him the desired result; but the quantity per acre is woefully small and the cost of production so much

increased, that it does not pay. I could name one estate which headed the list of averages, and was the pride and glory of the proprietors at home, and the envy of others not getting half the price for their teas in Mincing Lane. But what happened? This estate, which got an average of 1s. 10d., has had to drop its pride of place, and come down to the hard facts of profit and loss, *i. e.*, quantity versus quality. As a matter of fact, the estate was being strained to compete with those at a high elevation, whose soil was never exhausted by coffee; estates, too, which have all the natural advantages of rich soil and great elevation—a combination only which can produce the class of tea with fine flavour, and for which a high price will always be paid in England. Such also, has been the case with other estates, more or less. It is also found, with more ripened experience, that the yield from estates at a high altitude and in good soil is much greater than was anticipated in the earlier days of tea planting. Finally, to show what, in my opinion, is the common mistake at home—*viz.*, the quality and quantity theory—presuming the desired end is to make an estate yield a good dividend, and that estates favourably situated as regards elevation, and soil only can produce high-class teas to pay, those old (coffee land) estates at lower elevation should not be forced by proprietors to compete for high prices; they should be satisfied with prices even lower than the average for all Ceylon. And rest assured that, with cheap working and high yields per acre, it is the only way to make estates so situated remunerative; the opposite result will inevitably occur if fine plucking is adopted. I do not go into the question of 'the survival of the fittest,'—when the struggle comes we shall naturally know more than we do now; but, so far as Ceylon tea lasting and its stability being in danger I have no fear."

TEA IN MOROCCO.—From statistics prepared by Sir C. Euan Smith, British Minister in Morocco, it appears that tea to the value of £75,000 was sent from Great Britain to Morocco in 1890.

ENGLISH GROWN TEA.—Last Saturday week their Royal Highnesses Prince and Princess Henry of Battenberg and the Princess Victoria of Schleswig-Holstein visited the tea gardens at the International Horticultural Exhibition, and were much interested in seeing the tea plants growing in England, and the manufacture of tea in all its various stages, as shown by Mr. Macgregor. Their Royal Highnesses tasted the tea and pronounced it delicious. Many tea planters from India, Ceylon, &c., have visited the tea gardens, and are agreeably surprised to see their old friend, the tea plant, flourishing in London in the open.

PARAGUAYAN TEA.—In the new number of the Kew Bulletin there are some interesting particulars of this important shrub, which is extensively used by the entire population of South America. Strictly speaking, it is not a tea plant, but a species of the Paraguayan ilex; but the active principle in its leaves is caffeine, identical with that which is found in tea and coffee. Though closely allied with coffee, it is stated to be slower in yielding up its principles to boiling water. In preparing it the leaves are scorched and dried while still attached to the branches brought in by the collectors. They are then beaten, separated, coarsely ground by rude mills, and packed in skins and leather bags. The leaves are infused in small teapots, and the tea is sucked with a bombilla or tube with wire net-work or perforations at the bottom. Specimens of the shrub have long been in cultivation at Kew.—*H. & C. Mail*, July 22.

BANANAS seem to have been imported in great quantities into England this year. Of all the vegetables which furnish food to man this fruit is the most prolific. A single cluster often contains from 160 to 180 pods, and weighs from 60 to 80 lb. Humboldt says that a piece of land of 120 square yards will produce 4,000 lb. weight of fruit, while the same area will rarely produce more than 30 lb. weight of wheat or 80 lb. of potatoes.—*Sugar Journal and Tropical Cultivator*, June 15.

GENERAL NOTES.

PARAGUAY TEA.—Some attention is devoted to Paraguay tea in the *Kew Bulletin*, but it is hardly likely that this wonderful beverage will become popular in Europe. The virtues of *yerba de mate* are undoubted, however, but it is a curious-looking mixture when put in drinking form, and the flavour also is somewhat against it. Besides, now that the Assam and Ceylon products have come upon the market, tea-drinkers have discovered a fresh charm about the old beverage and they are not likely to be converted to an entirely new taste just at present. The consumption of *mate* in South America, however, would seem to be greatly on the increase.—*Colonies and India*.

TEA IN KOBE.—Since the commencement of the tea season until the beginning of June, says the *Choya Shimbun*, the inferior grades of tea sent from Shikoku and Kiushiu to Kobe found no purchasers, and even the best kind fell to the low figure of 9 *yen* per picul. But from the middle of June a gradual rise of price took place. Tea for which only *yen* could be obtained at the end of May, fetched over 12 *yen* in June, and the best grades of Yamato and Yamashiro which were quoted last year at about 17 *yen*, now sell for 23 *yen* per picul. Again Chikugo leaf which, at the end of May could be had for 11.50 to 12 *yen* per picul has risen to 14 or 14.50 *yen*. In fact the state of the tea market this year is contrary to all expectation. Such prices have not been seen for 13 years. Moreover a report dated the 1st instant says that the supply at Kobe does not exceed 4,000 cattiees, and that in view of this small quantity, there is no reason to expect a fall in price.—*Japan Weekly Mail*, July 16.

JAPANESE AGRICULTURE.—A recent report of the United States Department of Agriculture contains much interesting information in regard to Japanese agriculture. The farm implements in use were, until recent years, very primitive. The plough is very small, with only one handle, and a threshing machine was not known; the heads of grain were separated from the stalks by pulling the latter through a row of long iron teeth projecting from a small log of timber, while the winnowing fans were worked at the same time. The spade and hoe did the larger share of tilling, and sickles are merely straight iron blades, some four inches in length, pointed and sharpened on one side, and set at right angles in a wooden handle about 15 in. long. The greater part of the cultivated land consists of rice fields divided into lots of various shapes and sizes by small ridges about a foot wide, and varying in height from a few inches up to 2ft. or 3ft. The soil is worked to a sufficient depth, and small rivulets are run through ditches which are cut for the purpose of irrigation. Soon after the plants are transferred from the beds these fields are generally covered with water to a depth of a few inches until harvest. The higher lands are also carefully tilled, producing wheat, rye, barley, millet, Indian corn, potatoes, and edible roots of all kinds. The finest rice is produced in the fertile plains watered by the *Tongawa*, which enters the sea at *Tokio*, and in the province of *Shimosa*, on the eastern side of *Yedo Bay*, where the paddy fields occupy from 20 to 25 per cent. of the total area, while in *Owari* and *Kawachi*, on the east coast of the main island, they occupy more than 25 per cent. The amount of rice produced in the whole Empire is surprising. According to a recent return of the foreign trade the total surplus of rice exported to various countries was 685,657,326 pounds, without counting the still

greater quantity consumed yearly in making *saké* (rice beer). Besides, the natives use rice flour in making all kinds of confectionery. Next in value to rice production is that of wheat and barley; the flour of these grains is used in making varieties of *vermicelli*, and it furnishes more than half the food for the lower classes of people throughout the Empire. Great attention is also paid to the cultivation of rye and oats, and corn is raised to a small extent. All kinds of leguminous plants are raised in abundance in almost every part of the Empire, beans being largely used in the manufacture of soy, a kind of sauce. It is made up almost entirely of beans and salt water with a small quantity of wheat, and is used in preparing almost every kind of food in addition to its table use. The annual yield of beans is about 16,000,000 Winchester bushels. The chief vegetables are turnips and radishes, while the cultivation of sweet potatoes occupies nearly 600,000 acres of land every year. Live stock were reared solely for the purpose of transport and tilling the soil, beef being considered objectionable as food among the Japanese until the advent of Europeans. But recently great care has been taken to improve the breed of farm animals. During recent years common agricultural implements and labour-saving machinery, as well as the chemical fertilizers, have been successfully introduced, and careful experiments at the Imperial College of Agriculture in *Tokio* have been carried out for the purpose of testing the usefulness of different fertilizing elements in Japanese agriculture.—*London Times*, July 9.

BLANDYTE.—Under this name a new industrial product is being introduced which promises largely to supersede indiarubber in its various manufactured forms, and, to some extent, leather also. The basis of the new material is what is known as waste-crumb vulcanite, which is, in fact, old rubber goods which have more or less perished either in use or from exposure. This waste material—which we understand several have tried to utilize, but without success—is incorporated with certain hydro-carbons and oxides and with *Trinidad asphalt* in certain proportions. After the asphalt and waste have undergone chemical treatment for the purpose of eliminating all the water contained in them, certain vegetable oils are added, the water being replaced by sulphur. The compound is then subjected to heat, and upon the proportions of the ingredients and the temperature to which the compound is submitted depends the ultimate success of the manufacture. Blandyte can be produced in the hardest and densest form, or in a very soft and elastic condition, with any intermediate grade of hardness. It is also applicable for waterproofing, and, in fact, for use for the many purposes to which indiarubber and vulcanite are applied. It can also be used, either wholly or partially, in the manufacture of boots and shoes, for which purpose it lends itself very conveniently. It is suitable for tubing and for engine packing, in which latter capacity it has been in use for some time by a large engineering firm near *London*, who write that they find it superior to other steam packing tried by them. Blandyte is now being manufactured commercially, and we recently inspected a variety of products of the nature indicated, which were of a very satisfactory character. An important feature in these productions is their cheapness as compared with either rubber, vulcanite, or leather goods. This cheapness is due to the fact that the bulk of the material consists of a waste product. The manufacture is being carried on by the *Blandy's Patents Syndicate*, of 78, *Gracechurch-street London*.—*London Times*, July 9th.

A SUBSTITUTE FOR CATTLE MANURE (?)
COCONUT DUST, LEGUMINOUS PLANTS AND
MOSSES.

The number of the *Magazine of the School of Agriculture* for August has a letter from a coconut planter on a proposed substitute for cattle manure, which is worthy of attention from tea planters. We should like to have the opinions of experienced planters on the proposed compost. At present the favourite mode of manuring on tea plantations is to apply bones and white castor poonac, just as was done when coffee, a fruit-yielding plant, was cultivated. Potash is sometimes added; but as the object is specially to promote the growth of leaf, we should think that an article so rich in nitrogen as dissolved Peruvian guano could be used with advantage. In any case, whatever, salts may be applied, the introduction of some bulky material into the manure holes seems advisable. Tea prunings at least ought always, if possible, to be thus used. The amount of humus arising from their decay may not be very great, and their own manurial properties may be but slight, but while undergoing the process of decay they keep the soil open so that it gets aerated and comminuted. Whether it would pay to carry compressed coconut dust up to hill estates, and use it as suggested, might be at least worthy of experiment. Estates at a distance from highways and with but little grass and few cattle are at a disadvantage, compared with others more favourably situated; but in many cases mana grass could be grown and utilized as a humus-yielding material. Ashes from tea furnaces are, of course, valuable additions to the manure heap and should be carefully conserved for this purpose.—Some time ago we published a letter from a planter who traced deterioration in the quality of tea to the application to the bushes of artificial manure. The case must have been very exceptional, and in weighing its lessons we should like to know the substances applied and the quantities per bush or per acre. It is scarcely conceivable that manure which benefits all other cultivated products should be in any way injurious and not entirely beneficial to tea. The questions now are:—What artificial manures are the best to use (there being no question as to the value of cattle manure), and how can the benefits of bulk be best and most cheaply secured? As it seems now beyond all question that leguminous plants (especially peas), and also the mosses occasionally found so troublesome on estates, do really derive appreciable nitrogen from the atmosphere, it seems clear that some species of lupins or peas should be cultivated on tea estates and that the resulting crops and all mosses growing on the soil or on tea bushes should be buried between the rows of tea plants.

FROM THE METROPOLIS.

July 22nd, 1892.

CEYLON PRODUCTS AND THE LONDON CHAMBER OF
COMMERCE.

A few days ago I was suddenly asked by the Secretary, Kenric Murray whether Monday, the 25th would be suitable for the paper about Ceylon staple products which I had promised to give before the London Chamber of Commerce. I had just previously heard that the meeting for Mr. Grinlinton to give a report on Chicago was fixed for that afternoon; but on this being mentioned, Messrs. Murray and Leake kindly arranged that the one gathering should follow the other; that in the Chamber of Commerce at Botolph House, Eastcheap,

coming off at 2 p.m., when Sir Arthur Birch has promised to take the chair; while the gathering to hear the Exhibition Commissioner will take place in the Ceylon Association Room at 3-30. This arrangement makes me very busy putting together the information for the required paper and must be the apology for only a short letter by this mail. One practical object I have in view is to indicate what products can be produced in such abundance in Ceylon and adjacent countries as to make it unwise to encourage pioneering and planting experiments in new lands! The risk of "over-production" and unremunerative prices which has overtaken the cinchona bark trade, may well be considered in view of what Ceylon, India and Java can do in respect of tea, and cardamoms, and the products of the coconut palm, as well as cinnamon. Surely, it will be wise in respect of the planting of such products in new lands—except in so far as local consumption and not the European market is to be served—to tender the famous negative advice of Mr. Punch in another department, and say "Don't." The case is rather different in respect of coffee, and perhaps cacao—certainly in respect of rubber and perhaps pepper. We may possibly have an interesting discussion in which my opinions may be contradicted; but all who can get away are moving for the holidays now: Mr. Rutherford is always in Scotland, Mr. T. N. Christie has gone North, and many more are preparing to follow.

A NEW PATENT "TEA-MAKER."

In connection with our staple, it is of interest to mention that Mr. J. H. Barber has just added to his list of inventions a patent "Tea-maker"—very simple in construction, but well calculated to make it impossible for the English housewife to turn out infusions of tea of the black, poisonous colour and consistency condemned by Sir Andrew Clark. The arrangement is in fact self-working,—automatic; the tea is placed in a receptacle, boiling water poured over it and in due time (4 minutes) the infusion passes through filters into the pot, and is ready to be poured out and drunk. The invention has been taken in hand by a well-known City firm who report that all the tea experts who have so far seen it, give it unqualified approval. Mr. Barber brought me one this forenoon, and our trial of the little invention was certainly very satisfactory. Now comes a further benefit which Mr. Barber may be able to confer on his brother tea-planters. I see a contemporary's London correspondent referring to my second letter to the *Financial News* criticising Sir Andrew Clark, considers it was equivalent to "whipping a dead horse." It would be a good thing if such were the case; but his remarks still meet you very often in prominent places as an argument for using China rather than Ceylon or Indian tea. Well, Mr. Barber intends if possible to interview Sir Andrew with his new "Tea-infuser," the invention of which he will frankly confess was due to his (Sir Andrew's) complaint about tea standing too long and so containing a large and dangerous proportion of tannin. It will be easy for Mr. Barber to give the veteran physician a cup of superior Ceylon tea and to get his approval perhaps patronage, for an "Infuser" which has been received with favour by tea experts in the City. I have indeed suggested to the inventor that he should ask permission to call his patent "The Sir Andrew Clark Patent Tea Infuser" for Ceylon and Indian teas—a title which ought effectually to neutralise the influence of the address of October last!

Messrs. Gow, Wilson & Stanton report a splendid increase in the quantity of

CEYLON TEA EXPORTED FROM LONDON

during the six months ending 30th June last, as compared with the same period of 1891—no less than 105 per cent.

The letter of "Tropical Rustic," which I duly forwarded to the *Financial News*, appeared in the issue of the 18th inst. and is very much approved of in "the Lane"—one Ceylon proprietor calls it "most interesting."

The Edinburgh *Scotsman* has had a long article on

"ASSAM AND ITS TEA PLANTERS"

(which I send you) and among other things urges the Indian authorities to hurry on improvements (by railway connection and extension) so as to place the Assam tea producers in a better position to compete with Ceylon planters whose produce is cheaply shot down from Nuwara Eliya "in the Kandy hills, by railway into the ship at Colombo; while that of Assam struggles to Calcutta after a costly fashion by boat through a roadless land at a cost of 3d. per lb. equal to the English duty." You will no doubt republish the whole article, if you have not indeed already done so.

The hope is expressed that Ceylon tea may now—that the elections are over and that the China tea is proving a disappointment—materially improve in price: one proprietor thinks that the failure of your monsoon should still further reduce imports for a time.

A NEW PRODUCT FOR WYNAAD.

We have frequently pointed out in these columns (*Madras Times* of 14th July) how necessary it is for the well-being of the planting industry that attention should be paid to the cultivation of products other than those already flourishing in the different districts of Southern India. The whole history of the planting enterprise in every tropical or sub-tropical country shows that an epidemic is liable at any time to break out, which all the skill and care of the cultivator is unable to stay, and the only means of stemming the tide of ill fortune and preventing it from overwhelming with widespread ruin the districts, so lately prosperous, is to have some reserve in the shape of an entirely different cultivation to fall back on. We have on numerous occasions shown how particularly suitable, both in climate and soil, Wynaad is for the cultivation of tea and we have learnt with pleasure that extensive clearings have already been made this monsoon, and that arrangements are in hand for even larger clearings next year. In some districts coffee still gives a good return in spite of the thousand ills that it is heir to, and certain varieties of cinchona are still worthy of the attention of planters even though the unit hovers only just above the penalty. Pepper as a by-product is found on many estates, and now we are glad to say that a new plant is engaging the notice of growers in this district. This time it is the *fourcroya gigantea*, an aloe indigenous to South America, which yields an excellent fibre of great strength, which is used largely at home for the manufacture of ship's ropes. Some half a dozen planters are opening out land this year with this aloe, and several hundreds of thousands of plants will be put down. This is no rash experiment, but the result of a trial shipment of this fibre which gave the most satisfactory return, and there is every reason to believe that in a very few seasons the fibre of the *fourcroya gigantea* will form a valuable adjunct to the exports from this district. A certain amount of attention has already been paid to the different fibrous plants which either grow wild or flourish in a semi-wild state in Wynaad, but with the exception of *rhea*, this has been of a very desultory character.

Rhea was systematically cultivated on a large scale for some years in South-East Wynaad, and the fibre was extracted satisfactorily, but it was found that the machinery employed at home for work-

ing up fibres was unsuited for it, and manufacturers declined to go to the expense of setting up entirely new and expensive plant, unless a certain number of tons was guaranteed by the growers every year, which was practically impossible. Hence the failure of *rhea* cultivation. But with *fourcroya* this is different. It already forms one of the chief exports of that hurricane-swept island, Mauritius, and the demand for it among rope manufacturers at home is large, for after Manila, it enjoys the greatest popularity. That it will of only grow but flourish exceedingly, in Wynaad, is evidenced by the gigantic hedges which are frequently met with in that district. Here after the plants were once put in, little or no care was bestowed upon them beyond keeping down the weeds and secondary jungle growth during the first year. The land which appears to suit best is of poor stony soil, for if the soil is too rich the leaves put on too much fleshy substance and fibre suffers. The chief difficulty in the profitable cultivation of all fibrous plants is the heavy cost of transport of the leaves from the field to the mill, for it must be remembered that, to instance the *fourcroya*, only $\frac{1}{3}$ to 1 per cent of the weight of the leaf when cut is of value, the other 99 per cent consisting chiefly of water; and, further the fibre, to obtain a profitable price, must be extracted as scum as cut. Many a planter has turned longing eyes on the groves of wild plaitain that abound on the hill sides and in the sholas of Wynaad, but he has hitherto always been met by that insuperable difficulty, the cost of carrying the stems to a central mill. As regards the *fourcroya*, we understand that this difficulty has been overcome, and a machine of the most simple nature has been invented, which will enable the bulk of the water to be pressed from the leaf in the field, before it is taken to the mill for final treatment. As regards the different qualities of the fibre itself, experiments already made point to this difference being dependent chiefly on the age and size of the leaf, and so it is thought that it will be possible to sort these qualities sufficiently for all practicable purposes in the field, and thus no further expense need be incurred after the leaf has finally passed through the mill, beyond baling and marking for shipment.

As we have already remarked poor, stony soil is best suited for the cultivation of the *fourcroya*, and the distance at which it is planted varies from three to four feet. Cutting can be commenced in the third year, and an estate once established, never requires replanting or any cultivation worth mentioning. The manner in which this aloe is propagated, is by the parent plant throwing up a stalk in resemblance like a huge asparagus, on which, after flowering the young bulbous plants may be found growing. The wind blows down these tiny bulbs, with roots already formed, which spring up with marvellous rapidity. After seeding the parent plant dies, but as one stalk often yields from two thousand to three thousand seedling bulbs, there is little chance of the *fourcroya gigantea* ever becoming an extinct species. These bulbs are collected as they drop, if required for planting out, for in the same manner as hyacinths, tulips and other bulbs, they may be stored for months at a time without injury. We understand that the present price asked for seedlings is five rupees per thousand and that these are of a size large enough to put out at once in the fields. Considering the large amount of poor, stony soil which exists in Wynaad, we cannot but regard this new product as likely to become a valuable source of profit to planters in the near future. In Mauritius, the machinery employed for the extraction of the fibre is of the most rudimentary nature, and worked entirely by hand,* whereas in Wynaad, water-power will be utilised for this purpose. The expenses connected with the cultivation of this aloe will be trivial, as, beyond planting, weeding the first year, and harvesting, they will be nil. So far as is known up to now, this aloe suffers from no pest nor enemy, and wherever it has been planted in Wynaad, it has grown like a weed. We have always held that the superiority of Wynaad over other districts lies in the fact that it is

* The accounts we have read are very different.—*Ed. T.A.*

equally well-suited for the cultivation of half a dozen different plants, and we believe that experience will prove that the cultivation of *fourcroya gigantea*, its latest new product, will be found not the least profitable of its many agricultural enterprises.—*Indian Planters' Gazette*, July 23.

[If they have machinery in the Wynaad which will profitably prepare the fibre of the green alce, they have succeeded where Ceylon planters have failed.—Ed. T.A.]

WATERPROOFING WALLS.—In order to prevent water and rain permeating walls and masonry, a foreign contemporary recommends the following:—The interior surface of the wall is covered with a solution of soap; after leaving twenty-four hours coat of alum solution is applied and the process repeated.—*Chemical Trade Journal*.

IS COFFEE A DISINFECTANT?—At the ordinary meeting of the St. George the Martyr Vestry, held at the Vestry Hall, Borough Road, some discussion took place in reference to the disinfecting of the parish. Dr. Waldo, the medical officer, stated that for some years past the chemicals used by the Vestry for disinfecting purposes had cost about £80 a year and he was of opinion that the money was well spent, and that the present system should be continued. Mr. Hennesy asked the doctor whether he had ever heard of, or tried, the plan of disinfecting by means of coffee. The system was very popular in Asiatic countries, and was considered to be very effectual as a disinfectant. Dr. Waldo said he had travelled very considerably in Oriental countries and had heard of the process, but had never seen it in operation. He was of opinion that it might act as a deodorant but he certainly did not think it could in any degree be regarded as a disinfectant, and therefore he could not advocate its use as such.—*Chemist and druggist*, July 16th.

THE ORIENTAL BANK ESTATES Co., LD.—The Chairman's speech at the annual general meeting of this company, held on 27th July, is given on our last page, and will be read with interest in Ceylon. It will be seen that Mr. Crichton denounced as utterly baseless the oft repeated statement that Ceylon profits paid for losses in Mauritius; nor, on the other hand, did he believe that the management of Ceylon tea estates was more expensive than that of other estates. The suggestion to appoint a practical Ceylon man to the board of management was, it will be noticed, negatived. The *Financial News* of 28th July has the following remarks on the meeting:—

After all the misfortunes which have lately befallen the colony of Mauritius, in the shape of smallpox, a hurricane of unexampled severity, the failure of the New Oriental Bank (whose troubles, by the way, did not originate there), and the general jeremiad raised by the holders of securities of all classes in the island, it is refreshing to find that at least one important concern, having very large interests at stake, is able to take a cheerful view of the position. The Oriental Bank Estates Company, Limited—a report of whose annual meeting will be found in another column—possesses large estates in Ceylon, as well as in Mauritius; and the directors, while prudently declining to pay a dividend out of profits, in face of the damage caused to their property in the latter island by the cyclone, were able to assure their shareholders that, so far from their sugar business being carried on at the expense of the Ceylon tea branch, as was suggested, the net profit made in Mauritius during the past year was over R3,00,000, and the yield of all the estates was improving. We trust that other Mauritius land and produce companies will be able to show as good a record.

THE OIL SEED CROPS OF INDIA

are only second in importance to grain, and their contribution to the commerce of the country is very great. They are the subject of a memorandum which we have received from the Revenue and Agricultural Department of the Government of India, in which the effects of the weather and the prospects of the season are dealt with. It is stated that "the present memorandum deals with linseed, rapeseed and mustard, the principal oilseeds harvested at the same time as wheat. For the reasons stated in the memorandum of last year rapeseed and mustard are shown together." It is added in a note:—"For Bengal, the statistics given are for all the oilseeds grown in the Province, as it has not been found possible to separate the figures of linseed, rapeseed, and mustard, which are the principal oilseeds, from those of castor, sesamum, and a few others of less importance which, however, cover but a comparatively small area."

Area and Outturn.—Excluding Bengal, the figures for which are given separately, the totals of area and outturn are shown below:—

	1891-92.	1890-91.	Average of last five years.
Area (acres) ...	16,936,400	17,169,200	16,895,600
Outturn (tons)..	976,400	892,200	953,700

The area is thus slightly below last year's, but a little above the normal, while the outturn shows a large increase as compared with both the normal and last year's. This is due to the superiority of the "mixed" crops in the North-Western Provinces and Oudh and satisfactory yields in the Central Provinces and Berar. The Punjab, Sind and the "pure" crop in the North-Western Provinces show diminished outturns.

Export Trade.—The export trade in oil seeds, though fluctuating, has been of considerable importance for several years, as may be gathered from the fact that the exports of oilseeds of all kinds as compared with wheat are valued at 1,001.50 and 732.45 lakhs of rupees respectively. These figures represent the average of the ten years ending 1890-91. The value of the total exports of grain and pulse for the same period was 2,104.45 lakhs of rupees.

The greater part of the oilseeds exported comprise linseed and rapeseed. Taking the figures for the past five years, the percentages which linseed and rape including mustard exported bear to the total seeds exports are:—

Linseed ...	52.17
Rape and mustard ...	17.02

As remarked last year, broadly speaking, the linseed trade belongs to Calcutta, while rape and mustard are exported chiefly from Bombay. The consignments go in the largest quantities to the United Kingdom, France, Belgium and the United States. In 1891-92 Germany received a large share of rape. The period of active trade is from March to July inclusive.

There is also a considerable Inter-Provincial Trade. It is added that

As is well known from the reports on external trade, the despatches of vegetable oils as compared with the foreign exports of seed, are insignificant. The oil chiefly exported is castor, which goes principally from Calcutta for lubrication of machinery. Small quantities of oil expressed from coconuts, groundnuts and "other" oilseeds are also exported, but most commonly the oil locally expressed is used for culinary or illuminating purposes, the remaining seed or 'cake' being used for feeding cattle, and occasionally for manurial purposes.

The inter-provincial trade in vegetable oils is not extensive, and presents anomalies difficult to explain. Thus, as pointed out many years ago in the external trade reviews, castor seed is exported from Madras to Calcutta to be made into oil in the latter place. The inland trade returns also seem to show that mustard seed sent to Calcutta from Assam is returned to that province as oil.

Correspondence.

To the Editor.

COMPARATIVE PRICES AND QUALITIES OF CHINA AND CEYLON TEA.

13, Rood Lane, London, E. C., 8th July.

DEAR SIR,—We are sending by this mail a sample of the New China teas 1892-3 crop which have just arrived per s s. "Moyune" and we also send a sample of fair ordinary Ceylon tea now selling on the market.

As many persons interested in the tea trade had for some time been hoping for a revival in the China department owing to an anticipated improvement in the manufacture, and as such a revival would doubtless have done harm to the Ceylon Tea Trade, we think you will be interested in comparing these two growths of tea.

When you notice that the China tea was actually sold in London at 11½d per lb. and the Ceylon is a tea on the market at about 8 per lb. you will at once observe how much cheaper and more serviceable the Ceylon tea is of the two. This must sooner or later be also observed by the country at large, and we hope foreign markets.—We are, dear sir, yours faithfully, GOW, WILSON & STANTON.

[Messrs. Somerville & Co., to whom we submitted the samples, report as follows:—"China tea.—London value 11½d. Greyish rather small well made Moning. *Liquor*.—Good flavour and quality. Infused leaf bright. Ceylon tea.—London value 8d. Greyish rather small well made pekoe leaf. *Liquor*.—Fair strength good flavour and quality. Infused leaf bright. We make the Ceylon better value compared with the China tea."—Ed. T.A.]

TEA CULTIVATION AND SCIENCE.

Upcountry, July 18th.

DEAR SIR,—A week ago "Another Proprietor" asked your correspondent "An Old Coffee Stump" to elucidate his statement continued in his letter to you of the 28th June last, viz.—"Ceylon is drawing too much from the soil, where the supply is limited, instead of drawing more from the atmosphere, where the supply is unlimited."

I have been anxiously looking for the solution of this bit of scientific theory, and I trust "Old Coffee Stump" will tell me in plain and humble language how I am to set about "drawing more from the atmosphere," because I have drawn about the last bit of nutriment from the soil, and the proprietor of this estate who reads the *Observer* at home will, after reading "Old Coffee Stump"'s letter, be instructing me to now "draw more from the atmosphere." ENQUIRER.

[*En route* from the hills we noticed several tea estates on which the tea bushes were pruned so close to the ground that at some distance it was difficult to realize that the surface was not bare. This sight suggested the query whether "Old Coffee Stump" had such cultivation in view in his enigmatical utterances.—Ed. T.A.]

CINCHONA BARK PROSPECTS.

July 18th.

SIR,—A friend at home, who is the owner of a cinchona estate in Southern India, has asked my opinion as to the quantity of bark I would estimate there is still left in Ceylon, supposing all the trees were uprooted. Can you or any of your subscribers assist me to form an estimate?

From inquiries made in Colombo I learn that the amount of bark sold locally is larger than usual, and that, up to the end of June, the total shipped is 565,000 lb. in excess at the same date last year. A large portion of this, I understand, came from the Badulla district, and is probably bark containing over 3 per cent of sulphate of quinine. It does not pay to ship the common red bark at the present rate per unit.

My friend has sent me his "Review of the Bark Situation"; and, although it may not interest many planters at this period perhaps you may find room for it.—I am, &c.,

EDWARD HAMLIN.

REVIEW OF THE BARK SITUATION.

The present ramous state of the bark market is caused by overproduction. Not only is the market overloaded with stocks, but the present rate of production exceeds what is required for consumption.

Producers have, however, the remedy in their own hands, were they to destroy all bark yielding under 3 per cent of quinine, or more than 3 per cent. of the total production, what would be the probable effect on prices?

Shipments from	English lb.	Under 3 per cent.	Percent- age.	Leaving for ship't.
Java for 1891	9,000,000	2,520,000	28	6,450,000
Ceylon "	6,000,000	4,000,000	67	2,000,000
India "	4,500,000	2,025,000	45	2,475,000
	19,500,000	8,545,000		10,925,000

If large quantities are thrown on the market they are bought up by speculative manufacturers or speculators and stored for use, or to be resold. The effect of this is not only to depress prices at the time but for years to come.

Most of the producers have bark of different kinds, and if they, alone, were to destroy instead of shipping those barks yielding under 3 per cent, the supplies would be reduced by nearly one-third. What then would be the effect on prices?

2 crops of 10 tons each—results compared:—

	£	Profits.
3 tons 2 per cent. at 1d per unit ...	56	
Less expenses of harvesting, shipping, and selling at £20 ...	60	
2 tons 2½ per cent. at 1½d per unit	58	
Less expenses as above ...	40	18
5 tons 5 per cent at 1½d	291	
10	100	191

5 tons destroyed (under 3 per cent.)

5 tons 5 per cent. (average of good ledger)

at 2d per unit ...	466	
Less expenses as above ...	100	366

In the latter case, the value of the unit has only been raised to 2½ per unit, but would it stop here?

If the value of the unit is 1d to 1½d, bark under 2 per cent. would be worth 1d, under 3 per cent about 1½d per unit, over 3 per cent about 1½d per unit.

Agreement as to some plan.—This is a point which producers should consider reasonably. It is unreasonable for all growers to expect to be equally benefited by any plan. It would be cruel to expect a really hard up planter to sacrifice what may perhaps be his remaining all. It will be useful as to hope for combination of the part of South America.

Ceylon contains most of the bad kinds* of cinchona, but planters there are doing well with tea, they would therefore be the better able to sacrifice their bad bark

* He means red bark as compared to ledger and officinalis, which are the only types now cultivated in South India.—E. H.

MESSRS. BERRY WHITE AND THOMAS
CARITT AT THE JOKAI TEA COMPANY'S
MEETING.

24th July.

DEAR SIR,—There can be no doubt but that the growth and expansion of the Ceylon Tea Enterprise is creating a deal of uneasiness at home amongst Indian Tea Co. shareholders, and the more so as one cannot walk many yards in a street at home without coming to some advertisements of Ceylon's fragrant article. These in themselves would create a sufficiency of alarm in the mind of the ordinary shareholder of the pick-nothing-but-the-broken-pekoe type. Hence no doubt the question asked. You will observe that the replies are in answer to a Mr. Rostron. The "rough edge" must be toned down, and indeed if shareholders are satisfied by the statement that Ceylons will always want a certain proportion of Indian tea to give them strength and backbone well and good. It is a statement that would sound well at a public meeting such as the above; otherwise I think we may dismiss it as if little value to those in the "know."

Mr. Thos. Carruthers' remarks were well calculated, no doubt, to give an extra fillip to the proceedings, but why at the expense of Ceylon? He says "as far as he could see, the quality of Ceylons was falling off every year."

The following questions then present themselves to us:—1stly, Can he see?—and 2ndly, if so, how far?—Yours faithfully,

R. J. B.

MR. F. SUTTON HAWES AND MESSRS.
W. J. & H. THOMPSON & CO.

DEAR SIR,—Kindly oblige me by inserting the following in your next issue:—

I have only just returned from the country, and have been shown your issue of June 2nd in which, with surprise, I see a letter written in a highly autocratic tone from Messrs. W. J. & H. Thompson in which my name appears, *re* the subject of the "Stability of the Ceylon Tea Industry." I think as this article and the correspondence alluded to was commenced by Messrs. Thompson in a London commercial paper, it would have been more gentlemanly and businesslike, if they had continued their remarks in the same journal as they have since alluded personally to me—and the subject under discussion could have been fairly judged by those interested.

Messrs. Thompson send you the article and their letter relating to it, but omit my letter with their criticism on the latter, as "In their opinion it needs no reply!" They did not write to this effect to the *Financial News* here. Fortunately you have received and republished my letter, so their intended slight has been defeated. Messrs. Thompson may be an older established firm than my own, but as regards practical knowledge and dealings in Ceylon tea on this market, I think as for the last 8 years I have given my sole attention to Ceylon teas and tasted as far as possible every sample that has been offered at auction, I may claim to have had as much experience, if not more, than Messrs. Thompson; and the opinions I have expressed may perhaps be of a little more value than Messrs. Thompson choose to place on them.—I am, dear sir, yours faithfully,

F. SUTTON HAWES.

THE O.B. ESTATES COMPANY, LTD.

Kandy, 5th Aug. 1892.

SIR,—Report and balance sheet to 31st March 189 of the Oriental Bank Estates Company, Ltd., as usual does not give much information to its

shareholders, especially to those interested in Ceylon.

ASSETS.—The item of cost of estates, buildings, &c., is put down at £451,354, 18s 0d. Seeing that no dividend for the last half-year is to be paid, owing to the hurricane in Mauritius (so we are told!), shareholders would have been better able to follow the balance sheet if the cost of the *Mauritius estates, buildings, &c.*, had been entered as one item, and that of *Ceylon* as another—the produce from each place should also be shown separately, and shareholders have a right to expect this, in the only report they receive.

The items of share in Companies.. £55,556 10s 0d
Advanced on mortgages.. ..£73,831 11s 5d
are large items, and have come into existence since the £150,000 4½-per-cent mortgage debenture stock was created!

What interest is received for this the accounts do not show, nor it is mentioned where and in what this money is invested.

LIABILITIES.—Accounts payable is a very heavy liability, viz.: £106,207 8s 0d. In last year's accounts it was only £40,978 6s 1d.

In the report for 1889 the Directors referring to having raised the mortgage debenture stock of £150,000 say:—"A saving in the working expenses of the Company will be effected by this additional capitals." I cannot see that any gain has accrued to shareholders or to the Company; we certainly have not received any increase in the dividend, and our liabilities are increasing by leaps and bounds:—

The total liabilities in 1890 were £628,385 5s 5d
" " " 1891 were £647,598 13s 6d
" " " 1892 are £725,877 7s 8d

The £150,000 Debenture stock is included in all the above totals.

Why cannot the Directors of this Company publish with their report, as many companies do, the particulars of acreage, &c.? If they consider it detrimental to the interest of the Company to give particulars of each estate, at least we might be told the total acreage under each product, and whether in full bearing or not.

In the report we are informed that the *profits* from sugar showed a *good increase*, and in "Ceylon" the *progressive* increase in the output of tea, and the *profit* therefrom has been maintained &c." After all this I find, comparing last year's report with this, that the increased profit is only £3,49 12s 3d!! or under 1% on the paid up capital! Comparing this Company's dividend with others, I fail to see where the *good increase* and *progressive increase* in profits are shown.

It is surprising to me that no mention is made of the failure of the New O.B.C., seeing that the Company banked with it up to the very last, I believe. If, as I surmise, the balance of £18,271 13s 8d available for dividend is all or partly locked up in the New O.B.C., this is the *correct* reason why we receive no dividend and *not* solely on account of Mauritius—if this is so, what were our Managing Directors doing not to have protected our interests better?

How can it be explained that the prof. shares are at a discount, and ordinary shares at nearly 50 per cent and very difficult to sell? when the profits, as shown by balance sheet, have gone up from £25,841 0s 8d in 1889 to £30,101 14s 10d in 1892?

Can it be that there is a want of confidence in the management of the Company?

In 1889 report the following appears:—"In view of the falling market, they (the Directors) consider that the interests of the Company lie rather in the direction of increasing the yield per acre, and improving the manufacture by judicious

outlay and careful attention, rather than in extending the cultivated area."

In 1890 report it is remarked:—"During the past season it has not been deemed advisable to extend the area of land planted with tea." When recently passing through some of the estates belonging to this Company, I noticed very considerable preparations for planting both forest and other land, when the price of tea is fully 3d to 4d per lb. lower now than in 1889 and 1890!

Have the Directors' private and confidential information that a boom in prices is to be looked for later on? If not, how do they explain this change in their views?

A lot of the land that is now being opened, I am sure, would have been planted long ago, had it been left to the visiting agent and managers of the estates, and had there been a practical Ceylon man on the Board he would have insisted on having it done.

Large shareholders should join together and insist on having a Managing Director who has practical knowledge of the cultivation of Ceylon estates, or I fear shares will become unsalable.

After comparing this balance sheet with those of other companies, in which I am interested, I can only sign myself

A DISGUSTED SHAREHOLDER.

WANTING TO KNOW RESULTS OF
EXPERIENCE IN CEYLON, IF ANY, WITH
"TEA PLUCKER."

Kotagala, Aug. 16th.

DEAR SIR.—Some time ago, a circular was issued by Mr. E. B. Creasy along with the *Observer* advertising a "Tea Plucker" or leaf cutting shears for tea, claiming amongst other advantages that 20 coolies with these pluckers could do as much as 100 by hand that the bushes were greatly improved etc.

Will any of your readers who have used these shears kindly give their experience?

Heavy rains here at present.—Yours faithfully,
M.

[We hope some planter will be able to answer.
—ED. T.A.]

LOWERED ESTIMATES OF TEA PRODUCTION.

SIR—I feel sure the news you publish as to probable reduction in output of tea from Ceylon for the current year will be hailed with satisfaction by all interested in its production.

The contingency that Ceylon is likely to run "thirteen million" lb. short of your estimate should help to strengthen the tone of the London tea market. This information should be circulated and sent all over the world, as soon as possible, and I feel sure it will help prices up a bit.

From the higher elevations we hear of cold winds obchecking "flush."

We also hear of "finer plucking," which means reduced yield per acre.

Summarizing these statements with the figures you have given of quantity already harvested, I would go lower than your latest record and place the total yield for the year from Ceylon at

SEVENTY MILLION LB.

[The more generally accepted estimate was 80 millions, and London brokers in their circulars now mention 70 as the revised estimate.—ED. T.A.]

TEA IN KASHMIR.

(From a Vocabulary of the Kashmir Language, by W. J. Elmstie.)

CHAI. Tea.—Two kinds of tea find their way into the market of Kashmir. These are called Surati and Sabz. The Surati tea is like English tea. The Sabz tea, on the other hand, is the famous brick tea which reaches Kashmir by way of Ladak. The Surati tea reaches Kashmir from Ladak and Panjab.

There are two ways of preparing tea in Kashmir. The first is called Mogul Chai. For every tola of tea five cups of water are poured upon it in the Bhogun or teapot. It is then boiled for half an hour, when more cold water is added, along with condiments and sugar, after which it is hoiled for half an hour more. Milk is then added. It is now ready for drinking. The colour is reddish.

The second mode of preparing tea is called Shiri Chai. The tea is placed in the teapot with a little soda and water and boiled for half an hour. Milk, salt and butter are then added, after which it is boiled for another half hour, when it is ready for drinking. Tea imported from China via L'hasa is a state monopoly.

BURJ.—The inner bark of the *Betula Tartarica*. It keeps out damp admirably, and so is used as an under covering of the roofs of houses. It is used as paper for rolling up fruit, tea, sugar and such like things.

DRAB. The Toon tree (*Cedrela toona*).

TUNI. Do do.

PHUL. A salt used in the infusion of tea. It is found in the Nubra Valley in Ladak. The "phul" contains the carbonate and the sulphate of soda, and a little of the chloride of sodium.

CONSULAR REPORTS: YOKOHAMA.

Mr. James Troup writes to Mr. Fraser, H.B.M.'s Minister in Japan, on April 30th, on the trade of the port during the year 1891, as follows:—

The returns transmitted are compiled from the revised Customs returns; the returns of shipping and of foreign residents and firms from information supplied by the various foreign Consulates and by the Customs. I am also, as last year, indebted to the statistics compiled by the Yokohama General Chamber of Commerce and to private sources for various information respecting the course of trade in different articles during the year.

Exchange.—In the valuation of imports the Customs figures are converted into sterling at the rate of 3s. 4d. per dollar, being the average for the year of the quarterly rates used by the Customs in their conversions from gold into silver; in the valuation of exports and in other calculations in this report the dollar is taken as equal to 3s. 2½d., being the average bank sight rate here for the year.

Gross Trade.—The total value of the foreign trade of the port for the year amounted to £12,803,455, being £4,830,469 value of imports, and £7,972,986 value of exports. The total value of the trade in 1890 was £12,077,808 being £6,604,946 value of imports, and £5,472,862 value of exports. It thus appears that the total value of the trade of the port, as expressed in gold, was last year greater by 6 per cent. than that in 1890; that the import trade had decreased nearly 27 per cent. in value, and that the export trade had increased 45-2-3rd per cent. The relative position of imports and exports last year was, it will be observed, the reverse of that in 1890, exports figuring last year largely in excess of imports. According to the estimate of the Chamber of Commerce deliveries of stable imports had fallen off by about 7 per cent. It may further be remarked that the total value of the trade of the port last year was greater than in any previous year. This result arises from the large export; on the import side the trade was smaller than in any year since 1886.

Specie has been imported to the value of £411,670, being £34 in gold, and £411,636 in silver; and exported to the value of £165,330, being £8,912 in gold and £156,418 in silver.

The year may be characterised as most unsatisfactory as regards the import trade. The fall of the dollar in its relation to gold has constituted a constant source of embarrassment and loss to importers. The same cause has naturally operated as a stimulus to exports, and has thus undoubtedly thrown money into the country; but this would appear to have been absorbed to meet previous indebtedness rather than have the effect of reviving business in imports. It is believed that more of the capital of the country is locked up in joint stock enterprises, such as the privately-owned railways and industrial concerns, than the country can afford.

Earthquake.—An event which seriously affected Japan last year should not be overlooked in an account of the trade of the year—the greater earthquake, namely, which occurred in the Gifu-Nagoya district, on October 28th. Several cotton mills were entirely disabled through this catastrophe; the potteries of Seto were wrecked, and buildings generally, railway and other structures destroyed, and industries interrupted. The extent of the severely-shaken district was over 4,000 square miles, a large part of which was a populous region. 7,248 persons were killed and 11,635 wounded in the earthquake in the Gifu-Nagoya district.

British Trade.—The trade between the various portions of the British Empire specified in the third table of the returns of this port amounted in all to £1,191,596 declared value of exports, and £2,520,053 value of imports, or £3,711,649 in all. This constitutes 29 per cent. of the total foreign trade of the port, a decrease of somewhat more than 10 per cent., as compared with the ratio of the British to the total foreign trade of the port in 1890. The trade with the United Kingdom alone has decreased 26 per cent. on that of 1890; that with Canada and other British America has increased 5½ per cent.; that with Australia has decreased 42 per cent.; that with Hong Kong increased nearly 14 per cent.; and that with British India decreased 56 per cent.

EXPORTS.

Tea.—The quantity of tea exported last year was 30,644,396 lb. or 3,182,174 lb. in excess of that in 1891. In May inquiries here ran largely on lower-priced grades, the notion being that such would prove the more lucrative investment. The consequence was that a great quantity of hurriedly prepared low grade leaf was brought forward from the country in May and June, and bought up at excessive prices. This led to the belief, on the part of the dealers, that quantity was more an object than quality. The careful manipulation of the leaf, which was noticeable at first, disappeared, and the character of arrivals continued to be unusually poor. What had at first promised to be a satisfactory season thus proved to be disappointing. The prospect of large supplies induced a depressed market at the consuming centres, where importers have found it difficult to realise cost for any teas deficient in quality. The demand for better grades, on the other hand, has been well sustained.

There has been rather more inquiry for Japan congenus, but the prices obtainable have not been remunerative to the growers, and it is unlikely that this mode of preparation will ever be an important feature in the trade from this country.

The following is an analysis of the export, showing the destinations of the tea:—Canada, 10,846,075 lb.; Chicago 7,606,474 lb.; New York, 6,807,832 lb.; California, 4,647,629 lb.; Europe, 451,017 lb. and the balance, for the most part, to China.

The routes by which it was carried were as follows:—

By Pacific Mail, and Occidental and Oriental steamers	8,918,524 lb.
,, Canadian Pacific steamers	2,784,195 ,,
,, Steamers in connection with Union Pacific Railway	3,599,161 ,,
,, Sail and rail via Tacoma	4,277,911 ,,
,, Sail and rail via Vancouver	3,620,198 ,,
,, Sail to San Francisco	642,528 ,,
,, Steamer to San Francisco	38,226 ,,
,, Steamer via Suez	6,509,883 ,,

Tea freights by Canadian Pacific, Pacific Mail, and Occidental and Oriental steamers and rail to eastern cities of the United States and Canada, at the opening of the season in the end of April and beginning of May, stood at 2½c and 3c per lb. gross. They gradually fell, until towards the latter part of the season they reached 1½c and 1¼c. Rates by the Canadian Pacific were, as a rule, lower than by the other two lines.

Throughout all Japan there are now open to traffic 1,717 miles of railway.

HIOGO.

Consul Erslic reports on April 8th to the Marquis of Salisbury on the foreign trade of the Consular district of Hiogo for the year 1891:—

Tea—Up to the end of February some 2,500 piculs of old tea were sold.

The new teas were first offered on April 27th, and found buyers at prices ranging from \$1 to \$3 above what had been paid for early teas during the previous year.

A very active business, amounting to 127,000 piculs was done up to the end of July, when the common teas monopolised the attention of buyers. The enormous demand for these teas caused the teamen to hurry forward supplies, without paying care to the style in which they were brought to market, and for some time prices were higher than in 1890, whilst the fine teas were no dearer.

The total quantity of tea sold during 1891 was 162,534 piculs, or about 5,000 piculs more than during the previous year, the average price paid being \$17 per picul, whereas a few years ago it was about \$20 per picul.

The quality of the crop generally was not so good as in 1890, and the teas also showed careless preparation.

Of late years there has been a falling-off in the style of the higher grades from the best districts, due in a measure, probably, to the diminished demand. It is advisable for those interested in the business to see that more care is taken in the growth and manipulation of these fine teas, in order to maintain the reputation they have enjoyed for many years in the consuming markets.

The increasing volume of the tea trade here is as follows:—

	1882.	1888.	1889.	1890.	1891.
Piculs...	96,790	137,000	144,000	157,154	162,534

—*L. and C. Express*, July 22.

ORIENTAL BANK ESTATES COMPANY, LIMITED (MAURITIUS AND CEYLON).

Under the presidency of Mr. Alex. William Crichton, the annual general meeting of this company was held on Wednesday, 27th inst., at Winchester House. There was a fairly good attendance of shareholders.

The Chairman in proposing the adoption of the report said that shareholders would be glad to see a net profit of £31,000 for the year against £28,000 the previous year.

Before dealing with the important matter, viz., the effects of the Mauritius hurricane, he would briefly allude to a few items in the accounts. Taking the balance sheet, the increase in "Sundry creditors" was caused by an alteration in the method of financing the working expenses of the Ceylon estates, drafts being drawn at different usances, while accounts payable were for the new machinery at the Britannia Estate, amounting to £14,000, payment of which, however, was to be distributed over three years. The fine central factory now erected would, however, be in the future a great source of saving in expenses. The remainder of the items was composed of advances by buyers of the sugar, which had since disappeared from the accounts with the sale of the produce.

On the assets side, it would be observed, there had been a considerable addition to the block cost of the estates, an analysis of which was as follows:—200 acres new planting in Ceylon, £2,000; buildings, in both Ceylon and Mauritius, £6,000; tea machinery and new plant, £22,000; total, £30,000. As regarded investments in shares, they had altogether 2,600 shares in Mauritius companies, with the working of which they

were thoroughly acquainted. In regard to the great hurricane of April 29th it had been quite unexpected. It was usually considered that after April 1st in any year there was little fear of any such occurrence, and there was no record of such a hurricane so late in the season. They did not fear the advent of a hurricane as such; it was the particular season at which it came that hurt them; and on this occasion it was at a time when the canes were 7ft. high. The extreme velocity of the wind on previous occasions had not exceeded sixty miles, while on this occasion it had been as much as 123 miles. Up to within a week of the storm all reports had been favourable, and prospects were good for a very large crop, and their manager had been congratulating himself on having passed the critical time of hurricanes.

The speaker then read a brief but vivid account of the awful calamity. Making a survey of the loss, he might say that at Britannia, buildings blown down, &c., loss about £2,000; at another estate buildings and one mill, £4,000; at Highlands, roofing only, small; at Beau Séjour, roofs and huts only (?). As regarded the loss in crop it was almost impossible to estimate at all closely, but their superintendent gave as a rough approximation that at Britannia it would amount to 33 per cent, at St. Valette 60 per cent, and at the other factories from 25 per cent up to 33 per cent loss in quantity. Rebuilding and repairs were, however, promptly set in hand, and everything, it was hoped, would be ready by crop time, and they would be able, no doubt, to purchase cane, in order to fully utilise the machinery. Looking to the losses, which would trench on their working capital, it had been thought prudent not to divide any profit either on the ordinary or, indeed, even on the cumulative preference shares. Speaking of shares, he might mention that it was intended to call up the balance due on the small number of shares on which only 1s had been paid (about £1,300.) They were much indebted, he would say, to their local superintendents and assistants for the prompt measures taken on the occasion of the storm, and to the prompt precaution to minimise losses, which might otherwise have been greater; and in this connection he specially alluded to the bravery of two of their men, Messrs. Dépre and Remiare, who had, at great risk to themselves, set free a valuable stud of horses and mules housed in a building which was just about to fall. In accordance with the recommendation of the committee of shareholders, they had acquired both the Britannia and Sanbalette freehold properties, and filled them up with new machinery in place of the old open battery system, and had also supplied horse loes and ploughs to reduce the heavy cost of weeding, both of which resulted in an increased yield. At Britannia they had as much as thirty-eight tons of cane from the acre, while the product of sugar had increased from 3,900 lb. in 1886-87, to 5,390 lb. in 1891. At Sanbalette they had made R40,000 profit. With regard to the Highlands Company, they had secured the agency, and in the Beau Séjour Company they had availed themselves of a favourable opportunity to acquire more shares, and now held five-sixths of the shares and the controlling influence. The product of this estate, under the efficient control, had risen from 5 million to 8½ million lb. of sugar, while the debt which it owed to the Crédit Foncier had been largely reduced, and in two years would be altogether liquidated. Apart from the service of the debt, the expenses of this estate were only about R520,000, while the crop was valued at R750,000, even extremely low prices for sugar. He concluded by moving the adoption of the report.

Various shareholders made remarks, critical or otherwise, of the state of affairs and the position and stating of the accounts, and in reply the Chairman remarked:—1. That the Company held no shares in the Oriental Bank. 2. That the liquidators of the Oriental Bank did hold shares of this company, but that would in no way prejudice this company. 3. The Oriental Bank had been their bank, and they had various accounts with that institution, some debit and some credit, but no loss was anticipated. 4. As to their mortgages, they were all on first-rate properties, about

which they had full information, and were amply covered. 5. In their expenses of management everything was done to keep them down. 6. As to Ceylon profits paying for losses made in Mauritius, he had frequently heard this averred, but it was entirely without foundation. Both countries were doing their share to contribute profit, and Mauritius gave about a clear three lacs of rupees of profit. 7. As regarded the management of their Ceylon tea estates, he did not believe it was more expensive than that of other estates; but shareholders must remember that the company took over most of the properties for bad debts, and that of course there were good and bad properties among them, and that in some cases the capital value was too high to yield good returns. As to Mr. Nash's management in Mauritius, he believed that he was generally regarded as a man of exceptional capacity, and the results of the working of the estate showed this. 8. As to changing the name of the company, so as to omit "Oriental Bank," as had been suggested, there were various difficulties in the way—expense, &c.—but this would have their consideration.

Various shareholders suggested and strongly urged that both in regard to capital and profit and loss the working of the Mauritius sugar estates and the Ceylon tea estates should be shown separately in future, and the Chairman was understood to say that the suggestion would be kept in view, though it was questionable whether this would be of advantage to the interests of the company, owing to the publicity which it would give in their affairs to their competitors.

After the re-election of the retiring directors and auditors—a suggestion to appoint a practical Ceylon man on the board having been negatived—with a vote of thanks to the Chairman the meeting concluded—*H. & C. Mail*, July 29th.

COFFEE PICKING IN HAMBURG.—The days are gone when 20,000 men, women and children found employment in Colombo in preparing for shipment 800,000 to 1 million cwt. of coffee. But in the *London Echo* we read:—

South America sends annually to Europe millions of pounds of unbelled coffee. The bulk of this cargo goes to Hamburg, where there are 1,000 women employed as "pickers." Six hundred of these women are married, and they are forbidden by law to work more than six hours a day. At a certain hour they are obliged to return home and prepare the midday meal for their husbands and children.

GOOD PLANTING.—It is not unusual (says the *Indian Agriculturist*) to hear people say that they cannot understand why trees die under transplanting, considering that they give planting the very best of care. What is considered the best of care is often very bad care. It is amazing to see the careful planter without experience occasionally on his knees dressing the earth in around the roots with his fingers, for fear of crushing the fibres. It is impossible to get the earth properly packed around the roots in this way. In nurseries, where it is presumable planting is thoroughly understood, a man stands with a rammer, while one is putting in the earth, and hammers the earth in as tightly as though he was hammering in a post. This packs the earth in more tightly than can be done by either feet or hands. Some are afraid of crushing the roots with this hammering process; but with the pressure all around, the force is directed towards the roots and not away from them. It is not necessary, however, to go into any reasons as the universal experience of the nursery is in favour of hammering in the earth as represented. This is the essence of good planting and other planting is decidedly bad. Trees properly planted need no staking. The fact that a tree needs staking is a proof that it was not properly planted.

THE CEYLON TEA FUND.

MEETING OF STANDING COMMITTEE.

From Mr. A. Philip, Secretary of the Planters' Association, we have received a copy of the minutes of a meeting of the Standing Committee of the "Ceylon Tea Fund" held within the Local Board Room, Nuwara Eliya, on Friday, the 12th inst., at 4 o'clock in the afternoon. There were present Messrs. W. Cross Buchanan (Dimbulla and Kandy), A. E. Wright (Maskeliya), A. Melville White (Kandy and Kelebookka), Wm. Forbes Laurie (Chairman, Dikoya Association), G. M. Ballardie (Kandy) and A. Philip (Secretary, Planters' Association of Ceylon, Kandy). The notice calling the meeting was read. Mr. Giles F. Walker (Chairman, Planters' Association of Ceylon) having to leave after the meeting of the General Committee owing to other engagements, Mr. Wm. Forbes Laurie was asked to take the chair. The minutes of a meeting of the Standing Committee held at Kandy on Thursday, the 9th day of June last, were taken as read and were confirmed.

CHICAGO SUBSCRIPTIONS IN THE COLONIAL TREASURY: EXPENDITURE AND NEED OF FURTHER SUPPORT.

Letters were read from the Colonial Secretary. The Secretary submitted the following memo. showing all the balances as at 10th August in the banks on account of the "Chicago Exhibition Fund," and the "Ceylon Tea Fund," also abstract of collections on account the Chicago Exhibition Fund from 16th November 1891 to 10th August 1892.

E. & O. E. Kandy, 10th August 1892.

It was resolved:—"That in reply to the Colonial Secretary's letter of 5th August copy of the foregoing statements submitted by the Secretary be transmitted to Government for its information, and that the Government be asked if it will be prepared to receive as security the fixed and deposit receipts therein referred to, and in the meantime to continue to advance the necessary funds required for the Chicago Exhibition."

Letters were read from Mr. W. W. Mitchell. The following resolution was submitted to be proposed by the Chairman of the Planters' Association at an early general meeting on the question of further expenditure and the need of further support:—"That in view of the great importance not only to the planting interests, but to the colony generally that Ceylon should be adequately represented at the Chicago Exhibition, Government be requested to continue the present railway rates upon tea for a period of eight months or for a longer period if necessary from the 1st October next (or such early subsequent date as may be decided upon for reducing these rates to the same level as rates upon other agricultural produce) and to set aside the amount of the difference for this period between the old and new rates as a Planters' contribution; and further to supplement this contribution by the grant of an equal amount from the General Revenue." It was resolved:—"That the Resolution has the approval of the Standing Committee of the Ceylon Tea Fund."

FINANCIAL POSITION OF THE TEA FUND.

A statement of account of the Tea Fund as at 30th of June 1892, was submitted; and it was intimated that since the 1st of July a further sum of R8,117 51 had been collected to date. It was resolved:—"That the statement of account as at 30th of June 1892 be sent to the newspapers for publication."

Telegrams and letters from Mr. J. J. Grinlinton were read.

A letter was read from Mr. Geo. Hardie regarding subscriptions to the Chicago Exhibition from the Kelani Valley.

A letter from Mr. W. Herbert Jones was read. It was resolved that the consideration of the proposal be deferred till Mr. Grinlinton's arrival.

A letter from Mr. E. S. Grigson was read, suggesting that green teas made in Ceylon should be represented at the Chicago Exhibition. It was resolved:—"That a copy of Mr. Grigson's letter be forwarded to Messrs. Darley, Butler & Co. with a request that they will kindly take the necessary steps to obtain as early as possible the samples of green teas asked for."

CEYLON TEA IN RUSSIA.

Mr. Wright gave notice that he would wish the question of Ceylon Tea in Russia placed on the paper for next meeting of the Committee.

TEA FUND SUBSCRIPTIONS.

A letter from Mr. W. H. Harman was read. It was resolved:—"That Mr. Harman be thanked for his letter, that a copy of last year's report (1891) be sent to him, and that it be stated that the Standing Committee hopes that Mr. Harman will subscribe to the Tea Fund."

Letters were read from Mr. F. H. Christian, Messrs. Cumberbatch & Co., Mr. R. S. Duff Tytler, Mr. T. C. Anderson, and Mr. O. J. Donald, Agent, Oriental Bank Estates Company, Limited. It was resolved:—"That the Secretary do reply giving the figures for the year 1891, and up to 30th June 1892."

A letter from Mr. James Bett was read.

CEYLON TEA IN GERMANY.

It was intimated for the information of the Standing Committee that the first instalment of the conditional grant of Ceylon tea to Mr. Schrader for free distribution in Germany had been duly shipped and paid for, and the second instalment would be shipped without delay.

CEYLON TEA IN VIENNA.

A letter was read from Mr. Wm. Martin Leake, Ceylon Association in London, forwarding an application from Mr. Channing Esdaile for assistance from the Tea Fund in pushing the sale of Ceylon tea in Vienna.

It was resolved:—"That in reply Mr. Leake be informed that for the present the Standing Committee of the Tea Fund does not see its way to meeting Mr. Esdaile's request."

A letter was read from Mr. Charles Oswald intimating the arrival of the grant of 500 lb. of Ceylon tea for free distribution in Vienna. It was resolved that the claim be paid.

A letter was read from the Imperial Royal Austrian Commercial Museum, Vienna. It was resolved:—"That the claim be paid."

CEYLON TEA IN SIERRA COUNTY, CALIFORNIA.

A letter was read from Mr. Joseph C. Dunbar. It was resolved:—"That the Ceylon Tea Company be requested to purchase and to hold at Mr. Dunbar's disposal 100 lb. orange pekoe made up in half lb. packets for free distribution in Sierra County, California."

CEYLON TEA IN TASMANIA.

A letter was read from Mr. George Finlayson. The Standing Committee of the Tea Fund then adjourned.

NOTES ON PRODUCE AND FINANCE.

INDIAN TEA IN GERMANY.—We referred last week to the growth of the demand in Germany for tea. We now learn with much regret that, owing to the breakdown of the health of Mr. Harington, the special commissioner sent to Germany by the Calcutta Tea Association, there seems a likelihood that the work commenced there with some vigour by Mr. Böttcher, of Hamburg, in conjunction with Mr. Harington, will come to an end. Some time ago it became very evident to those who were cognizant of what was in progress there, that unless the effort was supported with an adequate sum of money, to be spent on advertising and other initial expenses, little real progress could be made. If a moderate sum, say £200 or £300 a year, were even now forthcoming, the business could probably still be carried on with eventual great advantage to the tea industry. Private individuals, however, like Mr. Harington himself, or Mr. Böttcher, can hardly be expected to put their hands in their pockets to keep the ball rolling, knowing that some years must necessarily elapse before money so spent can be recovered again, and probably many years' work expended before any substantial profit can be realised from the enterprise. Now that the Calcutta and London associations are engaged in organising a strong "fighting fund" for such purposes, we can only hope that they will see a way to subvention this apparently expiring German scheme before it is too late. There is no doubt that there exists, especially in North Germany (which, moreover, is also the high road into Russia) a magnificent opening for Indian as well as Ceylon teas, but money would have to be spent freely to secure it.

OVER PRODUCTION OF TEA.—To the planters both of India and Ceylon—burdened by the unbearably ever increasing production and the resulting continuous fall in prices—there was a grain of comfort in some of the remarks made by Mr. Ferguson, of the *Ceylon Observer*, at his lecture this week before the members of the London Chamber of Commerce. He pointed out:—1. That only the South-Western portion of Ceylon—say less than half the total area of the island—is suitable for tea planting. 2. That nearly all the land suitable for cultivation either of tea, or, indeed, of other products also, has now been planted, and that consequently it is improbable that we shall see any further large extensions. 3. That expectations are sanguinely expressed that before long the native population both of Ceylon and India will see the advantage of drinking a warm concoction of tea in preference to cold water, which is, in tropical climates, so frequently a source of sickness.

THE AMERICAN TEA MARKET.—The Northern Pacific, Union Pacific, Canadian Pacific, and Southern Pacific Railways are all competing with the idea of diverting the China tea trade from the Suez Canal route. Two steam lines to San Francisco are under the control of the Southern Pacific Company, and the tea once landed goes over that system. The Canadian Pacific Railway has three steamers already engaged in the trade, while the Union Pacific has chartered three steamers to load tea for its line via Portland, and is delivering the tea on the Atlantic seaboard at the rate of 1½ cents per lb. The Northern Pacific has hitherto been employing sailing vessels, but this year the company, in order not to be outdone by its competitors, has secured six steamers, three of which are running between Yokohama and Tacoma, and delivering tea in New York at 1½ cents per lb. These liberal tonnage engagements will, it is believed, out into the Suez Canal traffic with New York to a considerable extent.—*H. and C. Mail*, July 29,

QUALITIES OF TEA: CEYLON V. CHINA.

The ever-increasing partiality for Indian and Ceylon teas, in preference to China growths, displayed by the British public, appears to be somewhat of a puzzle to our contemporary the *American Grocer*; but then in this country we do not succeed in getting that delicious fragrance out of China tea which is dwelt upon so eloquently in the article from our contemporary which we quoted last week. Formosa Oolongs, we allow, are fragrant—the best of them used to be a perfect bouquet—but preserve us from the average China Oongou which is sent to America! Its fragrance usually partakes too much of the characteristics of old boots or newly-tarred rope. According to one of our leading packers, Ceylon tea “recalls the delicious flavour of the finest Chinas of thirty years ago;” and whether this be so or not, fine Ceylons have undoubtedly both flavour and fragrance. Of late, unfortunately, fine teas have been conspicuously scarce, and producers are apparently doing their best—by plucking common leaf and sacrificing quality to quantity—to destroy the reputation gained by the island. As far as we know, the tastes in the two countries, Great Britain and America, are exactly opposite, the average Englishman taking his tea, like his beer, strong. “As black as your ‘at and as strong as ‘Ercules” used to be the want; but as the art of making tea has become better appreciated, so the average cup one can buy is far ahead of a few years since. Not very long ago a piece of soda was considered a *sine qua non* in the pot. What would our American friends think of that resource?

It took some years, though not many, to bring the British public on to Indian teas. Ceylons went well from the first, and we have not the slightest doubt that a comparatively short time will see a complete revolution in American taste. Of late the export demand for both Indians and Ceylons has increased enormously, and it is expected that the Chicago Exhibition will open up the trade in an immense number of new quarters. We know nothing of the effect, harmless or otherwise, on the constitution; but we do know that almost anywhere throughout this country one can now walk into a restaurant (always excepting railway stations) or a cake shop and get served with a decent pot of tea. Not often could that be obtained in the good old days even when China tea was at its best.

Tea drinkers are getting more and more educated, and this fact will prevent China tea from ever coming to the fore again. We have never heard of a solitary instance of anyone who has once been converted to Ceylon tea going back again to the China leaf, and many grocers have informed us that they are very soon told of it by their customers should they put a sprinkling too much of China even in their commonest blends.—*Grocer's Gazette*, July 16.

BAD TEA AND COFFEE AT THE HOUSES OF THE UPPER CLASSES IN LONDON.—“Miss Mantalini” writes in the *Pall Mall Budget* of 14th July:—

“And such bad tea, too,” as the Duchess remarks in Mr. Oscar Wilde's much-abused success at the St. James's. Speaking with “a sad sincerity” (to quote Emerson), I cannot fail to endorse the sentiments of that noble lady. Tea at fashionable afternoons is bad. Bad? The term, like the infusion it attempts to describe, is not strong enough—vile, detestable, are more truly descriptive of the miserable hot fluid provided at so many houses for afternoon callers. The reason is not far to seek. The brew is generally left to servants, and servants have as much idea, as a rule, of making tea as a Zulu of making corsets. Of course, there are honourable exceptions, but they are few and far between. After dinner, coffee at most houses occupies the same “bad eminence” as afternoon tea, and yet as I write I bethink me of a modest establishment in “Greater London” where the coffee used is sent to England by an English official at Aden, to whom it is presented by a native merchant—a house where it is roasted and ground as required, and is made by the hostess herself. Such coffee is indeed a luxury.

TEA CULTIVATION.

The Planters of Wynaad have to thank you for the attention that has been directed to their district by the leaders and correspondence in your columns, especially in the matter of tea cultivation there, which you have so successfully fostered.

Tea cultivation is now being undertaken on a considerable scale, but there are still many men of authority who are doubtful of its success.

The first argument used is that the production of tea has increased so enormously of late years, principally in Ceylon, that there is no hope of the demand increasing in proportion with the supply; and that the price of tea must fall, so as to be no longer remunerative to the producer.

The following figures are quoted as the average price of Ceylon tea during the past eight years, and the steady fall in value is striking:—

	s.	d.
Average price Ceylon tea ..	1885	1 3½
do do ...	1886	1 1
do do ...	1887	1 0½
do do ...	1888	11½
do do ...	1889	11
do do ...	1890	10½
do do ...	1891	9½
do do ..	1892	9

At the same time exports of tea from Ceylon have increased in an enormous ratio:—

	lb.
The export of tea from Ceylon 1885	4,411,578
do do 1886	8,111,137
do do 1887	13,800,545
do do 1888	24,381,296
do do 1889	34,048,085
do do 1890	46,901,554
do do 1891	68,274,420

and these figures are accepted as evidence that the cultivation of tea is being overdone, and that the price must continue to fall. But there is another aspect of the matter. Notwithstanding the enormous increase in production in Ceylon, and a very large increase in India, the stocks of tea in the world have not materially increased. The stronger quality and cheaper cost of Indian and Ceylon tea has driven the China tea from the market; the supply of China tea to the English market has fallen by one half.

The total consumption of tea in the world is about 400 million pounds per year, of which China used to provide about 300 million pounds yearly. Of this quantity England alone consumes two hundred million pounds yearly, and the consumption, for many years past, has increased at the rate of about ten per cent. yearly. India and Ceylon had to find a market for their tea in competition with the established China trade, and to do this they had to force China to produce less tea; a great decline in price was therefore inevitable, and the fall that has occurred in the last few years has brought the price below China cost, so that their tea must be sold at a loss to the China grower, or to the China merchant, unless it fetches a better price than average Ceylon and India tea.

The force of circumstances and necessity has caused the Ceylon Tea Planters to introduce so admirable a system in the cultivation of their estates, and so efficient, and yet cheap manufacture of their tea, by the introduction of almost perfect and automatic machinery, and the most careful study of economy in every detail, that their tea can be placed on the market at a cost that was considered impossible in former times. Not satisfied with having established the command of the English market, the Ceylon and Indian Planters are now striving to open markets for their wares in other countries, where China teas are still in general consumption. America and Australia are being thoroughly exploited, and efforts are also being made to displace China tea in the Russian markets. It is a struggle which must end in the survival of the fittest, and already the great tea trade of China is admittedly doomed.

Even in the present low price of tea, the cultivation in both Ceylon and India is paying exceedingly well,

Very large dividends were paid even last year by most of the Tea Companies.

There are two elements of success: high quality or large quantity of produce. The strong highly flavoured teas still command high prices, and must continue to do so, as the supply of such must be limited. It is the price of the low quality tea, which competes with ordinary China tea, that has fallen so much. Quality, as has been ably explained by "Rustic" in the Ceylon papers, depends not only on scientific and careful manufacture, but also on elevation, soil, high jât (which means the nearest approach to pure Assam), and especially to fine plucking, that is gathering from the tea only the smallest leaves, and not taking the leaves which are made into the Souchong and Congou marks.

The cost of plucking, manufacture, packing, carriage, shipment, freight, and home charges, is about the same on all tea, and may be taken at from 4d to 5d per pound, according to circumstances.

The cost of upkeep and cultivation of the plantation may be taken at R40 per acre,* or with a yield of 640 lb made tea per acre, at 1d per lb; 320 lb per acre, the cost will be 2d per lb; 160 lb per acre, the cost will be 4d per lb. Thus at 9d per lb, average price of the tea, 640 lb per acre will give a profit of £8 sterling per acre; 320 lb per acre will give a profit of £2 4s per acre; while 160 lb per acre, will only pay the cost of production, and it can only be very high quality, from fine plucking, that will pay at such a small yield per acre.

The above figures can only be carried out on an estate of not less than 300 acres, thoroughly cultivated, as it would be in Ceylon, kept free from weeds, and with the best and newest machinery. It would cost £20 per acre, or, say, £6,000 for 330 acres, to bring the plantation completely into full bearing, with buildings and machinery. Applying the above facts to Wynaad, what are the advantages of this district? Accepting the principle that in the struggle for existence it is only the fittest that will survive, with the prospect of continued extension of tea cultivation notwithstanding the collapse of China, yet Wynaad will have special advantages. Although there is still very much to be learnt, yet vast strides have been made in the last few years, especially in Ceylon, in the scientific study of the industry, and in taking up the business now, it will have the advantage of Ceylon's experience to guide and warn the Planter. In the rush to open tea quickly in Ceylon, sufficient regard was not given to the purity of the seed; when good seed could not at once be obtained, any seed or plants available were accepted, so as to get the fields planted.

In Wynaad there is now a very considerable supply of pure Assam seed. There is probably some 30 acres of seed bearers available, whose pedigree can be traced back sixty years; when the seed was brought from Assam by the then Collector of Salem. And as these Assam plants bear no seed until they are over five years old, it is of the utmost advantage having such a supply of good seed to start on. The great importance of this high jât tea in opening a plantation is now generally admitted; the produce per acre is very much larger than from China and hybrid plants and the quality is also very much stronger and more valuable.

So fully is this recognised in the North of India that whole gardens which had been planted with inferior tea have been gradually uprooted and replanted with the purest Assam. In Ceylon at the present time more than one plantation of pure jât tea is reserved for seed bearing, so great is the demand for good seed there now. One estate, the original seed of which was collected by its proprietor from wild indigenous Assam plants in the forest, has been a source of large profit to its owner, without manufacturing any leaf. The experience so far obtained in Wynaad goes to show that the production per acre is very large, and that the quality of the tea made from these high jât plants is exceptionally good.

* Declared by a subsequent writer to be impossible.—

There is a large area of good land available here (Wynaad) not in a wild district, but in opened country, with a really splendid main road, and good minor communications. Bazaars, hospitals, magistracy, and police are established, as well as post and telegraph, and it lies in the midst of populous districts, where ample labour is available, and where the cost of labour is some 30 per cent less than in Ceylon. It is this vicinity to their own villages that has made the labour in Wynaad, hitherto, irregular; being able to reach their homes quickly make the occasion of a native festival the excuse for a general exodus, and it is probable that for the permanent labour which is necessary, a considerable increase in the rate of pay will be required, to obtain men from more distant districts.

Wynaad has, unfortunately, an evil name in the London money market. So much capital was collected and squandered in the gold mania of a previous decade that it is thought that no good thing can come out of it.

But this prejudice is being gradually overcome, and we may hope to see the district rise again, before long, to something of its former success. New blood and new capital will again flow in, to the encouragement of the old Plauters who have survived the many vicissitudes of the past, and of whom the planting community of Wynaad mostly consists, among whom is
SENEX.

—Madras Times.

NOTES FROM OUR LONDON LETTER.

LONDON, July 29.

THE TWO PUBLIC OCCASIONS

to which my last letter made reference came off during the present week on Monday last. The first of these, the reading by Mr. John Ferguson of a paper on "The Production and Consumption of Tea, Coffee, Cacao, (Cocoa), Cinchona, Coconuts and Oil, and Cinnamon, with reference to

TROPICAL AGRICULTURE IN CEYLON," before the London Chamber of Commerce took place at the Chamber's rooms in Eastcheap at 2 p.m. on the day referred to above. Unfortunately this paper has not as yet been printed, and pressure of time has prevented him, Mr. Ferguson tells me, from preparing a copy of it to send you. So he has suggested I should forward you such notes of his paper as it was possible for me to take during its reading. The room—a large one—was filled to its utmost capacity, many attendants, who included a number of the leading London merchants, being unable to find seats. Sir Arthur Birch presided, and among those present were Sir Arthur Gordon, Sir G. W. R. Campbell, Mr. D. Morris (of Kew Gardens), and Messrs. Epps, J. Whittall, Grinlinton, Robert Wales, W. J. Thompson, J. Chambers, Charles Shand, W. M. Leake, J. Haddon, John Capper and John Anderson.

The DEPUTY CHAIRMAN of the Chamber, whose name is not known to me, briefly opened the proceedings. He referred to visits paid by him to Ceylon and to his having on these occasions made the acquaintance of the lecturer and of his venerable uncle, both of whom, as journalists and writers, had done so much to bring the subject of tropical agriculture prominently before the public. He begged to propose that Sir Arthur Birch, whose name had been before associated with Ceylon, should take the chair. Most of those present, he thought, must know a great deal about Ceylon, but doubtless Mr. Ferguson would be able to extend their knowledge of it most usefully and pleasantly.

Sir ARTHUR BIRCH, on taking the chair, said he had known Mr. Ferguson for many years, and that the subject to be treated of in the paper that

gentlemen was about to read to them could not be in better hands.

Mr. FERGUSON remarked that he was afraid a paper which must deal so largely with statistics could hardly be made a pleasant one, but he had confined any detail of figures to an appendix, and would not weary his audience by reading them. He proceeded to review the conditions under which agriculture, and especially planting agriculture, was carried on in Ceylon, stating that one great advantage included among them was an unstinted supply of cheap labour from India. This was now being largely supplemented by resident native labour, now becoming habituated to labour on the estates. The lecturer next acknowledged the great indebtedness of Ceylon and other colonies to the authorities at K. w. He mentioned the diversity of training required to make

A THOROUGH CEYLON PLANTER.

Among other requirements he said he must become partly an engineer, so many were the constructive and mechanical works he had to supervise. He must also learn to speak the native language, colloquially, and become an expert in every department of tropical agriculture. It was no wonder that, with such a training as this, an experienced Ceylon planter held a passport for employment in every part of the world. After the collapse of the coffee industry about 300 planters left the island to seek a livelihood elsewhere. They found this in Trinidad, the Straits, Borneo, Jamaica, Grenada, California, New Guinea and elsewhere; while but recently two most experienced Ceylon planters had been engaged in reporting on the capabilities of the country around the ranges of the Andes for various forms of tropical planting cultivation. He might instance how highly Ceylon experience was valued by planters everywhere by citing a story told him by a long settled West Indian planter. This person mentioned having asked a Ceylon man how far he thought cacao was suited to a particular island. The reply was that he feared wide hybridizing, whereupon the questioner remarked:—"Ah! from your answer I can recognize the locality of your training. Such a remark I should never have heard from a West Indian." Mr. Ferguson proceeded to admit that many products had been tried in Ceylon which had not answered expectations:

THEIR PRESENT CULTIVATIONS

were "the survival of the fittest." He might mention, he said, tobacco as a particular instance of such failure. Although this was largely grown, it had become evident that its regular cultivation by Europeans could not be profitably pursued. Cotton, also, had not been a success, and sugar, which had been tried many years ago, had had to be entirely given up. The island seemed to be but suited to spices and tea. Proceeding to deal with existing forms of production seriatim, Mr. Ferguson referred first to

CINNAMON,

reviewing the earlier endeavours made by the Portuguese and Dutch to regularly cultivate it. He stated that the cinnamon was among the indigenous growths of the island, and that inland the forests contained large trees of it. It had always been a valuable island product, the Romans in the time of Nero having paid as much as £8 per pound for this Ceylon spice. He was sorry to say that the present prices hardly paid expenses of cultivation and preparation. This was greeted the fault of the Ceylon cultivators, who had flooded the market with enormous quantities of chips,

PEPPER,

was the next item dealt with, the lecturer observing that this had been an early cultivation of the island, and it had obtained celebrity as early as 1602. The Dutch had given great attention to it. As to

CARDAMOMS,

or grains of Paradise, Mr. Ferguson said that they were now an article of large export, as they had been indeed, some centuries back, although afterward, comparatively abandoned until of late year. The failure of coffee compelled the planters to seek for new industries, and cardamoms had largely and profitably engaged them. There are about 5,000 acres now under cultivation with this product. Speaking of

CINCHONA,

it was remarked that this article furnished probably one of the most striking instances of fluctuation that could be quoted. These had been without precedent in the whole history of trade. Its cultivation had afforded no gain to Ceylon. Kew had sent the first seeds to the island in 1863 or 1864. The trees had first been planted either for ornamental or shade purposes, but eventually no estate was to be found without large numbers of them. The highest price for the bark was reached in 1880, since when it had diminished so rapidly that the bark had become scarcely worth the cost of collecting. Mr. Ferguson thought there might be a great future for

INDIARUBBER

in the colony. The demand for the gum was large and increasing, while the supply was falling off. Para now exports about 17,000 tons per annum and obtains between £300 and £400 per ton for it. Attempts to cultivate the vine in Ceylon were made some twelve years back. The production sold well, and the vines were rich in yield, but the rush for tea, and the age required to make the vines profitable, had nearly stopped their cultivation. There are now about 400 acres under its growth. Probably the great demand and the high price now obtainable would resuscitate this as a planting industry, and in such a connection further items, such as gambier and the kola nut, might be cited as offering inducement for trial by Ceylon planters. Mr. Ferguson assigned a high importance to the cultivation of

THE COCONUT.

He said that there were 1,000 known varieties of the palm family, but only 25 of these were to be found in Ceylon. Several of these were of vast importance as local food suppliers, but commercially little notice need be taken of any of them save the coconut. This, in the form of coppa and desiccated coconut and as oil, was now a very large article of export, statistics as to which would be found in the appendix. With reference to

CACAO

Mr. Ferguson informed his hearers that this had first been introduced by the Dutch. Systematic planting by the English had begun in 1872. It was an exceedingly troublesome product to grow until the plant has attained some ten years of age. The demand for cocoa was fully up to it not in excess of the supply, and Mr. Ferguson contrasted the cultivation and preparation as pursued in Ceylon with the forms of both practised in the West India islands, asserting that Ceylon cocoa held the pre-eminence in all European markets. His strictures on the West Indian practice with regard to this article

evoked a good deal of defensive comment during the after discussion of the paper. Turning next to

COFFEE,

the lecturer traced the history of its cultivation up to 1877, when the export of the berry had risen to 30,000 cwt. in excess of the round million. He remarked upon the woful change brought about by the leaf-disease as evidenced by present statistics. Dr. Thwaites of Peradeniya Mr. Ferguson asserted to have been the one authority who first predicted the fearful results to this pest when it first became observable. Upon these results, he said, he need not now dwell. The high prices now obtainable for the small amount of coffee Ceylon yet exported might and should lead the planters of the island to open up fresh fields in other countries. Ceylon men had brought the preparation of the coffee berry up to a wonderful pitch of excellence, as indeed they had done with reference to every form of cultivation they had undertaken. It was not only in Ceylon that coffee had suffered from the devastating disease. Every Eastern coffee-growing country had similarly suffered, and it was only a few districts in Mysore in India that had apparently escaped its ravages. Liberian coffee grown in Ceylon had not borne the effects better than the older form, but Mr. Ferguson expressed the opinion that the cultivation of this description might yet be profitably extended in Ceylon.

TEA.

"Finally," Mr. Ferguson observed, "we come to Tea." This must now be regarded as the staple product of the island, and every confidence might be felt in its permanence. The earlier attempts at this cultivation were noticed by the lecturer, who said that Mr. W. M. Leake had been the first to introduce the tea seed from Assam and to enter on the cultivation on a large scale. Some of the leading statistics evidencing the rapid strides made with it were next read, it being then remarked that the warm, moist climate of Ceylon was especially suited to this form of growth. There was also an unlimited supply of cheap labour available, and this was a prime factor towards success. Another more important factor was the introduction and use of most efficient machinery for the preparation of the leaf. The existing factory arrangements for dealing with this seemed to be as perfect as they could be. As for future extension, the planting area may be enlarged successfully if remunerative prices can be obtained. Experiments involving a large cost had been carried out both in India and Ceylon, and to those no doubt was owing much of the success, which had been attained in both countries. The drinking of tea had become a wide-world habit. It had been observed that nothing was so fatal as the drinking of cold water. The Chinese would never do this, and it was to their practice of tea drinking that had been assigned the comparative immunity among them from cholera. The future of the tea industry in Ceylon must be largely dependent upon the opening up of new markets. Mr. Ferguson said he was glad to see among his audience the Commission appointed by Ceylon to represent it at the forthcoming Chicago Exhibition. He regarded America as a most promising field for the future enlarged disposal of their tea. Much had already been done towards securing this, and their representation at Chicago would certainly have a much-to-be-desired effect. Concluding, the lecturer said he had ventured to take up a very wide subject, scarcely to be efficiently treated within the limit of time at his disposal. There was still ample room in Ceylon

for experiment and action with regard to the cultivation of

NEW PRODUCTS.

Much, for instance, might be done with fibre plants and other growths. Timber, of which the island possessed a large and valuable supply, should in the future prove remunerative, and the opening up of the Northern Province by railway would largely aid as to this.

THE PLUMBAGO AND GEM INDUSTRIES

of the island would, he hoped, receive further development ere long. Capital might safely be invested in them. Surely, Mr. Ferguson concluded, it would be better to invest British capital in a British colony than to sink it, as had been done, in the Republic of South America.

Sir Arthur Birch then called upon your Commissioner for Chicago to open

THE DISCUSSION.

Mr. GRINLINTON said he had not expected to be called upon to speak. What he could find to say would only have to be repeated within a very few minutes in another place. His late mission to America had resulted in very complete success. The American Ceylon Tea Company had done its best to advertise Ceylon tea, and had ably prepared the way for a fuller development as the result of what he hoped would be done at the Chicago Exhibition. But more than that Company had been able to do was yet required. "You must put your hands in your pockets," said the speaker, "if you wish to achieve all you want." An enormous quantity of tea was drunk in America, but it was vile stuff, and it was difficult to change ideas when once established. There were great ignorance as to Ceylon in America. Many people there did not even know where the island was, several he had met believing it to be situate on the east coast of Africa. Mr. Grinlinton said it would require all our energy and all our skill to place Ceylon teas on the American market. The Americans at the first taste preferred their China and Japan teas to those of Ceylon. He had been very successful in obtaining sites for Ceylon from the authorities at Chicago, and exceptionally favourable terms had been granted for the sale of its teas in kiosks. Mr. Grinlinton concluded to the effect that "if you want the Americans to drink your teas, you must prove your desire that they should do so by putting your hands in your pockets."

Sir Arthur Birch next called upon Mr. D. MORRIS, who said that he could add little to what Mr. Ferguson had so admirably placed before them. That gentleman's numerous publications on tropical agriculture, with which his venerable and worthy uncle was associated, had been invaluable throughout the world. He thought the Ceylon planters, of whom he had the highest opinion in every respect, had one fault. They had too much energy, and rushed everything they undertook. They spoiled matters by

GLUTTING THE MARKETS.

For instance, annatto was a product but little in use and until lately small quantities only came to hand. But the other day, comparatively, a Ceylon planter took up this cultivation, and a trader refused offers from ordinary sources, because, he said, 'all our wants have already been met from Ceylon.' It was time the Ceylon planters passed a self-denying ordinance. Perhaps it was hard to expect this of them, but certainly it was required. Let them do as much as they could with indiarubber. They could scarcely go beyond the demand which was arising, and that must develop almost without limitation. If the Ceylon planters could meet this with a supply of good quality they would

deserve all praise. He could not see, Mr. Morris continued, why the Europeans did not go in for

RICE CULTIVATION IN CEYLON.

There was nothing to prevent it. In Carolina the white planters of this were most successful. The Ceylon planters had done much with cacao, and their production of this was the best that came into the market, but if Ceylon went on increasing its supply of this, the West India islands would suffer dreadfully. He hoped nothing would cause tea to fail. When in Ceylon he had observed that the coffee had been enormously pruned and forced by stimulating manure. This he deemed to be hurtful to the permanence of the plant, and if the same course was pursued with tea it might be followed by the same result. "You cannot go on for ever in the same way with any form of plant cultivation." The authorities at Kew were most desirous to help all institutions throughout the world. The late Dr. Thwaites had had much to do with starting both cinchona and tea. Mr. Ferguson had alluded to

THE LATE EXPEDITION TO THE ANDES.

But why, he would ask, should we go into foreign countries to find land suited for coffee when we possessed any amount of such land within our own possessions? He could tell them of land in British Honduras admirably suited for this, where there was an abundance of labour. It was the finest land in the world for coffee. In Dominica coffee had died out, but there was no reason why it should not be successfully recultivated there. Thirty to forty thousand acres were ready and available in that island, and they had never had any leaf-disease in the West India islands. He begged to thank Mr. Ferguson for the compliments that gentleman had paid to the authorities at Kew.

Sir ARTHUR GORDON said that as he had to attend another meeting his remarks must be brief. He thanked Mr. Ferguson for his very interesting paper. He had no remarks to offer that would be worth hearing, but he had been struck with two points in the paper read. In the first place—what a splendid example Ceylon offered of British obstinacy, of Britons who do not know when they are beaten! As to the second point he was strongly reminded of the unwise wisdom of paving all your eggs in one basket. There was plenty of room in Ceylon for further trial. He thought hardly enough had been said by Mr. Ferguson as to coconut cultivation. To his mind it was a most stable industry. He was naturally interested in Ceylon as an old Governor, but for the same reason he had sympathy with the planters of the West Indies, and he thought Mr. Ferguson had hardly done justice to the planters of those colonies. Both they and those of Ceylon were in a friendly rivalry, but neither one nor the other of them should abuse each other.

DR. KIRTIKAR ON THE VEGETABLE KINGDOM.

The fourth public lecture of the season under the auspices of the Dnyan Prasarak Mandali was delivered at the Framjee Cowasjee Institute, Mr. K. R. Kama, president of the Society, being in the chair. The subject selected for the evening was "Reproduction in the Vegetable Kingdom," and the learned lecturer, Surgeon-Major K. R. Kirtikar, handled his subject in such a popular and interesting manner that the discourse was listened to with marked attention throughout. Dr. Kirtikar commenced his address as follows:—

"Reproduction in the vegetable kingdom as a

general rule occurs by means of seeds, which are the product of the fertilization of the ovule—a part of the female element of a complete flower—by the discharge of pollen from the male element known as stamens. The vegetable kingdom differs from the animal kingdom in its method of reproduction in this—that, whereas animals are born direct from the parent in the shape of eggs, or actually formed beings, in the vegetable world, on the other hand the seed of a plant has to be sown in the ground or other suitable material, before a new plant comes into existence. There are exceptions to this general rule. Flowers are generally the organs of reproduction. It is in them and through them that the seed is formed. There are some plants, however, which are flowerless, such as fungi, lichens, mosses, ferns, &c. In them innumerable spires are formed instead of what we usually understand as "seeds." These spires reproduce the parent-plant. It is not that all spires perform the work of reproduction. If they did so, one single fungus, say, a puffball, will reproduce so many of its kind, as to cover a whole country within a very short space of time. Even among flowering plants, such as the potato, the seed is not absolutely necessary for producing new plants. The little "eyes" on the tubers of the potato represent the buds of the future plant. A potato cut into pieces, with each piece out carrying on it an eye, will be enough to give a new plant complete in all respects, which will be fit in every way to bear fresh potatoes. Thus the growth of the potato is independent of the seed. Similarly in the arum-order, reproduction takes place from its tuberous roots, as in *Sooran* and *Aloo* as also in *Karinda*, *Rataloo*, *Kanayi*, though they bear flowers, and often showy ones too. The tuberous roots throw up new shoots of the future plant, which as it grows, absorbs the tuber, and when it has completed its growth by drawing its nourishment from the substance of the tubers, it throws out a fresh tuber, which proves the reproducer of the future plant. And so the process goes on from year to year, or season to season. The *Ananas* (pineapple) in same way requires no seed to reproduce its kind. The tuft of leaves, which graces its top, if planted, gives a fresh plant, capable of producing a perfect *ananas* popularly known as its fruit. Plants produced in this way are, however, limited in number—thus, for instance, from one tuber of *Sooran* or *Aloo*, you can get only one plant at a time, two or at the most three; but from one flowering plant which bears seeds several plants can be obtained at a time. Hundreds and hundreds of fruits are produced, for instance, by the *Wamla*, which is so prolific that it is known to bear on a single tree as many as five hundred and thirty-nine thousand seeds every year. Linnæus has calculated that a single tobacco plant is capable of throwing out forty thousand seeds. Ray calculated on one occasion as many as thirty-two thousand seeds off a fruit-bearing branch of poppy. Were all these seeds to perform the work of reproducing plants, they would within a short space of time cover the whole earth with nothing but vegetation, and man and other animals will have hardly an inch of ground to move. Generally speaking the male and female organs of reproduction are to be found in one and the same flower, or separately on one and the same tree; or the male and the female organs may exist on separate trees of the same kind, far apart from each other. Darwin has enunciated the doctrine that the seed produced from the male and female elements of the same flower is weakly, and germinates in time; the seed produced from the female flower of one tree, and the male of another similar tree is healthier, more vigorous, and better able to perform the function of reproduction. From this, however, it must not be supposed, that equally vigorous, substantial, and useful seed is always incapable of being produced by the former process, or that the plants of such seeds as is obtained by cross-fertilization is *always* or infallibly capable of producing a plant of the best kind, or that for the purposes of producing a plant of the kind, cross-fertilization is absolutely necessary. For the researches of Sacks have amply incontestably shown that for hundreds and thousands of generations

plants have reproduced themselves vigorously without the intervention of flowers, and have never shown the slightest trace of degeneration, although they have followed from time immemorial this process of reproduction. The potato is the best illustration of it; so is the *Ananas*. It is true, however, that cross-fertilization when possible has produced much variety in flowers as regards their colour, form, fragrance, and fruit. Plants, again, are reproduced from "cuttings" and "buddings," such as in the cultivation of roses. They are also reproduced by grafts. The good varieties of mangoes and oranges are commonly from grafts of a superior fruit bearing plant stuck on to an inferior plant. Plants are also reproduced by inarching. This is a practice followed commonly in mango cultivation. Then there is a process of "layering." These processes are, however, tedious, and require individual care. The reproduction of plants from seeds, however, is the most natural process; it is easier and, numerically speaking, capable of reproducing more abundant supply of new plants within a much shorter time. Reproduction among flower-bearing plants is of two kinds: one where the ovule is fertilized as it lies uncovered, as for instance in the pine, cicad, and genetum order; and the other where it is fertilized as it lies in a covered ovary in the remaining orders of the flowering plants.

After describing in detail the mode of fertilization in each of these, the lecturer went on to mention the various agencies whereby seeds are transferred from one place to another, from one country to another, and from one hemisphere to the other. He said:—"In the air were the seeds, travellers bearing plumes and parasols of featherlike appendages which helped them to descend or ascend mountain heights." The lecturer next described how oceanic currents, rivers, and mountain cataracts helped in transferring seeds and even branches of large trees from America to the shores of Spain; from the West Indies to Iceland and the Orkney Isles, from the Seychelles Isles to the Indian Coast of Malabar, journeying or rather voyaging over 1,500 miles of the Indian Ocean. As an instance of how germs of plants are carried about by the prevailing wind, the lecturer drew attention to the white patches of lichen which cover the windward bark of the numerous palms that grow between Virar, Palgur, and Boisar stations along the line of the B. B. & C. I. Railway. Extending his remarks to the seeds loving to dwell in tranquil waters, the lecturer referred to the Nile-lotus and the lotuses inhabiting the ponds and tanks of Bombay, and how their peculiar life was rendered easy by a suitable boat like home for their seeds floating on the surface of the water, or rising high above the water-surface, so that the deleterious and soddening action of the water may not affect them, and thereby destroy the vitality of the embryo of the future plant.

He next referred to the third method of the migration of seeds—*viz.*, through the agency of birds and beasts. "Buffaloes and cows that swallowed raw *Bajri* and *Jowari*," said he, "often passed the grain whole from insufficient chewing of the cud—but sufficiently moistened through the internal moist heat and intestinal juices of the animal to germinate in their excreta very shortly after they are passed. Mice, squirrel, and such other fruit-devouring creatures often store fruit and seed in their dens, where either from the abundance of fruit or from there "storing agents" being killed by higher animals, the fruit rots and the seed germinates in due course. Such animals as goats and sheep carry on their fur seeds of the *Mulvaceæ* order. Parrots eat chillies and guavas, and drop their seed in their excreta. So do crows eat the various fruits of the fig-order, and give rise to plant wherever they deposit their excreta round palms—as seen along the whole of our western sea-coast, and on the tops of old castles and churches that are now to be seen in ruins all over Salsette. A very interesting account is given by Dr. Pauchet, how the nutmeg survived the destructive hand of the conquering Dutchman in the Indian Archipelago Isles, in days gone by. In order to restrict the growth of the nutmeg to Ceylon, the Dutch destroyed

the nutmeg tree in every other place but Ceylon. But the nutmeg-eating pigeon in a body came to the rescue. They ate the fruit and away they went to the ravaged islands. They were too weak of stomach to digest the nut. They managed to appropriate only the soft pulp covering the hard nut. The result was but natural; they had to deposit the seed-nut as their excreta, which, as both luck and nature would have it, gave fresh plants of the nutmeg, which was a God-send to the poor islands which had suffered not long ago from Dutch mercilessness.

The quadrupeds also add their quota to the reproduction of plants. Pauchet mentions of a civet in Java and Manilla who feeds on the coffee-berry, but can digest only the pulp of it and not the seed. The seed comes away as excreta ready for germination. The natives know this so well, that they are not ashamed of collecting such seeds for the purposes of cultivation."

Lastly, the lecturer referred to the reproduction of plants through human agency. Men travelling from one country to another, or voyaging from one hemisphere to the other as discoverers, conquerors, merchants, or mere travellers, have carried with them to a distant country or brought back thence to their own, plants which have become quite naturalized in their land of adoption, or more truly their *banishment*. But as banished man may be happier in the land of exile, and that is literally the case with some of our exotic but naturalized plants, for witness what could be more delicious than a Mahableshwur potato, I ask those who knew it when the Chinaman cultivated it twenty years ago.

The lecturer concluded his lecture, which was illustrated with fresh specimens and illustrations of some of the plants mentioned in the discourse by a reference to some touching lines from the poet Crabbe, who speaks in his simple yet forcible style of "Flora's triumph over the falling tower."—*Times of India*.

CARDAMOM CULTIVATION IN KALIMPONG.—

The Government of Bengal have decided, in connection with the Kalimpong settlement, that lands newly prepared for cardamom cultivation, may be held rent-free for the first three years, and after that will be assessed at the rate of R10 per acre. For the first three years the annual average yield of one acre of cardamom is *nil*, but in the fourth and fifth years about two maunds are obtained annually, and from the sixth to the eighth year, three, four and subsequently five maunds. In consideration of there being no yield for the first three years, Government have allowed the ryots immunity from rent for that period. The average price of a maund of cardamom at Kalimpong for the past year is stated to be R35, but with the spread of cultivation, the price is likely to fall considerably within the next ten years. A good deal of trouble has been experienced in assessing the present rate, as cardamoms are an exceptional crop, and it was found difficult to make a comparison with rates in other parts. In Sikkim and on Chaboo Lama's zemindari, for instance, a royalty of R5 per maund is levied, which is equal to R25 per acre, when the plants are in full bearing. This seemed to Government an exceptionally high rate, considering the amount of labour and illness that cardamom cultivation entails. The cultivators are obliged to keep the plants entirely under water when the pods are ripening, to protect them against rats, and spending so much of their time at the bottom of unhealthy valleys leads to a good deal of sickness. In assessing the rate in Kalimpong at R10 per acre after the first three years, Government have endeavoured to arrange matters to the cultivators' advantage as much as possible and with a view to encouraging the industry. Allowing for the limited quantity of land available for cardamom crops, this rate seems to us to be very moderate.—*Indian Agriculturist*.

FROM THE METROPOLIS.

LONDON, 29th July 1892.

TROPICAL PRODUCTS: THEIR CONSUMPTION AND PRODUCTION.

I am not able to send you a copy of my paper prepared for the London Chamber of Commerce, because, unlike the Colonial Institute, they do not have their papers printed beforehand,—all the Secretary required was a résumé to have multiplied by type-writer, for the use of the daily press. However, the MS. left in charge of Mr. Kenrie Murray will appear in the "Journal" in due course; while the greater part is likely to be reproduced in some of the weeklies—the *Grocer* for instance—from whom requests came after the meeting for the use of the copy. Nearly all the London dailies too, had summary reports of more or less fullness, that of the *Times* being at once the clearest and most concise, while the *Evening Standard*, *Daily Chronicle*, *Morning Advertiser*, *Financial Times*, and especially the *Manchester Guardian* had fuller details. I send you the *Times'* notice in case your regular correspondent has misread it:—

TROPICAL AGRICULTURE IN CEYLON.—Before a meeting of the London Chamber of Commerce, held yesterday in the Council-room, Botolph-house, East-cheap, Mr. J. Ferguson read a paper on "The Production and Consumption of Tea, Coffee, Cacao (cocoa), Cinchona, Coconuts and Oil, and Cinnamon, with reference to Tropical Agriculture in Ceylon." Sir Arthur N. Birch, late Lieutenant-Governor of Ceylon, presided, and among those present were Sir A. Gordon, Sir G. W. R. Campbell, Mr. D. Morris, (Assistant-Director of Kew Gardens), Mr. Epps, Mr. J. Whittall, Mr. Robert Wales, Mr. W. J. Thompson, and Mr. J. Chambers. Mr. Ferguson referred to the position of Ceylon, its forcing climate, its command of free cheap labour, and its immunity from the hurricanes which periodically devastated Mauritius from the cyclones of the Bay of Bengal, and from the volcanic disturbances affecting Java and the Eastern Archipelago. The plantations of Ceylon afforded, he said, the best training in the world for young men in the cultivation and preparation of tropical products, and in the management of free coloured labour. The cultivation of cane sugar, although tried at considerable outlay on several plantations 40 and 50 years ago, proved a failure. More recently experiments by European planters with tobacco had not been a success, notwithstanding that the natives grew a good deal of a coarse quality for their own use. Although cotton growing had not been successful, the island had proved a most congenial home for many useful palms, more particularly the coconut (spelt without the "a" to distinguish it and its products from cocoa—the beans of the shrub *Theobroma cacao*) and palmyra, as also the areca and kitul or jaggery palms. Within the past few years Ceylon had come to the front as one of the three great tea producing countries in the world, India and China being the other two, with Java at a respectable distance. Mr. Ferguson said one of the chief objects of his paper was to demonstrate which of the products of the island it was safe to recommend for extended cultivation in new lands and which were already in danger of being over-produced and he had arrived at the conclusion that coffee, cacao and rubber-yielding trees were the products to plant, while tea, cinnamon, cardamoms, cinchona bark, pepper, and even palms (for their oil) did not offer encouragement to extended cultivation. Statistics relating to the total production and consumption were given in an appendix.

The chief practical object I had in view was to show City men and British capitalists generally, in what direction the cultivation of tropical products had been, and might be, overdone. I had no duff-

culty, of course, in demonstrating that cinnamon, cardamoms, and cinchona bark were products which it would be foolish to grow for the European or American markets in any new countries, in view of what Ceylon could do at prices scarcely, if at all, remunerative in some cases. Then there were the oil and fibres of the coconut palm, for which prices were very low at present, though, of course, there would always be a "home consumption" in new countries for palm products. And there was pepper, which I had put down as a product to be cultivated for a good demand beyond supply; but fortunately I ran round "the Lane" before the time of my meeting and learned from Mr. Figgis how much the case was the other way,—that pepper was coming in almost superabundant quantity from the Far East and the price falling to 2d a lb.! So I put pepper also among products in danger of being over-done. Lastly and chiefly, of course, I dwelt on tea and showed that in view of what India, Ceylon, China, Japan and Java had done, were doing, and could do,—it would be foolish and shortsighted of English capitalists to encourage tea growing in other countries, unless for a local market. But, on the other hand, I showed that there was encouragement to extend coffee cultivation, that of cacao and especially rubber-yielding trees. In respect of coffee, I hoped that Ceylon would begin soon to do something more with "Liberian," and I referred to what Ceylon planters were doing in other countries, notably in Perak, North Borneo, East Africa, Jamaica, Grenada, Brazil and the reports on Easter Peru. I also expressed the hope that cacao culture would be extended, especially in Uva after the railway opened; while a great deal more ought to be done by us in respect of "Rubber"—"a tough subject" as Mr. D. Morris humorously called it in the after-discussion, when strongly recommending attention to the trees.

The paper which occupied three-quarters of an hour in reading seemed to give general satisfaction, and I ought to have said that so large a gathering has seldom if ever taken place in the Chamber's Hall—an ante-room having to be thrown in for the accommodation of visitors. This was due not only to the considerable number of City men interested in the subject of the paper, but also to the many Ceylon friends who put in an appearance. Among the members of Council present, Mr. Thompson (of the well-known Broking Firm) made a very complimentary speech in opening the meeting and moving Sir A. N. Birch to the chair; Mr. James Chambers of Fenchurch Street, who, being Chairman at a lecture I gave at Croydon, was the means of getting me to prepare the paper for the Chamber of Commerce; Mr. Robert Wales, and two or three other old merchants whose names I did not catch. Mr. D. Morris of Kew and Mr. Epps, a member of the firm that was the first to introduce Ceylon cocoa, sat at one end of the table, and Sir Arthur Gordon, Mr. Grinlinton, Sir G. Campbell, and Mr. Whittall, near the other. Right in front were Mr. O. S. Hadden, Peter Moir, S. Butler, G. S. Duff, Alex. Brooke, P. C. Oswald, W. M. Leake, C. Shand, Alex. Ross, John Anderson, G. G. Anderson, Norman Grieve, Tom Gray, T. J. Lawrence, W. H. Anderson, Geo. White, John Hamilton, H. Walker, also Messrs. R. S. Atkinson, W. Scorey, J. H. Barber, W. Sproule, Hon. C. Seneviratne, T. J. E. Johnson, John Hughes, Arnold White (and Mrs. White), A. C. Folkard, Wm. Digby, J. M. Morgan, J. Offord, John Haddon, Lloyd, Massingham, and many more whom I now forget; I hope your regular London correspondent will be able to give a résumé of the interesting discussion which followed. This was opened by Mr. GRINLINTON.

ton, who, referring specially to tea, gave an account of what had been done to win over the Americans to the Ceylon product and of the prospects of the Exhibition. Mr. D. MORRIS followed in a very practical interesting address: he criticised and took exception to some of the statements in reference to West Indian, as compared with Ceylon cocoa; he thought more might have been said about the coconut as a promising product for planters, and also in reference to Ceylon that Europeans might go in for rice cultivation; but Ceylon planters really required to pass a self-denying ordinance to prevent their going too far with any one product in the future as in the past. Mr. Morris referred in an appreciative and interesting way to his own experience of the planters in Ceylon, as also to his stay in the West Indies; and he specially returned thanks for the references to the good work of "Kew" and said how ready they were always to aid the tropical planter. By the way he mentioned "arnotto" as a minor product of which a certain supply had always come from the West Indies, but now the market for this was destroyed, through Ceylon operations (chiefly I fancy through the work and invention in better curing of poor Borron). Mr. Morris paid a high compliment to our *Tropical Agriculturist*, Planting Manuals and other works as helping to develop enterprise not only in Ceylon, but all round the world. Sir ARTHUR GORDON came next with a vote of thanks to the lecturer expressed in gratifying terms: he further pleaded that the planters of Ceylon should carefully consider the danger once more of having "all their eggs in one basket" and the advantage rather of at least "two strings to their bow"—that cultivation should be diversified even on tea plantations, and he also advocated further attention in the lowcountry to coconut cultivation.—Mr. Epps came next with information about the different kinds "Cacao" and "Coca" which was of much interest: he referred to my quotation from Berthelink's book which he had before him and did not think his *couleur de rose* statements as to the great age to which cacao trees would live and bear profitably, could be depended on. He said that Trinidad and Ceylon cocoa were each good in their way and were used for different purposes and he deprecated the criticism of the mode of preparing the former. Mr. BARBER came next with reasons, from his own experience, why planters were not likely to do much in extending rice or palm culture. (Mr. Barber tells me that Mr. Seneviratne was ready to speak in support of his views had time permitted.)*

Our meeting beginning at 2 p.m. was to be followed by one in the Ceylon Association Room at 3-30 to have

* Mr. Barber writes to me:—"I ventured 28 years ago at Kegalla with 200 acres. But the enemies,—porcupines, white ants, and beetles, gave me such a lively time, that I never went into coconuts again after I got rid of that property. Besides coconuts, to pay, should be cultivated in the approved native style, that is allotments of small acreage should be given out to small cultivators to plant what they like while looking after the place for you gratis for a number of years, at the end of which time you pay them a rupee per tree, or even less. After such an exhaustive lecture as yours, I was surprised anything could be said over and above offering you the meed of praise in terms of unqualified thankfulness. For if it came to rice and coconuts or even the commodities commonly vended by the poor inhabitants of Kotta, who hawked them from door to door, I am sure you could tackle the subject with truthfulness and interest. Mr. Seneviratne told my nephew he was glad I corrected Morris. If he had an opportunity he would have said as much."

Mr. Grintinton's report; so the time being up, several had to leave. A vote of thanks to Sir A. N. BIRCH was moved by a member of Council whose name I did not catch, and duly seconded.

It was a very pleasant meeting and talking with old friends after the meeting, among the rest Mr. Morris, and Mr. E. S. Duff, who looks wonderfully fresh and hearty, notwithstanding his white whiskers. He hopes to visit Ceylon this winter and he enjoyed my remark that I must get the "senior editor" to visit once more England and America, and travel with him.

I omitted in the proper place to say that in acknowledging the vote of thanks and the kind things said, I referred to Mr. Morris's remarks about "rice," and pointed out that my paper was confined to products exported to Mincing Lane, or I could have noticed other palms (such as areca, kitul, palmira, &c.) and minor products; that for this reason of a home market even the coconut produce was not in high request, and that in respect of his own and Mr. Epps' criticism I could only quote what Dr. Trimen said in his last report in reference to the frequent inquiries he had from the West Indies about the superiority of Ceylon "cocoa," that he could only put it down to the better and more careful preparation. By the way had there been time, Mr. A. Ross would have also offered a correction from his own knowledge, of some remarks offered about the West Indian mode of preparation.

CONSTITUENTS OF TEA AND CACAO.

P. S.—The accompanying letter from Mr. Hughes will be read with interest and no doubt will be carefully considered by you:—

Analytical Laboratory, 79, Mark Lane,

London, E.C., July 26th.

I send you the following figures which will prove that cacao as a crop is not so exhausting as tea. 1,000 lb. weight of Trinidad cacao seed, as removed from the pods, contains as follows:—

Nitrogen	23 $\frac{3}{4}$ lb.
Potash	10 $\frac{1}{2}$ "
Phosphoric acid	8 $\frac{1}{2}$ "
Lime	2 $\frac{1}{4}$ "
whereas 1,000 lb. of made tea contains	
Nitrogen	45 lb.
Potash	22 "
Phosphoric acid	8 "
Lime	2 $\frac{1}{4}$ "

From the above results it will be seen that cacao as a crop cannot be considered as exhausting as tea.

The principal mineral constituent in both cacao and tea is *potash*, hence the importance of the soils selected being as rich as possible in this particular mineral constituent is very obvious. I should imagine that cacao soils should be generally a rich loam capable, under favourable climatic conditions, of producing crops of good quality for a great number of years with but little manure.

I believe it will be found that tea will require manuring, if estates are to keep up their yield of made tea of good quality; but that cacao if planted in naturally good and suitable soil will continue in a flourishing condition and yield well for many years without any manure whatever.

I should like to have made the above remarks at yesterday's meeting when your interesting paper was read at the Chamber of Commerce, but there was no time; so I have thought it well to put them in writing.—Yours very sincerely,
JOHN HUGHES.

CULTIVATION OF COCOA IN CUBA.

The French Consul at Santiago, in a report to his Government, says that the cultivation of cocoa is closely connected in Cuba with that of coffee, and is carried on at the same time and on the same properties. In fact every coffee planter, if the nature of the soil permits him to do so, sows

between the rows of young plants cocoa berries, which will produce trees that will continue to bear crops when the coffee plants have ceased to produce. It is impossible to discover the precise date at which the cultivation of cocoa was introduced into the island, but as this plant was cultivated in Mexico and in New Grenada before the Conquest, it cannot long have remained unknown to the Spanish colonists in Cuba, who kept up constant communication with the possession of Spain on the American continent. It was not, however, until about 1830 that several planters made an effort to introduce cocoa into Cuba, and at this time plantations of a certain importance were formed at Figueroa and elsewhere. Unfortunately for many years the cultivation of the cocoa remained unprofitable, in consequence of the small demand and the low selling price. The price slowly rose however, the number of cocoa plantations increased, and by 1860 every coffee plantation in Cuba combined the cultivation of the cocoa, if the nature of the soil permitted it. The cocoa-tree lives longer than the coffee plant, but it is much slower in producing. It takes in fact five or six years before the newly planted cocoa begins to bear fruit; it is at its full bearing at the end of the year, and begins to decline at the end of fifteen, but without ceasing to bear; on some old estates there exist cocoa-trees of upwards of fifty years of age, which still produce. The cocoa is usually planted in the spring, by preference directly after rain; an interval of from ten to twelve feet is usually left between the plants. The kinds which are most used are those of *Caracas*, *Guayaquil*, and the *Creole* variety, which latter is said to come from Trinidad. The Caracas and Guayaquil varieties bear the finest fruit, but they are not so hardy, and do not bear so well in Cuba as the Creole variety. The Caracas, however, fetches the best prices. The crop is gathered from the month of October to the month of August. During this period the trees are covered with blossom, and little bunches of ripe and half-ripe pods. The crop may therefore be gathered day by day, but as it is difficult to obtain the labourers necessary for the work, the owners generally prefer to harvest monthly or fortnightly. To prevent fraud as much as possible, the labourers are paid by piece-work, and receive wages calculated upon the number of measures of fruit which they pick. There is no harm done by leaving the pods on the bushes for one, two, or even four weeks, except in the spring, when, if possible, they should be picked at shorter intervals. The cultivation of cocoa, like that of coffee, is undertaken with the aid of colonists, who are hired by the day. The day is calculated from 6 a.m. to 4 p.m., for which time a man is paid about 2s. 6d. if food is not included, and about sixpence less if it is. The colonists are farmers to whom the proprietor of a cocoa plantation has let a piece of ground, with the right to cultivate fruit or vegetables, but with the obligation of yielding the planter half or two-thirds of the cocoa gathered on the same piece of ground. Cocoa is weeded in the same way as coffee, but as the cocoa-tree sometimes grows to a height of fifteen or twenty feet, it is not so much troubled by coarse weeds as the coffee is. The spread of weeds is, moreover, checked in cocoa plantations by the continual fall of leaves, which soon cover the ground. The cocoa is pruned in the same way as the coffee-tree, with a view to prevent each plant growing too high and mingling its branches with those of its neighbours. It is necessary always to take great care to remove the suckers which are continually being thrown up from the foot of the tree. As soon as the pods are ripe, they are pricked and broken on the spot. The berries, which are full of a curious syrup, are measured and piled up in heaps, covered with leaves. These heaps are allowed to ferment for two or three days, the fermentation being regulated every morning by a rearrangement of the heaps. This process softens the bitterness of the berry, destroys the gum which surrounds it, and enables the cocoa to dry more rapidly. Moreover, the colour of the berry depends on the proper conduct of the fermentation. Cocoa, like coffee, is then spread for two or three days on a sort of platform made of cemented stones, called a *secadero*,

there to be exposed to the sun and dried. As soon as the cocoa is thoroughly dry, it is rubbed, cleaned of all the detritus which has gathered upon it, placed into bags, each containing about 105 lb. of cocoa, and sent on the backs of mules to the market at Santiago. The conditions of transport are the same as in the case of coffee. Each mule carries two sacks, or 210 lb. of cocoa, and travels ten leagues every day. Each group of twenty mules is led by a *capataz* and two watchmen, and travels by night to avoid the heat. The conductor, or *arriero*, is responsible for the arrival of the convoy, which is paid at the rate of fivepence a mile, and per mule, or from five shillings to five shillings and sixpence per day's journey of twelve leagues. Part of the cocoa grown in Cuba is consumed in the island, but the berries of the finest quality are sent abroad, and generally to Barcelona. France imports no Cuban cocoa whatever. The Cuban cocoa is, says the French Consul, exceedingly fine in quality, and it appears strange that there is no market for it in France. The price of cocoa in Cuba varies from twelve to sixteen piastres the quintal, and sometimes, but rarely, rises to eighteen piastres. The Caracas berries are sold one piastre dearer than the other varieties. The Consul says it would be difficult to foretell the future of cocoa cultivation in Cuba. Many cocoa plantations were destroyed during the civil war, but cocoa has suffered on the whole much less than coffee from the effects. In many of the largest plantations in the island the cultivation of coffee is now entirely abandoned, and the cocoa plants only are depended upon for a return. Many planters moreover prefer cocoa growing, because for small capitalists it is an industry which requires much less outlay than coffee.—*Journal of the Society of Arts.*

COTTON SEED MEAL AND HULLS AS FOOD FOR LIVE STOCK.

BY ALEXANDER P. HULL

The history of cotton seed for the past twenty years has been one unceasing wonder. No other product of our soil has ever developed into such a many-sided material before, and every few months a new use for some product of cotton seed is discovered. Perhaps petroleum is the only substance which has ever paralleled cotton seed in the history of its manufacture into useful articles of commerce. Twenty-five years ago cotton seed, except as a fertilizer for cotton-growing lands, was considered almost totally worthless, and the annual product, about 3,500,000 tons, was allowed to a great extent to go to absolute waste, generally being left to rot around the gin houses. Then oil began to be manufactured from them, and to-day more than 1,000,000 tons is used by the oil mills, and the Southern farmers receive about \$13,000,000 for the seed they dispose of to the mills. Now, this oil is one of the every day articles of commerce, entering into a thousand products which need in their composition a pure vegetable fat. Next, a new wonder came to pass. It was discovered that after thirty-five gallons of oil had been extracted from a ton of seed, the remainder was a better fertilizer than the cotton seed before. The hulls were used as fuel and were burned under the oil mill boiler, and it was found that the ashes of the hulls were of the highest value as potash, and the refuse of the whole could be manufactured into the purest soap stock to carry to the toilet perfumes of the best manufacturers. So much in preface for cotton seed in general. One would naturally suppose that its uses had all been discovered, and investigation has reached a final limit. But no, a new use was discovered that may turn the South into as fine a cattle country as the far famed prairies of the West. This last discovery was that the hard brown hulls mixed with cotton seed meal made the finest possible feed for cattle, and at the same time, the cheapest. For the past year or two this mixture of meal and hulls has been used to a considerable extent in the

immediate vicinity of the oil mills, but our people seem to have paid very little attention to it. Numerous experiments have been made, of which I quote a few. Professor W. E. Stone, of the Tennessee Experiment Station, writes as follows:—

Our investigations seems to justify the following conclusions:

1. The practice of feeding cotton seed hulls and meal as an exclusive diet is well established and increasing in the vicinity of the centers of the cotton seed oil industry. All the information available indicates that the practice is economical and profitable.

2. It seems in no way harmful to the health of the animal nor to the healthfulness of the products (beef and milk) resulting.

3. The diet seems adapted both to the production of beef and mutton as well as milk.

4. The average ration should consist of 52-35 pounds of hulls and 5-8 pounds of meal daily.

5. The hulls are a cheap and effective substitute for hay.

6. The manure produced by this system of feeding is an important factor in considering its profitability.

Mr. A. H. Rice, of Tennessee, gives the following result of feeding cattle on cotton seed meal and hulls:

As requested, I give you below the results I obtained in feeding three (3) year old steers, on this feed in comparison with other food under similar circumstances for sixty days.

Two Jersey steers, twin calves, precisely alike, except that one was thirty pounds heavier than his mate; hence the heavier showing more thrift. I will number him one (1) and the other twin two (2). These two steers were weighed on the evening of January 26, 1889, without food or water, thus making a fair test.

No. 1 weighed	759 pounds.
No. 2 weighed	720 pounds.
No. 3 weighed	740 pounds.

No. one (1) was fed on cotton seed and corn mixed, and sometimes corn meal instead of corn—all he would eat. No. two (2) was fed on cotton seed hulls and meal—all he would eat. No. three (3) was fed on shelled corn—all he would eat. All were watered alike, and had what wheat straw they wanted.

On March 27, 1889, I weighed them without food or water, with the following result.

No. 1 weighed 780 pounds..	a gain of 30 pounds
No. 2 weighed 825 pounds..	a gain of 108 pounds.
No. 3 weighed 715 pounds..	a loss of 25 pounds.

I am sure No. 2 was the inferior steer, and showed less thrift. I did not keep a correct account of the cost of the above experiment, but am positive the feed of No. 2 did not cost any more than that of Nos. 1 and 3.

My only regret is that I did not know the value of this food sooner. I am so well satisfied with this experiment that I have put all my fattening cattle on cotton seed hulls and meal, and another year I shall feed extensively, and cotton seed hulls and meal shall be my feed.

Mr. W. M. Towers, of Rome, Georgia, gives the following result of his experiments in feeding cattle on meal and hulls:

We bought, April 14, 1888, a very handsome ox, but thin and gaunt, who had been ridden by a boy about fifteen miles. Weighed April 13, 1888, 1,325 pounds; April 17, 1,360 pounds; April 19, 1,460 pounds; April 20, 1,465 pounds; April 27, 1,450 pounds; April 30, 1,510 pounds; May 1, 1,500 pounds; May 5, 1,560 pounds; May 7, 1,590 pounds; May 10, 1,595 pounds; May 15, 1,615 pounds; May 17, 1,625 pounds; May 24, 1,650 pounds.

The writer has the results of numerous other experiments before him, all proving that cotton seed meal and hulls make a magnificent stock food. It is needless to give more, as the above suffice to show the value of them to our farming classes. Cotton seed meal and hulls mixed in the proportions given above cost about \$1.50 per month for feed per head for cattle, and therefore is about the cheapest feed which can be procured. The result of this

discovery will be to render fine pastures unnecessary for raising cattle, and every farmer can have the fattest beef whether he has pastures or not. The benefit of this will be great in many sections of the South, and it is greatly to be hoped that our farmers will soon be supplying our city markets with beef instead of our having to import it from the far West. I was informed by a gentleman living in Fulton county, Georgia, a few days ago, that for the past two years he had been buying all the poor cattle he could find in the county, feeding them for a couple of months on cotton seed hulls and meal, and then selling them for the fattest beef at a profit of from fifty to seventy-five per cent. over and above the cost of the cattle and the feed together. It would seem that nature has given the South every advantage possible for supplying her people with every necessity of life, and they should not be slow to utilize this great discovery, which will save the necessity of owning "pastures on a thousand hills" for grazing their flocks and herds.—*Dirie—Oil Paint and Drug Reporter.*

KAINIT.

The use of kainit as a fertilizer is almost universal in Germany, and has extended largely into other parts of Europe, the coffee plantations of Brazil and Ceylon [? E. C. O.] and is now commanding the earnest attention of farmers in the United States. Its use as a fertiliser has increased to an enormous extent from a comparatively small beginning, and has attained an importance equal to that which Peruvian guano reached years ago. Thousands of tons have been exported annually, and the quantity is increasing rapidly.

An analysis of kainit shows that it contains sulphate of potash, 24.80 per cent; sulphate of magnesia, 14.30 per cent; chloride of magnesia, 12.62 per cent; chloride of sodium (common salt), 32.00 per cent; moisture, 14.36 per cent; insoluble matter, 1.92 per cent; total 100.00. Guaranteed 23 per cent sulphate of potash.

It is chiefly valuable for the potash contained in it, which is an ingredient of every cultivated plant, and without which none can grow. Potash is necessary for the formation of starch in the leaves, stalks, &c., for without it the plant cannot assimilate the materials needed for its growth, nor show any increase in weight. It is a well-known fact that all plants absorb potash from the soil—some to a greater extent than others; as, for instance, hay, clover, corn, tobacco, hops, potatoes, and roots absorb largely, whilst grain crops exhaust it less. Commercial fertilisers, such as superphosphates, bone, fish, and slaughter-house refuse, &c., contain little or no potash. The well-known Peruvian guano yields but a small percentage. It will be interesting in this connection to note carefully the following remarks made by Dr. Franz Giersberg, a celebrated professor of agriculture in Germany, in lectures delivered by him by order of the German Government, before agricultural societies throughout the empire. After alluding to the nourishment of plants in general, and the most beneficial materials needed for such nourishments, he says: "There is no doubt about the fact that the application of bone-dust, as well as other phosphates to the soil, may and will produce large yields for several years, the soil, by reason of such application (mainly in connection with nitrogen), being stimulated to more vigorous action. The soil yields largely of the nourishment which, in addition to phosphates, all plants necessarily require, but, as no compensation is allowed for the absorption of the former, we, but too often experience the result that where a soil receives only phosphate manuring for a length of time it will become eventually entirely unproductive. Phosphate manuring only restores to the soil the one, omitting the other nourishments needed for the active thriving of the plants, and as a consequence, the soil and crops deteriorate in quantity and quality. One-sided manuring will not produce satisfactory results for any length of time, but we may justly claim and expect for the use of potash salt (kainit)

a larger and better fertility, since potash is absorbed by most plants in double, even four times, larger quantities than phosphates.

Thus it will be seen that potash is absolutely essential as a plant food, but the expense attending the artificial production of it, by boiling sea water, would be too enormous to entitle it to serious consideration. Nature, in anticipation of its exhaustion from our lands, has made ample provision for a plentiful supply, by a process of evaporation of sea water on an enormous scale in Germany, and, as a result we have kainit, containing the nourishment needed, at a trifling expense. There are furnished abundant indications that in the older States the available supply of potash has become greatly reduced, and must be replenished, or the crops will fail. We are now passing through the same costly and bitter experience that the farmers on the other side of the Atlantic had to encounter, and we must seek the same remedy that they applied so successfully—kainit.

The value of sulphate of magnesia contained in kainit, as a plant food and an aid in the development of seed, has not received the careful consideration that its great importance deserves. Experiments made from time to time, prove that the quantity of magnesia in seed greatly exceeds the quantity in straw, and furnishes ample evidence that it is indispensable to the perfect formation of seed. For instance, we find in the ashes of grains of wheat 12 per cent. of magnesia, in conjunction with 30 per cent. potash; in rape seed 12 per cent. magnesia, and 23 per cent. potash, and in all other seeds a similar proportion.

It is a great aid in the proper and thorough diffusing of potash through the soil, bringing it within reach of the roots, and at the same time effecting a prompt and complete action of the ammonia of manures used.

Chloride of sodium (common salt) is useful in rendering other materials available.

In order to allow the chlorine combinations contained in kainit, which may be injurious to some plants, to lose its effect on such plants, it is recommended that kainit be applied as long as possible before the seed is sown, as, for instance, in the late fall for the following season's crop, thereby securing the benefit of all rain or snow falling in the meantime, and a consequent deep and thorough incorporation of the kainit ingredients through the soil—those which may be injurious sinking deeply and beyond the reach of the roots of plants to be grown, those which are beneficial and nourishing being within a ready access of all the roots, and not confined in single places. This method of applying kainit will prove itself highly advantageous, whether alone or in combination with stable manure, farm refuse, phosphates, or other fertilising materials, and should be strictly adhered to, unless positively impracticable.

It is recommended by many who have made a study of the effects of kainit that it be mixed with an equal part of lime, as experiments have proven such application to have been highly advantageous, not only in the yield, but in surely overcoming the possible danger of any injury to the plants by the chlorine combinations above mentioned.

It may be safely laid down as a rule that calcareous (lime), light and sandy soils, and those composed largely of decayed vegetable matter, are deficient in potash, while clayey and loamy soils are more plentifully supplied. In either of these cases, however, the supply necessary for perfect growth may not only be reduced, but almost exhausted by constant cropping.

Regarding the quantity of kainit necessary for one acre, and the proportion to be used in combination with phosphates, etc., it is recommended that from 200 lb. to 400 lb. be used alone, spread broadcast, as long before crop is planted as possible; and at the proper time one-half of that quantity of phosphates, if latter is needed. To all farmers, whether acquainted or not with kainit manuring, we will say that it will be better to use little and often than a greater quantity at long intervals.

For the benefit of those who may not be acquainted with kainit its use and results, we will add the following notes regarding the results on different crops after its application.

For oats, wheat, corn, and the like, an application of 300 lb. kainit in the fall and the proportionate quantity of phosphate in the spring, per acre, showed, by many experiments, vastly improved yields over former manurings, both in the strength and stand of the straw and size of the grain.

Kainit, whose fitness as a prominent fertilising mineral manure is world-wide known, will also act when applied to the soil in preventing, to a large extent, the disastrous effects of the disease known under the name of "rust."

This disease is visible to the naked eye by red spots on the leaves of plants, especially on wheat. By scientific researches made in Germany and other countries, it has been established that these spots are fungi, parts of which detach themselves in time, are carried away by wind, and will spread the disease when settling down.

Stable manure will, of course, contain more or less of these injurious matters. For this reason, stable manure ought to be little used in wheat-growing, and preference given to artificial manures. These contain a combination of acids that will weaken or even expel the rust.

This is so well known in Germany that no farmer in that country would think of raising wheat crops of stable manure, but they all apply artificial manures, among which the potash salts are foremost.

For beans, peas, hops, beets, potatoes, and the like, the quantity generally recommended is about 300 lb. and the result will be pleasing and profitable. The yield, particularly of beets, was striking, and where the manufacture of beet-sugar is carried on the introduction of kainit to the beet farms will be productive of immense good, as its use will amply repay its cost. These farms may require more than the above quantity of kainit, as this crop exhausts potash from the soil in large quantities and very quickly.

For garden vegetables it seems, in many cases, that a larger quantity of kainit is recommended than the average needed for other growths, and the results excellent. In this connection we would like to call attention to the profit (peculiarly) in its use on asparagus. Repeated experiments show that a rather large quantity was needed, and the asparagus grown were very large and of excellent quality. For cucumbers it is also particularly beneficial.

For fruit trees and berry vines, spread the kainit around the trees, &c. and rake the ground evenly and level. If too late to do it, or not convenient, the next best plan is to dig six to ten holes, say one to two feet deep, about one and a-half to three feet from the trees or vines, and pour the kainit in these holes.—*Kuhlow.*

BAHAMAS FIBRE.

BY GOVERNOR SIR W. ROBINSON, K.C.M.G.

It is just sixteen years since I landed in Nassau, New Providence, as Governor of the Bahamas, and I can say, without in any way depreciating the larger and more active sphere and the far greater picturesqueness and beauty of Trinidad, that I spent nearly six of the most enjoyable years of the best part of my life in those well-known Coral Islands. When I arrived I found matters in a very bad way. There had been several unfortunate seasons. Oranges and pine-apples had failed or were at the mercy of American "Rings" and were a glut in the market. The crops of salt were, owing to high duties in the United States so many white elephants, and of course at a discount. Even the sponge fisheries appeared to be giving out. The result was severe commercial depression and what was more serious and a tangible fact which I venture to think few Administrators have ever had to grapple with: the salaries of the public officers were upwards of six weeks in arrear.

It was not an encouraging state of affairs for a young Governor to try his prentice hand upon. I have no intention, however, of referring to this crisis at any length excepting as a matter of introduction to this article; but I may say that before I left the Bahamas the surplus of Revenue over Expenditure exceeded £6,000 per annum, the total Revenue being

about £45,000. [Less than the revenue of Colombo.—Ed. T.A.]

It was natural in the absence of any great staple such as sugar, cocoa, or coffee, that a Governor should give a fillip to other industries. Three months after I arrived I therefore started, or resuscitated, a Board of Agriculture and appointed "Local" Boards in all the out-islands which have continued in existence ever since. Amongst other subsidiary industries hundreds of thousands of Coconuts were planted, great attention was directed to Fibre-giving plants, Fruit of all kinds, and Tomatoes of the most succulent nature were cultivated with great success. The export of this last-named product increased from some 12 crates in 1876 to upwards of 12,000 in 1880.

In the prospectus of the first Agricultural Show which was held in 1876 I find that the following prizes were offered for fibres:—

Fibre of American "Pita"	\$5 00
Indigenous Aloe and other varieties of Agave	5 00
Mahi (<i>is this any relation to "Cousin Mahoe?"</i>)	5 00
Palmetto	5 00
Pine-apple leaf	5 00

In the absence of a Botanical Garden or of an ubiquitous superintendent like Mr. J. H. Hart, F.L.S., we were sadly ignorant in those climes of the value and even nomenclature of these fibres. What we did know was that the so-called "Pita" plant grew everywhere; that it was regarded as a perfect pest; that its fibre was nevertheless long, white and strong, and that the fibre of the pine-apple leaf was of the most beautiful silk-like appearance and texture.

Samples of all these fibres were sent home by me to the Director of Kew Gardens and the value of the "Pita," the commonest plant of all, was then said to be 3½ cents a pound. It is this "Pita" plant which has recently come into such great notoriety, and as "there is a tide in the affairs of man which, taken at its flood, leads on to fortune," so it has occurred that its value has recently risen to 11 or 12 cents per pound and that it has been the good fortune of Sir Ambrose Shea to take this tide at its flood. Sir Ambrose is a thoroughly practical long-headed man of business, and with his numerous commercial friends and large business connexion has so astutely handled this Fibre question as to make it a matter of certainty that, if prices are maintained at anything like the present figure, there is a great future in store for the charming Bahamas and their sturdy and industrious inhabitants. He estimates that in a few years' time the value of the annual exports from the Bahamas will advance from \$60,000 to several MILLIONS.

There is one matter, however, of great interest from a personal point of view in connexion with this subject which has not been satisfactorily settled by the "competent botanists" and the experts who have had to deal with it: that is—To whom are the Bahamas indebted for this magnificent, economic plant? Is it indigenous, or was it introduced by human agency? Upon this point I have arrived at a conclusion which I am prepared to maintain against Dr. Perrine, Dr. Schott, Dr. Parry, Mr. Priestoe, and even Mr. Hart.

I think it is a matter of considerable importance when it is probable that the Revenue of those Islands may be doubled or trebled within the next few years, and hundreds of persons may be enriched by this valuable plant. On the principle of *palman qui meruit, ferat*, I claim that it was introduced into the Bahamas by the late Honorable C. Nesbitt, who was for many years Colonial Secretary. This claim I am now in a position to prove conclusively. Mr. Nesbitt entered the service in 1831, and died in 1876 at the age of 73 or 74. He administered the Government of St. Vincent from 1860 to 1862. Forty-five years ago, viz., in 1845, he procured from Sisal, Yucatan, a few hundred plants of this Agave and had them set out at his country residence three miles from Nassau. He was not a "competent Botanist" but he was, like the writer fond of Agriculture and convinced of the value of subsidiary

industries. Mr. Nesbitt was much struck with the vigour of this plant when grown in New Providence. He knew it as the "Pitaya plant," and as a superior variety brought to Sisal from the vicinity of the Pitaya mountains near Popaya in South America. In 1851 Mr. Nesbitt reduced a great number of the leaves of this plant into Fibre and placed samples of them in the Nassau Museum. At the same time he sent specimens of them to England and received very favourable replies in regard to their value from London. Unfortunately the merchants at Nassau at that time, like merchants and planters elsewhere, were making plenty of money in other ways and they looked with no friendly eye on an industry which might possibly disturb the cheap labour which was at hand for sponging, as well as for wrecking purposes which was then an "industry" in those waters. The prevalent idea at that time was that the wealth of the colony was in the water and not in the land. Mr. Nesbitt however believed thoroughly in agriculture and also in the necessity of having two strings to one's bow. He was convinced that this fibre would ultimately be of great value, and he took every opportunity of distributing plants all over the Bahamas and Turks Islands, fully believing that in the "sweet by and bye" necessity would move some fortunate Governor to cause the Legislature to accept his importation as the saviour of the Bahamas.

That fortunate Governor is Sir Ambrose Shea, and the happy Legislature is that which has been in existence for the last three years. It is quite refreshing to me, knowing these Islands and the inhabitants as well as I do, to hear of the great prosperity in store for them and of the general buoyancy of the spirits of the population. The progress made in the development of the culture of this fibre is really marvellous. A few years ago not a dollar of Foreign Capital was invested in the Bahamas; now dollars are actually "going a begging." Capitalists in Great Britain, Canada and the United States within the last three years have bought thousands of acres of land which hitherto were thought worthless. Amongst the principal capitalists may be mentioned Messrs. Monroe & Co. of Newfoundland who own 20,000 acres. Mr. Keith, of Edinburgh, 2,000 acres, and three London Companies with 20,000 acres each. In addition to these wealthy capitalists and others too numerous to mention, there are several local companies notably the "Bahamas Hemp" and the "Inagua Hemp Company." I tried a year ago to get some shares in the former Company but was unsuccessful. About 200,000 acres of land have already been disposed of. I reduced the price of Crown land to 5s. an acre in 1875—today it is selling at £1 and upwards—and applications for large tracts are pouring into the Surveyor-General's Office from all sides. It is very difficult for any one living in Trinidad with its luxuriant and comparatively gigantic vegetation to realize what the Bahamas are like. There is no hill over 120 feet in height in any one of the Islands, there is no forest, and indeed excepting in Eleuthera and one or two of the Islands chiefly devoted to pineapples there is apparently little or no soil. Four-fifths of the surface of the Bahamas are coral rock with pockets of soil varying from a few inches to a few feet in depth. When uncultivated the land is covered with low bush. Several small shipments of fibre have already been made, and in a newspaper dated November 12, I saw that 16 bales of hand-picked fibre had been shipped from Harbour Island to New York. It is not likely that any large export will take place before the expiration of eighteen months or two years, but after that an enormous increase may be looked for.

In conclusion, therefore, I claim for Mr. Nesbitt the distinction of having introduced the "true" Pita or Heneguen into the Bahamas from Yucatan, and I would ask whether the Florida plant has, or has not been identified with the *Latif* of Karwinski and Perrine.

The plant which Perrine introduced into *South Florida* "35 or 40 years ago" is said to be a variety of the *Agave Rigida* called Yaxci. The plant or variety which Mr. Nesbitt introduced into Bahamas 45 years ago and afterwards into Turks Island and St. Vincent is, I believe, what has been named the *Latli*. Supposing such to be the case, what becomes of the "undisputed proof" that the Bahamas are indebted to Florida for the fibre-giving plant which is confidently expected to be in the future a permanent source of wealth to the inhabitants of those Islands, and where is the proof that Trinidad has even yet obtained the "right article"?

USE OF PINEAPPLES.

This is a unique and peculiar fruit, and it will pay one who is not conversant with its peculiarities to refer to a reference book where many interesting things will be learned. Just now there are quantities of them in the market, and at very reasonable prices.

Like other good things, its delicacy depends upon its preparation, whether for dessert or canning. The ordinary cook will invariably handle one in such a manner as to waste the very best part of it, and it is seldom served to the best advantage of either fruit or eater.

The outside should be cut off with a very sharp knife, deep enough to remove the traces of the green line which runs around the "eyes," but cut no deeper than this, for close to these "eyes" lies the best of the pine, as the delicious juice decreases in very perceptible quantities toward the stem, or core. After stripping the outside a smaller, sharp-pointed knife should be used to remove the eyes. Then instead of slicing it across the core and having the round slices that are usually seen, cut very thin pieces up to the core, working around it in cutting. The result is a dish of dainty slices, which can be easily cut once or twice with the spoon, if necessary, when it is eaten.

A liberal quantity of sugar should be put with it as soon as it is cut, and then it should be allowed to stand from three to six hours before serving, as it then becomes more tender and thoroughly seasoned.

Besides its palatable qualities as a dessert, it is said to possess wonderful digestive properties. The Medical Record states that its "proteid-digesting power is quite remarkable in its intensity; three ounces of the juice will dissolve ten or fifteen grains of dried albumen in four hours. A well known meat powder is said to be prepared with the help of pineapple juice."

There is no other fruit that passes through the canning process so little injured by the heating as this. They may be prepared the same as for dessert, allowing about a pint of granulated sugar to one good-sized pineapple, and after it has stood long enough for the sugar to melt allow it to come to a scalding heat and then fill the cans; or, if preferred, it may be put in the cans first and then heat.

When preserved in this manner it looks so much more tempting than the "hashed" and "minced" product of the canning factories, where it is always chopped—core and all!

If the juice is extracted, scalded and put up in sealed bottles, it will keep and may be used for ices and flavoring purposes.

If some pineapple is left over from dessert it may be utilized by making it into pudding. Add nearly as much sugar as there is fruit and cream together, say for half a pine, a tablespoonful of butter and four eggs, and add half a cup of milk. Line a deep dish with puff paste and bake in a "slow" oven.

Pineapple marmalade is a delicious preparation of the fruit. Nice ripe ones should be selected and pared, then grated and an equal weight of sugar added. Set it over a moderate fire and boil about an hour, skimming it thoroughly before removing it from the fire.

If one can secure good cream and has a quick freezer, first class ice cream may be made in little time and without much trouble. To flavor with pineapple, take a ripe one and cut it into very thin, small pieces and cover it with a pound of sugar, then set

it on ice for three hours at least. Beat one quart of cream, add a small pinch of salt, and then drain off the syrup and beat into the cream. When the cream is partly frozen some of the slices may be added if desired.—Country Gent'eman.—*Florida Dispatch*.

THE CEYLON TEA TRADE.—The consumption of Ceylon teas in South Australia has largely increased during the last year or two. One of the largest and most regular importers of these teas, the Import Company of Australasia, informs us that this is on account of the superior flavour and greater strength of Ceylon teas, combined with lower cost, that the demand has increased to such an extent. They have been advertising in our columns a special line of blended Ceylon teas and sugar with great success as regards sales, and if the multitude of testimonials sent them by purchasers of these goods is any criterion of excellence, it only remains for them to increase advertising expenditure in order to get the major part of the tea trade of South Australia. The Import Company, whose only address is 131, Grenfell-street, City, have large premises, a portion of which, together with a specially selected staff, is devoted to packing and forwarding of Ceylon teas. —*Adelaide Observer*, Aug. 13.

TROPICAL AGRICULTURIST
MONTHLY.

Vol. XII.]

COLOMBO, OCTOBER 1ST, 1892.

[No. 4.

THE NECESSITY OF NEW MARKETS FOR
CEYLON TEA, AND RENEWED
EFFORTS AND LIBERALITY.

If any doubt existed in the mind of any person interested, it must surely be by this time removed. The average price of Ceylon teas in the London market have gone down, steadily in half-a-dozen years, from over 1s 3d per lb to 8d, or nearly 50 per cent. Let our readers look at the figures in Messrs. Gow, Wilson & Stanton's tea circular, and they will find that with full knowledge of a large reduction in the estimate of crop from Ceylon, buyers gave prices for our teas which can only be described as wretched. One description of pekoe souchong, which sold in July 1890 at an average of 8½d, realized only 5½d; another souchong went down in the two years from 8½d to 4½d; one description of pekoe shows a fall from 9½d to 7d, and another from 9d to 5½d. Our average in the sales of 28th-29th July was only 81 per lb. against Assam 1s 2½d, Darjiling 9½d, and the Doonars 91. It is small comfort to us that teas from Cachar and Sylhet sold for only an average of 7d, Kangra Valley 7½d, Nilgiris 7d, and Travancore 6½d. The generally low prices are in the face of comparatively smaller supplies from India, Ceylon and Java. The consolation offered us, and we certainly need it, is that

“Ceylon medium Teas are now offering such extraordinary value that they cannot fail to open up more new outlets in quarters where China Tea has now the monopoly. A demand would thus be created which in turn should beneficially affect prices.”

This was the process in the case of Ceylon coffee. But surely it is better actively to cultivate new markets than to wait until prices, which, however advantageous they may be to the consumer, are to the producer unremunerative to the verge of ruinous, have done the work. Can 4½d for pekoe and 4d for pekoe souchong possibly pay? We trow not. We have talked

of over-production and a repetition of the cinchona crisis, and lo! both are upon us. What are tea planters to do? Certainly not to fold their hands and close their purses. Energetic effort and liberal giving are the remedies. Those who have contributed and can afford further help will not, we feel sure, be wanting. But what is specially needed is that the non-contributors to Tea or Chicago Funds should be personally canvassed and shamed into giving, if they will not from any higher motive perform the duty they owe themselves and the community. But it is now evident that the funds required (£20,000, of which £5,000 may be expected back) cannot be obtained by the working of the voluntary principle added to the Government vote of £50,000. As we showed, the latter is not the equivalent of much more than £3,000 at the present rate of exchange. It ought to be doubled. That would give £5,000 even if the rupee goes down by the time the World's Fair is opened, to one shilling, which it is likely to do. Then, if the proposal of the Planters' Association is accepted by Government, that the difference between present and reduced railway rates on tea (the reduction being taken for granted) should go for a certain period to the Chicago Fund, there is likely to be a sum of £100,000 realized by deferring the reduction for eight months. We think most planters will be prepared to extend the period to one year. £150,000 thus obtained would, at 1s to the rupee, yield £7,500. We thus have £12,500 made up, and surely the Tea Fund and contributions from individuals, estates and firms interested can be relied on for the balance £150,000 or £7,500 at 1s to the rupee. If not, money could be borrowed on the security of the buildings, plant &c., which Mr. Grinlinton expects to give back £5,000, from his minimum requirement of £20,000. The objection still remains that all the tea produced is not carried by railway; but we cannot meet every difficulty, and we suppose an export duty would be deemed objectionable, except in circumstances of great urgency.—Our readers will see, in the interesting report of the meeting with Mr. Grinlinton at the rooms of the Ceylon Association in London, that our Commissioner was deemed to have been only too successful in pressing the claims of Ceylon at Chicago, and that the Governor had personally remonstrated with Mr. Grinlinton for the mode in which he was committing the colony to large expenditure. But the Commissioner—and who can blame him—replies, “Better not put in an appearance at all at the World's Fair, than to be represented in a manner unworthy of the colony

and calculated to injure rather than help the cause sought to be benefited." The main object is, of course, to promote the consumption of our tea. But other products and manufactures as well as minerals, cabinet woods, jewelry precious stones and curios will be shown, Mr. Grinlinton making a speciality of Ceylon lace and other women's work. There is strong justification, therefore, for liberal grants from general revenue, as well as for private liberality, and we trust the latter will be developed in the face of the crisis which has overtaken our chief product, after a fashion which will render us proud of the colony instead of feeling shame for the undeserved credit given it.

REPORT ON SAMPLE OF SOUTH CAROLINA TEA (MANUFACTURED BY H. COTTAM, LATE OF CEYLON), BY A NEW YORK TEA EXPORT AND TASTER.

Extract from letter addressed to Dr. Shepard, of Pinchurst, Summerville, South Carolina.

"Good original stock and is *unusually well prepared*. "Has all the characteristics of an Indian or Ceylon tea and is particularly brisk or toasty in firing, which is desirable. I am inclined to believe that it is better tea than Tetlow's."

Dr. Shepard has planted from 10 to 12 acres of Assam hybrid tea now three years old a photograph of which points to the healthy condition of the tea plants. The negro children receive free education on Pinchurst estate and are ready to pluck tea when called with a lady *Kanyani* in charge of them.

There is an abandoned tea garden planted ten years ago by Mr. Jackson of India who died in South Carolina. I believe the tea is strong and healthy.

REPORT ON FOUR SAMPLES OF TEA GROWN AND MANUFACTURED IN SOUTH CAROLINA. (FROM H. COTTAM.)

Extract from letter addressed by Mr. Reid, tea taster and importer of North 13th St., By Arch St., Philadelphia, to Dr. Charles U. Shepard, of Pinchurst, Summerville, South Carolina:—

"Your teas I find have an individual distinct and pronounced character different to the teas of any other country, consequently I describe their character flavor as 'South Carolina flavor.' They have merit and intrinsic value of a high order.

"I have very much pleasure, my dear sir, in offering you my sincere congratulations on the complete success of your enterprise in having produced from the soil of the United States of America the commercial article 'tea leaf' equal in style and value and on a par with the fine teas of the world."

REPORT.

Report and valuation of four samples of Pinchurst teas as prepared by Mr. Henry Cottam, June 1892:—

No. 1.—Rather hands me, rather small even blackish leaf with pekoe flower *strictly extra fine tea*, strong full and rich South Carolina pekoe flavor.

No. 2.—Blackish even leaf with a few pekoe tips. Fine to extra fine strong brisk South Carolina pekoe souching flavor.

No. 3.—Rather bold, evenish curled black leaf, middling tea, rather strong, fresh-burnt South Carolina souching flavor.

No. 4.—Bold black uneven curly leaf middling tea, rather strong, fresh-burnt South Carolina souching flavor.

NOMINAL VALUATION.

No. 1	..	60 to 70 cents per lb.
No. 2	..	50 to 60 " "
No. 3	..	35 to 40 " "
No. 4	..	30 to 35 " "

The soil and climate within the yellow pine belt of South Carolina is suited to the growth of tea a sister plant to the *Camellia Japonica*.

H. COTTAM.

[We can only repeat, that, while there is no doubt that good tea can be grown and manufactured in the Southern States of America, the cost of labour will prevent the carrying on of the enterprise on a commercial scale.—Ed. T.A.]

TEA AS AN EXHAUSTING CROP: PROPOSED EXPERIMENTS.

The Secretary of the Planters' Association sends us the following letter:—

Copy.

John Hughes, Agricultural Analyst, Analytical Laboratory, 79 Mark Lane, London, E.C., July 15 h, 1892.

Alexander Philip, Esq., Kandy.

Dear Sir,—At the present time when the permanence of the Tea Industry is of such great importance to the interests of Ceylon it appears very desirable to ascertain how far tea, as at present produced, is an exhausting crop, and secondly how its requirements in the way of plant food can be most economically supplied.

How can this be done in a practical manner is naturally asked. I would suggest the following:—

When a patch of tea is just fit for plucking, let some 3 or 4 trees representing sizes varying from the largest to the smallest be selected, and these trees completely stripped of all their leaves.

The leaves in separate heaps to be then weighed and carefully dried in the sun, but protected from rain should showers come: when fully dried and again weighed to be packed in quantities of 2 lb. in bottles carefully sealed, labelled 1, 2, 3, 4 according to size of tree, age of garden and other particulars and packed in boxes to be forwarded to my address.

In order to make practical calculations it would be necessary to weigh the fresh leaves taken from each tree and again to weigh the sun-dried leaves, when fully dried after two or three days exposure (as hay is made in this country).

With a knowledge of the number of trees on the acre and the weights of fresh and dried leaves respectively we should have the necessary details for extending the chemical results obtained by the subsequent analysis of the dried leaves in London.

I make this suggestion for the consideration of your Committee, and doubt not if the proposal should be considered formally, that two or three members would be willing to undertake the collection of the samples in the manner suggested. My own idea is that we should find that of the large quantity of Nitrogen present in the leaves a very large proportion must be originally absorbed from the air rather than from the soil. With the previous analyses of Ceylon soils which I have, by me, I could then ascertain how far this opinion was borne out by previous results, and some useful information be obtained not only in reference to the amount of Nitrogen, but also of the proportions of the mineral constituents, which must of course be absorbed from the soil alone such as Potash, Phosphoric Acid, Lime and Magnesia.—Awaiting your reply, believe me, yours faithfully, (Sgd.) JOHN HUGHES.

TEA CULTIVATION,

TO THE EDITOR OF THE "MADRAS TIMES"

Sir,—Referring to Mr. C. N. Grey's letter on this subject, I am glad to see that the matter of my letter to you is attracting the attention of planter, and Mr. Grey's detailed estimate of the cost of working Tea which he has published is valuable.

Except in the arrangement of his calculations his figures do not greatly differ from mine.

Mr. Grey in his Estimate gives details of superintendence, and cultivation expenses amounting to 11,700

or R39 per acre.

Then he details many other charges including manuring, charcoal fuel, assessment which varies according to tenure, (some of these charges should be included under crop expenses) 3,420

or R11.6 per acre.

And then takes the expenses incurred in plucking, manufacture and carriage to coast of the crop taken at 640 lb. per acre 23,320

or R77.12 per acre.

83,440

and calls all these cultivation expenses. There is an error of R700 in his additions as published, he makes this R39,140.

Mr. Grey's calculations for crop expenses are exceedingly moderate, and only amount to 2d. per lb. on the tea made delivered in Madras. But his charges for superintendence are a great deal more than I calculated on, as they amount, including Writer, Teamster and Maistries, to R6,000 per year or R20 per acre; the allowance for this is generally taken at R15 per acre. Manuring, which he includes, is an extra charge, which should be covered by increased yield.

In my calculations I have allowed a cost of 5d per lb. of made Tea, for all expenses connected with the crop, from field to delivery and sale in London.

If this was calculated out as an acreage charge on 640 lb. per acre on 300 acres, say 192,000 lb. of Tea at 5d per lb. and taking the anna and penny as equal, the crop charges amount to 360,000, or R20 per acre—which is a great deal more than Mr. Grey put it at.

In addition to this I make the cultivation charges:

	R
Superintendence at R15 per acre =	4,500
Weeding 12	3,600
Pruning 78	2,250
Roads &c. 1	300
Tools, upkeep, build- ings, &c. med. and Tappal and contin- gencies 4-8	1,350
Total...	12,000

No doubt these figures can only be taken as an average, and must be corrected according to the circumstances of the district; but they about tally with Ceylon Estimates where labour is more expensive. Mr. Grey would, I think find it safer to make all his calculations on the amount of Tea made—and not on the acreage cultivated. If he can pay all expenses on crop, from field to Board Ship, for 2d per lb. little fault should be found with his extra charge for superintendence; the Ceylon average cost for this is 15 cents, say 2½d. The additional cost of superintendence and estate cultivation varies according to the amount of crop per acre—and the profit to the owner depends on a just medium between quantity and quality. SENEX.

—Madras Times, Aug. 15.

MINING IN CEYLON.

INTERVIEW WITH MR. JOHN FERGUSON, OF COLOMBO.

Although there is, probably, no part of the Queen's Dominions about which more has been written, and about which the average intelligent stay-at-home book-reading Briton has read more than Ceylon; yet, on the other hand, the vast resources of the "utmost Indian isle" are but imperfectly understood and appreciated by most except those whose immediate business relations necessarily place them in possession of more than a merely superficial knowledge of the colony. In commercial geography it certainly, and most deservedly, occupies an important position, as it should, in view of its large and yearly increasing exports of such staple commodities as tea, cocoa, coffee, cinchona bark, cinnamon, coconut oil, and plumbago to the United Kingdom and other countries. But as a modern mining country it is not yet recognised, as we reckon mining countries here at home. Yet it has vast treasures of mineral wealth, although, perhaps, these do not cover any great range in the matter of variety. It is one of those colonies whose mineral resources have yet to be exploited in the light of modern mining and financial practice, and the first step towards any such consummation is to let it become more generally known what the character and extent of its mineral deposits are.

With a view to placing our readers in possession of some reliable data on this point, we have taken

advantage of the presence in this country on a short visit of Mr. John Ferguson, of Colombo, a gentleman who is regarded by general consent to be a leading authority on all that pertains to the social and material concerns of Ceylon. Mr. Ferguson recently read a paper on "Ceylon: Its Attractions to Visitors and Settlers" before the Royal Colonial Institute, necessarily referring *en passant* to the gem digging and plumbago mining interests of the colony. But what we desired to obtain for the benefit of our readers was the most up-to-date and authentic information we could secure. On representing our wishes to Mr. Ferguson he very courteously consented to being interviewed, and called by appointment at *The Mining Journal* office for that purpose, having also, with much kindness, placed documents in our hands which enabled us to gather other useful information for present or future use.

JOHN FERGUSON, Esq., of Colombo, Ceylon.

Mr. John Ferguson, whose portrait we give—and we do not mind saying that it is an excellent likeness—is a Scotsman by birth, which goes at once to prove what an admirable colonising race our friends beyond the Tweed are. And more than a Scotsman—Mr. Ferguson is also a Highlander, which is a synonym for grit, and pluck, and energy, and staying power. He was born at far-off Tain in Easter Ross, in December, 1842, and was educated at the Royal Academy in that town, where he won the distinction of being gold medallist. He prepared for his press career—for he it said Mr. Ferguson is co-Editor of *The Ceylon Observer*, the chief newspaper in the colony—in Inverness and London, and left for Ceylon, which has been his home ever since, in October, 1881, to become Assistant-Editor of the important and well-known journal just mentioned, and at that time a bi-weekly. Two years afterwards he was enabled to allow his uncle, Mr. A. M. Ferguson, C.M.G., the proprietor and editor of the *Ceylon Observer*, to have his first holiday trip home after 26 years' residence in the island. Mr. John Ferguson extended the bi-weekly paper into a tri-weekly, and at a later period it became the daily newspaper which it is at present, while the overland mail edition for Europe, &c., became a weekly instead of a fortnightly publication. Mr. John Ferguson became partner and co-Editor with Mr. A. M. Ferguson in 1877.

Tropical agriculture being, necessarily, the subject most largely dealt with in the columns of the *Ceylon Observer*, Mr. John Ferguson, in 1881, when his uncle and partner was acting as Commissioner from Ceylon to the Melbourne Exhibition, started a monthly

periodical entirely devoted to the products grown in the tropics, including coffee, tea, cacao, fruit trees, sugar, rice, cinchona, tobacco, cinnamon, &c., &c., and calling it *The Tropical Agriculturist*. This publication, unique of its kind, is now circulated all over the world, and is, we believe, regularly filed in the Agricultural Department at Washington, by the different West Indian and Colonial and by some of the Australian, Central and South American Governments, and in all the Indian Agricultural Departments, besides circulating freely amongst the planters of India, the Straits Settlements, Java, Sumatra, Borneo, West Indies, Queensland, Florida, California—in short throughout the whole tropical-agricultural world.

Besides being an indefatigable worker in the field of journalism, Mr. John Ferguson has indulged in authorship in other directions. He is the author of a popular illustrated work on *Ceylon*, which has passed through three editions, a fourth being now in the press; and for many years he has been responsible for the compilation of the *Ceylon Handbook and Directory*, which is, perhaps, the most complete volume of agricultural statistics published for any colony. To this *Handbook* Mr. Ferguson specially contributes a "Review of Planting and Tropical Agriculture," including in its main features the subtropical world. He has also edited and aided in compiling a series of "Planting Manuals," and other works.

Mr. John Ferguson is Hon. Corresponding Secretary for the Royal Colonial and Imperial Institute in Ceylon, and in the former capacity read, as already mentioned, a paper on "Ceylon," before a crowded assembly in the Whitehall Rooms, in March last, when Lord Aberdeen occupied the chair, and a number of colonial authorities took part in the proceedings. Mr. Ferguson is also to read a paper on "Tropical Products" before the London Chamber of Commerce about the end of July.

It is interesting to add that Mr. A. M. Ferguson, C.M.G., is the oldest British editor in Asia, having been born in Wester Ross in 1816, arriving in Ceylon in 1837. After being in business, trying planting and Government service, he became co-editor of the *Observer* in 1846 with Dr. Elliott, purchased the paper from him in 1859, and was joined in 1861 by his nephew, who relieved him from office duties in 1879, though he has continued to take an active part in writing for the *Observer*. In 1882, in acknowledgment of his services as Commissioner for the Colony at the Melbourne Exhibition, Mr. A. M. Ferguson was made a C.M.G. He began the series of *Ceylon Handbook and Directory* in 1859, since 1863 continued by his colleague. He published his illustrated *Souvenirs of Ceylon* in 1864, and has since written many papers which have been published in pamphlet form. In colonists of the stamp of Messrs. A. M. and John Ferguson, we find those who, by ceaseless energy, abundance of mental resource, tact and tenacity of purpose, have contributed more than the conquering and destroying sword to make our colonies what they are, and our Empire as a whole the mighty fabric which dominates the world.

BEAUTIFUL CEYLON.

It goes without saying that Mr. John Ferguson is a great admirer of Ceylon. To him that land of "the hyacinth and the ruby," that "pearl drop on the brow of India" is a sort of materialised fairy vision of tropical beauty. As has been said by a visitor whose words formed the closing sentences of the paper read before the Colonial Institute, "The way there is in these days, as easy as rolling off a log; it is only the way back that is hard—hard, because as the low, palm fringed shores sink beneath the horizon, and the Peak of Adam corks itself afar in a mantle of majestic mystery, you feel and know that yonder flashing point of light in your wake keeps watch by the gateway of an Eden where you fain would have lingered, and marks the portal of a summer isle, where the brain-fagged workman may stand apart from the strain and stress of life, and the lotos-eater may take his fill."

Nor is Mr. Ferguson alone in his eulogy of the glories of Ceylon. Its praises were sung even by ancient Greeks and Romans, and it was the "Scribdib" of Arab and Persian geographers. The Portuguese historians of four centuries ago wrote of it as "the island of spices." In later years its almost every aspect has been written upon over and over again, and it has even been seized as a picturesque setting for romantic fiction. Of its natural beauty, all who have visited it speak in rapturous terms. "It is one botanic garden," says Mr. Ferguson, and his statement needs no confirmation. It would seem to be

"An Eden of the Eastern wave"

alike for the tourist, the health-hunter, the sportsman, the naturalist, the antiquarian, the Orientalist, or the sociologist; in short, as Mr. Ferguson puts it, it is "a paradise . . . for the intelligent traveller" of every sort or condition. The time may come when it will be all this and something more to the British mining engineering and the British mining investor.

THE MINERAL RESOURCES OF CEYLON.

With the multifarious natural resources of Ceylon we cannot, obviously, deal on this occasion, but it will serve a useful purpose to investigate its mineral products and its mining possibilities. To do this we fall back on Mr. Ferguson's encyclopædic knowledge of the island.

"What, Mr. Ferguson," asked our Editor as soon as our visitor was comfortably seated in the editorial sanctum at Finch-lane with his memoranda before him, ready for the imminent extraction process, "broadly speaking, are the mineral resources of Ceylon?"

"The only commercial mineral of importance," replied Mr. Ferguson, "is graphite or plumbago."

"And it is extensively worked, I think?"

"Yes."

"The industry is progressive, is it not?"

"Yes. Of late years there has been considerable development, as you will see from the figures I hand you (given farther on). Geologically speaking, a large portion of the island is composed of ancient sedimentary beds. Our mountain ranges are primary metamorphic rock. The principal rock is gneiss, with beds of laterite and dolomite. There is plenty of iron ore in Ceylon, some of it yielding up to 90 per cent., but there is little or no trace of coal. The only professional mineralogist we have ever had inspecting (Gyaxi), about 40 years ago, left a report, in which he stated there was plenty of anthracite coal, but since then we have never been able to find it. It is now thought he made a mistake."

"Has anything been done in the way of iron mining?"

"Nothing European. Cheap iron coming from England has long ago cut native iron out completely. The Sinhalese had been accustomed for hundreds of years to work their own iron, and they have shown wonderful skill in making tools and muskets from imitation. Traces of their smelting furnaces are to be found all over the country. Manganese and platinum are found in small quantities, as well as abundant traces of gold in many of our rivers, but too fine to pay as far as we have yet discovered. The Sinhalese must have worked gold in ancient times, from their names for a number of places we know. Of recent years we have had experts who declared that the rocks showed very promising quartz, but we have never yet made a thoroughly systematic investigation."

"What is your own view. Do you think it would pay to prospect?"

"If I had the money to spare personally I should scarcely feel justified in taking the risk. It is a thing only a syndicate could manage."

"Do you attach any importance to Ceylon as a place for prospecting for gold?"

"Seeing the success of the gold mining in certain parts of Southern India, I do think there is encouragement to extend operations, after careful investigation, farther south, and to the Ceylon hill ranges. I

think there is room for a powerful syndicate to do the thing thoroughly, with a good chance of getting a paying return. Our gold yielding quartz has never been properly and fully tested.—Referring to other features, nitre is found in caves. Salt forms naturally on the coast and is also manufactured. We have very slight evidences of volcanic action, and only get the outside of earthquake shocks from Java. Ceylon is too far south to be affected by the cyclones from the Bay of Bengal, and too far east for the hurricanes of Mozambique. Gems are abundant in the island."

GEM DIGGING AND PLUMBAGO MINING IN CEYLON.

"You consider the industry and trade in precious stones second in importance to that in plumbago, do you not?"

"Oh, yes, certainly."

"How are the present gem-digging enterprises carried on? How are they capitalised? By local or by English capital?"

"Europeans are only just beginning to attempt to work gems; it has hitherto been a purely native industry."

"It is worked, too, in a primitive fashion?"

"Yes, very primitive."

"Now, as to the gems?"

"A few years ago, attention drawn to the gems in Ceylon led to the formation of syndicates to exploit for gems and plumbago, and these sent out men of high repute in the mineralogical, if not in the mining, world, one of whom at least (Mr. Barrington Brown) gave a very favourable report; but the depression in the financial world (the Barings' crisis) prevented the intended action. One company which set to work rather hurriedly was not very successful in gems; but the other sent out a practical engineer, who found that the employment of European machinery would save time and labour in working the plumbago pits. Both companies took up a number of native pits and leased them, and also land supposed to contain plumbago."

"Are there any open works?"

"Plumbago is occasionally found near the surface, but in some cases the native miners have gone down some 300 feet. As a

"As to the facilities offered by the Crown, I take it that there is nothing to keep mining back?"

"No; nothing at all. But there is generally keen competition among the Sinhalese for plumbago land."

"What officials control the mining?"

"There is no special mining officer. It is generally under the control of the district revenue officials. Since 1880 the development of the plumbago trade has been enormous; the exports having doubled in ten years. But the gems have been worked by the natives for 2000 years, and are still worked very much in the same primitive fashion."

"Could they be worked according to modern principles?"

"We feel out there that the application in well-selected spots of machinery, such as is used for diamond mining in South Africa, should lead to a profitable industry for European capitalists."

"Do the gems run into great variety?"

"The valuable ones are limited. Gygax has stated that the Ceylon sapphires are among the finest in the world. The rubies are the most valuable after those of Siam, and are found in the beds of rivers, or in dolomite and clay ironstone debris. Cat's-eye, or *Chrysoberyl*, are found sometimes of fine quality, with an olive tint behind the ray. One piece, found 18 months ago, was valued at about £1500. As many as 20,000 natives (men, women and children) are chiefly dependent on these gem diggings."

"Is it remunerative to them?"

"There must at least be £20,000 worth of precious stones got every year, on the average, to support these natives. It cannot be less than that. Then there are moonstones, a species of *Adularia*; an inferior diamond, zircon; another stone called Alexandrite, hard and useful, of a green colour by day and red by night. The Oriental topaz, too, is much prized by the natives. It is a yellow variety of sapphire. A variety of spinel, of a fine green colour, is known as the Oriental emerald. A purple variety is the amethyst; a yellow variety; the garnet is known amongst the Orientals as the hyacinth.—A trade had been carried on between China and Ceylon so far back A.D. 400. The Chinese got precious stones and gave, in exchange, porcelain and

A GEM-DIGGER'S HUT IN CEYLON.
(From a sketch by John Dent Young, Esq., Ceylon.)

rule, the best mineral is found in depth. There is a great deal of plumbago land in the hands of the Crown still not taken up."

copper. Ceylon was always noted in early times for its gems, Marco Polo, in the 13th century, reported that the grandest ruby in the world was

that owned by the Emperor of Ceylon. It was a span long, thick as a man's arm, without a flaw, and of a brilliant colour. Experts now believe this must have been an amethyst. Chinese history reports that in the 14th century an official was sent to purchase an enormous carbuncle, and it was used as a ball for the Emperor's cap. It was shown at night, which got it the name of the Red Palace Illuminator. Some of the most valuable of the stones in the Island are in the Kandy Buddhist Temple. They are held by the priests, and, perhaps, the only time of late years they were fully on view was on the occasion of the visit of the Prince of Wales. It is believed by experts that as fine stones can be dug out as any the natives have yet obtained.

"How deep have the native miners gone?"

"The greater part is mere surface work. But on some parts of the hills they have gone down 40 and 50 feet."

"I take it that all an English syndicate would have to do to proceed to work would be to secure a license?"

"There has been a change of law inaugurated with regard to gem digging which has been a great deal complained of as unworkable, but it is almost certain to be modified, and the license on easy terms again introduced. Attempts have often been made by individuals to find the matrix of the gems, the last being by Sir Samuel Baker when on a hurried visit, but with no special results. In Colombo there are quantities of artificial stones, poor gems, which are sold by the native jewellers to visitors and passengers on steamers, but the greater part of the valuable gems are taken to India, though they are never entered in the Customs' returns. They are smuggled out of the colony by many ingenious devices. A ready market is found for them at the Courts of the Indian Rajahs."

"Then, as a matter of fact, the returns published do not give a true representation of the quantity of gems in the island?"

"No, the returns are very imperfect. Amongst the Sinhalese jewellers there are silversmiths and goldsmiths' castes. In the north of the Island—Jaffna—the Tamils do gold filigree work, which is minute and highly finished, like the Maltese, but it is generally worked with tortoise shell and pearls. The Sinhalese of the low country have got into the Portuguese way of working their jewellery. The lapidaries cut their precious stones after a very primitive fashion, and sometimes rather spoil valuable gems."

"What about mica, Mr. Ferguson?"

"Of late years an industry has been started in exporting mica sheets. Kaolin, or pottery clay is found in some parts of the island, and it is on record that 600 years ago the Chinese got pottery clay from Ceylon."

FACTS AND FIGURES ABOUT CEYLON PLUMBAGO.

Before leaving the subject of mining in Ceylon, we find some interesting statements as to the position occupied by plumbago in the commerce of the island in a monograph by Mr. A. M. Ferguson read in 1885, and published in the *Journal* of the Ceylon branch of the Royal Asiatic Society. It is there mentioned that Thunberg, the Scandinavian naturalist, who wrote in 1777, was the first to notice plumbago as a product of Ceylon. In modern times, as our interview with Mr. John Ferguson demonstrates, the plumbago interest, even in its present position, is a considerable one for the island. It has, of course, its drawbacks, as all mining and other enterprises have, but the author of the paper on plumbago which we are now dealing with—probably the most elaborate and complete of the kind ever published on plumbago, and brimful of interesting facts and figures respecting that mineral generally—contends that, "with all its drawbacks, the plumbago enterprise is invaluable to the country not only for the revenue it yields, but for the generally remunerative employment it has given to many thousands of the population (from 20,000 to 40,000 men, women, and children, probably, including cart-

men and carpenters) especially since the period when the collapse of the once great coffee interest led to so much distress in the country."

Analysis of Ceylon vein graphites has given the following results:—

VARIETY	SPECIFIC GRAVITY.	VOLATILE MATTER per cent.	CARBON per cent.	ASH per cent.
Columnar ...	2.2671	0.158	99.792	0.070
Foliated ...	2.2664	0.108	99.679	0.213
Columnar ...	2.2546	0.900	98.817	0.283
Foliated ...	2.2484	0.001	99.284	0.115

The following figures represent the exports of plumbago during certain years:—

YEAR.	QUANTITY EXPORTED Cwts.	VALUE (NOMINAL). Rs.
1834	2,782	12,654
1840	23,221	58,330
1860	75,660	239,555
1870	85,248	345,622
1880	205,758	2,057,385
1891	400,268	4,002,680

These figures sufficiently indicate the progressive character of the Ceylon plumbago mining industry, even under present conditions. What it might become with the introduction of British capital and modern systems of pumping and mining is sufficiently evident to suggest that British enterprise might do worse than direct its attention to it, as well as to the gemfields and the quartz reefs in Ceylon.

There is much more that we might add here to what we have already said, but the exigencies of space compel us to desist. We hope, however to return to the subject of Mining in Ceylon on another occasion; and for the present we desire to acknowledge our indebtedness for an instructive interview and for much valuable information to Mr. John Ferguson, whose zeal and enthusiasm for the industrial welfare of Ceylon may, we hope, be permitted to continue unabated for many years to come.—*Mineral Journal*, June 25th.

LIBERIAN COFFEE.

The cultivation of this variety of coffee is apparently engaging the serious attention of planters, not only in Southern India, but throughout the East, and in the space of a few years "Liberian" is likely to become one of the best known qualities of coffee in the London market. Considerable extensions are reported to have been made in Java and in the Straits Settlements, and North Borneo planters are opening out estates with this product. In that part of the world, there has lately been some sharp correspondence between the advocates of Arabica and those of Liberian, and a gentleman writing from North Borneo in favour of the latter sums up the position as follows:—"The comparison between the two plants I should sum up somewhat as follows: Liberian is a strong, hardy, handsome plant, growing rapidly, and doing its planter credit from the first day it throws out new leaves. It blossoms at short intervals all the year round, bears heavily and with certainty, laughs at droughts, rain and leaf-disease, does most of its own weeding, and is a perfectly satisfactory plant in every way, costing infinitely less to upkeep, and bearing much more and sooner than C. Arabica. C. Arabica is a finicky pernicketty little plant, requiring constant care and attention, bears sparingly, is choked by weeds in 10 time if left to itself, and leaves the owner in constant fear that it is going to be snuffed out by *Hemilea vastatrix*, green bug, cottonias, or something." We must confess that though the writer is somewhat unfairly hard on Arabica, there is very much truth in his comparison, when it is remembered that he refers more especially to cultivation at a low elevation. We make this further extract from his letter which is of interest:—"With regard to Liberian Coffee taking seven or eight years to come to maturity, I must retaliate upon the writer the elegant words 'rubbish' and 'absurd' used by him towards Mr. Ridley, while as to its requiring more attention to weed and keep clean, one of the main points about Liberian (in North Borneo at all events) is that given anything like a fair start, it grows

rapidly, over-shadows the ground, fights most weeds for itself, and bears heavily with scarcely any care or attention."

Very much of what this North Borneo planter says is equally applicable to the cultivation of Liberian Coffee in Southern India, though when he talks of it coming into bearing sooner than Arabica he is undoubtedly wrong, so far as experience in this part of the world goes. The oldest estate in Southern India, we believe where Liberian Coffee has been systematically planted and cultivated is the Venture Estate, in North Travancore, and we are indebted to the courtesy of its proprietor Mr. Henry M. Knight, for these very interesting particulars:—"Venture is situated to the N. of the main road, through Travancore from Shencottah to the Tinnevely side to Trevandrum and Quilon. Elevation 500-800 feet, aspect general. Rainfall about 100 inches. The Liberian coffee was planted in 1882 and 1883 from seed, said to be selected from Ceylon. Five years from the latter date it gave a fair crop, but previous to this, tea had been planted through most of it, and in the 'Vacancies' for no more coffee was planted after 1883. A year later it again gave another fair crop, and since then it has always done well. This year it has beaten all previous results, however, and fifty per cent. over the estimate has already been shipped. New York is the chief market for Liberian coffee, but I sell now-a-days in London, where I have sold at 97s. 6 l. per cwt., but the average must be taken as being quite 10s. lower. There is some difficulty about the curing for it cannot easily be pulped like the Arabian coffee the pulp being much thicker and the berries more variable in size, but the manipulation is not nearly such 'touchy' work for the cherry may be heaped and dried when weather permits, without much fear of its going 'off' in the bean. In Wynaud this year about 300 acres, I believe, are being planted up with Liberian. In Travancore there are about 250 acres already planted, the greater part of which however, is not over 2 years old. Returns from Liberian cannot be looked for so soon as from the more delicate Arabian variety, but its power to withstand leaf-disease (*Hemiteia vastatrix*) and its consistent crops make it a very desirable cultivation; moreover the cost of cultivation need not be so expensive, weeds not having the same prejudicial effect as on the older kind, and pruning not being an absolute necessity." It will be noticed that even at so low an elevation as from 500 800 feet, it was four years, at the earliest before the trees gave any crop, and at an elevation of a little over 3,000 feet, we have been assured that it is six years before any return worth mentioning can be looked for. But this delay is far more than counterbalanced in all districts where *hemiteia vastatrix* has devastated with fatal effects acres of Arabica. Where this has not occurred, and there are still many districts in Southern India where in spite of leaf-disease, Arabica continues to flourish and to give handsome returns. Liberian is not likely to gain the same popularity as the Arabian variety, but in less favoured districts we feel assured that the planter has in Liberian coffee, a good friend which is likely to stand fast by him for many years to come.—*Madras Times*.

NOTES FROM THE SIEVAROYS.

(From our own Correspondent.)

YERCAUD, 5th Aug. 1892.

Rain last month was very short; I only registered 3.61 and for the year to date 20.12 inches; very much below the average, but more than 4 inches over what we had last year to the same date. It has, however, been well distributed and coffee everywhere is looking remarkably well; the berries have swelled nicely, and there is every promise of satisfactory crops, while the weather has been cloudy and showery, and very favourable for supplies and new planting. Wells are still very low, though there is no longer the difficulty about drinking water there was some time back still more rain is very much wanted; we had a good shower yesterday and there are heavy clouds nearly every day, which must, I think, result in rain soon. The weather at present is

almost perfect; last month my thermometer in the house only varied between 62° and 72°. I am sorry to say green bug has made its appearance up here and in some places rather badly, and I should be much obliged if my brother planters would give me their experience. I find (in Nietner's Insect Pests) the white bug; and the black bug; and the brown bug; but nowhere the green bug; has it ever been described? and if so, where? and what, if anything, is done for it? When a year or two ago it made its appearance on the Nilgiris, there was a howl from planters generally, but really—no one seems a penny the worse! There and upwards too it seems to attack the shade trees and specially guavas;—but does it do any harm to the coffee? Does it even attack it at all or to any appreciable extent? Is it advisable to cut down the shade trees affected? Might not this, perhaps, drive it on to the coffee? If the shade trees are left alone, will the green bug stick them or will it get on to the coffee? There is much the same sentiment as with black bug, with which we are all familiar and, of course, coffee under the "buggy" trees get covered with it. Does it do them any harm? There has been green bug now in some of our districts for years, and some of our planters must know a good deal about it; will they give us the benefit of their experience. Once more—

1. Does it hurt the coffee?
2. Is it advisable to cut down the shade trees affected?
3. Is there any cure which can be applied at reasonable cost?

—*Madras Times* Aug. 8.

[This planter is behind the literature of the time in regard to green bug, which was fully described some years ago by Mr. E. E. Green of Ceylon. In this colony it was and is considered a deadly enemy to coffee, generally completing the work of destruction commenced by leaf disease and white grub.—*Ed. T.A.*]

CEYLON TEA IN MELBOURNE.

The *Agrus* of 23th July says:—

The tea market has been quite today and only moderate sales are reported, comprising 50 packages Ceylon at 6d to 8d, a small parcel fine Ceylon at 1s 3d.

In its issue of the 27th *Argus* says:—

The tea market has been quite during the week. In consequence of the large quantity of duty-paid stocks which were cleared before the increase of the duty, prices obtainable in bond for tea on which the duty is payable at the higher rate show a slight fall. The principal business has been in Ceylons, of which 600 packages have been sold during the week at 6 1/2d to 8d. The Custom-house statement of receipts and deliveries of tea at the bonds for last week, together with the stocks in bond at the close of the week, is as follows:—

	Receipts		Deliveries.		Stocks on July 16.
	Into Bond.	For Home Consumption.	For Home Consumption.	For Export.	
	Lb.	Lb.	Lb.	Lb.	
China ..	—	252,277	130	—	34,495
India ..	—	41,304	134	—	23,631
Ceylon ..	83,012	120,095	455	—	12,207
Totals ..	83,012	413,616	719	—	70,433

During the 12 weeks ended 16th inst. duty was paid on 5,134,349 lb. tea. On the other hand, the exports under drawback amounted to 989,979 lb., leaving 4,244,370 lb. for net home consumption, and, after allowing for current consumption, the duty paid stocks in the hands of the trade have been augmented to the extent of about 1,750,000 lb.

CHINA TEA AND TEA TRADE.

AN AMERICAN CONSUL DENOUNCING GREEN TEA.

A Consular report, recently issued by the Washington Statistical Bureau, includes a comprehensive report on the history and present position of the China tea trade, by an American, whose impartial conclusions should interest all lovers of the cheering

beverage. The famous herb is referred to in the Chinese annals as far back as 2000 B.C., at which period it was cultivated and classified almost as completely as today.

An ancient legend says that its virtues were learned by accident, by a Chinese monarch, King Shen Nung. "The Divine Husbandman," who flourished forty centuries ago, and who, in boiling water over a fire made from tea branches on which the leaves still hung, allowed some of the latter to fall into the pot. During the reign of Shen-Nung-She, B.C. 2737 to 2796, he not only discovered the curative virtues of plants, but also first fashioned timber into ploughs, and taught the people the art of husbandry, and instituted the practice of holding markets for the exchange of commodities. Tea was highly esteemed in nearly every ancient Asiatic city near the sea, and was used as a royal gift from the Chinese monarchs and great merchants to the potentates of the East. At the time of Buddha, China possessed a large foreign commerce in tea throughout Eastern Asia, as well overland as by sea.* This commerce culminated during the dynasties of Huug-Fung and Tang-Chi, about A.D. 1600, and from that time there was a gradual decline to about twenty years ago. The decline since then has been very great, the trade today being scarcely one-quarter of what it was in 1870. In fact the industry is on the verge of bankruptcy; the demand from abroad yearly diminishes; the people themselves are taking to other beverages; while the taxation necessary to Government, which in the former years of prosperity was a mere trifle, now threatens an utter extinction of the tea trade of China.

China was far more liberal in her commercial policy when ruled by her own people than she was after the Manchu Conquest, A.D. 1641. After this, foreign trade seemed to drop out of existence, as it were, and foreign traders lost all status. This condition of affairs continued for nearly two centuries.

European influence, and especially the European steamship, has wrought a profound change in the China trade. In the early part of the eighties, the great cities were in the interior, and only a few communities on the sea-board, and these of no political importance. Today everything is just the opposite. Canton, Kowloon, Hong-Kong, Swatow, Amoy, Takow, Shanghai, and the Yangste river cities are drawing to themselves the trade and wealth of the empire, and the old inland cities are visibly falling into ruin. Peking, the present, and Nanking, the ancient capital, are scarcely half as large as they were a hundred years ago. They display all the symptoms of decay and death. In the seaports the population is comprised chiefly of "Young China," energetic, enterprising, and commercial, and offers a marked contrast to the conservative and literary communities of the interior. From the former will come the rulers and policies of the next century. Even today their power is so great as to be a stumbling-block to the Mandarins and a menace to the Imperial Government.

The tea-growers are in the hands of usurers, merchants, and exporters, who charge 10 per cent. per month on advances taking the land and growing crop as collateral security, with the condition of having the first chance of buying the crop at market rates—of course, the money-lenders bear the market as much as possible, in order to profit by the lowest rates.

Of late years, the Island of Formosa has become a tea-producing country, and appears to possess unlimited possibilities. Its crops increase in quality as well as quantity. Formosa tea is probably the best in the world, and Americans consume about 95 per cent of the total output.

Amoy teas are still on the downward path. In the year 1890 the output was 50,000 half-chests, and the average price \$13 per picul, or fivepence per pound. The following year (1891), it did not exceed

48,000 half-chests in quantity, or \$12.50 per picul. Amoy at one time was the greatest tea country in the world, and exported as high as 500,000 half-chests (10 times its present production). At one time the Amoy teas were excellent, and the tea districts correspondingly prosperous. By degrees its reputation fell, until it became known as the vilest and filthiest compound in the market. Today no tea drinker knowingly uses it.

In those days, Formosa did a business of 25,000 to 50,000 half-chests per annum, when Amoy was doing 100,000. Now the figures are exactly reversed. But the tea trade is passing more and more away from China. Thus, for example, in 1878, the export of tea from Ceylon was 25,000 lb.; in 1891, the export was about 61,000,000 lb. while the consumption of China tea in England fell from 125,000,000 lb. in 1879, to 61,000,000 lb. in 1889.

Tea culture is assuming large proportions outside of the Chinese boundaries. The Spanish authorities have tried to raise it in the Philippines; the Dutch in Sumatra, Java, and Borneo; the English in the Straits Settlements, and the French in Cochinchina.

The Consul concludes his report by a few words of advice of tea drinkers:—"When I left the United States I was considered a fair judge of tea. Now after having visited Ceylon, Formosa, and the Amoy district, I find I knew nothing of tea. We Americans don't know the first principles of making tea. The delicate leaf should never touch metal. It should be kept in paper, wood, glass, or porcelain. To make it, put a small quantity into a porcelain cup, fill the latter with boiling water, cover it up with a porcelain saucer, and let it stand for three minutes. Then, if you desire to be an epicure, drink only the upper layer of the golden liquid; throw the rest away, rinse the cup, and begin drawing *de novo*. Never use sugar any more than you would sweeten Chambertin or pour molasses into Mummy's extra dry. Do not use milk. It ruins the flavour of the tea, and the combination injures the stomach. The cloudiness produced by adding milk to tea arises from the action of the tannin upon the casein, and is, chemically speaking, pure leather.* Above all things, do not boil tea. The heat drives off the perfume, spoils the flavour, and extracts the tannin—the astringent principle. If the boiling be done in a tin or iron pot, the tannin attacks the metal and makes the liquid black. The fluid is simply diluted ink. Never let the tea stand, except in a tightly-closed porcelain pot. Standing changes it from a delicious, wholesome beverage into an ill-tasting and bitter liquor. Better make it in small quantities, and make it often. In summer when you want to cool off quickly, sip the tea boiling hot, with a slice of previously-peeled lemon, or nicer still, of orange without the rind, floating in it. In winter, especially when you have a cold and require a sudorific, add a wineglass full of arrack to it, and drink it down as hot as you can stand it. It will bring out a profuse perspiration, when punch or hot Scotch fails to thaw you out. Beware of green tea!† It is an abomination and a fraud. In the first place, it is unripe leaf, and bears the same relation to the real article that the green does to the ripe peach. The green tea of commerce derives its rare colour from being cured, or rather killed, in dirty copper pans, from being mixed with weeds and shrubs, from being stained with indigo and chrome-yellow, from being coloured with verdigris, grass juice, or chlorophyl. Every green dye known to commerce has been used to produce that much-admired, but death-dealing colour, excepting it may be Paris green. As soon as the use of that poisonous substance will give a profit of a cent a pound, no doubt it will be liberally used by the mercenary Mongolian merchant, and the much more mercenary cultured European tea trader. I will venture the statement that there is no fine tea in the United States. What goes to our country is the chief stuff used here by the coolies and jail inmates."—*Discovery*, July 16th.

* That is about twenty-four centuries ago! We have already expressed a desire for confirmation of a statement which gives tea an antiquity beyond all other accounts we have read.—*Ed. T.A.*

* An absurd exaggeration.—*Ed. T.A.*

† And let us add, "Beware of spoiling black tea with arrack."—*Ed. T.A.*

POSITION OF THE FOOCHOW TEA TRADE.

The *Foochow Daily Echo* of July 23rd states:— Following the information we published last week of two rich natives embarking in the tea trade tempted by hearing of others retiring from it on their profits, we learn this week that they have been greatly disappointed, growers being unwilling to pick at the very low price offering, the said price, they say, not being enough to pay for the laborers' food in picking, let alone other items of expense which fall on them. It would appear from this that the growers having been caught with their picked first crop and, no doubt, to a great extent with their second crop teas, decline to go on picking unless an advanced selling price is first agreed upon. They would, they say, be spending their time more profitably by working in the rice fields. It was understood that the teamen intended this season to combine together against the growers to bargain at the lowest possible figure, the ostensible reason being to place foreign buyers in a position to compete with India and Ceylon, and so save the trade. They succeeded. The growers with all their tea ready picked and ready for sale had to give in with such a formidable combination against them; and it is said the tea changed hands at unheard of low prices. The broad reason given for the combination, however, seems to have been forgotten. If foreigners have bought at 10 to 15 per cent lower tea price than last year it is doubtful whether the teas are laid down low enough to compete appreciably with the cheap coasting Indian and Ceylon produce; while if the teamen had given up half of their profit, say another 10 per cent (out of the 20 per cent made by them) the comparison with our rivals' laying down costs would have very favourable and at such costs the demand for Foochow Ocongou would have sprung up again. Now it would appear that we shall have to pass through another season before we shall be able to show our power of being able to lay our teas down at prices really low enough to compete with our rivals. We scarcely believe in the threat of the growers giving up picking altogether. They had become so accustomed to getting their own prices through a long series of years, while the competition amongst buyers lasted, that they feel aggrieved now a change has come about, and are apparently making a stand. Times will show whether they mean to abide by it. The news sounds something like a crisis upcountry, but it is the first we have heard of it, and we need be under no apprehension of insufficient supplies so long as the daily arrivals to this market continue on their present scale.

TEA CULTURE IN THE UNITED STATES.

There seems to be a revival of interest in an industry that attracted some attention about twenty-five years ago, says the *Jacksonville Times Union*. When Commissioner Le Duc was at the head of the department of agriculture it was his hobby that the growing and manufacture of tea should be made a great Southern industry. He started an experimental tea plantation in South Carolina, and for a year or two it received a good deal of notice from the press.

But the southern planters were then realizing big prices for the fleecy staple, and they did not look with favor on the idea of engaging in a competition with the Chinese tea growers. Before Le Duc's tea garden was fairly in shape for practical experimentation he was superseded by Mr. Watt, who had no faith in the experiment, which thus came to an end before it had actually begun.

But it seems that the South Carolina tea garden has survived official neglect and is still a source of supply of the fragrant beverage for the neighbourhood. Meanwhile the ideas of southern farmers in regard to the profits in cotton have undergone a radical change. They are anxiously to find other crops which can to some extent take the place of cotton, so as to reduce the evil of over-production and to afford a greater variety of products for home consumption.

At present the farmers of the south, directly or through the merchants, are sending all of the ready money they can get hold of to the northern and western States and to Europe and Asia for commodities which to a large extent would be provided at home but for the faulty economic system, which has become established under King Cotton's rule.

If it costs, as is stated, 25 cents a pound to pick tea leaves with negro labor, it is evident that it will not pay to grow tea for sale, except at retail prices near home. But it is highly probable that it will pay to grow tea for home use, just as it pays a farmer to produce milk, butter and eggs, although he may not have a market for these articles. It is by practicing such small economies that the farmers of the north have come to be so much better off than those of the south. It must be admitted, however, that the consumption of tea in the rural districts of the south is so small that the home production of it cannot be regarded as a very important economy.

One thing is certain, that the tea plant grows well in the Carolinas, Florida, and most of the other Southern States. It ought also to be true that American ingenuity can devise means of cheapening the manufacture of tea. With a tea plantation well established at Seemerville, there is an excellent field for experimentation, and it would seem that the subject ought to receive further attention from the department at Washington.—*Florida Agriculturist*, July 6th.

THE TRAVANCORE EXHIBITION.

(From our Own Correspondent.)

TREVANDRUM, 11th Aug.—The Travancore Agricultural Exhibition of 1892 was formally opened yesterday by His Highness the Maharajah in the presence of Mr. Hannington, the British Resident, and an immense concourse of visitors, both European and native. The whole was a grand success. The weather was most favourable. Punctually at 7 o'clock His Highness the Maharajah arrived at the building and was received by Colonel Brereton, the President of the Exhibition Committee, and was led to a seat on a raised platform at the entrance of the building, where were already assembled the Valia Kovil Tampuran, Dr. Noel Hodges, the Bishop of Travancore, the Dewan, Mr. Shungra Soobier, the Dewan designate, and many European and native officials. A Company of the Nair Brigade, with band and colours, was stationed near the entrance and saluted His Highness the Maharajah and the British Resident on their arrival. As soon as His Highness had taken his seat Mr. H. S. Ferguson, the Secretary, advanced and read the following Report of the Committee:—

It is now eight years since an exhibition was held in Trevandrum, which was the third of the kind that had taken place here, two having been held previously in 1867, when Sir Madava Row was Dewan. The effect of the two was little felt in 1884, and many difficulties were met with, and much prejudice, the result merely of ignorance, had to be overcome. The Committee, however, in its report, predicted that the Exhibition would do good, and further observed that, "whenever another is held, it will be found that its objects will be understood and its benefits acknowledged." Since 1884, a series of Exhibitions have been held in the different divisions, the credit of starting which is due to the present Dewan who, as Dewan Peishcar, first began them in the Cottayam Division. The Exhibition held here in 1884 and those held subsequently in the Divisions have rendered the work of the Committee for the present Exhibition comparatively light. The Rules drawn up in 1884, based on those in force in Madras, were found to work well and to need little or no modification, while the prize list was found to require only slight alteration. The ryots and others, having taken part in various minor Exhibitions, have been quite alive to the importance of this one in the capital, and many interesting exhibits have been sent from all parts of Travancore. The experience gained has

been of material service in enabling the Secretary to arrange the cataloguing of the exhibits in a practical way, and the general result will, it is hoped, be found to compare favourably with that of the Exhibition of 1884. At that time it was found necessary to pay the cost of the transport of the exhibits from the various taluqs to induce exhibitors to come forward. This is now unnecessary, for, though the prizes offered are not so large as those offered in 1884, there has been little or no falling off in the number of exhibitors, and the articles sent in for competition are even more numerous. In one point, however, not much improvement has been shown, that is in giving detailed descriptions of the exhibits. For the most part descriptions are wanting and the exhibits are left to speak for themselves. This is to be regretted, as it is very necessary that in manufactures the art of production should be stated, and in machinery the art of production, the purpose for which the machine is to be used, and the cost of so using it should be stated. In fact, the more information given the better. This, however, is a minor point, and it is hoped that many exhibitors will be present, and will be able to give orally the information which they have neglected to write. It is not necessary to call attention to any special portion of the Exhibition, for in all the sections there is a good display. Much ingenuity has been shown in the articles manufactured in imitation of foreign ones, and a considerable number have been sent in. Some exhibitors appear to have confused the purposes of the Exhibition with those of the museum, misled, probably, by the fact that the Secretary is the same in both cases, and have sent in animals which hardly come under the description of live stock; such, for example, as frogs and cockroaches, birds and other animals, whose only merit, I quote from the description, is that "being of different nationalities they yet live together in harmony." With regard to coffee, there is a good show of Liberian, which seems to be doing well and which will prove, it is hoped, more lasting than the Arabian variety. With regard to tea, the Committee would point out that the prophecy made in the Report of the Exhibition of 1884 with regard to what was then a rising industry has been amply fulfilled. The Committee then remarked while regretting that the tea industry was not better represented, that "there is no doubt, from the specimens received, that it has a great future before it in Travancore." An inspection of the exhibits now sent in in this class will show that that future is at hand, and that the tea industry has been successfully established in Travancore, and that Travancore tea now rivals, if it does not surpass, the teas of Assam and Ceylon. The committee has now to offer its thanks to the ladies and gentleman who have so kindly undertaken the task of judging. Several of them officiated at the last Exhibition in the same capacity, and a series of interesting Reports was drawn up. It would be well if on this occasion greater publicity were given to these Reports, for they would show the ryots and others where improvement is required and in what way it can be attained. The Committee begs to offer its hearty thanks to Your Highness for showing so much interest in the Exhibition, and for so kindly consenting to be present on this occasion. It now asks your Highness to declare the Exhibition open.

As soon as the Report was read Mr. F. Watts, Chief Secretary to Government, by command of His Highness, read the Maharajah's reply, which was as follows:—

Mr. Hannyngton, Gentlemen of the Committee, Ladies and Gentlemen,—It is always very gratifying to the ruler of a country to witness the progress made by the people in their arts and manufactures and in improving the productions of the earth—and there is, perhaps, no better means of watching this progress than by periodically bringing together the best of such in Exhibitions like the present. The officers of Government, entrusted with the duty of looking to the advancement of the country, have the opportunity of comparing the present state of cultivation and manufacture with the record of the

past, of noting defects and shortcomings and of applying the remedy. The farmer and the artisan see the superior growth and workmanship of their fellows, and, stimulated by the prizes they have carried off, enquire into the methods employed and strive to produce still better at the next Show, or to excel them in the market. Thus the means of improvement are demonstrated and a wholesome rivalry established which has a very beneficial effect on the country at large. We cannot hold a World's Fair, as London or Paris or Chicago can do, but we can, and ought, to do the best within our power and means. I would suggest as a further means of demonstration and instruction, that a series of popular lectures be delivered by competent men at the next Exposition, on the more prominent of the exhibits. Such lectures, delivered in the buildings to the assembled exhibitors and others, cannot fail to be of use in directing the progress we so much desire. I will also order the Committee's Report and lists, with whatever suggestions it may make, to be translated into the vernacular, printed and widely circulated. From the repeated Exhibitions held in Travancore since 1867, and more recently in the districts under the present administration, the people have so far come to understand their object and scope, that the picture-show stage, which my predecessor so felicitously referred to in his reply to the Committee's Address on the last occasion, may now be safely believed to have passed, and the real instruction stage entered upon, the fruition of which, will, I hope, be both speedy and abundant. So far as the Europeans residing in the country are concerned the special industries in which they are engaged bear clear evidence of marked improvement and an enlarged sphere of operations. The tea, coir-matting, tiles and cotton yarn appear to much advantage, and I trust will soon rival the productions of the most favoured countries if some of them already do not do so. And, for the first time, paper locally manufactured, cotton cloth woven in the European style, Liberian coffee and plumbago are numbered among the marketable productions of the country. Talc and iron will I hope soon follow as there is evidence that they exist in Travancore. A very gratifying feature is that my subjects have learned from the European to manufacture some of his wares—though on a smaller scale and more imperfectly. They have taken to weaving coir-matting and rugs, and I was very pleased to hear that the Dewan had lately received samples of khaki and cotton checks manufactured by a firm of Syrian Christians in Cottayam which is said to compare not unfavourably with the productions of the German Mission looms in Mangalore or the Bombay Mills. I could well wish that tea was grown in the low country so that the natives might take to the cultivation of the plant, which they are sure to do, if they could find a curing establishment to buy up their raw produce. The projected railway to Quilon will probably enable tea growers at low elevations to take the produce to some of the estates where machinery is established for manufacturing tea. This railway will give an impetus to production far beyond the offer of prizes at Exhibitions, and I sincerely trust my people will profit by the advantages when they are placed within their reach. The mining industry which the enterprising firm of Messrs. Parry and Co. have started is also one which my subjects may profit by, if they will learn from the European and combine among themselves to invest capital in it. The native Ceylonese have taken kindly to mining and I see no reason why the people of Travancore should not. And now, gentlemen of the Committee, and Ladies and Gentlemen who have so kindly undertaken to adjudge the prizes, it remains for me to thank you, and that I do most cordially for the willing sacrifice of your leisure to serve in the interests of the Exhibition, and more especially do I acknowledge the service of the President and Secretary, who have had, no doubt, to bear the burden of the work, which those who are acquainted with the details of organisation and execution will realise to have been neither light nor easy. I trust the exhibitors will

give attention to the remarks of the Committee, and at the next Show, appear with a better description of their exhibits and the method employed in producing them. With these remarks I declare the Exhibition open.

The reply being read, His Highness was conducted by the President and the Secretary round the building, and he expressed himself well pleased with the general arrangement and the exhibits, which he inspected very carefully and with great interest. The Brigade Band in the meanwhile had taken its station in the centre of the open quadrangle inside the buildings and played a choice selection of music, which greatly enlivened the proceedings. The immense concourse of people which had assembled from all parts of Travancore comprising of a large gathering of European ladies and gentlemen, native officials of the State and people of all nationalities including even groups of quaintly dressed Gingalese from distant Ceylon, presented a picturesque and striking scene. After His Highness left the building the judges proceeded to their duty of examining the exhibits and adjudicating the prizes. The exhibits were more numerous than those of former exhibitions and numbered about 10,000. About four thousand rupees were given away as prizes.

A few remarks on the more notable exhibits will probably interest the readers of the *Madras Mail* and I proceed to give them. The exhibits were arranged in four sections, A, comprising live stock, B, vegetable productions, C, dairy produce manufactures and miscellaneous produce, and D, machinery. The live stock were housed in fine ranges of sheds outside the main building. A thousand rupees were allotted for prizes in this section, there being generally three prizes of R50, 25 and 15 respectively under each head. The first prize for the best cow of any breed suitable for breeding dairy stock was awarded to Mr. J. Matcher. Two fine pairs of halls exhibited by Mr. J. B. Gomez carried off two prizes, and a beautifully marked bridled cow which attracted the attention of all, looking for all the world like a painted Mohurum tiger, secured a second prize. Rams and goats were well represented. A great variety of poultry, both English and country, were exhibited, but owing to defective housing on the part of the Mahramat Department that built the sheds the exhibits were not seen to advantage. Competition was very keen under this head and the prizes awarded were well deserved and well adjudged. Proceeding next to section B, Vegetable Production, there was a remarkably large exhibition of grains, of paddy alone, one exhibitor, Parai, one of the richest land-holders of North Travancore, exhibited 22 distinct varieties, and carried off the first prize of R5, which all declared to be utterly inadequate to the magnitude of the exhibit. The other cereals, comprising ragi, thenua, chams, cumboo and cholam, were good, but the number of exhibits were insufficient considering the exceptional facilities afforded for such cultivation in fertile Travancore. The pulses were good, but the oil-seeds were poor. It was disappointing to find that ground nuts, the cultivation of which the Government has been trying for some years to encourage, has not been more extensively taken up by the people. The similarity and complexity of the exhibits in the above four classes of vegetable productions must have caused immense trouble to the Judges, Messrs. Shungra Sobier, Raghunatha Row and Knngu Ramen Nair, who went through their duties most conscientiously, and if some of the exhibitors were disappointed it was largely due to the unsystematic way in which the articles were arranged by the exhibitors. Under the head of fibres some fine specimens of cotton were exhibited, and it is a pity that this article of commerce is not more largely cultivated in Travancore than it is, for owing to the recent establishment of cotton spinning and Weaving Mills in this country an immense demand for this product has arisen. There were a splendid exhibition of fibres. The extensive virgin forests that clothe the mountain ranges of Travancore afford a varied and inexhaustible supply of fibres suitable for the manufacture of paper, cloth and cordage, and untold wealth lies hidden in these as yet undeveloped industries. Large collections of well prepared fibres from

aloes, hemp, palms, reeds, grasses, barks and leaves of trees were exhibited, and considering the immense trouble taken by these pioneers of our new industries to prepare their collections, one could not help feeling that more encouragement was not given. About seventy separate kinds of fibres were shown, the collection sent in by Messrs. Koblöff and Maslamony was prepared with exceptional care and well merited the first prize of R45. Green fodder was well represented, but considering the wonderful fertility of Travancore soil this cultivation is susceptible of immense development. Government has, I believe, already taken steps to introduce new varieties of fodder into the country.

The moist soft soil of Travancore is ominently well fitted for the production of yams and other roots and Travancore is a veritable land of yams. But yet strange to say the exhibits were not nearly so fine or varied as they ought to have been. Some fine clusters of tapioca roots were exhibited and the specimens of prepared granulated tapioca sent in were exceptionally good. This is an industry fast spreading in the land, and if machinery were only introduced for the manufacture of this flour the almost inexhaustible supply obtainable in the country will cause this produce to take an important place in the exports of the land. As might be expected, there was a magnificent exhibition of country vegetables, some of the pumpkins, ashpumpkins, cucumbers and brinjals being simply enormous. Of brinjals a market gardener exhibited about nine distinct varieties. The English vegetables were poor, which is to be regretted, since the climate and soil afford facilities for their cultivation. Perhaps the lateness of the season is answerable for the poor display. No part of India is so well suited as Travancore for the growth of the cocoanut, the plantain and the arecanut and yet the exhibits sent in but poorly represented the wealth of the country under these heads. The rough but excellent brushes made of cocoanut and palmyra fibres will, I hope, give a hint to manufacturers regarding the enormous expansion that this industry is capable of. The jack fruit is another typical representative of Travancore, forming the staple food of the poorer classes during several months of the year, and some gigantic specimens were exhibited. A great variety of ferns, foliage plants and annuals were sent in, but owing to the lateness of the season the roses were not in bloom, and the specimens sent in were not sufficiently representative of the fine collections that may at other times be seen in the flower gardens of Travancore. The green rose craze has reached even this ultimate thule of India and a plant in flower was exhibited. The rose collections were unfortunately placed in an out of the way corner of the building, and consequently a large portion of the visitors went away without seeing them. The annuals exhibited by the Residency and Mrs. Ferguson, and the roses sent in by Mr. Retnaswamy Iyer, excited well merited admiration.

Under plantation and special produce a high meed of praise must be given to the wonderfully good tea and coffee. Travancore tea, as is well-known, has secured a prominent place in the great sales of Mincing Lane, London. Three first prizes were awarded for tea, Mr. J. Stewart carrying off one for a box of the fabulously costly "golden tips." The tea from Peshhurst and Bon Ami Estates carried away the other two first prizes. But how the quality of the teas was ascertained without the usual test of tasting the brewed liquor is difficult to comprehend. There were about 60 entries under teas. Some fine specimens of Liberia coffee, which has taken so kindly to the soil of Travancore, were shown, the first prize being taken by Mr. A. M. Knight, and the second by Mr. R. Ross. The first prize for Arabian coffee was awarded to Mr. J. Fraser and the second to Mr. J. C. Joseph. Some specimens of oinohona bark were shown. Miss Mead carried off a prize for prepared flours and a good collection was sent in by Mr. J. Caraner. It is to be regretted that this branch of industry is not more largely developed. A great future lies before

flour prepared from plantain and banana, many varieties of which flourish in every nook and corner of the country. Some fine collection of purified oils was sent in, but, as the Judges remarked, the value of those collections would have been greatly enhanced if their medicinal properties had also been indicated on the labels. The gums and resins of Travancore were poorly represented, though there are countless varieties of them in our extensive forests. Some excellent carpets, jamkals and grass mats were also on view. The cotton checks sent from Cottayam, Quilon and Nagercoil were very fine. The Mulagamood tiles and drain pipes sent by the Very Rev. Father A. Victor were much admired and a model of the Quilon tile factory gained a special prize. The newly started Paper Mills of Poonloor contributed a representative collection of various kinds of papers manufactured there. If improved machinery and larger capital could only be secured by that Company, the inexhaustible paper materials of Travancore could supply all the paper-markets of Southern India. Tanned hides of superior quality were sent in by Messrs. Marse and Co. and B. John; but the prizes awarded were, as the Judges themselves remarked, disproportionately low, as the industry of tanning which is at present very little known in the country, deserves encouragement. Special prizes were awarded for a set of harness. Some exquisite specimens of lace and embroidery were sent in by the Nagercoil and Neyoor Missions and the Trevandrum and Quilon Convents. The first prize for needle work was carried off by Miss Eliza Rodriguez. Some of the carvings in ivory and coconut shells were specially good. Photographs in opal glass and bromide enlargements of Mr. L. D'Cruz deserve high praise, and so also does his ingenious hand organ. It was disappointing that the extensive coir matting manufacture, for which Travancore is carrying a high name in other countries, and which brings such vast wealth to her people, was so miserably represented. Some Travancore muslins of delicate texture and gold lace and embroideries must not be forgotten.

Passing on to machinery it is to be regretted that the excellent models of English ploughs shown at the last Exhibition have not been adopted by the ryots. Mr. J. Cartner was awarded the first prize under this head. Wonderful skill and ingenuity were shown by some of the native blacksmiths in Travancore who produced excellent locks in imitation of Chubb's locks, one of which was rivetted to a tiny box made out of an eggshell. The head mistry of the D. P. W. workshop exhibited a model of a fire engine and a garden fountain. The prize of R50 offered for a churn was not awarded, as the specimens exhibited were considered by the judges as not up to the mark. A weaving loom started by the newly established firm at Cottayam and shown in operation attracted great crowds and fully deserved the special prize of R40 awarded it. Dr. H. P. White earned a prize for a splendid dog cart built under his supervision. Mention may also be made of a working model of a horizontal side valve engine and vertical boiler by a Travancore artisan, and last but not least of the many interesting articles on view as an enormous block of pure plumbago, weighing $\frac{1}{2}$ of a ton, exhibited by the enterprising firm of Messrs. Parry and Co., who recently started the new industry of plumbago mining in Travancore, and who have sunk a large capital in the concern. Extensive fields of plumbago have been discovered by that firm near Trevandrum, and they afford occupation to quite an army of workmen, both sons of the soil and experienced Cingalese miners. A special prize of forty rupees was awarded for their exhibit.

All yesterday and today thousands of sight-seers have been flocking into the Exhibition buildings and returned home with minds enlarged and stocked with information and with useful hints, the leaven of which will, we hope, will leaven the national mind and result in lasting good to the country. All honour therefore to the liberal-minded Maharajah and his Government who have provided this method of educating the people, and to the Exhibition Committee

and especially to their Secretary, Mr. H. S. Ferguson, for the tact, energy and zeal which have made the Travancore Agricultural Exhibition of 1892 a grand success it has undoubtedly proved to be.—*M. Mail.*

NOTES ON PRODUCE AND FINANCE.

A NEW FIBRE COMPANY.—Under the title of the British and East India Fibre Company, Limited, a new company has just been registered with a capital of £75,000, in £1 shares. Object.—To carry on in all its branches the business of manufacturers and dealers in fibrous and textile materials and substances of every description; and to acquire, sell, license, or deal with patents or inventions relating to the preparation or manufacture of textile or fibrous materials. The first subscribers, who take one share each, are:—T. H. Warland, St. Mary's Lodge, Catford; W. J. Toney, 24, Granard Road, Wandsworth, S.W.; H. J. Rumball, 16, Ruvignay Gardens, Putney; J. H. Coulson, 76, Oakley Road, Canonbury; H. A. Pullen, 21, Great James's Street, W.C.; W. M. Finnis, 76, Lausanne Road, Hornsey, N.; T. B. Liley, 58 Sandmere Road, Clapham.

THE ADULTERATION OF COFFEE IN CANADA.—The art of blending rubbish with coffee is practised with much success in Canada. A Toronto paper says:—"The manufacturers of sophisticated coffee do not by any means confine themselves to the use of chicory. Roasted peas and grain are also ground in with and sold as part of the resulting 'compound.' There are, moreover, large quantities of a substance imported under the name of 'essence of coffee' for adulterating purposes, which is a species of burnt sugar, and from its containing dextrin is probably made from some of the bye-products of the glucose factories. It costs in New York and Philadelphia from 3c. to 5c. per lb. As it possesses no organic structure it is apt to be overlooked in the microscopical examination. It contains about 75 per cent. of matter soluble in water which has great colouring power and a little of it is capable of imparting a strong brown coffee colour to water."—*H. and C. Mail, Ang 5th.*

SPRING VALLEY COFFEE COMPANY, LIMITED.

Directors:—John Brown, Esq. (Managing Director), Edward Conder, Esq., Leon Famin, Esq., Henry Hart Potts, Esq.

The following is from the report of the directors:—
CROP 1890-91.

In last year's report, shareholders were informed that the coffee crop of the above season was estimated at 3,400 cwt., and it will be seen that the actual weight sold in London amounted to 3,464 cwt. 3 qrs. 21 lb. This crop, inclusive of inferior coffee sold in Ceylon, realised £17,237 4s 8d, the average selling price in London being 98s 5d, as compared with 102s 4d per cwt. obtained for crop 1889-90.

The yield of tea on Spring Valley amounted to 156,866 lb, the estimate in last report being 160,000 lb, and this, together with 57,328 lb, bought from neighbouring estates and manufactured at Spring Valley, sold for £9,556 9s, or an average of 103d per lb., the average selling price last year being 114½ per lb.

Oolanakande Estate produced 21,205 lb. of tea, which realised £848 1s 11d and brought an average of 93d per lb. as against 92d per lb. last year.

Cinchona bark to the extent of 13,556 lb. was also sold for £120 7s 10d the average selling price being 2½d per lb. or ½d. per lb. under last year's average.

The total proceeds from the sale of produce amounted to £27,762 3s 5d and deducting from this the total expenditure in Ceylon and London, there remains a profit of £7,297 2s 4d on the year's working.

To this has to be added the sum of £58 12s. 4d. brought forward from last year, making a total of £7,355 14s. 8d. at the credit of profit and loss.

On the 14th January last an interim dividend of 2½ per cent. was paid on the capital of the company, and the directors recommend that a further dividend of 3½ per cent. be now declared, making 6 per cent. for the year, and leaving £2,555 14s. 8d. to be carried forward to next account.

CROP 1891-2.

The estimated coffee crop for this season is not satisfactory, and it is thought that it will not exceed 1,300 cwt. From the experience of several past years it seems that good coffee crops can only be looked for in alternate seasons, and must not be relied upon in two consecutive years; the above crop is no exception to the rule, the directors therefore consider it prudent to carry forward a substantial balance at the credit of profit and loss to help the revenue of season 1891-2, and if their moderate expectations of the coffee crop of that season are realized, they hope to be in a position to continue a fair rate of dividend.

The area under coffee is maintaining its vigour well, and appearances are in favour of a good average crop for season 1892-3; there is, moreover, every reason to expect a fair yield for that season, as the small crop now being gathered will in no way tax the strength of the trees, thus leaving them very capable of maturing any crop that may set.

The directors are glad to report that the area under tea continues to improve, and the crop for season 1891-92 is estimated at 190,000 lb. from Spring Valley, and 25,000 lb. from Oolanakande Estate.

The condition of the coffee is such that the directors have not thought it necessary to replace any of it with tea, so that the area remains as follows:—

TEA.		Acres.
Planted Nov.-Dec., 1884, on Spring Valley	..	271
„ May, 1885, on Oolanakande	..	143
„ Nov.-Dec., 1885, on Spring Valley	..	230
„ May, 1886, on Oolanakande	..	7
„ Nov.-Dec., 1888, on Spring Valley	..	20
„ Nov.-Dec., 1890, on Spring Valley	..	96
Total area under tea		.. 767
Total area under coffee		.. 872

—H. and C. Mail, Aug. 5.

CEYLON TOBACCO COMPANY, LIMITED.

Mr. A. Philip as liquidator of this Company has issued a memorandum in which he states "that the properties named at the foot of this memo. have been sold; but there has been considerable delay in obtaining the purchase money in full from different causes, that it would serve no useful purposes to enter into in detail, as Shareholders will of course bear in mind that the acquisition of the allotments forming the estates of the Company itself were not all completed at the date of going into liquidation, while many matters required adjustment, tact, and patience. For similar reasons the Liquidator feels that it would not be prudent to divide money as collected, while the Ratwatte estate is unsold and funds are required for its upkeep and cultivation, without which the property would have to be abandoned, thereby causing, it is believed, unnecessary loss to the Shareholders. The Liquidator is disposed to recommend the formation, without delay, among the old Shareholders and others of a new Company to be styled possibly the Ukkuwelle Tea and Cacao Company, Limited, to take over from the Tobacco Company the Ratwatte estate, as he has reason to believe that the concern should pay well and afford a good opportunity to the Shareholders of working successfully on a fresh basis one of their own properties to their profit, and as a satisfactory means of assisting in closing the present liquidation. As regards the remaining lands the property of the Company, the Liquidator is strongly of opinion that they should be held until such time as the money spent on their purchase is realized; and further it will be necessary to spend money in completing several of the blocks unless the Shareholders are prepared to lose every cent

of the money advanced on the intended purchase of these lands. It is possible that the proposed company or another syndicate might take over all the lands referred to. Such offer, if made, would certainly be entertained, but in the interests of the Liquidation no scheme should be unduly pressed, as in the opinion of the Liquidator time is still required to satisfactorily deal with the lands in question. The tobacco leaf unsold remains safely stored; and in view of recent legislation increasing the duty on imported tobacco, the Liquidator is sanguine that better prices will rule shortly.

As regards a dividend, the liquidator proposes to declare the first as soon as practicable after the transaction *re* the Arampolla Estate is closed and the purchase money paid. The liquidator continues to press for this, and hopes to be able to sign the transfer on an early day. Meantime the shareholders may be reassured that their interests are being carefully watched."

Appended to the memorandum is a statement showing the property belonging to the Tobacco Company, the sale of which has been completed or negotiated for.

Property.	Price Realized.	Remarks.
Wattapollowa Land	2,510 00	Transaction closed on 25th April 1892.
Matale Estate ..	30,000 00	Transaction closed on 26th July 1892.
Arampolla Estate..	30,000 00	Transaction unclosed at date. R5,000 paid on account 12th April 1892; transfer still to be completed.
Digonnellan ..	2,600 00	Transaction unclosed at date. Purchase money R2,600 paid 5th August 1892; transfer only to be completed.
Killakapolla Land..	3,100 00	Transaction unclosed at date. R310 ten per cent. deposit received 5th August 1892; transfer still to be completed.
Tobacco Leaf ..	4,539 83	Amount recovered to date.

THE ORIGINAL HOME OF THE SUGARCANE.

Dr. Edmund Von Lippman, an eminent German chemist, and an authority on sugar, gives the following brief sketch of the history and development of sugar culture and manufacture in a lecture, a synopsis of which appeared in the *Deutsche Zuckerindustrie*:—

The original home of the sugar cane must be looked for in the coast region extending from Bengal to Assain, at the northern extremity of the Bay of Bengal. It is remarkable that there is no such thing as *wild sugar cane*, whilst four-fifths of other formerly wild, but now cultivated plants, are still in existence in a wild state. Not the slightest chronological indication as regards the time when it was first known is to be found in Indian annals. A Chinese compilation of the third century states that the province of Bengal sent sugar cane as a tribute to China, from which we may conclude that at that time solid sugar was not known. The first indication of sugar itself is found between the third and sixth century in India, while the Chinese were not acquainted with its manufacture until about the year 640. In the ninth century clarified sugar was prepared by drying raw sugar in the sun. The companions of Alexander the Great speak of a sort of honey which they met with on their way to Asia, which grew there without bees. At the commencement of the sixth century there was sugar

cane on this side of the Indus, at the confluence of the Euphrates and Tigris. The conical shape of the sugar loaf has existed since the seventh or eighth century. The refining was effected chiefly by the ashes of plants.

Sugar came first into Europe at the time of the conquest of Sicily by the Saracens in 827. From Morocco the manufacture of sugar extended to Spain and attained such a development that it amounted to 100,000 tons per annum. In the year 990 the Doge Orseolo concluded the first treaty of commerce with the Arabs and refined sugar was then introduced into Venice. From thence sugar found its way into Germany, and is first mentioned in the poems of Wolfram of Eschenbach and Gottfried of Strasburg. Columbus took the sugar cane with him on his second voyage to America, but it appears to be again lost sight of there. In Germany the first refinery was established in 1573, at Augsburg, by the patrician family of Roth. The next refinery was set up in 1597, at Dresden.—*Louisiana Planter and Sugar Manufacturer.*

ASSAM AND ITS TEA PLANTERS.

There is a province in India where drought is unknown and famine never stalks, a land of great rivers, green valleys and fertile hills; but it is far from civilisation, and it is destitute of roads. Assam, to the north of Bengal and west of Upper Burma, fills up the north-eastern corner of India, where the Himalayas cease, or give a passage south to the rivers of Tibet. There China proper begins to march with British territory. For sixty-eight years this most desirable land has been ours, and during all that time it has been almost the most neglected part of the Queen's dominions. With the area of England, it has only the population of Scotland, but a population that increases steadily by emigration chiefly, till now it is at the rate of 112 to the square mile. Save when the Mongol tribes of the north—one of whom, the Aham, gives its name to the province—raid the villages for human heads to offer in sacrifice, or when the Lushais of the south break forth and carry off the imported labourers and burn down the tea factories as they have been vigorously doing of late, the Government of India lets Assam alone. No Imperial money is spent on it, no Governor-General has yet made it a pet territory or sought a name for himself by developing its resources. The wars of Burma and Manipur have for a moment forced it into notice, but Calcutta and Simla soon forget it again. Yet Assam possesses capabilities greater than those of many a non-tropical colony, and, indeed, a great part of its finest soil lies outside of the tropics altogether.

The Scots, we may be sure, have not neglected such a land, and once more they are crying to the Government to do its duty. The year after the British occupation two brothers, Scotsmen, named Bruce, first discovered the tea plant there. Another of our countrymen, and a famous man in his day, David Scott, was the official Commissioner. Major R. Bruce happened to be familiar with its forests and jungle when the first Burma war broke out, and Mr. C. A. Bruce, his brother, was put in command of gunboats up the Brahmapootra, so far as the Suddra, on the Chinese frontier. When so engaged he "penetrated the forests, visited the tea tracts, and brought away specimens of earth, fruit, and flowers," to use his own account of it. He was really in the original home of the Tea plant of commerce, from which it had long before been introduced to China itself. The Chinese tradition is that an Indian devotee named Dhrma, about the time that the first Buddhist missionaries were sent to the Flowery Land, resolved to teach the northern peoples the true religion. After incredible hardship in crossing the mountain ranges the ascetic fell asleep. On awaking he was stung with remorse at his weak indulgence of the flesh, and plucked out both his eyebrows. The hairs, as they were cut on the ground, became at once metamorphosed into plants. With no little curiosity, he tasted the leaves and found that they gave new

vigour to his body; while they promoted meditation. Such was the origin of the tea plant and the discovery of those powers which have made it the favourite drink of the civilised race since the East India Company introduced it into Europe, and it became the indirect cause of the independence of the United States of America. Lord William Bentinck was not slow to take up the enterprise of the Bruces and to reward them with grants of land. He sent a scientific expedition to report on the plant, "with reference to the geological structure, soils and climate" of the province. His minute of 1834 on the advantage India would derive from the cultivation of tea was a remarkable production for that time. He appointed a "Tea Committee" of the ablest, civil servants and botanical experts, who sent a Mr. Gordon* to China to report on the manufacture and cultivation. Experimental gardens were opened along the Himalaya slopes from Assam to Dehra Doon, and, ultimately, Kangra in the far Punjab, chiefly by an Edinburgh man, Dr. Jamaicaison. By 1839 the Assam Company was formed to work the Government gardens in that province as a commercial enterprise. The Scottish manager soon turned out tea which distanced that of China in the London market, and the Company's shares commanded a premium of 150 per cent. Other joint-stock speculators entered the field after a time, till both land and labour were temporarily exhausted. The indigenous people would not work at more than their own cultivation, and their natural laziness was intensified by the almost universal consumption of opium, which the Government soon stopped. Coolies were imported from the over-populated districts of Bengal, especially Chutia Nagpore and Santalia, but under conditions which at first led to great mortality and many abuses. Government interfered by means of labour Acts. At the same time, it sold jungle and forest tracts, in freehold, under wasteland rules most favourable to the early settlers. Not a few shrewd Scotsmen, chiefly doctors, explored the Cachar district to the south, where also an Assam coolie had discovered the wild plant, and these pioneers laid the foundation of fortunes. In the years between 1860 and 1870 there was a rush of adventurous planters to the new lands. Neither houses nor proper food were available. Malarious fever prevailed. The mortality of planters and coolies alike was excessive as the tea enterprise passed through the inevitable time of transition, which to this day Government has done nothing to relieve by making roads and public works, or by protecting the exposed gardens from the attacks of the border tribes.

In spite of all that, Assam tea cultivation has struggled on to a great success, yielding, as it does, the bulk of the Indian tea exported to Europe, Australia, and even America in larger and larger quantities every year, till it is pushing the old China produce out of the English market at least. Whereas, in 1865, 93 per cent of all the tea imported into the United Kingdom was from China, only 35 per cent now comes from that land, while India supplies 45 per cent, and Ceylon has begun to send 16 per cent. The rivalry of Ceylon with India proper has become so serious that the Indian Tea Association of Calcutta, which represents all the great producers and firms of Assam and Darjeeling, has resolved to take vigorous action. Ceylon, having seen its once profitable coffee cultivation destroyed by the exhaustion of soil, has found in the tea culture a still richer industry. Its produce is cheaply shot down from Nuwara Eliya, in the Kandy Hills, by railway into the ship at Colombo; while that of Assam struggles to Calcutta after a costly fashion by boat through a roadless land at a cost of 3d per lb., equal to the English duty. Ceylon, too, has learned to advertise its produce after so lavish and thorough a fashion that every village grocer sells what is represented as finer tea than that of a India, though it is really inferior to the average bulk of the Assam teas. By forming a syndicate, the Indian Tea Association has succeeded in introducing its teas into the Australian

* Fortune?—Ed. T.A.

colonies, which took six million lb. last year. Now it has resolved to seek possession of the United States market by taking advantage of the coming Chicago Exhibition. The Tea Districts Association in London is to co-operate with it. The great firms of Calcutta and gardens of Assam have rated themselves so as to raise large funds for this purpose, and for a thorough system of advertising the merits of Indian tea. But it is felt in Assam itself that Government ought no longer to neglect the development of the resources, by public works, of a province which may now be described as a Scotch-Irish colony. Mr. P. Playfair at the recent annual meeting, reminded the Government that the late Lord Napier of Magdala most appropriately called the province of Assam the Eden of India; yet it is still a land of roadless jungle, at least on the south or Soorma Valley side. The Brahmapootra with its affluents—the third river in India next to the Ganges and the Indus—supplies with a splendid natural highway, but there is no civilised means of reaching it, or of dispatching from its steamers the labour and the goods which its waters can carry up to the very frontier of China from Calcutta. "The manner in which large factories have been established and equipped with heavy machinery transported through jungle and across roadless tracts, is nothing short of a marvel," said Mr. Playfair. The late census reveals the number of Christians in Assam and North Lushai as 16,884, not many of whom are natives as yet. At last there is a prospect of the early opening of the Chittagong-Assam railway. Work is to be begun by Mr. Byers, the contractor, simultaneously all along the sections from Chittagong by Comilla to Silchar, and the completion of the line in three years is promised. What is wanted besides that is an extension of the Central Bengal Railway beyond Jessor through Madaripura to a point opposite Chandpur, where the train could be ferried across the great river, so that the produce of Assam, Cachar and Sylhet may reach ship at Calcutta without breaking bulk. The rivalry of India and Ceylon in their efforts "to make the Americans drink our tea" will give us a practical interest in the Chicago Exhibition, and we wish both the most complete success. The produce of Ceylon must always be limited by its small area, but, as the great firms of North-Eastern India boast, the resources of Assam and the Himalayas are capable of producing the world's consumption of tea as it is at present known, as regards both the quality and the quantity required. Certainly the Scotch-Irish settlement of Assam has a great future, to which Lord Landsowne and his successors should do justice, too long delayed.—*Scotsman*, July 13.

QUALITY IN TEA.

Quality in Tea may be said to be the question of the hour in Ceylon, and it is one that has to be approached with care. Numerous complaints from many quarters have reached Colombo that the quality of Ceylon tea is deteriorating, and sweeping assertions are often indulged in that this is a sure sign that the soil is becoming exhausted, and that unless heavy manuring is constantly practised, the history of the tea industry in that Island is likely to be but a repetition of the history of the cinchona industry. Such sweeping assertions can only be ascribed to ignorance, because though, undoubtedly, the average quality of Ceylon tea is not as high as it used to be many estates continue to export leaf not a whit inferior than when the tea bushes were two or three years younger, and on other estates it has been found more profitable to pay less attention to quality than to quantity. On the other hand, there is but little doubt that in the rush that followed the successful cultivation of tea in Ceylon, a large number of acres were opened out in a reckless manner, and by men devoid of capital, who have been unable to bestow on them the cultivation that the bushes required. To this fact is in no small measure due the abuse that is being freely showered on Ceylon, and it will be to

the advantage of the tea industry in general, and Ceylon, in particular, when such gardens have returned again to jungle. Besides this, and it is a fact that must not be lost sight of, there is, undoubtedly, some constituent in soil which has never before known tea, which produces certain qualities in the cup, which land two or three years under cultivation cannot furnish. This was the case in Ceylon, and again in Travancore, and when early consignments of tea from both these countries were put in the London market, the most common phrase to be met with in brokers' reports was that such teas were not to be met with anywhere else. Whether these qualities were due merely to the taster's imagination or in reality to something in the soil, which becomes exhausted after a short while, is a question which hardly needs asking, but because an estate cannot continue to produce fancy qualities for a long series of seasons, it does not follow, by any means, that with proper cultivation, good machinery and careful superintendence, its produce will not continue to be of very high excellence.

There is but little doubt that there are many estates in Southern India where not nearly sufficient attention is paid to quality and where, with more care and intelligence, prices might be considerably improved. A Ceylon contemporary writes:—"The quality of tea—that is to say, its main characteristics—are subject to but slight control; they are inherent in the leaf itself when it is plucked and, though they may be modified, they cannot be eradicated." We do not question the truth of this for an instant, but it happens not infrequently that blame is cast on the inherent quality of the leaf, which rests rightly on the factory. It may sound somewhat foolish to ask how many managers and superintendents really know what is the inherent quality of the leaf they grow, what is due to climate influences, and what characteristics can be modified or controlled. It is only by tasting daily for several years that this knowledge can be arrived at with certainty, and special note has to be taken of the liquor at the various seasons of the year, and after different works in the field. But if the manufacture of tea can be only brought to the highest pitch of excellence after a man has been on an estate for a number of years, great improvements may be made by special care in the manipulation of the leaf. Machinery of the best is a *sine qua non* if proprietors wish that the quality of the tea should be of the highest, and it is useless for them to expect big prices when their factories are lumbered with antiquated rollers and driers. In this connection we cannot do better than quote the words of a well-known tea-man of Colombo, Mr. Francis Street, when writing a short time ago about the lack of quality in Ceylon tea: "Teas with quality were again conspicuously absent. We have never known a season before when fine teas were so scarce. Our home critics are entirely in error, in my opinion, when they attribute this falling-off in quality to exhaustion of the soil. In a very large majority of cases it is due to inadequate factory accommodation and machinery for the leaf to be treated, or to some defect or defects in manipulation—more often the latter."

Having touched lightly on the effect of soil and manufacture on the quality in tea, we came to that question which has been the cause of much heart-burning in many tea-gardens, both in India and Ceylon. When should quality give way to quantity? We, of course, take for granted that the leaf possesses quality, and to this end it is of vital importance that the bushes should have been raised from seed of good *jât*. Elevation, soil, cultivation and manufacture are powerless to turn out good quality if the *jât* be bad, and we urge on all who are opening out new tea estates to pay the very greatest heed to this point. But to revert to the question of quality and quantity, it is merely a matter of pounds, shillings and pence, and so long as the manager and proprietor of a tea estate are identical, or both are planters, we hear but little of it, but when it comes to dealing

with directors and proprietors whose ignorance is only equalled by their assurance the question is different. They argue that the size or abundance of their cabbages and gooseberries does not affect their excellence, and why then should it their tea-bushes. It is for each manager to ascertain the highest quality and the greatest quantity that his estates can produce and then to draw the line where it is to the advantage and profit of the estate for the one to give way to the other. Before we conclude these remarks we may express our regret that there is not in Southern India some public tea-taster who is able to pronounce, authoritatively, on the quality of tea and to offer opinions regarding the manipulation of the leaf. Tea cultivation is advancing in many of our districts, and we cannot but think that if such a man was to come forward, it would very soon be found to the advantage of planters to obtain frequently his opinion.—*Madras Times*, Aug. 8.

GENERAL NOTES.

AN ORANGE FAD, says the *Horticultural Times*, is among the possibilities of the day. Free consumption of the fruit is said to be good for the complexion, and many ladies are testing the claim. The value of the orange in other ways has long been recognised. It is reported that in some inebriate asylums oranges have proved an efficient substitute for alcohol, patients sucking the juice of them abundantly every time the thirst for liquor comes upon them. This fact is so well recognised that at many temperance coffee stands piles of luscious oranges are always on show. Generally speaking, oranges are gathered in Spain from October to December, and, by a strange coincidence, it is found that the trees from which the fruits are picked green bear every year, whilst those upon which the fruit is allowed to ripen produce abundant crop once in two years only.

JAPANESE LACQUERED WARE.—One of the most thriving industries in Japan, says the *Indian Agriculturist*, is the manufacture of lacquered ware. It has existed in that country for a long time, and, unlike many other industries, is continuing to yield handsome results. The reasons for this state of things are not far to seek. There is no competition in this manufacture in Europe, nor in any other part of the world, for the lacquer varnish is obtained only in Japan from a tree peculiar to that country, the *Rhus Vernicifera*. In Ceylon and in some other places a variety of lacquered ware is made with the lac obtained from the *Croton Lacciferum*, but do not in the least approach the Japanese articles in quality or appearance. Hitherto the difficulty in introducing the lacquered ware industry to other countries has been solely owing to the want of the lac-producing tree, but now it is stated that *Rhus Vernicifera* plants have been successfully established in some German botanical gardens, and there is every prospect of their being largely cultivated in that country. The only question which remains is whether the tree grown in Germany or elsewhere would produce the same quality of lac as is produced in its native country. With a view to settling this point experiments have already been undertaken, and there is every hope of their turning out successful. It would not be too much to say that the introduction of this plant to India deserves serious consideration, as with it a flourishing minor industry would undoubtedly come into existence.

UNDER date of Foochow, 23rd July, we have received the following advices of the tea market:—The export to Europe is 9,343,000 lb. against 8,936,000 lb. at the same date last year, representing shipments of about 1½ millions during the fortnight, carried in the calling steamers "Titan," "Pembrokeshire," "Dardanus," "Glengyle" and "Peking." By the end of the month the export

will be less than on the corresponding date last year. The market has been quiet. The settlements are reported at only 27,000 chests congon against 48,000 chests the previous fortnight. More than half of the purchases have been for Australia. The tendency of prices has been towards easiness—indeed a decline might have been quoted had the quality of the latest settlements been fully equal to that of those made a fortnight ago. As regards supplies, the expected shortness of the second crop is likely to be more than realised, only 30,000 chests having as yet come down. The tsamen estimate the deficiency at 25 to 30 per cent., attributable chiefly to excessive rains at the time of picking. The arrivals of Congon to date are 226,000 chests against 359,000 chests at the same date last year, and 317,000 chests in 1890. The settlements of Congon to date are 176,000 chests, against 163,000 chests to the same date last year. The stock is 50,000 chests against 96,000 chests on the same date last year. Exchange closes firm at 2/10½, for 4 months' sight credits; and Freight is 30s per ton of 40 cubic feet.—*N.-C. Daily News*.

BENID SEEDS AS A SUBSTITUTE FOR COFFEE.—In an article on "The Old time Southern Garden" in *Garden and Forest* occurs the following passage, the okra in which indicates the plant which produces the bandekais:—

Tomatoes had come to be generally grown, though not relished by all to the present extent. Egg-plants I never saw, nor Okra till the seed was needed as a substitute for coffee during the war. Paroled and ground, they formed the most popular beverage of those scant times.

THE BUITENZORG BOTANICAL GARDENS.—On May 18th last the seventy-fifth anniversary of the founding of the Buitenzorg Botanical Gardens was celebrated with considerable festivity. Dr. Treub, the director, reviewed the history of the gardens in a long speech, which has since been published in pamphlet form. An interesting feature in the festivities was the presentation to the Garden of a handsome address of congratulation and appreciation signed by a number of the principal German scientists.—*Chemist and Druggist*.

PROTECTIVE INFLUENCE OF TEA.—The following is from a home paper:—The attempt to revive the thrashed-out controversy as to the action of Looch Katrine water on lead pipes recalls the memorable discovery of Sir Robert Christison—that a very small amount of peat extract in solution prevents the action of an otherwise pure water on lead; that other vegetable solutions, such as tea and calumba-extract, have the same effect; and that probably all vegetable solutions which form an insoluble compound of oxide of lead will have this protective influence.

WILD STRAWBERRIES.—Mr. Nock writes to us:—"With reference to your question about wild strawberries, I may state that the same species, *Fragaria vesca*, that grows so luxuriantly and fruits so abundantly in Jamaica, is now growing wild in many places in the Nuwara Eliya district. If the soil here was as good as it is in the Blue Mountains of Jamaica, and there was less Nilu (*Strobilanthes*), this strawberry would soon be as plentiful in the hill districts of Ceylon as it is there. When I was Superintendent of the Government Cinchona Plantation in Jamaica, I have given as many as 20 free tickets in one day to old women and children to gather strawberries among the Cinchona Plantations. I have known them gathered by the bushel and carried 22 miles to the Kingston market, where they always commanded a good price. I may state here that I have, this year, raised seedlings of six of the best English varieties, to which I intend to give a fair trial in this locality."

NOTES BY WANDERER.

Aug. 22nd.

QUININE.—Your co-editor Mr. John Ferguson is always pressing on the attention of those interested in cinchona or quinine the propriety of extending its use by making it up in small packets and selling it at a cheap rate to the poorer classes. The Indian Government has evidently got hold of this idea, for they are using the agencies of the post offices in India to sell Indian Government quinine to the poor classes throughout the length and breadth of India.

TIMBER TREES.—What will my brother planters say to the following cutting from the "Indian Agriculturist" re the despised blue gum?—

The eucalyptus is declared to be the most valuable tree introduced into France, and its cultivation is rapidly extending in the Southern departments. Its bark is in great demand by the French tanners. Its fibres are employed in the making of mats and baskets, cordage packing and blotting paper and filters. A resinous substance is extracted from it by distillation which is known in commerce as vegetable naphtha. An illuminating oil is obtained from it which affords a brilliant light without smoke and without odour. Fragrant essences are distilled from its flowers. Its chemical products enter largely into the French Pharmacopœia, and a decoction of this wood, after having been cut into fine flakes, is found to be superior to any other agency for cleansing the calcareous incrustations which gather on the insides of the boilers of steam engines.

TEA BLIGHT.—Apparently there is truth in the proverb "the ours is worse than the disease" if the following extract from an Indian paper is correct:

The Director of Land Records and Agriculture at Bombay recently published a memorandum, recommending that Bouillie Bordelaise should be used as a cure for the potato disease that is ravaging the Poona fields. It may interest him to read in the annual report of the Agri-Horticultural Society of India that, in recent cases in Assam, when Bouillie Bordelaise was tried on some tea gardens as a cure for tea blight, the blight was immediately checked—but the following flush in these affected parts produced tea with a "peculiarly offensive taste." If the remedy have this effect in Poona, the cultivators will have little cause for thankfulness.

CATTLE FOOD.—We often hear planters complain that while they have enough and to spare of grass in the rainy season, they are very hard up for the commodity in the dry. Here is a recipe for making a silo:—

TO MAKE A STACK SILO.—Cut the freshly cut grass to a convenient spot and then throw it off on the ground without bed or bottom. Spread it and gradually shape it into a four-sided figure. The heap should be laid out 3 feet wider than is required, and trimmed back afterwards. Then when the heap is three or four feet high, walk two buffaloes or bullocks on its top round and round. Stacking should be done gradually, so that the mass may get time to heat. I have taken buffaloes on to the stack when it was over eight feet in height by making a slope of the green stuff. The bullocks may be kept on the stack at night, or, if removed, the stack should be weighted to press it down. When the required height is attained, the trimmings should be laid on to the top, thick branches of trees put on, and weighted with stones 2 feet deep. Stones should be of the size of a fist to a man's head. Stones of larger size require more labour in loading and unloading.

MANURING.—I see you wish your planting friends to give you their ideas on the value of coconut fibre as a manure. Personally I think the way for an editor or any other person to get really valuable advice on estate matters is to pay a fee of Rs100 to a really good V. A.; but to show you there is no bad feeling between us I commit myself to the following; that I don't believe much

in bones unless you are going in for the sale of tea seed. I think "Coconut Planter"'s suggestion a good one, and would like to see it get a fair trial.

A LONDON IVORY SALE.

The *Leisure Hour* publishes in its July number an instructive account of the London ivory market. Four times a year, says the writer, in January, April, July, and October, ivory sales are held in Mincing Lane, and the display of the goods in the warehouse is one of the strange sights of London. The floor is crowded with ivory of all sorts and sizes, in tusks and sections, and odds and ends, some of it in huge teeth weighing 70lb. each, some mere trifles of 20lb. a piece, some mere pigmy "scrivelloes," and crooked, cracked, hollow, decayed and broken. The wilderness of teeth seems all in movement round the gigantic pair of travelling scales in the centre; the curving tusks are like so many worms, all strangely scratched and scribed, and are of all colours from white, through the browns, almost black; and an expert can tell at a glance where each came from, and can sort the lots from the pink Calcutta to the black West Coast which comes wrapped up in the raw hides bearing the mysterious name of "schroons." What would an elephant think if he were to get a peep at this floor so crowded with his relatives' incisors? Here would be a *memento mori* for him more significant than that of the mummy at an Egyptian feast! Each pair of tusks means a life, for the elephant is as yet ignorant of the dentist's forceps, although we hear of elephants driven mad with the tooth-ache and have specimens of tusk disease in our College of Surgeons' Museum; and the few cases of monstrosities having three, four, and even nine tusks at a time may be disregarded. Mr. Stanley tells us that in the Congo basin there are two hundred thousand elephants, each with 50lb. of ivory in his jaws, the total being worth half a million of money; but even that stock would soon be exhausted if the Congo alone had to fill this floor four times a year.

WHERE THE TUSKS COME FROM.

And besides the London sales there are sales at Liverpool and Antwerp and Rotterdam. Most of the Liverpool ivory comes from the West Coast of Africa, and a quarter of it goes to Sheffield, a quarter to London, and half to Germany, France, and the United States. To the London sales the ivory comes from all parts. Recently the year's import amounted to 11,763 cwt., declared at £537,527. Of this large quantity—the freight of which is reckoned at 61 cwt. to the ton—the British East Indies were responsible for 3,180 cwt. and Hong Kong for 40, thus making the Asiatic contribution 3,220 cwt., to which we must add 37 cwt. from Java and much of the 1,241 cwt. from Holland before we can approximate to the total yield of the Indian elephant. But a classification of this sort is vague and valueless. Ivory is both imported and exported direct by us, and much of it reaches through European ports. For instance, Europe, omitting Holland, sends us 1,415 cwt., which may be either Indian or African, though the bulk undoubtedly comes from the Dark Continent. Much of the North African ivory reaches us by way of Malta, and much of the East African from Aden. Out of the 11,000 odd cwt. Malta sent 565 and Tripoli 309, making 874 as the Northern contribution; Aden sent 1,821 and East Africa 331, making 2,152 as the Eastern lot; West Africa sent 2,429, and South Africa 181, making up the African supply to 5,636 cwt. at the very least, to which we should certainly add the French ivory from the Gaboon.

THE COST OF BILLIARD BALLS.

The tusks for billiard balls fetch the highest price in the trade; as much as £110 per hundred-weight has been paid for them, which is more than double the rate for the ordinary kinds. As ivory ages the water it contains evaporates, and for this reason the Tithe Commissioners will not use ivory scales, as the evaporation of the fluid makes them alter in length and breadth. The shrinkage is also taken account of in the billiard ball trade. The balls alter in the two diameters at different ratios if they are kept in a different temperature from that in which the teeth have been stored, hence the keeping of the teeth in large quantities, and the making of the balls out of tusks only a little bigger than themselves, so that there may be no margin in the ratio of shrinkage. Ivory keeps white longest if exposed to light under a glass shade, but in that position, as in museums, it dries as it gets old, and then it flakes, and has to be restored by boiling in gelatine.

CUTTING UP THE RAW MATERIAL.

There is a process for cutting the tusks in spiral shavings so as to obtain large-sized sheets, and some such device seems to have been used by the ancients, not only for their tablets, but also for the faces and naked limbs of their heroic chryselephantine or tereutic statues, of which we have heard so much. The cutting up of a tusk in the ordinary way to the best advantage is a delicate operation. The saw is about two feet long, a fiftieth of an inch thick, and from an inch and a half to three inches wide; the teeth, five or six to the inch, sloping a little forward, at an angle between that of the hand-saw and the cross-cut saw. The tusk is never quite circular in section, and this irregularity has to be allowed for in making out the cuts, and all along the centre of the tusk there is a speck due to the apices of the successive hollows, which also has to be dodged by the cutter; and sometimes he will find a bullet in the tusk to bother him, and rarely, very rarely, the bullet may be of the golden sort, used by Eastern potentates so frequently in fiction and so seldom in fact. No part of the tusk is wasted: the blocks go to the turner and carver and tableknife-maker, the spills or rinds go to the penknife-maker, the sawdust, like the shavings, goes to the confectioner's as a stiffener for jellies, and to the lacemaker's as a dressing for curtains, and to other trades in which a strong fine size is required; the scraps go to the ivory-black burner, and out of every hundredweight only 15 lb. remains to be burnt into black, which is, however, worth from £16 to £20 per ton.

POLISHING PROCESS.

After the ivory has been turned or carved, it is polished on a wheel. The ivory worker's wheel is like a gigantic penwiper; it consists of round pieces of cloth screwed fast between disks of wood two or three inches less in diameter than the cloth, and thus affording a pliant edge projecting beyond the wood for the curvilinear surfaces of the umbrella or parasol handles, or whatever it may be that is submitted to its touch. Common work is polished on a series of wheels, one fed with Trent sand, one with loam, another, perhaps, with chalk; the better work is treated first perhaps with emery paper of the finest, made finer by rubbing two pieces face to face; secondly, with whiting and water thick as cream used on wash leather or linen or cotton rag so thin that the fingers can feel through it; thirdly, with clean water; and fourthly, with a slightly oiled rag.

INFERIOR IVORY.

But all ivory does not come from the tusk, some comes from the grinder, and though it is not always easy to distinguish between an Indian and an African tusk, there is no doubt about the species when the molars are examined. There are now only two species of elephants, the Indian and the African. The Indian has molars with parallel folds, the African has them with lozenge-shaped folds; the other distinguishing marks being that the Indian has small ears, while the African has large ones, a yard long; the Indian's trunk has a finger at the upper lobe while the African's trunk has both lobes much alike; the Indian's hind foot has four or five nails, while that of the African has but three, and the Indian is ten feet high, while the African is eleven. But though elephant ivory is almost the only kind now seen on the ivory floor, there was, and is, a sort of ivory, commercially so called, coming from the hippopotamus and the walrus. The Custom House description of ivory is, "Teeth elephant's, sea-cow, sea-horse, or sea-morse." Walrus ivory is poor stuff, the outer part of the tooth being alone of any good, the middle being more like coarse bone, but "sea-horse ivory," which by some perversion had become the name for hippopotamus ivory, is harder all through than elephant ivory and the outer coat of enamel is so hard that it resists steel and strikes fire, and has to be removed on the grindstone before the inner material can be worked. At one time sea-horse ivory was chiefly used by dentists for artificial teeth, but the day for that has gone by, and the only ivory practically known to commerce is that of the elephant, which the disappointed broker threatens to boil for tea when it does not realise the price on which he can make a profit, and which costs on the spot in Africa about a third of what it is expected to sell for in Mincing Lane.

CONSULAR REPORTS.

TAMSUI (FORMOSA).

Mr. W. Holland forwards on April 29th his report on the trade of Tamsui for the year 1891. He writes:—

TEA.—Though the actual export of tea was 18,139,733 lb. or some 938,000 lb. in excess of 1890 the value was only £667,383 at the 1891 rate of the tael. Even if the value is reckoned at the 1890 rate of 5s. 2d., it only gives £701,318 or more than £95,000 short of the figures for 1890. The only conclusion therefore, is that the teas were of an inferior quality, and so commanded a poorer price. This has been explained to me as follows by the agent of one of the British firms in Tawatutia:—

"The Tamsui tea planters had to contend against two things which undoubtedly militated against the quality of the first and second pickings. Heavy and continuous rains washed the goodness out of the spring tea, whilst the holding off of foreign buyers for two months later than usual necessitated the sorting of unpacked and partly fired leaf in the country, with very imperfect accommodation. Thus tea which, under ordinary circumstances would have arrived in a brisk and fresh condition came down in frequent instances with most of its attractive points evaporated, this being particularly noticeable in the higher grades."

I may mention that the holding off on the part of foreign buyers for two months was due to the fact that Oologs were obtainable at the opening of the season at more favourable rates in Amoy than in Tamsui; and therefore as nearly all the firms here are branches of Amoy firms, the latter went in for large purchases, whilst the Tamsui branches held off.

That this was possibly a doubtful policy in the long run is shown by the result above alluded to, namely, the appearance of an inferior tea, when Tamsui buyers ultimately commenced business.

The population of Tamsui and Kelung is generally estimated at 100,000, but owing to the absence of any reliable census, it is difficult to arrive at any accurate knowledge. The same may be said of the aborigines, whose numbers are, I fancy, absolutely unknown to anyone, including the Chinese themselves.

Chinese industries here are many and various—tea, rice, and fishing accounting for probably a large majority of the workers. Tea planting appears to be on the increase, as every walk into the hill country shows new patches of hillside being cleared for planting. The picking is done entirely by the girls and women, so the whole family is kept busy.

RICE-PLANTING.—The hardest work must be in the rice fields. Two crops are sown and gathered in the year, harvest times being in the fifth and tenth months of the Chinese year, or about June and November. From sunrise to sunset the plodding native is busy whatever the weather may be, plunging up the field, with the assistance of the patient but hideous water-buffalo, and manuring them in readiness for the coming crop, which is meanwhile gradually springing up in little wet nurseries carefully sheltered from the north wind by straw screens. When the fields are sufficiently ploughed irrigation has to be carried out, and a familiar sound at such times is the harsh squeak of the clumsy-looking but ingenious water-wheel which is worked with the feet by revolving treadles. The economy of the Chinese prompts them to make use of every little patch that is conveniently near a stream, and in such little patches where there would be no possible room for the clumsy buffalo to get round with a plough, I have seen a most ingenious contrivance used for breaking up the lumpy wet surface into a level smooth enough for transplanting. The labourer was trampling all over the wet patch with huge wooden skates, as they might be called, but having four deep wooden blades instead of one; also, instead of fastening such heavy things to his feet, a long loop of rattan from the skates to his hands enabled him to hold them tight to his feet, and thus equalise the labour of legs and arms. The result was all that could be wished.

With regard to the transplanting, the rapidity with which this carried out is wonderful. Little bundles of the young shoots are brought from the nurseries by boys to the men who are standing up to their ankles in mud and water, and I have seen as many as twenty shoots planted in a minute, or at the rate of 1,200 in an hour. The average rate is doubtless much less, but the rapidity and skill with which these men plant the shoots with the right hand only, the left holding the bundle of shoots, is marvellous.

Finally, when the rice is fully grown, the water is drained off the fields, the grain quickly ripens and the harvesting begins. In this as in everything else the procedure is primitive in the extreme. A large deep wooden tub is brought in to the field, at one side of which is fixed a rude screen formed by three or four bamboos, and a piece of as cheap sacking as can possibly be procured. A man standing in front of this tub thus screened receives bundles of the rice from the reapers, and holding a large double handful brings it down with a smart thwack inside the tub. This repeated once or twice threshes out the grain, and the straw is thrown aside to be afterwards piled in straw stacks that remind one of the ricks at home. Thus no threshing floors are used here, but every farmhouse has its smooth mud-plastered floor, on which the rice is laid out to get thoroughly dried in the sun.

AMSTERDAM.

Consul Robinson, in his report on the trade of Amsterdam for 1891, states:— * * *

TEA.—There was but little fluctuation in prices. Of China tea Amsterdam imported 2,643 quarter chests, as compared with 3,042 quarter chests, in 1890; and of Java tea 18,944 quarter chests, as compared with

30,022 quarter chests in 1890. The home consumption is comparatively a very large one, averaging for the years 1885-89:—Netherlands, 5,173,694 lb.; Germany, 3,975,882 lb.; France, 1,168,317 lb. Java-Assam tea is preferred to the ordinary sorts, but British-Indian teas find no market here. * * *

COCOA.—This article is continually increasing in importance, the quantity brought to this country in 1890 being:—Netherlands, 6,995 tons; London 10,390 tons; Hamburg, 7,380 tons. Java cocoa now begins to be an important factor in the trade, the importation being:—1891, 170 tons—as compared with 1890, 104 tons; 1889, 35 tons; 1888, 20 tons. The price of first quality Java varied from 11½d per lb. to 18 0½d per lb. * * *

CHINESE IMPERIAL MARITIME CUSTOMS. EXTRACTS FROM ANNUAL REPORTS FOR 1891. CANTON.

FOREIGN TRADE.—TEA.—Though the Canton figures account for but little of it, the business done in Tea has largely exceeded that of any year since 1887, the aggregate exports through the Kowloon, Lappa, and Canton offices amounting to 131,500 piculs, an increase of over 22,500 piculs as compared with the figures for 1890. Too rapid shipments at the outset were further facilitated in June by a reduction of about 30 per cent. made by the native Customs in export duty on all but the very finest class Teas. Dealers could thus lay down junkborne Tea in Hong Kong cheaper than they could deliver it "free on board" the steamer at Canton, and foreign buyers were able to execute many orders which would otherwise have been impracticable. Dealers were encouraged to continue buying freely in the country, and when in November a heavy drop on the London market put a stop to buying, the tea-men could only avoid worse disaster by becoming large shippers on their account. * * *

AGRICULTURE.

MANURES AND MANURING.

With the establishment of the School of Agriculture the reproach that attached to Ceylon of being backward in scientific agriculture must be gradually withdrawn. The practical portion of the work of the school most be extended however before it can be able to supply a long felt want. At the present moment a small plot of ground is cultivated, generally to establish preconceived notions, or to put it more mildly, to test the truth of what is taught within the walls of the School, and all the experiments are directed towards that end. A very good thing in its way and absolutely necessary to stimulate students; but hurtful from a habit it engenders of generalizing from so limited data. The liberality of Sir Arthur Havelock has given the School forty acres of ground attached to it, and this ought to aid the talented Superintendent with his teaching staff, to extend the practical portion of his work so as to embrace the cultivation of many products and to test the value of different manures.

It has been remarked often that the School has very unpromising soil to work on. I think this a distinct advantage, for the credit of growing paying crops on a poor soil is great, while no particular credit attaches to the profitable cultivation of a rich soil. Besides, the conversion of the poor, light, sandy soil of the Cinamon Gardens, to a fertile soil with body in it, will be a course of practical instruction, worth all the theoretical teaching the School can impart. Many persons, with a very limited knowledge of practical agriculture, talk glibly of giving body to light soils by the admixture of clay or clayey soil, and increasing the porosity of heavy soils by the addition to them of sand. They read of these operations in books on agricultural science and prescribe them off-hand. The practical man knows the immense and almost prohibitory cost of these operations. The work is not so easy and the cost so light as many imagine, to transfer

the sandy soil from one portion of a property, even if it is flat land, to the clayey portions, and *vice versa*. It may then be asked "How is the improvement of the soil to be carried on?" That problem is not an easy one to solve generally, but is possible at a not very high cost in Colombo. There are mountains of fibre dust at the various coir mills in Colombo, very much in their way, which it will pay owners of properties to remove and apply to them. Carts specially fitted up with high, open sides are necessary so as to transport a good load. This substance, if spread over the land and dug into it, cannot but improve all classes of soils. If some manurial substance be added to it the effect, as a matter of course, will be greater.

The "Magazine of the School of Agriculture" announced not very long ago that an attempt was about to be made to systematically improve the soil of the School grounds by the penning of cattle on them. The work will be accelerated and be rendered more thorough, if a thick layer of fibre dust be spread daily over the cattle droppings. By this means the volatile ammonia will be conserved and the ground can be gone over very much faster. The School will have to establish its own cart service, the cattle of which will aid in the operations of manuring and enriching the soil.

Fibre dust has been recently suggested as a suitable basis for the manufacture of a compost to take the place of cattle manure. The question of transport stands in the way of its being used largely away from Colombo. Its cost can to a very great extent be reduced if the very large quantity of moisture it contains be pressed out of it. If the coir mills undertake to do this at a moderate cost, they will benefit themselves and the agriculturist. I do not believe that the cost of transport of fibre dust and the price of guano, which has been suggested to be composted with it, will anything like equal the cost of making cattle manure on an upcountry estate, involving as it does large and costly sheds, the wages of grass cutters for food and bedding, poonac, and the risks run with rinderpest or murrain.

The relative values of cattle manure and a compost made of fibre dust and guano can be judged when it is stated that a ton of well-rotted dung is said to contain

Nitrogen	..	9 to 15 lb.
Potash	..	9 to 15 lb.
Phos. acid	..	2 to 9 lb.

While guano contains:—
Organic matter and ammoniacal salts 59.11 per cent
Phosphate of lime and magnesia 19.31 "
Alkaline salts, chiefly chlorides of potassium and sodium 8.13 "

The proportion of guano to fibre dust, so as to assimilate the mixture as nearly as possible to cattle manure, will be for an agricultural chemist to determine; but every practical planter can, after he determines the quantity of guano the particular form of vegetation he cultivates requires, and the quantity of the fibre dust he is going to give each bush or tree of his, regulate the mixture of his compost. It may be well to reproduce the opinion of an authority on guano:—"This substance is remarkably rich in fertilizing materials, nearly every one of its constituents being material highly valuable for the growth of plants. For this reason guano may be considered as the richest and most concentrated of manures. Most of the complaints against this manure, and the disappointments that follow its use, may be traced to the ignorance of the fact that it is too stimulating a manure—too concentrated—to be used, but with the utmost caution. Nearly two-thirds of its weight consist of salts and other combinations of ammonia, more than a fourth of which is real or pure ammonia. This portion of guano contains many of the same compounds as are found in the urine of domestic animals so that we may regard this portion of guano as urine divested of its large quantity of water. Nearly a fourth of its weight consists of phosphate of lime."

It will be of interest and great value to have the opinion of so competent an authority and one so well acquainted with our means of transport, soil

and climate as Mr. John Hughes on this important subject. Ville, the great apostle of chemical manures as opposed to farmyard manure, says in praise of them, that they are more powerful than farmyard manure which contains foreign matter which hinders the action of its chief constituents. I do not think this objection will apply to the compost I have suggested, which to my thinking will contain fertilizing matter in a readily available form in combination with a mass of vegetable matter, which while helping to regulate the supply, will in its decay improve the chemical and mechanical condition of the soil.

I will in another communication give my ideas, the result of experience, observation and thought, on manuring. B.

GUTTA-PERCHA.

The following is translated from *L'Industrie Electrique*, and is a report of a Paper read before the Société d'Encouragement in June last by M. Jungfleisch. An abstract of a Paper read before the same Society by M. Sérullas appeared in *The Electrician* of May 20th; and in the following issue an article appeared traversing several of M. Sérullas' statements:—

Two months ago M. Sérullas, in giving an account of his expedition to Malaysia to discover the best gutta-percha tree, alluded to a new method of obtaining gutta-percha, but did not enter into details.

Having, in conjunction with M. Damoiseau, investigated the principal constituents of gutta-percha, the author succeeded in obtaining all three of them in a crystallised state, and in ascertaining some precise data with respect to their nature. The variability of commercial samples and the consequent impossibility of reproducing with any degree of certainty the results obtained with any given sample, however, made him postpone publication. The wish to carry on these investigations with gutta-percha, the origin of which was certain, called the author's attention to the results of the French expeditions then at work elucidating the question of our gutta-percha resources, and especially to the results obtained by MM. Seligmann-Lui and Sérullas.

In fact, until quite lately, only vague information had been available with respect to gutta trees. The plants themselves had, indeed, been described with all possible botanic science, but no relation had been established between a given plant and the quality of its gum. The French expeditions fixed attention on these important points. In 1888 M. Sérullas had already sufficiently numerous data to make sure that Hooker's *Isonandra gutta* was the gutta plant *par excellence*.

By all accounts, emanating from this source and from foreign expeditions, the Malay method of working, an essentially destructive one to the *Isonandra* forests, was the cause of the approaching exhaustion of these forests, and, therefore, of the exhaustion of a raw product now become indispensable to the electrical industry. The Malays, with their present mode of operation, could only work trees 25 to 30 years old, or shoots of from 14 to 15 years; and the tapping of a tree of 30 only yielded at the most 265 grammes (9½ oz.) of raw gutta, which was often mixed with half its weight of foreign matters of no commercial value. Setting to work with more care than the Malays, M. Sérullas had only been able to extract 220 grammes from a 30-year old tree; the gum was, however, purer than that obtained by the natives. M. Sérullas saw a tree 1.2 metres in diameter worked, and it only gave 382 grammes of raw gum.

Such improvident and unproductive processes were very amazing when the enormous consumption was called to mind. M. Trevenen, taking note of the gutta, good or bad, exported from the Malay ports in 1884, arrived at a total of 3,144,847 kilogrammes (3,200 tons), an amount which, according to the data mentioned above, corresponded to the destruction of more than 12 million 30-year old *Isonandra*. However, *Isonandra gutta* were not the only trees cut down, and it might be remarked that similar species gave bad gutta iq

abundance. But it was nevertheless certain that production tended to rapidly diminish as consumption increased. In 1881 the International Congress of Electricians which met in Paris gave utterance to the fears which this state of things gave rise with regard to the future of the electrical industry. Recently, and on all sides, the big European powers had been moved to safeguard such an important interest by acclimatizing the *Isonandra* in their colonies, and by pushing its cultivation. The remote results to be expected from plantations of this kind undertaken 20,000 kilometres from Europe, and on a scale necessarily gigantic if they were to be of any good, would explain the feeble efforts hitherto made. The difficulties encountered by those who endeavoured to bring the European powers to a proper appreciation of the matter made the author doubt the efficacy of the schemes proposed, and led him to try and see if the question could not be attacked in another way.

An examination of the samples brought home by M. Sérullas in 1888 showed that gutta was present in all parts of the plant; the parts of other than the trunk contained gutta in amounts apparently very much greater than the trunk itself yielded to the Malays. Was it not possible that the coagulable matter of the latex might accumulate in some part of the plant whence it could be obtained by means more delicate than those employed by the Malays? If by any chance these parts were such that we might separate them from the plant without injuring it, the problem would have made a long step towards solution. Previous unpublished investigations, indeed left no doubt as to the possibility of finding solvents enabling us to extract gutta from these parts, and to extract it alone. M. Sérullas, who was then setting out again for Indo-China, was good enough to undertake the verification of the numerous hypotheses which a series of trials carried out with this leading idea involved; he also arranged to send home samples gathered under agreed-upon conditions so as to permit of the necessary experiments. Leaving aside mere attempts and suppositions shown to be inaccurate, it only remained, said the author, to point out the facts which these experiments had established.

The solvents which enabled us to extract gutta-percha from vegetable cells were many, but toluene seemed the best in the present case; it dissolved the three principal constituents of gutta-percha, and it did not dissolve in appreciable quantity the substances which accompanied it, with the exception of a little chlorophyll. Comparative tests were made with—(i.) Leaves dried in air, and sent dry; that was to say, exposed to the oxidation of the air. (ii.) Fresh leaves despatched in water, rendered antiseptic, and dried on arrival. (iii.) Dried shoots deprived of their leaves. (iv.) Two-year old wood, dried and deprived of leaves.

Contrary to anticipation, all these portions supplied much the same amounts of gutta, amounts which were always large. This first result enabled one to predict a favourable issue. It immediately fixed the attention on the part of the plant the most advantageous for treatment. By plucking the leaves, which the plant constantly renewed of itself, the effect upon the development of the plant was reduced to a minimum. The method of extraction was, moreover, a very simple one. The pulverised material was first exhausted by digestion at 100°C., and then by being placed in a solvent, such as toluene. A solution of gutta having a green tint, owing to the presence of a little chlorophyll, was obtained. The direct evaporation of the solvent not being possible without injury to the product, the toluene was carried off by a gentle stream of vapour of water—that was to say, at a maximum temperature of 100°C. For every volume of water evaporated four volumes of toluene were carried off, the gutta remaining. The toluene was completely expelled by prolonging the action of the vapour on the mixture, which was kept at a temperature of 100°C., and in a state of agitation. The yields obtained from the various parts of the plant mentioned above fluctuated between 9 and 10.5 per cent.; they were, therefore, much better than could have been expected.

But it might be asked whether these large yields were not due to the mixture with the gutta of some of the vegetable substances dissolved by the solvent? At first glance the appearance of the resultant product seemed to support this hypothesis; the substance being greenish, whilst the Malay gutta was red. In reality, gutta-percha, naturally almost colourless, was tinted in the former instance by traces of chlorophyll, which could be eliminated by appropriate treatment, and in the second instance by fragments of bark and special vegetable substances, from which the material obtained by the use of solvents was entirely free. The point of capital importance was that all competent persons, whether merchants or manufacturers, who had examined the gutta produced by the new process, had unanimously considered it to be very superior and comparable with the best descriptions which were no longer procurable, much to the regret of the electrical industry. Larger quantities must evidently be made to enable investigations to be made under conditions likely to fix attention on certain details. It was, however, even now possible to assert that solvents would lend themselves if judiciously used, not only to the extraction of gutta-percha but to its commercial treatment and purification.

The author then exhibited a number of samples of gutta-percha obtained by the solvent process.

Contrary to what might have been anticipated from the great oxidability of gutta carbon compounds, the leaves which were sent home much exposed to the action of constantly renewed air yielded a product the quality of which was excellent. It was permissible, therefore, to anticipate an exploitation of the surviving *Isonandra* of Malay, which should be based on the plucking of the leaves and their exportation in a dry state to Europe, where they would be submitted to the solvent process. The very marked characteristics of these leaves would protect manufacturers from fraud, and would give them with some certainty a gutta of excellent quality. Moreover, if it were a question of producing leaves or small branches the immediate return would encourage planters in the extreme East to an outlay the reward for which could not be delayed. Under these circumstances it was permissible to expect more from private enterprise than from the undoubtedly great perseverance and prescience demanded of European States.

Meanwhile it was allowable to anticipate the stoppage, more or less rapid, of the present mode of working. The Malays would sell leaves, which were easy to gather, quite as readily as the gutta itself, which was difficult to extract. Thus, a 30-year old tree, according to M. Sérullas, bore from 25 to 30 kilogrammes of green leaves or about 11 kilogrammes of dry leaves, which would yield by the new process from 1,000 to 1,100 grammes of gutta, while if the tree itself were cut down it would yield at the most 265 grammes. Moreover, according to Malay methods, many times the amount of gutta obtained from the trunk was left in the leaves and small branches. The natives would, doubtless, soon understand that leaf picking carried on during several seasons of the year must bring them in much more money than the laborious work of felling the large trees. Carrying on the same train of thought, a 30-year old tree need only give 7 kilogrammes of fresh leaves, which was but a small yield, to give a continuous return equal to which it would give but once if cut down. Trees of every age and size, at present without immediate use, would, moreover, be available for paying working.

The complete transformation of the present mode of obtaining gutta-percha seemed capable, therefore, of assuring a proper supply of this interesting substance to the European market. It was also to be hoped that private enterprise, by undertaking plantations, to which it seemed possible to promise quick returns, would see to the future.

[A correspondent sends the above article, and he remarks:—"As there is a growing demand for gutta-percha it seems to open up prospects of a new industry for Ceylon." Unless the success of the French process of extracting gutta from the leaves and twigs of the *Isonandra* trees is certain, the difficulty as

to private enterprise will be the long period, about thirty years, required for plantations to come to maturity. But clearly the Forest Departments in India, Ceylon and the Eastern World generally ought to devote their attention to the cultivation on a large scale of these valuable trees. Our own Forest Department has already taken up the cultivation of one species of india-rubber-yielding trees.—*Ed. T.A.*]

RURAL INDUSTRIES OF EGYPT.

Subsequently to the special dinner of the Horticultural Club, on the 25th ult., Sir John T. D. Llewelyn, Bart, who presided, gave an able and remarkably interesting address on the horticultural and agricultural resources of Egypt, whence he has recently returned after a prolonged visit.

In this opening remarks, Sir John Llewelyn said that Egypt was a land of agriculture rather than of horticulture, for good gardens were few and far between, and these were taken but little advantage of for teaching the people the cultivation of the several classes of useful and ornamental plants that have a place in them. Agriculture, on the other hand, was most successfully carried out, but it was pretty much a question of water, especially from the Nile, and *Nea os* (new mud) tells the story of the fertility of the vast tract of land watered by this remarkable river. This, at the time of its flood is, as is so well-known, heavily charged with earthy matter which, when the water overflows the banks, is deposited on the land, and so greatly does this deposit contribute to its productiveness, that the point to which the water reaches is so clearly shown when the crops are in full growth that it is hardly a figure of speech to say that it is possible to stand with one foot in the desert and the other on fertile land. Of the cultivated area, about one-half is devoted to Wheat and other cereals, and the other half to Date Palms, Cotton, Castor Oil, Sugar, Lentils, Peas, Beans, and Poppies. Of the several crops other than those of cereals, that of Dates is perhaps of the most importance to the people, and it would perhaps be of the greatest interest to a body of horticulturists. Phoenix dactylifera, of which twenty-seven varieties were commonly offered for sale, is abundant in Egypt, but rare in Palestine. Its rarity in the last-named country is all the more remarkable from the fact that the name by which the land was known to the Greeks and Romans was Phœnicia, or the land of Palms. Again, when Vespasian wished to commemorate on his coins the capture of Jerusalem by Titus, he represents Judæa as a woman sitting weeping under a Palm. Probably in olden times the valley of the Jordan was full of Palms, and the shores of the Dead Sea are fringed with trunks that have been preserved from decay by the salt water, and tell of a time when Palms must have been much more common than now. In Egypt the Date Palm grows as a common tree, and under ordinary cultivation is very productive. It also grows freely in some parts of Europe—Italy, for example; but in Granada alone does it ripen fruit on the European continent. To the Moors belongs the credit of introducing this Palm to Europe, and they say "He must have his foot in water, and his head in the sun." It undoubtedly marks the presence of water, and in proof of this, Sir John stated that Major Lloyd told him that when he was engaged in a survey of the desert, he saw a decaying Palm trunk, and in consequence sunk for water, and found a spring. In Egypt, each Palm is taxed at 20 piastres, which is equivalent to about 2½d, and as illustrating the usefulness of the Date to the people, it was pointed out that, besides its employment for building, wine is made from the sap, and a spirit is distilled from the wine. The crown of barren trees is cooked as a vegetable; sugar is made from the syrup; mats, baskets, and various utensils manufactured from the leaves; horses are fed on the stalks, and camels on the pounded stones. The trees bloom in March and April, and the fruit ripens in August and September. When first ripe the Dates

are harsh and astringent, but, like Medlars, are more palatable after fermentation, and are very nice also when dried in the sun.—*Gardeners' Chronicle*, June 4th.

THE MASCARENE ISLANDS.

[An article so headed in the *Gardeners' Chronicle* possesses special interest in view of the catastrophe which has befallen the island of Mauritius. We extract some passages.—*Ed. T.A.*]

The terribly destructive hurricane which lately visited Mauritius has called public attention to the products of this fertile island. Some account of the cultural industries of these, and adjacent islands, may therefore be acceptable, and these we are enabled to supply, as Monsieur M. F. Jadin, Chief des travaux de botanique à la Faculté des sciences, was recently despatched on a mission to the Mascarene Islands, to continue certain investigations of cryptogamic botany, which have for some time past been carried out in France for the public benefit. The notes de voyage of M. Jadin were communicated to the Société Languedocienne de Géographie, and published in their late bulletin.

M. Jadin, after visiting Mauritius, was no longer surprised to find Sir G. Bowen, who was Governor of the island from 1879 to 1883, pronouncing this colony to be "the richest country in the empire, and, perhaps, the richest in the world." It is for this reason that the botanist prefers the descriptions of the Isle of France given by Bernardin de St. Pierre in his *Paul and Virginia* to those which are to be found in his former *Voyage à l'île de France*. The first seems to him more just, more true to life, and he suspects, he adds, strongly, that M. Arvède Barine,* the author of a very interesting study on Bernardin de St. Pierre, can never have seen the Mascarene Islands, when he writes, *à propos* of these said descriptions in *Paul and Virginia*, "The landscapes are copied from nature, and complete by a divination of what the tropical vegetation ought to be, in a country more fertile than the Isle of France."

After this natural tribute to the comparison of fiction with real life and the literary value of the great Mauritian romance, without alluding to which no French writer could possibly touch on anything to do with Mauritius, M. Jadin proceeds more prosaically to modern facts, which can therefore be given in his own words:—

"The principal cultivation in both colonies (Réunion and Mauritius) is that of the sugar cane (*Saccharum officinale*, L.)

* * * * *

"The two colonies export the fibre of the Aloës—so-called—but these fibres are not extracted from the true Aloë [Aloe vulgaris of Abyssinia, the Aloe, of Dioscorides], but from the leaf of several *Amarylidææ* allied to the Agave. The principal species is the *Fourcroya gigantea*, Vent., or *Agave foetida*, L., which locally bears the common name of Aloës vert—Green Aloe. This plant, which blossoms in throwing out a tall flower-bearing stem to a height of six feet, from its basal tuft of stiff leaves, does not bear seed. The flowers, which have the form of a white bell, with a very sweet odour, are never fertile; at the base of each a small bulb is put forth, which develops quickly, and when the flowers are dead these bulbs remain and develop. As soon as each of these little bulbs has one or two small leaves unsheathed, the stalk bends under the weight of these small plants, and finishes by falling; once on the ground the bulb develops itself into a new plant. Very hardy, thriving in the most arid and rocky soil, the Agave propagates rapidly, and without further care permits the production of fibre at a low price.

"The cultivation of Vanilla is far more delicate; this Orchid requires a light soil, rich in humus, and also a support. The support generally in use throughout the Mascarenes is a Euphorbiaceous plant, the *Jatropha curcas*, L., which vulgarly bears the name of Pignon d'Inde—Indian Nut, or "Physic Nut;" all the

* *Bernardin de Saint-Pierre*, par M. Arvède le Barine. Paris, Hachette, 1891.

same, in Réunion especially, we have seen Vanilla plantations of great importance, having the Orchid supported on one of the trees common to the country, the *Casuarina equisetifolia*, Forst., called Filao. [The translator remembers seeing Vanilla grown on the stems of Palmistes, in Mauritius.] This climber also succeeds on the *Pandanus utilis*, Bory., or *Vacca*, a most useful tree in sugar-producing colonies, for its leaves are largely required to make sacks for the outer covering of the sugar-bags. Besides the particular care which the plantations of Vanilla require, we must not omit to mention the operation of fertilisation. As usual in all the Orchideæ, the fertilisation of the seed rarely take place without external intervention; in order to insure a good crop, the cultivator must impregnate each blossom which he wishes to produce a pod. It is an easy operation, however, consisting merely of pressing the pollen on the stigma.

"Vanilla, Aloes fibre, sugar, are the industries common to the Mascarene Islands; all the rest of which we now proceed to speak are limited almost exclusively to Réunion.

"Coffee has been for a long time a source of riches in Réunion; unfortunately a fungus (*Hemileia vastatrix*) allied to mildew, has within the last few years attacked the leaf of the coffee tree. The attack of this parasite first shows in a minute yellow point, enlarging by degrees till the whole leaf is yellow, when it tumbles off and brings about the destruction of the tree. The agriculturists seem little disposed to meet this pest by the scientific means which succeed so well against mildew. Imbued by preconceived ideas, they prefer to give greater vigour to the plant by means of liberal supplies of manure, and they allege that good results are obtained. It is well-known that efforts of the same kind tried in France to resist the disease on the Vines have only retarded the death of the plant. The *Hemileia* is a terrible disease; at Ceylon, for instance, where it is called the 'leaf-disease' (*maladie de la feuille*), all the coffee plantations have been devastated to such an extent that the inhabitants of Ceylon have nearly altogether abandoned the cultivation of coffee for that of tea; so vast a change of cultivation cannot possibly occur without suffering enormous losses.

"The Cassava meal or starch industry (*industrie féculière*), also gives very good results at Réunion. The development which the starch industry admits of in this islands, is such that we do not hesitate to class it as second in rank in the order of importance," so writes M. Ed. du Bousson in his *Agricultural Industry of Réunion*. Starch and tapioca are extracted from the Manioc, manihot utilisissima, Pohl. This industry already employs two very important mills in Réunion. They extract the fecula from the root, which contains about 20 per cent of its weight of this article of commerce. Its cultivation is very easy, and the amount of the yield is calculated at 42,100 kilogrammes of fecula per hectare.

"The Manihot utilisissima, or Manioc, is one of the Euphorbiaceæ which seems to be a native of oriental and intertropical Brazil. M. Alphonse de Candolle, to whom it is always safe to refer, for the origin of cultivated plants, says:—"If we were unwilling to accept this origin in oriental, intertropical Brazil, we must have recourse to two hypotheses: either the cultivated Manioc proceed from one of the wild species modified by cultivation, or they are forms which exist solely by the action of man, after the disappearance of their kindred forms of spontaneous vegetation." (Alph. de Candolle, *L'origine des Plantes Cultivées*, p. 50.)

"However this may be, it was on August 14, 1741, that Mahé de Labourdonnais, the great benefactor of the Mascarene Islands, then Governor of the Isle of France, introduced the Manioc into that French colony. This plant met with a very bad reception. He (Mahé de Labourdonnais) brought from Brazil the plants of Manioc, which he distributed to the inhabitants and it succeeded wonderfully. But some black people who had stolen the roots of this plant, having eaten them without duly cooking them under the ashes, died from their poisonous effect. Labourdonnais, naturally much alarmed, selected M. de

Reine to manufacture some flour from the Manioc and Cassava. He sent to him, together with the memoirs of Père Labat, a root of Manioc, a basin, and a plate, and ordered him to make some cakes of Manioc flour. M. de Reine succeeded completely. Labourdonnais then invited to Mon-Plaisir (his residence) a large number of colonists, ate the Manioc cakes in their presence, and made them eat some too. This celebrated repast took place on the day following the Christmas Day, 1741. Labourdonnais, as well as Messieurs Bouloc, Haché, Bernage, De Ponsy, and others, embraced M. de Reine in their transports of delight. Labourdonnais gave orders to have these Cassava cakes distributed gratis every morning at the bazaar, or market, and, by degrees, after a little time the colonists and blacks became accustomed to use them.

"At the present day the Manioc is completely naturalised; its roots serve for nourishment to man and beast, and the féculeri (starch) industry at Réunion is on the way to complete prosperity.

"The manufacture of perfumes, although only started for a short time, is already considerable. Principally, it is confined to the essences of Geranium, Patchouly, and Vétiver.

"The essential oil of Geranium is incontestably that of which most is manufactured. It is extracted from the leaves of *Pelargonium odoratissimum*, a plant which grows and thrives very well at all altitudes in this climate. [It is doubtful whether M. Jadin forgets that the Piton des Neiges in Réunion exceeds 10,000 feet altitude, where only alpine plants are to be found?] The altitudes comprised between 400 and 600 mètres, i.e., between 1,400 and 2,000 feet are most favourable for its production; and here three crops are gathered within fourteen months. The yield from March to October exclusively is the most abundant, a period of lesser growth is that from October 15th to January 15th.

"Calculating at 40,000 feet to the hectare, each cutting gives about 14,700 kilogrammes for each crop. This weight of the yield (with the leaf a certain quantity of woody stalk is gathered which, while augmenting the weight, diminishes the yield), gives from 10 to 12 litres of essence. A kilogramme of essence is worth, generally, about 60 francs, which gives an annual return of 1,750 francs (£70) per hectare.

"The essence of Patchouly, which is extracted from the leaves of one of the *Labiatæ*, *Pogostemon Patchouly*, gives a still better yield with more advantageous results; 50 kilogrammes of its leaves give 875 grammes of essence, or thereabouts. This plant also thrives very well in these climates.

"Lastly, the essence of Vétiver is extracted from the roots of a grass—*Andropogon muricatus*. The plant is very common in the Mascarenes; it often borders the fields of sugar-cane, and does not require the least care for its cultivation. Of this essence 400 or 500 grammes are furnished by 50 kilogrammes of roots; but the difficulty of extraction has not hitherto enabled the planters of Réunion to export this production with the requisite purity for the market.

"Of these three essences, that of the Geranium is most in favour in our colony. [It is needless to remark that black people are extravagantly fond of using strong perfumes, for very obvious reasons.]

"During the last few years, several large plantations of quinine have been formed at Réunion. Dr. Auguste Vinson,* the author of a valuable work on the spiders, Arachnidæ, of Réunion, succeeded in obtaining some *Cinchona* plants from seed received from Monsieur Decaisne, through the kind services of General Murin. In 1888, some 31,700 seeds planted by the Colonial Forests' Department had proved successful, and from this source the Department has distributed to a number of proprietors 4,150 plants. The nurseries of the Government (*service dominal*) contain some 16,500 plants of *Cinchona*. These plantations succeed well between 500 and 1,000 mètres (1,700 and 3,500 feet) altitude. The sloping sides of small ravines or depressions facing the leeward side of the mountains are

* Dr. Auguste Vinson was in the Mission to Radama II., Imerina, in 1862, where the translator had the pleasure of making his acquaintance. S. P. O.

most propitious for the cultivation of the Cinchonas. We were enabled to inspect these plantations under favourable circumstances, and the Director of the Forests Department, Monsieur Neveu, hoped soon to be enabled to gather a certain quantity of bark. Already in 1889 the Director of Woods and Forests had been able to sell a small quantity.*

"In countries like the Mascarenes, where fever is so common and endemic, where the health deteriorates so rapidly in constantly fighting against the attacks of malarial poison, it is readily conceivable how useful these plantations of quinine will become.

"We must not conclude these few pages, treating of the agriculture of the islands, without mentioning the very praiseworthy efforts made, particularly at Mauritius, to introduce the cultivation of tea. Whilst at Réunion coffee is consumed in great quantities, Mauritius, under the soft influence of the English ladies, without abandoning the traditional 'cup of Creole coffee,' whose renown is so justly merited, consumes a great quantity of tea. The Obinese population is somewhat numerous, and assists a good deal in this consumption. In 1888 the importation of tea was 53,881 kilogrammes, amounting to a value of 186,652 francs (£7,466). These figures induce a certain attention to be given to the cultivation of tea, especially when it is known that localities unsuitable for the sugar-cane are well fitted for tea plantations.

"At Réunion, in the Brulé de Saint Denis,* at about 1,000 feet altitude, we have seen tea plants growing well, uncultivated, and without any care being given to them. At Mauritius, on the high ground of Chamarel, we have been able to witness the same circumstance; indeed, many of the high plains of Réunion are uncultivated and we understand that sugar cultivation has been abandoned at Chamarel. Could not such localities be utilised for the cultivation of tea? It is useful to note that the tea cultivation is highly beneficial, and ought to pay well. The example of Ceylon, before quoted, ought to act as a stimulant for the colonists of the Mascarenes.

"Some praiseworthy efforts, we repeat, have already been attempted at Mauritius; in fact, beside a Government plantation, already supplying a well-perfumed and agreeably-tasted tea, we have seen a private plantation started. It is of considerable importance, and we are convinced that it will give good results.

"We have already noticed that the orography of the two islands is different; we ought not, therefore, to be astonished to find their floras somewhat unlike one another.

"The high altitude attained by the mountains of Réunion determines a variety in its vegetation, which loses its tropical character, and assumes a special physiognomy. Here we see small stunted shrubs, with low and twisted trunks, nowhere surpassing the height of a man. Here are mostly the Ericaceæ of the genus *Philippia*, vulgarly called *Ambavilles* (Heaths), causing the creoles to give to these highlands the name of the region of the *Ambavilles*; and amidst these Heaths are some *Acacias* here and there (*Acacia heterophylla*).

"This region of Heaths is found at about 5,000 feet elevation; but even below, from 3,000 feet upwards, these Heaths begin to show themselves, and predominate more and more over the other forest species as you ascend. This region is succeeded below by a zone of Bamboos, *Nastus borboniensis*, which has been well observed and described by Bory de Saint Vincent. Below the Bamboo zone, the vegetation of the island of Réunion, like that of the sister island, Mauritius, has a physiognomy eminently tropical; in these lower regions the same character is observable in the two islands. 'Since the publication of Mr. Baker's well-known work on the Mauritius flora† in certain most

important books, like that of Griesbach* for instance, different estimates are given of the dissimilarity between the floras of Mauritius and Réunion; we cannot help thinking that it is, as yet, difficult to pronounce authoritatively on this assumed want of resemblance, and we sincerely hope that a flora of Réunion as complete as that of Mauritius by Mr. Baker, may be undertaken and published, in order that these ideas on the resemblances and dissimilarities of the floras of the two Mascarene islands may be definitely fixed. The large collections stored for a long time at the Museum of Paris could surely furnish all the necessary material and elements for the work. [An immense number of plants, collected by Commerson, yet remains all but untouched.]

"The point of departure of these modern ideas is the following passage in the work of Mr. Baker:—'In its orography and botany, Mauritius offers a striking contrast with Bourbon and Madagascar, where the highest mountain-tops are in the centre of the island, attaining a height of 10,000 or 12,000 feet, covered with snow during several months (p. 14).' This is going rather far in its conclusions, at least as regards Réunion. In this island, it is true, the Piton des Neiges rises to 10,000 feet, but it is seldom covered with snow (in 1890, the year of our visit to the Mascarenes, it was not so covered): as to the mountains of Madagascar, which are not higher than the Piton des Neiges, we doubt if they are often covered with snow. [Snow is unknown as remaining on the highest mountains of Madagascar. The highest peaks are those of the Ankaratra mountains, only about 8,000 feet, far below the limit of perpetual snow-line. A few flakes of snow, and a rare shower or two of hail, have been recorded on the highest regions of Madagascar, with hail-frost, but nothing more.]

"On the other hand, all the plants introduced into Mauritius, and which are there naturalised, are also naturalised in Réunion. The fruit trees are the same in the two islands; we give the following as the most important:—The Anona, *A. squamosa*, L., which furnishes the Atte, or Custard Apple; *A. muricata*, L., or Corosol, the Sour-sop; *A. reticulata*, which produces the Cour-de-bœuf or Sugar Apple. The Citrus, amongst which we may specify the large fruits of the Citrus decumana, the Shaddock or Pamplmonse; the *Mangifera indica*, L., or Mango, in very numerous varieties; † The *Spondias dulcis*, Forster, which yields the Hévis or Fruit of Cythera, the Otaheite Apple, introduced from the South Pacific by Commerson (after Bougainville's return voyage); several *Myrtacæ*, amongst which the *Engenia jambos*, L., or Jambosa and *Psidium guajava*, or Guava, are very common; the first growing on the sides of the smallest streams, and the second in uncultivated fields. The *Persea gratissima* or Avocado Pear; the *Papayæ* of the *Carica* *Papaya*, so common that pigs are fed on them. The fruit of the *Nephelium*, N. Lit-Chi. of Camboesèdes, and *Nephelium longana* of Camboesèdes, the Letchi or Lychee from China. Several *Artocarpus*, particularly *A. integrifolia*, L., or Jack-tree, which furnishes from its enormous fruits a seed recalling to mind the Chestnut in taste; the Musa or Banana, &c.

"Besides the fruit trees, the vegetation of the uncultivated fields is the same in the two islands; there are the *Leucæna glauca*, Benth., or *Acacia*; the *Terranthera laurifolia*, Jacq., or Bois d'oiseaux, Birdwood;

* *La Végétation du Globe*. Par Grisebach; translation by P. Tchihatchef.

† The Mangos, which are most appreciated in Mauritius, include the following named species, viz., *Mangue Alphonse*, M. Aristide, M. Auguste, M. Bombay, M. Bourbon, M. Charpentier, M. Collard, M. Colville, M. Danpbiré, M. Figet, M. gelée, M. Genève, M. Goa or M. Madame, M. Lartique, M. Legal, M. Maison Ronge, M. Papaye, M. rosa, M. Sabre, M. Torse. Of these, *Mangue Anguste* and *Mangue Genève* are by far the most tempting; a most luscious and delicious fruit, with absence of the turpentine flavour which often disgusts European visitors who take the first Mango they come across.

* Places where the lava flows have streamed down from extinct craters are called *brûlés* in Réunion. *La pays brûlé*, or *Le grand brûlé*, is the district still devastated by the recent lava steams from the active volcano S. P. O.

† *Flora of Mauritius and the Seychelles*. J. G. Baker.

the *Lantana camara*, L., or Vieilles-filles of Mauritius and the Corbeilles-d'or, of Réunion; this plant, introduced but lately, has spread with an extraordinary rapidity. The shores are shaded by the same tree, *Casuarina equisetifolia*, Forst., or Filoa, and where the coast-line is sandy, there grows the *Ipomœa pes-capræ*, Roth. (Batatrant, or Batate à Durand, of the Créoles), which covers the sand with its creeping stalks, with leaves of a bright green, mingled with blossoms of a violet-rose tint.

"In short, we know that agriculture utilises the same plants in the two islands, and if Réunion occupies herself more especially with some products which Mauritius does not manufacture, it is solely because certain lands in the French colony do not offer the same facilities for cane culture by reason of the difficulty of communication along the coast, the consequence of the orography.

"All that remains of the primitive forest, nearly destroyed, now especially in Mauritius, has the same character; mossy trunks covered with Orchids, numerous Ferns, climbing plants running from tree to tree, the Rubiaceæ, Myrtaceæ, Sapindaceæ several, Terebinthaceæ. Palms, Pandani, &c., form the principal characteristic forest habitants.

"Reverting now to the flora of Mr. Baker, this author describes 1,058 plants, indigenous to Mauritius, Rodriguez and the Seychelles, of which 869 are spontaneous at Mauritius. A little more than a third, about 267 species, are quoted by him as likewise existing at Réunion. [With regard to these numbers of species common to the two islands, Mr. J. G. Baker writes:—'This figure of 287 is quite delusive. It does not include the cosmopolitan weeds, most of which grow in Mauritius, and occur also in Bourbon.' And again he explains that the above figure conveys an utterly wrong idea:—'In the *Flora of Mauritius*, the extra-Mauritian distribution of every species not endemic is given. He [Jadui] has counted only the species where Bourbon is expressly mentioned not the plants of wide distribution, such as the cosmopolitan weeds, like *Solanum nigrum* and *Bidens pilosa*. Of course the widely-spread weeds that are found in Mauritius are nearly all found also in Bourbon. The species common to the two islands, must be nearer 600 than 287.']

"Nevertheless, Mr. Baker has not attempted to search all the available documents on the flora of Réunion—this was not within the scope of his work—we notice, for instance, quoting at hazard from recollection, several *Solanum* (*S. nigrum*, L., *S. auriculatum*, Ait.), the *Ipomœa pes-capræ*, Roth., the *Siegesbeckia orientalis*, L., and the *Bidens pilosa*, L., &c., which he does not indicate as existing at Réunion, and which are nevertheless very common in this island.

"The families, best studied in the two islands, as the Orchids and the Ferns, are those which present the largest number of types common to both islands, according to Baker's *Flora of Mauritius*; thus, out of seventy-four species of Orchidaceæ, considered as spontaneous at Mauritius, forty-three are quoted by the author as existing also at Réunion; among 144 species of Ferns indigenous to Mauritius, sixty are also found in Réunion.

"We fancy that a flora of the island of Réunion would augment in notable proportions the number of species common to the two islands, without altogether showing a perfect similitude in the vegetation of the Mascarenes. Besides this, at Mauritius itself, it can be pointed out that certain species are confined to the small islets situated to the north of the island without having representatives in Mauritius; such are the *Lantana Loddigesii*, Mart., or *Lantana* of Round Island; the *Hyophorbe amariculis*, Mart., or *Palmiste gargonlette* (Water-bottle *Palmiste*, from its bulbous trunk), the *Pandanus Vandermeerschii*, Balfour fil., or *Sea Vaca*—*Vacua* de mer, which are confined to the so-called Gunner's Coin Island, and to Round and flat Islands three small rocky islets separated from Mauritius by insignificant arms of the sea.

"Another reason seems to confirm this idea, and that is the similarity of the fauna of the two islands: no large carnivore, no venomous reptile [on Serpent

land there are poisonous snakes]; on the contrary, large birds of different varieties which have now disappeared, as the dodo (*Dolus ineptus*), the Aphanapteryx (*A. Broccki*), the Mauritius parrot (*Pseittacus mauritianus*), &c. . . . All this seems to give us reason to believe that Mauritius and Réunion formed one whole country, divided by some ancient dislocation, causing minor variations in the flora and fauna of the two islands, which preserve, however, in their broad lines, the same essential character.

"It seems to us, then, that if Mauritius and Réunion have nearly the same flora; the botany of these two islands differs considerably more from that of Madagascar than that of Mauritius differs from that of Réunion.

"These reserves being made, it remains to us to note, after the important work of Mr. Baker, that, out of 869 species spontaneous to the island of Mauritius, the dicotyledonous include 460 species, the monocotyledons 245, and the vascular cryptogams 164 species.

"The families represented by the largest number of species are in decreasing order, the Ferns, the Orchids, the Grasses, the Cyperaceæ, the Euphorbias, the Compositæ, the Rubiaceæ, the Leguminosæ, the Myrtaceæ, and the Pandani; this is very nearly the dominant order usual throughout all tropical countries. If instead of enumerating the number of species, we consider those species most common, and classify them in order of their frequency, it would give a far better idea of the physiognomy of the country, and then we should be far more struck with the resemblances than by the differences between the two islands, which in spite of human treaties made on paper, will ever remain the sister islands." *S. Pasfield Oliver, Moray House, Anglesea Gosport.—Gardeners' Chronicle, June 4th and July 16th.*

NOTES FROM OUR LONDON LETTER.

LONDON, Aug. 12.

THE CHINESE METHOD OF PREPARING TEA LEAD.

The *American Manufacturer* gives us some curious particulars as to the method by which the Chinese prepare the lead with which their tea chests are lined. It is well-known that this lead is considered to be the purest that can be obtained, and it is eagerly bought up here from the grocers for several special purposes. It makes the very best kind of solder, and is also valued for several other purposes. Now it occurs to me whether, after all, it may not be better worth the while of your planters to use lead, always provided that some extra prices can be obtained to compensate for the cost of it. For when all is said and done it is doubtful whether any of the modern substitutes used instead of tea-lead—and numerous such substitutes have been discussed in your columns—equal in efficiency this time-honored method of packing tea. This is a point, however, on which there is certain to be great diversity of opinion; and it is more than doubtful, of course, if the planter could by any means recoup for himself the extra cost of employing lead. The means by which this is prepared in China seems to be of the crudest and most simple description, but it is probable that more scientific methods would not be more efficient and in a country where labour is so cheap as it is in China it is scarcely likely that more scientific methods of preparation would effect any sensible economy. According to the *American Manufacturer*, the course of procedure is to provide a large brick the size of the sheets to be prepared, this being covered with two or three sheets of paper. On these the molten lead is poured, and another brick is placed on the top, which flattens the lead out to the required size and thickness. The sheets are then soldered

together to fit the tea chest; the tea is packed in, and the top sheet is fashioned in place. The workmen are said to be very expert and to turn out an immense number of sheets in a day. Have your planters attempted to manufacture this tea leaf for themselves, or do they import it from China? It seems to me that if they obtained the pig metal direct, and made the sheets in the simple way above described on the estates, the cost of this very superior article would be so reduced that it might well be worth their while to use it instead of the various forms of packing paper now in comparatively large use.

NOTES ON PRODUCE AND FINANCE.

A NEW TEA.—The *Kew Bulletin* makes reference to "Faham Tea," a product obtained from the flat dried leaves of a small species of orchid (*Angraecum fragrans*) with white flowers, which grows as a parasite hanging from trees in the forests of Mauritius and Réunion. Although the plant in question has been long known to botanists, and the beverage used locally, its introduction to Paris as an article of commerce is quite recent. Samples of this "orchid tea," and of cigars made of the leaves, which emit a vanilla-like aroma, according to the *Bulletin*, are now deposited in the Kew Museum, and the plant can be seen growing in the Kew orchid house. This perfumed tea leaves a fragrance in the mouth, and is as good cold as hot. It can be used to flavour custards and ices.

TEA ANALYSIS.—In Paris chemistry plays a more important part in its connection with commerce than on this side. For instance, Mons. Bürker, the vice-president of the Paris Society of Pharmacy, has given the members of that body a digest of some recent observations on the analysis and character of tea. He thought it pretty well established that the commercial value of black tea is in direct proportion to the amount of theine it contains. In the case of green tea this is not so, and it is a mistake to estimate the value of a sample upon the results of a theine analysis. Here the question to be studied is rather the amount of tannin contained in the sample.—*H. & C. Mail*, Aug. 12th.

AGRICULTURAL EXPERIMENTS IN BOMBAY.

The annual report of the Director, Land Records and Agriculture in the Bombay Presidency, for the year 1890-91, contains some interesting rather than valuable, information regarding experimental farms and other "freaks of the Executive." There are at present four Government farms in the Presidency; financially, they cannot be called model farms, seeing that they were all worked at a loss during the year. In the Bhadgaon farm an epidemic of rinderpest destroyed 11,000 worth of cattle, and the total loss on live stock was more than three times this amount. A herd of Mysore cattle was maintained at this farm "at a cost disproportionate to its value"; and this too, notwithstanding that 27 bull-calves were sold for an average of ₹40 a piece. A herd of goats was largely increased by additions from the best native and Arabian breeds, and besides being a source of profit it is hoped to effect a good deal in the way of "improving the local strain." In the Poona farm there is a herd of 55 head of cattle, and the dairy is worked at a profit. It meets the whole of the Commissariat demands for milk products, and has given a decided impetus to the adoption of scientific dairy methods. Dairy farming is a pursuit which is daily acquiring increased importance with reference to Commissariat requirements, and we therefore make no apology for inserting a few details on the subject.

The experiments conducted at Poona had two objects, (1) to introduce improved European dairy machinery and processes, and (2) to study systematically the feeding and management of milch cattle, and the value of various breeds for dairy purposes. The use

of separators was introduced, and has been considerably extended, twelve having been sold in Bombay itself, and another dozen to mofussil purchasers. One of these, we read, has established a separator at Nadiad in Gujarat, and separates about 700 lb. of milk daily, buying the milk at ₹28 per hundred pounds; he sends the cream in locked cases to Bombay, where it is made into butter next morning, and sold at twelve annas per lb. The profit comes to ₹15 a day. Separated milk finds a ready sale among the poorer classes of Poona and Bombay; it can also be made into curd; or again, it is sufficiently nutritious for ordinary purposes, and is useful for fever patients. Butter and milk was at Poona supplied by the department to the military hospitals; and the medical and Commissariat officers recorded a very favourable opinion as to its quality. The contract also proved a financial success, for the Commissariat Department saved ₹250 a month, besides securing a pure supply for the soldiers. Various experiments testing the percentage of butter fat in milk were worked out: it was, for instance, ascertained that the first seer of milk drawn from a buffalo contains only four per cent of butter fat, while the last seer drawn contains ten per cent. Cheese-making was also tried, partly with buffalo milk, and partly with half buffalo and half separated milk. The chief difficulty was experienced in ripening during which process an even temperature of 65° to 75° Fahr., with moist air, is required. The best cheeses were those made with whole buffalo milk. They were of good flavour, good texture, and had good keeping qualities. It is satisfactory for us, in these provinces to know that Mr. Kevenster, the Swedish expert, who superintended the experiments, is now carrying them on under more favourable circumstances at Aligarh, and that the apparatus used has been taken over by the local Government.

The experiments with crops offer less general interest. A giant variety of bajra from Nadiad was grown at the Bhadgaon farm, and attracted much attention owing to the large size of the ears and the sweetness of the grain. Jowari and lucerne were grown as fodder crops; and lucerne, wright for weight, showed a great superiority to jowari. Stack ensilage was tried; but its advantages in facility of construction and sweetness of fodder were more than counterbalanced by the heavy wasteage. A large number of manures were tried; but it was found that farm-yard manure and oil-cake, as commonly applied by the Kunbi, were more profitable than chemical and other expensive fertilisers. Green manuring was tried with success; but the "patent silicate manure," tried at the request of the Bombay Chamber of Commerce, was applied to irrigated wheat at the rate of 5 owt. an acre, and did not appear to benefit the crop either in appearance or in yield.—*Pioneer*.

A CORNER IN PINES.

The planting of a bit of woodland teaches a great many virtues, but perhaps its most obvious lesson is that of patience, which it sometimes unexpectedly rewards just when one's expectations have been finally resigned as vain delusions. Such a reward and delight was ours in the result of a broadcast sowing of Pine-seeds in the autumn of 1888, so, for the comfort and cheer of those who may be downhearted about their own apparent failures, I wish to record the story of a final success.

When we started out to reclaim the worn-out old pasture on the hill at Overlea we set out a great many little evergreen trees of different sizes, a fair proportion of which survive in a vigorous condition, the smaller ones, planted when a foot high, being altogether the most satisfactory in percentage of survival. But Pines are queer; there is no denying that. Sometimes, when a tall weedy one was brought home, there were many jibes from the head of the family upon the folly of expecting such a specimen to stand the weather even for one season, while the merits of a stout, stocky, burly bush were highly extolled as a promising contrast. But now and then

the burly bush succumbed, while the thin weedy tree pulled through, very much like some of those scrawny and tall New Englanders, who, though looking as if a high wind would blow them away, prove to possess a tough and staying quality which nothing in their looks presages.

Now, having had it affirmed as a fact that a hundred Pine trees to the acre were enough if they all grew, nothing would really satisfy us but to put in a thousand to start with on about an acre and a quarter of stubborn soil. That is the true American spirit—a desire to overdo. Now, the master, having not much confidence in the methods of the mistress of this farm, concluded in true scientific spirit to begin at the beginning, and plant Pine-seed by the bushel, as the easiest and most thorough way of producing thousands of trees in a wood-lot. It was in vain to quote to this opinionated person books on forestry, which stated that the results of sowing seed in the reforestation of France and Switzerland had proved less successful than planting of young trees; he was satisfied, like Sam Patch, that some things could be done as well as others, and that it was no reason at all that because seed was unsatisfactory in the effete countries of the Old World that it would not behave with perfect propriety in the more vigorous and self-respecting climate of Massachusetts, where all the hardy trees and virtues manage to get proper nourishment out of the most forbidding conditions. Therefore, furnishing himself with a barrel of Pine-cones, the doctor went ahead with his experiment.

It was quite a job to shell the seeds, but the factotum found time for this on rainy days in the late autumn, and when the light snow fell the sower went forth to sow, before the resin had time to harden in the seeds and interfere with their fructification. This part of the job accomplished, there was nothing to do but wait for Nature to do her part in furthering the experiment.

Spring came. Up popped little Oaks and Maples and Walnuts and Chestnuts that had been freely planted at the same time as the evergreens, but not a Pine condescended to appear. All through the summer belated nuts were putting in a tardy appearance, but still no Pines. Birds and field-mice were supposed to have devoured them, and we dismissed them from our minds.

A year elapsed. A few unhappy little Pines poked up their heads in sheltered holes, six or seven of them huddled together. We paid them frequent visits encouraged them to live, piled sods about them to shade the poor little spines, but under an August sun in a very dry summer they withered away. By last year (1891) most of them had disappeared, and there was some scoffing on my part and quotation of authorities to emphasize the fact that Pine-sowing was no good, which the experimenter bore with becoming meekness, while counseling me to wait. But this I concluded was only by way of argument, and because no man likes to admit that he can be beaten by the forces of nature—namely, birds and field-mice.

But in this year of grace, 1892, lo! a miracle took place! When the March winds had ceased to blow and the snow had melted, so that we could walk abroad over the uncut brown grass upon the hill, what should we spy peering up beside the withered Golden-rod stalks and the ghost of last year's Daisies but thousands of six-inch Pines, rearing their gallant little heads, undaunted by the weather, and evidently come to stay. We hailed them with shouts of delight—here a clump, there a single one, crowding closely in the mossy springy places, more scattered where the soil was thin; but unmistakably there, after all these years of waiting, evidently quite at home, having hidden themselves in the long grass of the preceding summer, while they had been sending down roots so far that when we try to separate some of the denser groups it is really hard to dig them up with a trowel without injuring their fibres.

My scientific companion magnanimously forbore to triumph; indeed, the proud result was as unexpected to him as to me, and was so gratifying that he could afford to accept it with quiet satisfaction.

Some of these little trees, in a spot sheltered from the north-east wind by a clump of tall Birches, have attained respectable proportions, so that we ventured to move them into separate holes. Though taken up on a cool evening with a ball of earth, and apparently no disturbance of their roots, the perverse things wilt and hang down their heads as if they were ready to misbehave, which they have no excuse for doing. On one evening we moved twenty-five very little ones, which all grew in one hole, and most of them bore it very amiably, though some of them perished. As these would have died any way, if left alone in the struggle for the survival of the fittest in that little space, we bore their loss as well as we could, though I must admit that your true planter cannot see the death of one seedling with indifference, which gives a new meaning to the text that "not a sparrow falleth to the ground without His knowledge." If he who plants mourns the failure of one tiny seed, it helps to the understanding of the Creator's interest in all the creatures into which He has breathed the breath of life, for, after all, those of us who struggle to bring to birth or to keep in existence some germ of vegetation approach the great mysteries of being, and feel that we have a hand in it.

Our corner in Pines teaches us a brave lesson. Our joy in our little wood-lot, with its fairy trees, is the greater for being long delayed. What comes easily never has the zest of the pleasure that is waited for. We value a result by the difficulties of its achievement, the triumph of its success. An acre of unsown Daisies is a trial, while a square foot of planted Pines is a satisfaction, showing that a longed-for and slowly-reached result is in itself a reward. Our Pines represent the achievement of birth after long and almost hopeless waiting. It is not so much the thought of the majestic forest that consoles as the assured fact that the unstayable seed has started and that it has a future before it. Under the old tree we sit and look back; it represents shelter and repose and peaceful satisfaction. Beside the seedling in its various stages we stand and watch; in it is hope, a future, a long look forward. Age and youth; in each an interest and a joy. In one the delight of fruition, in the other the splendid promise of birth and growth. In the establishment of a tree for coming generations there is an unselfish delight. It is not our own reward we seek, but we lend ourselves to the great forward movement of life, and in that creative instinct feel ourselves elevated and enlarged, at one with mighty forces which we cannot understand, but of which we can avail ourselves by directing their vivifying course.

It is this linking of the humblest with the greatest that lifts existence above the commonplace; that gives to the philosopher, the poet and the artist an ever new meaning and joy in the common things of the earth, which, to him who reads aright, are fraught with significance. To the thinker, as to the poet, the simplest things serve as types which represent the infinite; to them the humble is the high, the microscope as inspiring as the telescope, since each reveals new worlds to the imagination. The seed contains the germ of the tree. One Pine-cone in time will produce a forest, for the progression is geometrical. One acre of ground faithfully studied gives one the key to the problem of the universe; helps to a recognition of the miracle of creation, and, rightly valued, affords perpetual food for the intelligence, while supplying the body with lively exercise.

From our corner in Pines we win hope, amusement and patience. It opens for us a window into the future and an outlook into the immensities; it links us with a hereafter we shall not live to see; with a generation by whom our names shall be forgotten, and proves to us the truth of that vision of the poet, in which he sees that

The whole round earth is every way

Bound by gold chains about the feet of God.

Hingham, Mass.

BARK AND DRUG REPORT.

(From *Chemist and Druggist*.)

London, Aug. 11.

CINCHONA.—The auctions on Tuesday were again very light, the total quantity included in the nine catalogues being:—

	Pkgs.		Pkgs.
Ceylon cinchona ...	768	of which	760 were sold
East Indian cinchona...	53	do	45 do
Java cinchona ...	117	do	117 do
African cinchona ...	70	do	70 do
South American cinchona	444	do	267 do
Total	1,452	do	1,259 do

The tone showed some improvement upon the last sales, and at times competition was rather strongly accentuated. The general view is that the auctions resulted in a slight but general advance in values, the average unit being now 1 3-16ths d. to 1 1/4 per lb.

The following are the approximate quantities purchased by the principal buyers:—

	Lbs.
Agents for the Mannheim and Amsterdam works	104,129
Agents for the American and Italian works	32,023
Messrs. Howards & Sons	30,485
Agents for the Paris factory	23,598
Agents for the Frankfurt o/M. and Stuttgart works	21,516
Agents for the Auerbach factory	21,120
Agents for the Brunswick factory	18,855
Sundry druggists	22,385
Total quantity sold	274,141
Bought in or withdrawn	37,122
Total quantity offered	311,263

INDIAN TEA DISTRICTS ASSOCIATION.

Chairman: General Henry Hopkinson, C.S.I. (late Chief Commissioner of Assam). Vice-Chairman: George Williamson, E. q. Secretary: Ernest Tye. Office: St. Mary's Chambers, St. Mary Axe, London, E. C.

The following is the twelfth annual report of the association:—The committee of the Indian Tea Districts Association have the pleasure to submit to the members the following statement on the conclusion of the twelfth year of its operations:—

OCEAN FREIGHTS.

Overtures were made to your committee, shortly after the last annual meeting, on the part of the Calcutta Steam Conference or "Association of Steam Ship Owners engaged in Eastern Trade," for a renewal of the agreement for the exclusive carriage of the Indian tea crop for a further period of five years in consideration of certain concessions. A meeting of your committee took place on Aug. 11, 1891, at which the following resolution was passed:—"Resolved that in consideration of a reduction of 5s per ton, making a net difference of 10s per ton between the average or mean of the rates for jute, linseed, rice and wheat and tea—and having the rebate calculated and paid on periods of three months, viz, July 1st, Oct. 1st, Jan. 1st, and April 1st—each quarterly payment to be made in the following month, it is agreed to enter into an agreement for a period of five years from July 1st, 1891, and at the termination of such agreement the rebate account shall be made up to June 30th, 1896, and be paid to the respective parties." The equity of having no penalty attaching to the natural termination of the proposed agreement by the simple eluxion of time (a point on which the meeting was unanimous) was not, however, appreciated by the Calcutta Steam Conference, and the negotiations fell through. On Nov. 3rd the question came before another meeting of your committee, when the following resolutions were unanimously passed:—(1). "That as the negotiations with the conference liners for a new agreement have resulted in failure, due notice be given to Mr. Westray, on or before Dec. 23th next, of the intention of the parties to the agreement of April 23rd, 1888, to put

an end to the same on February 23th, 1892." (2) "That the secretary be requested to ask the signatories to the present agreement to sign the requisite notice." Notice of the termination of the agreement was accordingly drawn up, signed by all the parties to the original agreement of April 23rd, 1888, and lodged with the secretary to the Calcutta Steam Conference. The secession of one of the lines comprising the Calcutta Steam Conference having occurred, the agreements formerly made with the combination were materially affected. Your committee are strongly of opinion that the interests of the tea industry will be best served by abstaining from entering into an agreement likely to obstruct free competition; they think that a fairer scale of freights will be secured by encouraging a system of free trade among ocean carrying steamers, and they are, therefore, of opinion that it is inadvisable to enter into a contract with any combination of shipowners.

INLAND RIVER FREIGHT.

This subject continues to occupy the attention of the special committee to whom the question was referred, but so far no final satisfactory agreement has been arrived at. Negotiations, however, are still pending.

LABOUR SANITATION IN THE TEA DISTRICTS.

An International Congress of Hygiene and Demography was held in London in August last, when Surgeon-General A. C. O. De Renzi, C. B., who kindly consented to prepare a paper shewing the great progress which has been made in sanitation in the tea districts of India, was nominated as the delegate of the association.

PROPOSED LABOUR SUPPLY ASSOCIATION.

The prospectus of this proposed association, which originated in Calcutta, was considered by a large and representative meeting, held on Feb. 9th last, when a resolution was unanimously passed cordially approving of the proposal to form such an association and agreeing to support the scheme. On May 5th another meeting took place, when Mr. Cruickshank, of Calcutta, explained in detail the objects aimed at and the proposed method of working. The members present affirmed their adherence to the scheme, promised their support, and strongly recommended all employers of imported labour to join the association. Unfortunately, the project does not seem to have secured that unanimous support in Calcutta which the importance of the subject demands. This is much to be regretted for many reasons, and especially so in view of the probability that Government may take early action to deal directly with the malpractices that are said to exist in the recruiting districts. The formation of such an association with the avowed object of placing the system of recruiting on a more satisfactory basis would be of material assistance to the Government, and representations from such a body would carry considerable weight in dealing with all questions affecting the importation of labour generally which are likely to arise when the revision of the existing Act comes under discussion. It is to be hoped that the unanimous support on this side may encourage the Calcutta Association to reopen this important matter and carry through the proposed scheme to a successful issue. The following résumé of the correspondence lately published by the Government of India and sent officially to your committee, is submitted for your information:—The Government of India has lately published a long correspondence on the question rising out of the conditions of coolie labour in Assam and the mode of recruiting labour in Bengal for the Assam tea plantations. The correspondence is summarised in a despatch from Lord Cross, in the course of which he expresses his satisfaction that the result of a very complete enquiry into the matter is that the present system works satisfactorily, and that the emigrant is generally well cared for and prosperous. He concurs in the view that emigration from the congested districts of Northern India to a province where there is an energetic demand, both on tea gardens and on virgin soil, for additional labour,

is to be encouraged. He noticed the unanimity with which not only the Government, but all the higher authorities consulted, recognise that the special labour law of Assam, though necessary under existing conditions, is out of harmony with the general principles of legislation accepted by civilised Governments, and agreed that all amendments of the law should be directed to facilitating the disuse or abolition of the system of penal contract on which it rests. Two serious evils accompany the working of the existing system—first, the excessive mortality both on the way up to Assam and also on the gardens, and the malpractices connected with the recruiting system in Bengal, which seem to have their origin in the high prices paid by planters for coolies under long contracts. Lord Cross then considers the remedies proposed. He sees no objection to an employer requiring a medical certificate of a labourer's fitness to work; he approves of the amendment of the Act giving local authorities greater power of initiative in dealing with unhealthy gardens; and he attaches greater importance to control, both sanitary and executive, being rendered thoroughly effective over the transit of unregistered labourers from the district of recruitment. The Secretary of State, however, is inclined to take a graver view of the malpractices under the present recruiting system than the Government of India, and he asks for further information in regard to the precise measure to be taken for strengthening executive action in the recruiting districts. He agrees that the maximum term for contracts should be reduced from five to three years, and that local and time-expired coolies should not be allowed to contract for more than one year. He also approves of the measures proposed to be taken for improving the system of inspection in Assam. Although giving a general approval to the measures proposed by the Government, Lord Cross does so with hesitation on some points, and on one or two he objects altogether. This is notably the case with regard to the abandonment of the present rule prohibiting the arrest, without warrant, of a deserter within five miles of a magistrate's office. "It is better," the Secretary of State comments, "that some few deserters should get away than that we should give any further extension to the wholly exceptional privilege of summary arrest which Act 1 of 1882 allows to planters, and which can only be justified on the ground of the paucity of magisterial courts, and the want of rapid means of communication which prevails in Assam."

The correspondence published by the Government of India regarding the proposed amendment of the Inland Emigration Act 1 of 1882 clearly indicates that the defects of the "Arkati" system of recruiting have attracted attention, and that measures are contemplated for strengthening executive action in the recruiting districts. The planting community will no doubt readily welcome any remedial measures having for their object the removal of any recognised abuses attaching to that special form of recruitment. It is to be hoped, however, that while the Government admits (to use its own words) the advantages of encouraging emigration from the "congested districts to a province where there is an energetic demand for labour" and where "the emigrant is generally well cared for and prosperous," it will also carefully weigh the possible effect of any proposed legislative action upon an industry to which the present comparatively high state of prosperity of the province is essentially due, while the industry itself is hampered and hindered in its progressive expansion by the scarcity of labour and the onerous pecuniary burdens it has to bear in connection with its recruitment and retention. It will therefore be desirable that the London and Calcutta Tea Associations be prepared to carefully scan any draft bill which may be brought forward, and to furnish the Government with such information and suggestions as may tend to strengthen its hands for legislation of a beneficial character, while guarding as far as possible against any measure of a needlessly drastic or retrogressive nature being passed.

FOREIGN TARIFFS.

The opportunity afforded by the termination of the existing treaties of commerce with Spain and Portugal

in which countries very heavy import duties have hitherto greatly retarded the trade in tea—Spain levying from 10d to 13d, and Portugal 1s 10d per lb. of tea—was taken advantage of to raise the question of the policy of modifying the tax on such an important item of consumption. A preliminary meeting was first held at the London Chamber of Commerce, when the arguments to be used on the occasion of meeting the newly appointed Ambassador to Spain were considered. An interview with Sir Henry Drummond Wolff, at the Foreign Office, in Downing Street, subsequently took place, and finally a letter was addressed to Sir H. D. Wolff with a *resumé* of the case, so as to impress upon him your committee's views on the subject.

CHICAGO EXHIBITION, 1893.

Several circulars have been issued by your committee appealing for support in connection with this and kindred opportunities of making known the merits of Indian tea in foreign countries. It was considered at first desirable to raise a fund for this purpose in the form of an annual subscription for the next five years of two annas per acre of cultivation, plus half an anna per pound of tea made, subscriptions to be contingent on the owners of not less than 200,000 acres joining in the fund. In view, however, of the necessity of making immediate provision for the due representation of Indian tea at the above Exhibition, it has been finally decided to dispense with the above guarantee and to ask all interested to subscribe at once the smaller sum of two annas per acre of cultivation only towards the expense of sending a special commissioner to Chicago and thus having Indian tea properly represented there. Mr. R. Blechynden, of the Agri-Horticultural Society of India, has been appointed the delegate of the Indian Tea Association, and is now on his way to Chicago. The Government of India has already granted Rs 40,000, while the Governments of Bengal and Assam are being asked to assist, and it is hoped that great benefit to the industry may result from this act.

NEW MARKETS.

Satisfactory progress continues to be made in finding new markets in different countries for Indian tea. To Australia and New Zealand direct exports from Calcutta have reached 5,000,000 lb., while to Bombay and the Persian Gulf 3,650,000 lb. were sent for the year ending April 30, 1892. In France, the operations of the "Palais Indien Tea Houses Company," in Paris, where it now has three separate depôts for the sale both of infused and of dry tea, have continued to progress satisfactorily, but the company—owing to the comparatively limited support accorded to it—is in want of more funds to enable it to carry its objects to a conclusion. It is hoped that further subscriptions for shares or debentures may yet be forthcoming, as it would be a matter of regret if this laudable effort on the part of a certain section of the planting community were allowed to fail for want of adequate support. In Germany up to last autumn fair progress had been made under the direction of Mr. Harington, the Special Commissioner deputed by the Calcutta Tea Association, to represent its interests there. It is much to be regretted that through the breaking down of Mr. Harington's health it may not be practicable to continue the work, so well begun. In Russia, steady progress has been made at Moscow and elsewhere by Mr. Rogivue, who was originally supported by grants from the Ceylon Tea Fund, and there is reason to believe that if adequate support were given Indian tea might be introduced through his agency concurrently with Ceylon tea.

TEA STATISTICS.

The imports and deliveries for home consumption of Indian and Ceylon tea during the past six seasons (June 1 to May 31) are shown below, compared with those from China. The exports from London are also given. These figures show most satisfactory results on the year's working, and should encourage those who recognise the importance of opening up new outlets for British grown tea and who are working for that end.

IMPORTS.

*ANALYSIS OF EXPORTS:—			
	1890-91.	1891-92.	Percentage
Indian ...	2,300,000	4,000,000	74 per cent.
Ceylon ...	1,400,000	3,000,000	114 per cent.
Ohiva ...	29,300,000	29,500,000	2-3 per cent.
	33,000,000	36,500,000	

The very large substitution of Indian and Ceylon teas for those of China in the London export figures, shown above, is the subject of congratulation, as showing that a long continued low range of prices is not altogether without its advantage in promoting an increased use of our teas.

GENERAL COMMITTEE.

The members of the General Committee, as usual, offer themselves for re-election.—*H. and C. Mail*, Aug. 12.

THE CULTIVATION OF TEA IN THE WYNAAD, AND CINCHONA PROSPECTS.

The twelfth ordinary general meeting of the Wentworth Gold Mining and Indian Estates Company, Limited, was held on the 21st July, at the offices, 34, Nicholas-lane Lombard-street, under the presidency of Mr. Robert Ewing.

The Secretary read the notice convening the meeting, and the directors' report was taken as read.

The Chairman said:—Gentlemen, there is very little more to say beyond that stated in the report. We resolved to hold the meeting here as only a small number of shareholders attended on the last occasion, and because we wished to curtail expenses in every possible way. This course, I think, will meet with your approval. As I said, there is little to add beyond what is stated in the report and what was said at the meeting last year. We have continued to carry out the same policy of nursing the estates during the present time of depression in the bark market. Notwithstanding the expectations which had been formed very generally in the trade that bark and quinine would improve, the reverse, unfortunately, had been the case during the past year. We

intend to pursue the same policy; but we shall be taking rather more bark than we did before, for the benefit of the trees. The policy of the Board, I think, is expressed in the manager's report, from which I will read the following passage:—"My endeavour since I have been in charge of these estates has been to keep the coffee and cinchona in good order, to get what was possible out of the former, and to have the latter ready for any improvement in price that may take place." We shall probably take larger supplies of bark from the estates, because we wish to shave some of our trees so as to get renewed bark. Our estates, according to the Manager's report and the reports of the agents on the coast, who visit the gardens periodically, are in excellent order. We can get large and regular supplies of bark at any time we want them, and in this next year we hope the result of the working will go still further towards meeting the whole of our expenses than has been the case in the past year, which shows an improvement over the previous one. Tea, apparently, is a success in the Wynaad, the soil appears to be admirably suited for it, and there seems to be a general feeling amongst the planters there that in the future—perhaps not in the immediate future, but before very long—at considerable area of land will be opened out for this purpose. We think we are doing right in preparing our estates to be in a position to take advantage of any demand for tea plantations that may take place, should we wish to dispose of the estates in the future, by making them in this way more valuable, or to take advantage of the good returns that we hope will come from tea should we continue to work them ourselves. We have kept the expenses down to as low a point as possible. We cannot, however, let our estates go back—we must keep them up; and I think this has been done. The London expenses I need not refer to at all. I think you will agree with me that we have kept them down to a very low figure. The debit balance on this year's working is £879, which is caused entirely by our not taking so large an amount of bark as we might have done to cover the expenditure. With regard to the calls in arrear, you will see from the accounts that a considerable portion has been recovered since the date of the balance-sheet, and our solicitors have been instructed to take such proceedings as they may deem advisable to endeavour to recover what is still outstanding.

Mr. Todhunter: Gentlemen, I am very much obliged to you for the confidence you have placed in me in re-electing me to the directorate of this Company. When I became a director, you will recollect, the Company was in a very bad position indeed, and I think that, under the circumstance of a falling bark market, which has been the case ever since, we have done the best that could have been done in the interests of the shareholders. I would like to say now that I think there is a ray of hope. There is no doubt that we have got a fine cinchona estate, and the Ceylon statistics seem to show that the production is falling off and that there may be a time when cinchona will again become remunerative. If that be so, we shall certainly from cinchona alone be able to derive a very fair income; but I think that the action which the directors have taken during the last two years must commend itself to the shareholders—that is, in having ascertained after a great deal of care and investigation, that a large area of the land we hold is eminently adapted for the cultivation of tea, and as we told you on the last occasion, we have called up the remaining capital of the Company for the purpose, among others, of extending the tea cultivation. We have commenced it, and we have already, I think, planted something like 130 acres—at all events, the land is prepared for a total cultivation of about 130 acres—and we think that in the course of the next three or four years we shall be able to extend the cultivation to the extent of about 500 acres. Of course, tea does not come into profit bearing for three or four years, and we must wait for the results of that planting; but I do think that, with the experience of Ceylon, where coffee is going out in the same way as it is going out in the Wynaad, and where cinchona is being taken off the

land entirely because it does not pay, there is just a ray of hope for us in the future, that, with a possible improvement in the price of bark, and with the probable development of a tea estate, we may, in the course of a few years, be in a very different position to that in which we now are.

The Chairman stated that the bark was of very high quality, the analyses of the Ledgeriana bark averaging 6 per cent. of sulphate of quinine.

Mr. Tolpitt said it would perhaps interest the shareholders to know that an invention was being brought out which was likely to revolutionise the cost of tea-producing. It was the invention of a gentleman he knew very well, and it would save an enormous amount of labour in plucking.—*M. Times*.

TEA AND SOIL IN CEYLON.

(Observer, Aug. 30th.)

"India and Ceylon Teas and Prices." "Why is it that Ceylon now shows nothing like such figures?"

Because Ceylon soil is not in it compared to India and the little that is in it is being pumped out of it by *fine plucking*.

AN OLD COFFEE STUMP.

[People would pay more respect to the *ex cathedra* utterances of this correspondent, but for the fact that he accused Ceylon planters of taking too much from the soil and too little from the atmosphere, and then failed to respond to all demands for explanation.—*Ed. T.A.*]

NOTES ON PRODUCE AND FINANCE.

THE CUSTOMS REVENUE ON TEA.—The report of the Commissioners of Her Majesty's Customs for the financial year ending in March last, will be pleasant reading for Ceylon planters, as it shows the remarkable advance in the popularity of Ceylon tea. The revenue from tea in 1891-92 exceeded that of 1890-91, by £6,288, the gross amount being £3,424,830, against £3,418,592. But it is pointed out that the real increase in consumption is not truly marked by the small advance in the revenue. In 1890-91 the revenue derived from tea was unduly swollen by about six million pounds in weight having been held back from clearance in the early part of 1890, in anticipation of a reduction of duty. Making due allowance for this circumstance the real increase in the consumption of tea during the past year appears as about equal to 8,813,000 pounds. The chief feature of the year just expired is that Indian tea has decreased somewhat in popular use, while the demand for Ceylon tea has enormously increased. While Indian tea has fallen in public use by about three million pounds in 1891, the consumption of Ceylon tea has increased by no less than 16,700,000 lb, or over 48 per cent. This is properly described in the report as "a most astonishing advance for a single year." Yet it was surpassed in 1888, when the consumption of Ceylon tea rose to 18½ million pounds from less than 10 millions in the previous year, the rise being almost 100 per cent. In 1891, for the first time, the use of Ceylon tea has exceeded that of China tea, which has now sunk to less than one quarter of our total consumption.

COFFEE AND COCOA.—The consumption of coffee is still declining, the gross revenue from it having fallen from £181,900 in the year 1890-91 to £181,287 in the last financial year. But if, coffee is losing ground in the public estimation, cocoa is rapidly gaining in popular favour. There was an increase of nearly £3,000 in the revenue from it during the year under review. Its consumption has increased 34 per cent within the last five years. The quantity of foreign chocolate consumed, given as 92,813 cwt. shows a decrease of 31 per cent.

JAPAN TEA.—Official reports show that the quantity of tea exported last year from Tokio (Japan) was 30,644,396 lb., or 3,182,174 lb. in excess of that in the previous year. According to an analysis of the export, the distribution of the tea was as follows:—Canada 10,846,075 lb., Chicago 7,606,474 lb., New York 6,807,832 lb., California 4,647,629 lb., Europe 451,017 lb., and the balance for the most part to China. The report says:—At one period enquiry at Tokio ran largely on lower-priced grades, the notion being that such would prove the more lucrative investment. The consequence was that a great quantity of hurriedly prepared low-grade leaf was brought forward from the country, and bought up at excessive prices. This led to the belief, on the part of the dealers, that quantity was more an object than quality. The careful manipulation of the leaf, which was noticeable at first, disappeared, and the character of arrivals continued to be unusually poor. What had at first promised to be a satisfactory season thus proved to be disappointing. The prospect of large supplies induced a depressed market at the consuming centres, where importers have found it difficult to realise cost for any teas deficient in quality. The demand for better grades, on the other hand, has been well sustained.

AN OLD STORY RE-TOLD.—In an official report on the China tea trade the following remarks occur:—"The real mischief which is driving China teas out of the market is the heavy local taxation, which makes it impossible to compete with the untaxed produce of India and Ceylon. Duty and *lihsin* together come to about 5 taels per picul, which, considering that the average price of Shanghai-bought teas is 13 taels to 14 taels per picul, represents a taxation of some 36 per cent. On the commonest sorts it is as much as 50 per cent of the cost. These facts have been urged on the attention of the Chinese Government again and again, but they seem indifferent to the threatened ruin of the once great national industry. At the present moment Russia is the best customer for China, and if the Russian taste were changing to India—which is always possible—the China tea trade would soon be a thing of the past. It is a delusion to suppose that China tea has deteriorated; the apparent deterioration of late years in teas sent to England has been due to the low prices paid by English buyers, at which they could naturally only get inferior teas. Russian buyers who pay good prices get teas of the former excellence. If the crushing burden of taxation brought were down to something like what it was originally meant to be, viz. 5 per cent *ad valorem*, instead of 20 per cent to 50 per cent as it now is, there would be a good chance for China teas yet. For the time being, India and Ceylon teas are the most popular, no doubt, but there is a large consensus of medical and expert opinion in favour of the view that China tea is more wholesome, and in its method of preparation freer of tannin and other deleterious elements."

THE TEA TRADE OF CANTON.—According to the report of the British Consul at Canton the tea merchants have represented the year as unsatisfactory alike to foreigners and natives. One of them, to whom the Consul is indebted for information on the subject, states that "conspicuous were in small supply, but sold in London at lower rates than have ever been known previously." He adds: "Scented capers have been in over-supply, and the exports by the end of the season reached a figure much in excess of the most liberal estimates previously formed. This was brought about partly by a large increase of the supplies of the lower grades, caused in a great measure by the addition to them of leaf from inferior districts, partly by the natives shipping on their own account to an unusually large extent, and partly by a reduction in the duty on tea passed through the native customs. The consequence has been a most depressed market in London, where teas are now selling at 2½ to 3d under rates ruling at this time last year." As the demand for Canton tea diminishes with foreigners it increases with Chinese. Among the latter, Szechow

has come into favour, and is now packed in paper parcels and sent to all places where there are colonies of Chinese. The Parsees also do a considerable trade in Taisham Congou, which they export to Bombay. In June, last year, the Hoppo made an arrangement with the native tea merchants by which all tea exported by junk was allowed to pass on payment of a duty much below that levied by the imperial maritime customs. This irregularity lasted to the end of the season. It enabled the foreign buyer to get his tea cheaper, and it saved him the freight by river steamer. Thus an increased business was brought about, but the result has been productive of harm to both natives and foreigners, as the small reduction in cost in no way met the severe fall in values in London brought about by an increase of supplies and a diminution of consumption.—*H. and C. Mail*, Aug. 19th.

GENERAL NOTES.

In a late bulletin from the Agricultural Experiment Station, California, Professor Hilgard records some investigations made on prunes, apricots and peaches with a view to ascertain the proportion of pits to flesh, juice to flesh and sugar contents of the juice, and the flesh of different varieties. In regard to the nutritive value of certain fruits it has been stated in former bulletins that the orange in California rated the highest, but these researches give the apricot an equal rank, while the prune follows next with grapes, bananas, apples and pears succeeding each other probably in the order named. Grapes stand first among the fruits in the quantity of mineral matter they take from the soil. The apricot, taken according to weight, holds the second place in this respect while the prune and the orange come third.—*Garden and Forest*.

The last number of *Forest Leaves* contains an interesting illustration, entitled, "A Historic Tree in Transit," and it represents a tree, seventy feet long and thirty-six inches in diameter, placed on a platform and moved along on rollers by block and tackle. The tree itself has a historic value, as it is an offshoot of the great Penn Treaty Elm which stood in Philadelphia. This tree measured twenty-four feet around the base, and one branch of it was one hundred and fifty feet long. It blew down in 1810, and a shoot which came up from the roots of the old tree was carried to the Oliver estate at Bay Ridge, New York, where it has stood for more than fifty years. This is the tree which was removed from there to the grounds of General Paul A. Oliver of Forest Roads, Oliver's Mills, Pa., whose ancestors owned the ground on the Delaware where the Treaty Elm stood. It was a bold undertaking to move so large a tree for 175 miles, especially since it had to be moved by horse and hand-power at the beginning and end of the route. General Oliver wrote on the 20th of June that the tree seems to be growing well and promises to thrive in its new home on the mountain-side as well as it did by New York Bay.—*Ibid.*

"THE SILVER WATTLE" is thus noticed in *Garden and Forest* :—

A charming coloured plate of acacia dealbata gives special interest and distinction to the first number of the forty-second volume of the *The Garden*, issued on the 2nd of July. This is the Silver Wattle of eastern Australia, and one of the most beautiful trees brought from Australia. It is now a well-known plant in all semi-tropical countries, forming, where the soil suits it, handsome specimens fifty to one hundred feet high, and in spring flowering most abundantly. It is largely grown in southern France, especially in the neighbourhood of Cannes, and a considerable industry is founded on the sale of its fragrant flowers, which are shipped to the Paris and London markets in large quantities. In California, too, it has been largely planted, and is one of the best Australian plants which have as yet been tried in that state, although apparently capricious about soil and location. At Cannes, for example, it is perfectly at home, while at Nice, a few miles distant, and in several other towns on the

Riviera, it refuses to grow, owing, probably, to the presence of lime in the soil, which is distasteful to many Australian plants. A line a yard wide, it has been said, may be drawn between Nice and Cannes to mark the boundary of the territories in which this tree will and will not grow. In its native country it selects swamps and low ground, where it sometimes attains a height of one hundred and fifty feet.

STEADY PROGRESS OF ORANGE CULTURE.—At DeLend Mr. J. B. Stetson, the Philadelphia millionaire, who has a princely winter residence there, is adding grove to grove until he owns 400 acres. At a central point, near the railroad, he is erecting an immense stable for his teams and implements, and hard by another building nearly as large for a packery. He has contracted with a company to erect water works to irrigate 300 acres, and it is among the contingencies that the same company may supply the town and irrigate many other groves. A fertilizer factory has a contract to furnish him with 400 tons of fertilizer per year, which will cost him about \$14,000. Just before going north he told a friend that the groves he has gotten into good condition are the best paying properties he owns.—*Farmer and Fruit-grower*.

TEA MACHINERY FOR THE WORLD'S FAIR.—The *Indian Agriculturist* of July 2nd says :—

Irrespective of the probability of securing new markets for Indian Tea at the Chicago Exhibition, the representative of the Tea Association should be furnished with working models of the latest machinery in use on our plantations; for, admirable as they are in their way, they are still capable of improvement, and the well-known inventive genius of the Americans may suggest such alterations as would bring our rolling machinery as near to perfection as it is possible to attain. Were a plucking machine invented, the cost of production would be lowered some 25 per cent at least, and though one adapted to dealing with tealah lands appears to be unattainable, it seems to us there should be no insurmountable difficulty in elaborating one that could deal with plantations established on the flat blue land. The late Mr. Burland, of the East India Tea Company, actually did construct a rough model, but the expense of patenting his invention deterred him from proceeding with the matter, and, moreover, he died before the era of blue planting had been inaugurated. The contrivance consisted of a blade similar to the common reaping machine, bent in the form of an arch, and about four inches broad, including the teeth, the cut leaves falling into a receptacle made of pump leather resembling a bamboo *choonga*, with a quarter of its side cut out, which was attached to, and level with, the base of the cutter; this arch embraced an ordinary tea bush pretty low down, and rested on a wheel on either side, buckets being hung at the ends of this leather *choonga* to receive the leaf, as it fell down under pressure of the increasing mass above. Now, all who have seen trim box hedges in England will understand that the success of some such tea reaper will depend upon very careful pruning at the outset, so as to secure a uniform plucking surface, and to this the trained gardeners that have been imported of late years, should devote their attention. Of course, there are difficulties in getting a machine to fulfil all the requirements obtained by hand picking, and the erratic growth of the shoots presents an additional obstacle, while the reaper could not deal with such sprouts as lie beneath its range of action, and it might be necessary for the ordinary pluckers, to follow the machine, for gleanings. These obstacles, however, may well be left to those who have given us the sewing machine and all those manifold labour-saving agricultural and other machines and appliances; and there is little doubt that some good might reasonably be expected to result, if what is needed were intelligibly placed before machinists by a practical planter.

The writer seems to be unaware of the existence of the tea leafplucker recently advertised.

THE PLANTING INDUSTRIES OF UVA.

Now that, at length, the period is approaching when long-isolated Uva will be connected with Colombo harbour and all between by a railway line across the dividing mountain system, it is interesting to note what the Civil Servant in charge of the Province thinks and says of the position of the main enterprises and industries which are relied on to yield the larger portion of the goods traffic of the line. Agitation for the extension of railway facilities to Uva was commenced when coffee flourished specially in the Principality and the large crops of fine quality berry harvested had to contend with most serious difficulties of transit. Before success was achieved the glory and the importance of coffee even in Uva had largely departed and the railway was more urgently than ever required to enable the planters by means of tea to retrieve the ruin wrought by the decadence of the once famous Uva coffee. It still lingers in haunts where it was once supreme, but here as in other portions of the island tea is now king. Mr. Fisher, in his administration report for 1891, wrote:—

COFFEE.—Although the area under coffee has been considerably reduced, Uva will still continue to be a comparatively large coffee-producing district for many years to come. The remaining estates are, for the most part, valuable properties, highly cultivated, and yielding good returns, and there is no reason to suppose they will materially deteriorate so long as high cultivation is kept up. The acreage of plantation coffee is now approximately 19,630 or 3,760 acres less than the estimated extent under cultivation in 1890. This shows a serious falling off, but it must be remembered that the land which has gone out of coffee has been planted up with tea, and will still continue to be productive in some shape. The native coffee is all grown in small gardens, and it is difficult to arrive at any accurate statistical information in respect to them, but the aggregate acreage and yield is very considerable, and I am in hopes that the area under cultivation will be extended. It is to be regretted that the Liberian variety of coffee has not become more popular with the natives, as it would undoubtedly thrive better in the village gardens than in more exposed situations. It is reported to be doing remarkably well, under partial shade, in the Monaragala District, and is said to be giving handsome returns.

TEA.—The planting of tea has extended with extraordinary rapidity, the acreage under cultivation having risen from 9,868 in 1888 to 22,757 acres in 1891, while the production of manufactured leaf has reached 5,000,000 pounds showing an increase of 2,000,000 pounds on the previous year's out-turn. Nor can it be doubted that this rate of increase will be maintained for some years, as much new land is being brought under cultivation, and a good deal of the tea already planted is still immature. Some of the best yielding tea has been grown on patana land, but it is feared that tea so grown is wanting in flavour, and it does not apparently command so high a price as the produce of old forest land. The average price realised throughout the year was fair. Some apprehensions were felt about labour, but in reality I believe the supply to have been amply sufficient, and I see no ground for expecting a deficiency in future years; for as facilities of transport are improved, and outlying districts become more accessible, the inflow of immigrant labour will increase, and it can always be largely supplemented by local labour drawn from the Sinhalese villages. On the whole, therefore, I consider that the prospects of the tea industry are very promising, and that for the present at least the enterprise is being conducted on a firm basis.

CINCHONA.—I regret to say that the planting of

cinchona has been entirely abandoned, and the uprooting of trees is general. The acreage under cultivation has been reduced in the course of the year from 6,439 to 2,831 acres.

CACAO.—There has been no extension of cultivation, but where favourably situated cacao has done remarkably well, and has given large returns. It is probably the best paying product grown by Europeans, and I should much like to see its cultivation attempted in the low-country under shade, and with the means of irrigation.

CARDAMOMS continue to be grown in small patches. **TOBACCO** was tried on a considerable scale, but it did not prove a financial success, and the repeated failure of experiments in all parts of the country will probably prevent any more capital being invested in this product.

What Mr. Fisher writes about labour reminds us that one great purpose for which the railway was always demanded was to place Uva more on a level with other planting districts in regard to supplies of Tamil labour. This will now be the case.

THE "URET" (GRUB) PEST IN COFFEE, TEA, CINCHONA, SUGARCANE AND TOBACCO IN JAVA.

(Translated from the "Indische Mercur" of 2nd July by Mr. John Dent Young.)

I.

There are certainly few planters in Java who have not already and frequently become acquainted in a very disagreeable manner with the larva of a beetle, which is spread all over Java, and which bears different names in different residencies, such as urets, uler bumi, wawatan, engkook, &c.

The coffee planter sees his trees suddenly become leafless, and many branches dying off with such a check that it takes them fully four years to recover and bear fruit, according to the opinion of planters in Ceylon and British India. On examination it is generally discovered that the grub—oeret [or in English spelling "uret"] is the origin of the evil.

The tea planter sees his bushes fading away, together with their fine young shoots, and thus his tea—and on examining the roots of the bushes he finds oerets [grubs].

The cinchona planter sees the green covering of the leaves of his trees, which indicated a strong elaboration, transformed into reddish nearly withered leaves which furnish but small hope of a rich formation of alkaloids. Here also he finds the roots attacked by the grub.

The sugar planter deplures no less the loss of his cane, which turns yellow and perishes in the end, leaving him lamentably short of his estimated crop. In this as well is the grub the guilty cause; and starting with the idea that weakened plants are more liable to the attacks of a prevailing disease than those in a healthy state, we are led to inquire if the grub does not, to an important extent, contribute to the spread of leaf-disease in the coffee tree and of the scorch in the sugarcane.

In 1890 when travelling in the principalities of Jokjokarta and Soerakarta (Vorsteulanden) I heard nothing but lamentation over the ravages of the grub and leaf-disease. Several years previously many coffee plantations had been totally destroyed, the trees having died off.

About the same time when travelling through Deli and the high lands of Serdaug, I was told by a superintendent that a great number of his tobacco plants had died. On reaching this estate I found the soil infested with the grub. And what up to the present time has been done to combat this pest?

Attempts have been made to search for, collect and burn the insects on the ground and likewise to

catch the flying beetles during the night,* the larva being produced by them. When seeking and destroying seemed to be hopeless work by reason of the enormous numbers, chemical means were employed to get rid of these destructive insects—such as unslaked lime, petroleum, carbolic-acid, &c. And a sugar planter in the east of Java informed me that gas water from the gas works in Soerabaya had been made use of for the same purpose. But the destruction of ever so many thousands of the insects by such means as above mentioned could have no appreciable effect on the myriads of myriads which are yearly produced from the eggs of the beetles.

In the number of the 6th February last of this journal, in the yearly report of the cultivation at Goenoeng Sarie, I met with the following statement:—"The damage done by this long prevailing drought consists chiefly in the development of the green and white bug together with the oeler boemie"—or earth-worm (the grub). "As this last named pest was discovered soon after its first appearance, its destructive effects were much diminished, as, in the absence of very urgent works in the establishment, a large force of labor was available for the search after the grub and its destruction, and about 320,000 of the insects were caught and burnt."

The earth-worm here alluded to is the "urèt" [or according to the Dutch power of the letters oerèt] of greater or smaller size, according to the dimensions of the beetle that produces it. The coconut beetle produces larva of great size.

No. 1.

Fig. 1.

Since the grub is found in high and moist districts—as well as in the low and dry localities where cane fields are situated, I am of opinion that it is an error to assume that "the long continued drought" above-mentioned has any connection with the appearance of the pests in question. The eggs deposited by the beetles may have been in the ground for a couple of years. Not alone in India, but equally in Europe is this same larva the terror of cultivators.

* I think Mr. Geo. Wall advocated the catching of the beetles during the night, with the help of large sheets and torches. The total destruction of the coffee estates in and near Bamarabotawa, Sibaragamawa, was caused by the grub; and it was said that fully 75 per cent of the coffee plants put out in Makeliya were killed in like manner, but there the supplies succeeded.—Note by the translator.

Monsieur Grandean, the well-known authority on agriculture, declares that the damage done by this insect to the cultivators of France amounts to the sum of 300 millions of francs [£12,000,000 English money]. For a series of years the savants of France have been striving to find a remedy against this pest, but all their efforts have hitherto seemed in vain.

Monsieur Vivien, chemist at St. Quentin, suggested the idea in 1889 of instituting researches after some means of infecting these insects with a disease.

II.

On the 28th June 1890, Monsieur Le Moutt discovered in a field in the departement de l'Orne a quantity of larva covered with a white blight or mildew. At the recommendation of Monsieur Vivien, Monsieur Le Moutt sent the larva he had found covered with the blight to Monsieur Girard, professor of a school of agriculture. In December following Monsieur Le Moutt requested Mousieur Prillieux—the Inspector-General of Agricultural Instruction and Director of the Phyto-pathological Laboratory—as well as Monsieur Delacroix in their turn to help forward his researches. The result was that the blight champignon, named *Botrytis Tenella*, was found to infect and destroy healthy larvæ and beetles, whilst it was innocuous to plants and other animals.

Messieurs Fribourg and Hesse of 24, Rue des Ecoles, Paris, in their laboratory connected with the institution of Dr. Pasteur, have subsequently been actively engaged in the artificial propagation of this champignon parasite. Its cultivation has been carried on with the utmost care by bacteriologists of experience and repute.

Experiments on a large scale were immediately undertaken both in France and Germany in the open air and in the agricultural organs of both countries, I see it stated that larva infected with the parasite *Botrytis Tenella* had been buried some centimeters in the ground in several spots in a field, and that all the healthy larva in the neighbourhood had been infected, diseased and destroyed, and that when ploughed up, the entire field was white with dead larvæ which were all enveloped in the blight (champignon parasite) which with the help of the wind and other natural influences was so distributed about the adjoining fields that an entire district was freed from the terrible pest.

The beetles as well become infested and the females deposit their eggs in a contaminated condition. So that the evil is counteracted at their first coming into existence.

Having well informed myself of all these facts, I wrote to the above gentlemen Messrs. J. Fribourg and Hesse of Paris requesting them to send me some tubes of *Botrytis Tenella*, and I forwarded this means of infection to the Heer M. Luder, chief manager of the coffee and cinchona undertaking Pagilaran—in the Residency of Pekalongan [on the north coast of middle-Java J. D. Y.] The Heer Luder carried on experiments with great care and patience. He wrote respecting them to the director of cultivation at Pagilaran as follows:—"The experiments made with the infected matter to destroy the grub during the month of April were attended with favourable results. After preliminary trials in earthen pots, and repeated careful microscopic examinations which brought nothing new to light, I at last found indications of the white mould or blight to a remarkable extent. I set to work immediately, to endeavour to cultivate the pure parasite—and had the satisfaction to see this effort succeed. As far as I could follow the process, the specimens which became covered with the blight were infected not by the poisonous matter directly, but by the diseased insects in a secondary manner. I continued the trials and am now engaged in cultivating the pure parasite directly and indirectly, viz., from the diseased grubs, and from the remains of the poisoned matter, which I preserved for the purpose. I have not yet begun to apply the system in the open ground as I am desirous first to ascertain how the process develops itself in the earthen pots. I shall however soon extend my researches to the open ground when I

shall have a sufficient supply of material. I will not fail to return to these questions."

The larvæ as well as the beetles meet one another constantly by their incessant burrowing in the earth, and thus communicate the infection.

A plantation strewed with diseased larva and beetles thus becomes in a short time thoroughly infected, whilst the wind and other natural helps tend to disseminate and multiply seeds of the blight, and newly formed or freshly arrived beetles on all sides either infect others or are infected. The poisonous blight is thus newly produced.

As a tube of *Botrytis Tenella* is brought into the market by Messieurs J. Fribourg and Hesse for six francs, an entire estate could be infected at the cost of three guilders, provided the bacteria in the tube should fortunately retain full germinating powers.

The manner in which the effect is carried out, I hope to make clear in the following remarks.

III.

The annexed representation, fig. 2, gives a microscopic appearance of the spores of the blight plant *Botrytis Tenella*.

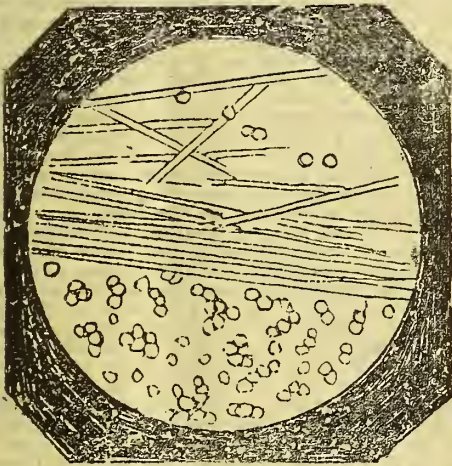

Fig. 2.

A hundred of the grubs are laid close together on a flat earthen dish covered with damp earth or sand.

They are then sprinkled one by one with these spores and the dish is covered with a plank on which there is damp moss. After about six hours the grubs become infected—they are then buried in a flower pot, and in about 15 days they will all be found dead, they will then present an appearance as shown in fig. 3, and will have assumed a light rose color.

Fig. 3.

In about a month after they present an outward appearance like the fig. below, 4.

Fig. 4.

Fourteen days later on they take the form shown by figure 5.

Fig. 5.

It can be easily conceived that the grubs (or sets) thus surrounded on all sides by poisoned spores—from which the blight plant itself derives its origin, the poison being buried right and left near the trees, cause the remaining still healthy grubs and beetles, which burrow in the ground, to come into contact with the infected remains of others, become diseased and die, and help to renew new the infecting poison, and to spread the deadly disease more and more in all directions.

It should moreover be remembered that besides the wind and the rain the digging up or plunging of the soil is naturally a great help in disseminating the poisoning blight plant.

When 100 grubs can be successfully infected with a tube of *Botrytis Tenella*—95 of them are buried in the soil about a foot deep. The remaining five infected insects are placed with some hundreds of healthy specimens in close contact in an earthen pot—the newly infected insects are buried in the soil, retaining some of them, for the purpose of communicating the infection to others—which in their turn are to be put out into the ground.

The infection germs can be cultivated in other ways namely by strewing the *Botrytis Tenella* on boiled potatoes mixed with glycerine. This preparation should be placed in different parts of the ground. The grubs and beetles which come into contact with it will become infected.

As all experiments are subject to failure I cannot sufficiently urge on the planters the necessity for perseverance, and for their not giving up the efforts in consequence of failure at first.

What has succeeded at Pagilaran may well be brought to pass elsewhere.

Since the Académie des Sciences at Paris has interested itself in the matter, and as the German Agricultural Journals have declared that on plunging an infected field the grubs (nrets) were found dead in thousands, it seems to me that in this matter science goes hand in hand with practice.

I could here produce a translation of letters by way of attestation to the importance of this subject, for example:—

From Monsieur de Bassoreille dated 21st Sept. 1891.

From the same, Bellevue, 15th Jan. 1892.

From Monsieur Devanse, dated La Bozoché, 19th Nov. 1891.

From Monsieur Tribondeau élève diplômé of Grand-Jonau, dated 13th Nov. 1891.

To infect the beetles, they are put into a box in which air, holes are pierced and powdered with the *Botrytis Tenella*.

At the expiration of 10 days the blight begins to show, and they assume an appearance like that shown in the figure 6. Buried in the ground they help to disseminate the poison.

Fig. 6.

It is an undoubted fact that the *urets* are the origin of an enormous extent of damage in the Government coffee plantation. Consequent on bad n-keep, nothing has been done to cause the destruction of this insect. In 1884 a Controller in the public service informed me that in the eastern extremity of Java, a vast extent of coffee plantations had been "written off," in consequence of the injury caused by these larvae. In the residencies of Pekoloogan, Tegal and Cheribon I could point out a great number of such abandoned coffee plantations. Are the Government coffee harvests not greatly diminished?

Seeing that the Académie des Sciences of Paris has attracted attention to the damage caused to agriculture by this insect, and that numerous foreign agricultural periodicals have for some time past been publishing articles devoted to this subject, it is to be hoped that the rulers of Java will invite the Director of the Experimental Garden and Laboratory at Buitenzorg to institute an elaborate research into the nature of the *Botrytis Tenella* and its properties.

Should the proposed remedy be found effective it becomes not only the interest of the governing powers to have the whole question thoroughly examined, but by acting with promptitude in the matter much good may be done to Indian cultivation.

The Hague, June 1892. (Signed) H. J. PRINS.

[The exemption in Ceylon of tea from attacks of grubs, so fatal in former days to coffee, is remarkable. We have seen dense swarms of cockchafer beetles on a coffee estate,—by striking a eucalyptus with a stick we have dislodged dozens from the stem, and we know as a fact of millions having been captured and killed on one property, while coffee was the culture. Now that tea has been substituted the sight of a beetle on this estate is as rare as that of a black swan.—Ed. T.A.]

AGRICULTURE.

MANURES AND MANURING.

II.

It must not be supposed that the remarks I intend making on this very large and important branch of Agricultural Science are *ex-cathedra*. Manuring is a very interesting and a very difficult subject and I, unfortunately for me, not having received a technical training can speak only as a practical and enthusiastic agriculturist, who by the aid of much thought and observation is trying to apply the principles of Agricultural Science to his daily duties.

In drawing attention to the communication on a substitute for cattle manure, you speak of application in holes. I thought this form of application was out of date now, and that the scientific and more beneficial plan of spreading the particles of manure over the soil and forking it in, was generally practised. The objections to manure holes are that the benefit of the manure is limited and the holes become one mass of rootlets, which of course is cut at the next application. The better plan will be to sprinkle the manure over the soil, leaving a clear space of about 15 or 18 inches round the bushes, and to fork it in with mamoty-shaped 3-pronged forks. In practice it will be found that this system is not more expensive than cutting holes and filling them up again, while for efficiency the

two systems cannot be mentioned together. It may be asked why I mention mamoty-shaped forks specially. Because I have seen, and read in the discussion in your columns on forking for tea, the evils of long pronged shovel-shaped forks in the hands of careless and ignorant coolies. They are driven deep into the soil near the bushes and levered towards them in such a way as to all but root them out. No wonder a tea planter finds his bushes "shut up" for a considerable period after deep forking. It may be said that on many estates the lie is too steep for forking. It is well-known that wash is less on a free than on a stiff soil, and surely soil that is subjected to the battering effect of frequent showers of rain, aggravated by the action of coolies' feet once a week or ten days when it is in a moist and sticky state, will be all the better for letting sun and air into it. If some consider it essential to bury the manure in the soil, I found very satisfactory results in coffee cultivation follow the application of manure in shallow depressions formed round the bushes by scraping away with small 3 or 4 pronged forks, the soil round the stem to a distance of 18 inches or 2 feet. If the coolies are taught to be always facing the bushes during the operation of scraping away the soil, the primary roots will be combed out and not broken, and the shock to the bushes will be slight.

In connection with the frequent stirring of the soil, perhaps you have not forgotten that I carried on a rather acrimonious (I say it with regret) discussion on this subject with a veteran Coconut Planter. The position I took in it was, that those who advocate and recommend it where perennials occupy the ground, showed a blind adherence to the teachings of Agricultural Science, which they adopted without modification or extension as circumstances required. That if by the breaking up of the soil and the comminution of its particles they were rendered soluble and available as plant food, then it was opposed to reason to disturb the roots, the mouths of a tree, just as they were beginning to feed on the food rendered available by the process of stirring the soil. It was particularly gratifying to me to find the views I enunciated on this subject confirmed in the "General Items" of the last issue of the "Magazine of the School of Agriculture." "It is certainly opposed to commonsense to suppose that the annual destruction or mutilation of the effective feeding roots of a tree should promote its health and luxuriance; on the contrary it is calculated to effect serious injury." Under these circumstances a careful planter will hesitate breaking the feeding roots of his tea bushes by annual forkings in addition to the mutilation the bushes suffer by the hacking they undergo and which is dignified by the name of pruning. I may mention *en passant* that I was always inclined to the belief that the cutting of manure holes with mamoties had a great deal to do with the old leaf disease had on the coffee bushes thus effected. How then it may be asked can the manuring of tea estates be carried on without mutilation of the rootlets? This is an impossibility, but the operation of manuring can be so carried on as to cause a minimum of injury to the feeding roots. The system I practice even with so hardy a tree as the coconut is, to dig manure one year in the space between four trees, the next year in the space between the trees across the line of coconuts and in the year following in the space along the line of coconuts. By this means all the feeding roots are never disturbed during any one operation, the whole surface of the ground is stirred and manured though not at the same time, the shock to the tree is lessened and the effect of the manuring is increased. If any one will take the trouble to sprinkle manure between every four of his tea bushes and fork it in with mamoty-shaped forks, he will find the cost about a fourth of cutting manure holes and covering them up again.

Though not a tea planter myself, I carefully follow everything connected with its cultivation as bearing on Agriculture. I read with interest the experience of planters that manuring gave them a weak tea. Tea and tea alone surely cannot be an exception to the rule that manuring improves and does not deteriorate

the quality of any product to which it is applied. I believe that if planters carefully taste their tea, they will find the flavor and quality improved a few months after manuring. I wish now to propound a theory accounting for the liquor from tea that has been recently manured being weak and flavorless. It may or may not be supported by the investigations of Science. One of the first results of manuring is an abnormal activity of growth resulting in heavy flushes. It is reasonable to suppose that in these flushes the sap, or in other words the constituents of tea, are found in an attenuated form and not concentrated as when the flush is normal. Is it not a fact that the tea made from the first few flushes after pruning when the growth is abnormal, is weak? Is not the tea made during the wet months of June-July invariably condemned as inferior in the Lame? Wasn't there a big outcry against the tea made during the excessively wet months of last year? I am strongly inclined to think that these experiences support my theory that anything that tends to diffuse the sap, prejudicially affects the quality of the tea.

The practical lesson to be deduced from this is, that a stimulating manure is unsuited for tea if the object of the planter is quality and not quantity. Practical experience will show whether the active properties of Guano will be checked by a large admixture of vegetable matter in the shape of fibre dust. I am inclined to the opinion that it will. If it be not, any suitable manure to be composed with it can be used. Vegetable matter decaying in soils is an absolute necessity for the healthy growth of vegetation, more especially in a clayey soil. For a "humus through its decay in the soil furnishes carbonic acid among other solvent agents, and this carbonic acid plays an important part by bringing the native" insoluble stock of plant food within easy reach. "Soluble plant food added to the soil in commercial fertilizers, needs the help of humus, finally, for its solution." "Plant food in most animal and vegetable residues used as manures, costs much less than commercial manures." This is a powerful plea for fibre refuse which through its decay in the soil if forked in will render soluble the large quantities of potash that clayey soils contain, not to speak of their other constituents. As a slow acting manure it will be interesting to have the results of the experiment on Mariawate with the shoddy manure Mr. Hughes recommended. B.

TEA AND COFFEE AT MERGUI.

The following are extracts from Mr. Ingram's Report on the experimental garden at Mergui for 1891-2:—Two small plots for planting Liberian coffee were cleared in the dry season and will be planted up during this rains. The number of Liberian coffee plants at the beginning and close of the year are shown below:—At beginning of the year 3,353. At close of the year 3,338. Decrease 15 due to two deaths among the larger plants and 13 among the smaller ones. The plants were again attacked by the leaf-disease of last year. As the dry season advanced the plants gradually recovered and shook themselves free of the disease, but it appeared again when the rains had properly set in. The result of two years' disease is seen in the very poor condition of the plants and in the crop, which was the smallest collected since 1887. The coffee crop collected during the year amounted to 47.45 viss. This together, with the balance from last year, 31.70 viss were all but 6.32 viss disposed of during the year. As there seems no likelihood of sanction being accorded to coffee being grown experimentally on a large scale (of 20 or 30 acres), the experiment with this species may be considered as closed, and the future usefulness of the small coffee plot in the Mergui garden will lie in its being used as a source of supply for seedlings and seed for free distribution or for sale.

The number of tea plants was reduced to 69. They were removed during the year to another situation on lower ground and near the stream. Since their re-

moval the plants have brightened up and are now looking healthy if still somewhat scraggy.

With reference to the foregoing remarks about Coffee the *Rangoon Times* says:—There is an inference in this that, if permission were granted to cultivate coffee on a large scale, it would be profitable to continue the experiment. The experiment with Liberian coffee has practically failed, and the failure cannot but have the effect of impressing the people with the belief that it would not be profitable for them to invest their money in the industry, and it must, also, make European planters timid of undertaking the cultivation of coffee in Burma. Would it not, then, have been wise to continue the experiment on a larger scale, especially as the Forest Officer in charge of the garden would appear to think that it is justifiable. The failure was occasioned by the plants being attacked with leaf disease, but that surely is not sufficient reason for throwing up the experiment and discouraging those who may be inclined to turn their attention to the cultivation of coffee.—*M. Mail*.

INDIAN PATENTS.

Applications in respect of the undermentioned inventions have been filed:—Andrew Charles Guy Thompson, Engineer and Tea Planter, Sagmootee, Nowgong, Assam, for "cultivating the ground between rows of plants, especially between tea plants or bushes and currant, gooseberry, and such like plants." Montfort Chamney, Tea Planter, Nowgong, Assam, for "the Disintegrating, sifting and oxygenising of tea leaf, after the process known in tea manufacture as Rolling."—*Bombay Gazette*, Aug. 31.

INDIAN AND CEYLON TEAS AND PRICES.—In glancing over Messrs. Stenning, Irskipp & Co.'s Tea Report of 11th Aug. our eye has been arrested by average prices for the teas of some Indian estates or companies, compared with which Ceylon teas are nowhere. The generality of Indian prices are no better than the present low prices for our own product, but then while the highest price quoted for Ceylon is only 11½d per lb., we have Assam teas selling 48 packages at 2/3½; 204 at 2/2; and 595 at 1/2½. Why is it that Ceylon now shows nothing like such figures? We should be glad to have an answer to the question, so that, if possible, the position of our staple product may be redeemed.

CHECK ON COFFEE PLANTING IN SELANGOR.—The collector of Land Revenue at Kuala Lumpur calls attention to his having recently received complaints from various planters who hold their land under the Land Regulations, 1882, respecting the cutting of timber on their estates by the holders of ordinary timber passes. It was formerly held that special permission was required for the felling of timber on alienated land in accordance with the provisions of Section 3, Sub-section 2, of the old Regulations. The Court, however, has decided otherwise. This is in his opinion a source of great inconvenience to the coffee planter, not only because it is desirable for the sake of the soil that the timber should be where it falls, but also on account of the difficulty of eradicating the brushwood which springs up immediately after the clearing of the jungle. He thinks it desirable that the Government should reserve the power to confer the right of timber felling on alienated land kept uncultivated, but that this right should be allowed to be exercised only in virtue of special permission. Coffee planting under European supervision is an industry which he finds it is most expedient to encourage, and while planters comply with the conditions of their grants they should be encouraged in every possible way. If they fail to do so, it is better to forfeit their land altogether than to punish them by allowing indiscriminate timber cutting thereon.—*Straits Times*, Aug. 24.

THE BRITISH CUSTOMS AND SMALL BREAKS OF TEA.

Our London Correspondent informs us that, having read in the last of our Overland issues received by him the letter written by the Secretary of the British Customs stating that the amalgamation of small breaks of tea would be permitted for the purpose of duty-paying, he sought further information on the subject. He appears to have satisfied himself that, although this departure from established custom had been made permissible, it was not in the least likely that the permission given would be availed of. Indeed, it is hardly conceivable that the Customs authorities could have properly understood what had been demanded of them, for we do not see that it could be within the power of the head of the great department responsible to overrule, even for the purpose of collecting duty, the stringent provisions of the Merchandise Marks Act. And it appears to us to be very certain that the object of those who first addressed the Customs on the subject could not have been solely amalgamation for the purpose of paying duty. There was an ulterior object, that of rendering it legal to put up such lots as might be constituted for duty-paying purposes in the gross at the public auctions. We have before referred to the great difficulties the handling of a number of small breaks of tea entails on those to whom they are consigned for public sale, and we can fully appreciate the desire these must feel to be relieved of a duty which must weigh heavily upon them and tend greatly to confine their business transactions. But so long as the brokers are willing to accept the dealing with such small breaks, so long, we apprehend, must they be content to put up with the inconveniences inseparable from such dealing. We have already pointed out the objections proprietors must entertain to the vending of their produce in association with that of other parties. Tea sold under such conditions could not be possessed of the advantages to be expected from the authority of well-known and favored marks. Parties purchasing would scarcely know what proportion of the lots bought by them could claim, or be possessed of, the much-valued *imprimatur* of highly reputed marks, and it is not to be doubted that for this reason both proprietors and purchasers would feel, were the proposal made carried out, that their interests had been sacrificed to suit the convenience of the brokers and Customs authorities alone. Therefore, we say, let the former of the two parties who desire to reap the benefits of the suggested innovation show a spirit of independence in the matter if they think it would be worth their while to do so. Let them notify to their constituents that they will refuse to accept the responsibility and trouble of dealing with breaks below a certain fixed standard of quantity. We have always admitted that we regard it as a mistake on the part of our planters and shippers to forward to Europe for sale the small breaks as to which complaint has arisen. And we have done so because we cannot but consider that it is inimical to their interests to do this; for it is well-known throughout the wholesale tea trade in London that, except for qualities of tea of extraordinarily fine character, these small breaks command less attention, and consequently fetch lower prices at the auction, than do breaks of more important dimensions. But, nevertheless, the practice of forwarding these small consignments continues, and probably will do so until the brokers take the step we have suggested that they should do and refuse to be troubled with them. This seems

to us to be the only practical course to be followed. Any attempt such as that indicated by the application apparently successfully made to the Customs would be sure to be resented by those whose interests, as we have pointed out, must be injuriously affected by it. And these last must be possessed of the whip-hand in the matter. No broker could be bold enough, or imprudent enough, as regards his personal interests, to include in a large break for sale consignments entrusted to him by constituents without previously seeking and obtaining permission from the last-mentioned to do so. We may be sure that this would be withheld under almost any conceivable circumstances; but even presuming that such might not in every instance be the case, it may well be asked whether the trouble and delay caused by reference to parties here would not much more than counterbalance the saving of trouble and labour which the existing system entails on the brokers. We feel assured that the permission granted by the Customs must remain, as our London Correspondent assures us will be the case, a dead letter in practice. Therefore let the brokers take the matter into their own hands if they deem it to their interest to do so; and notify to consignors that they will refuse acceptance of breaks below a certain standard. The practice complained of is an evil one in every respect, but it is not to be got rid of by any high-handed measure such as the brokers seem to have thought to be of possible adoption.

THE ORANGE.

AND THE FOOD REQUIRED TO PRODUCE IT.

The latest Bulletin (No. 17) of the Florida Experiment Station gives the results of a number of analysis of oranges made during the past year. The oranges were contributed by Rev. Lyman Phelps and Mr. H. S. Williams. The bitter-sweet and sour oranges, as grown in Lake City, were also analyzed, and the following table gives the average composition of all the oranges examined:

		COMPOSITION.	
	per cent	(a)	(b)
Moisture	87.710
Organic Matter			
(exclusive of nitrogen)246
Nitrogen	11.124
Silica009	1.00	1.00
Sulphuric acid042	4.86	4.86
Phosphoric acid077	8.63	8.63
Ferric oxide006	0.68	0.68
Lime207	0.916	2.77
Magnesia045	5.01	5.01
Potash479	52.05	52.05
Soda039	4.26	4.26
Chlorine011	1.23	1.23
	99.996	100.49	100.21
Less oxygen for chlorine28

Column (a) gives the percentage of the constituents in the fresh orange as a whole; (b) those in the pure, dry ash.

Our analyses of the ashes give sulphuric acid 3.3 to 6.8 per cent.; average, 4.86 per cent.; phosphoric acid, 7.5 to 9.8 per cent.; average, 8.6 per cent.; lime, 13 to 32 per cent.; average, 22.77 per cent.; potash, 42 to 59 per cent.; average, 52 per cent.; magnesia, 3.5 to 6.4 per cent.; average, 5 per cent.; soda, 2.8 to 5.5 per cent.; average, 4.26 per cent.

What proportions of the various constituents should an orange fertilizer contain?

Taking our average analyses as a basis, a fertilizer which is to restore to the soil the plant food removed by the orange should be composed as follows:

FERTILIZER INGREDIENTS BY WEIGHT.

	<i>Fla.</i>	<i>Cal.</i>
Phosphoric acid, parts by weight,	1.0	1.0
Nitrogen.....	1.6	3.4
Potash.....	6.0	4.0
Lime.....	2.7
Magnesia.....	0.6
Sulphuric acid...	0.5
Soda.....	0.5
Chlorine.....	0.14
Silica.....	0.10
Ferric oxide.....	.08

It is commonly accepted as true that the planter need concern himself only about the first four, all the others being, with rare exceptions, abundantly present in all soils. The rare exceptions are, perhaps, sulphuric acid and magnesia. The latter (as also lime) is always abundantly present in acid phosphate, or can be supplied in the form of gypsum or land plaster. Magnesia is rarely absent from any fertilizer, amounting sometimes to 10 per cent, or more. Silica never needs to be supplied; nor do ferric oxide, soda or chlorine; or, if they do, they are always present as incidental parts of all fertilizers, often to so great an extent as to be a nuisance. The orange draws *potash* from the soil in far larger quantity than any other constituent. This is, however, precisely that constituent which is relatively deficient in popular orange fertilizers now on sale in Florida. These fertilizers contain from 1 to 2.5 times as much phosphoric acid as potash, and 2 to 5 times as much phosphoric acid as nitrogen. Whereas according to our analyses, the orange takes from the soil 6 times as much potash and 1.6 times as much nitrogen as phosphoric acid (in case of the California orange, 4 times as much potash and 3 times as much nitrogen) That one of these three most important constituents of which the orange removes the least, the one, moreover, which is most likely to be present, and often actually is present in Florida soil in excessive abundance, namely, phosphate, is the one which these fertilizers supply in excess.

FERTILIZER INGREDIENTS BY PERCENTAGE.

A fertilizer who would return to the soil the constituents extracted by the orange, should contain about 2.7 per cent phosphoric acid, 4 per cent nitrogen, and 16 per cent of potash. These remarks have reference to old bearing trees. Our analyses are of the orange merely, not of the leaves, trunk root or twigs. The leaves and new growth extract food from the soil, but this should, by decay of leaves and burning of prunings, be returned. (In case of burning the nitrogen would be lost.)

A FERTILIZER AS IT IS.

The quantity of an excellent and popular fertilizer recommended to be applied on old bearing trees on pine land is such as would furnish yearly to each tree twenty-two to thirty-nine ounces of available, to say nothing of the insoluble, phosphoric acid; twenty-three to thirty-nine ounces of potash, and 10.5 to eighteen ounces of nitrogen. The phosphoric acid is greatly in excess of what would seem to be needed, and the nitrogen somewhat so.

The fertilization of fruit trees is a subject about which there is little accurate knowledge, and greatly needs to be studied. The formulas for orange fertilizers undoubtedly need to be revised; the quantity of potash relatively to the other constituents needs to be increased.

A FERTILIZER AS IT SHOULD BE.

A fertilizer containing something like 2.7 per cent of phosphoric acid, 4 per cent of nitrogen and 16 per cent of potash would restore these elements to the soil in something like the relative proportions in which the orange takes them. About 12.5 pounds of this fertilizer would be enough for the production of 1,000 oranges. The orange is a large consumer of lime, and makes no inconsiderable drafts upon sulphuric acid. Those constituents should be looked after. And there doubtless are soils which would respond gratefully to an occasional application of magnesia.

In the following table is a record of the

WEIGHT AND SPECIFIC GRAVITY

of ten oranges from week to week. It shows the interesting fact that, whereas the weight of an orange constantly decreases, the specific gravity increases for a while, then afterwards falls off. This means that for a period after plucking the orange becomes more and more compact, then afterwards "loosens up," so to speak. When the first weighings were made the oranges had been plucked from the trees three to nine days. The determinations of specific gravity were made at intervals of about a week, until decay of the orange was observed to have set in. In all cases, except one, the initial specific gravity was less than unity. This case is not to be reckoned as an exception, for the reason that the orange was three weeks from the tree at the time the determination was made. In eight cases the specific gravity gradually increased during the first three to six weeks, then declined. In two cases there was a decline from the first. In six cases the increase reached a maximum of over one. In all cases there was a constantly increasing loss of weight. If these ten oranges fairly represent what usually takes place, the matter may be summed up as follows. (1). The specific gravity of a freshly pulled orange is generally less than unity; that is, it will generally rise to the surface if placed in rain or distilled water. (2). The specific gravity of a fresh orange generally increases for a while as the drying-out goes on, then decreases the maximum often exceeding unity; that is, an orange which at first would rise in water will after a few days or a week sink, than later rise.

In making up the scale for honors and medals, weight is put down at ten. In view of our record, it would be manifestly unfair to compare the weights of oranges that had been pulled from the trees different lengths of time.

WHEN ORANGES GET SOLIDEST.

We have not room for this table; but we will summarize it as follows: No specimen when freshly plucked had a specific gravity greater than one; that is, they would all float in water. After being kept twenty-eight days the Majorca turned the point and became so dense as to sink; the Jaffa in twenty-one days; the Navel in twenty-eight; the Tangerine not at all, Columbia county (large) not at all; Columbia county (small) twenty-one; Maltese Blood thirty-five; Improved Malta fourteen; Double Imperial not at all; Indian River not at all; Indian river founding sixteen.

WEIGHT OF PEEL IN FLORIDA AND CALIFORNIA ORANGES.

Last year Professor E. W. Hilgard made an analysis of California oranges of the crop of 1891, which was published in the Pacific Rural Press of July 11, 1891. He analyzed twenty-two samples, from which we exclude three because they were coarse seedlings. The average percentage of weight of peel to the entire orange in the nineteen samples was 26.22 The Florida Experiment Station (Mr. J. J. Earle) analyzed fifteen, from which we also exclude three seedlings for the same reason. The average percentage of weight of peel in the twelve samples was 21.25.—*Florida Dispatch.*

BARK AND DRUG REPORT.

(From the *Chemist and Druggist.*)

LONDON, Aug. 25th.

CINCHONA.—Tuesday's cinchona auctions were again light, the total quantity of bark offered consisting only of:—

	Paokages.	Paokages.
Ceylon cinchona...	9 1 of which	849 were so'd
East India cinchona	111 "	84 "
Java cinchona	30 "	30 "
West African cinchona	40 "	40 "
South American Calisaya cinchona	435 "	284 "
Cuprea bark	3.3 "	— "
	1,850	1,287

The assortment was very poor, barks of high analysis being almost entirely wanting. There was also a noteworthy paucity of East Indian barks. Holders were very firm, while on the other hand there was a good deal of competition among the manufacturers, with the result

THE TEA ROLLER PATENT CASE.
JACKSON V. BROWN AND THE
COLOMBO COMMERCIAL COMPANY.

The case of Jackson v. Brown and the Colombo Commercial Company, in which the plaintiff alleges that defendants have embodied in their Triple Action Tea Roller certain machinery which he had patented in regard to his Excelsior Tea Roller, came on in appeal before the Chief Justice and Mr. Justice Lawrie in the Supreme Court on the 8th September. Messrs. Advocates Wendt and Sampayo appearing for the plaintiff, and Messrs. Dodwell Browne, Dornhorst, and Hermann Loos for the defence.

OPENING SPEECH OF COUNSEL.

Rising at 11-30, directly after the Judges had taken their seats, Mr. WENDT said that he might state in opening that both sides had agreed to accept a print of Mr. J. Kirby Maynard's shorthand notes of the proceedings in the Court below, and he desired to hand this print in, as it would be more handy for their lordships than MSS.

The CHIEF JUSTICE consented, so long as both parties agreed.

Adverting to the libel in the case, Mr. WENDT then said that the Court would observe that two defendants were sued, one being Mr. Brown who took out the specification of the Triple Action Roller in Ceylon; the other being the Colombo Commercial Company, who were sued as they were alleged to have done certain acts separately for which the plaintiff had a right to put in a claim. The allegation against the first defendant was that he imported into and sold in Ceylon the alleged infringements; while in regard to the Company the case was for importing, using and selling. To this action three lines of defence were given; the first being a contention that the procedure should not have been by action but by an application under the Patents Ordinance; secondly that there had been no infringement; while, thirdly, there were denials of the usefulness, utility and novelty of that which plaintiff claimed as his invention.

The CHIEF JUSTICE:—The objection to the procedure must be a legal objection, by demurrer.

Mr. WENDT said it was put in as a matter of law based on re-assertments of fact. The defendants objected that the plaint disclosed no cause of action—their reasons were set out—and as further matter of law on which they relied for their defence the defendants went on to say that on the 24th October 1888 (the Court would remember that the date of plaintiff's patent was 1881) His Excellency the Governor, with the advice and consent, &c. granted to the first defendant a patent for an invention for improvements in machinery for rolling tea leaf, &c. Such invention had always been known as Brown's Triple Action Tea Roller and possessed utility, so it was claimed, far superior to that designed by the plaintiff. Certain issues had also been agreed upon, as would be seen in the record. After the opening of the plaintiff's case the plaintiff himself with his witnesses were called, and, on behalf of the defendants three or four witnesses were called, and on this the learned Judge had pronounced the judgment he intended to lay before the Court that day. Of course, the most material thing in regard to the first issue raised was the specification of the plaintiff's invention, and to this he desired first to direct the attention of their lordships. He also wished to refer them to the models produced in Court, which were those introduced in the case in the lower Court.

The CHIEF JUSTICE:—Are they worked by steam?
Mr. WENDT:—No; by hand, and fortunately I am strong enough to work them here. The one marked as the Excelsior was a model of the machine patented by the plaintiff which had been put in and agreed to as embodying the invention patented.

MESSRS. BROWNE AND DORNHORST:—No, no.

Mr. WENDT:—Well, the plaintiff said that was a model and it had certainly been put in as evidence. Now, a great deal of time was spent in the lower

Court in determining what was the "case" or "jacket" so often referred to in plaintiff's specification; the defendants submitting that it was one inside portion of the machine which plaintiff only called the "lining" of the jacket, Mr. Jackson claiming that the whole upper structure of the Roller was the "case" or "jacket." On the question of novelty; on the question of utility; in fact on every single question but the question of infringement the District Judge had found for the appellant; in fact, in one part of his judgment his reasons would have been expected to be followed by a pronouncement that the defendants had infringed the plaintiff's patent. However, it concluded by saying quite the contrary; and the District Judge, therefore, found for the plaintiff on every point but this question of infringement, and here he found that the defendant's machine was not an infringement of the plaintiff's. Now, although this was so, he would briefly refer their lordships to another machine which was introduced in the evidence led in the Court below and which had a very material bearing on the question of these two competing machines now before the Court. This was the machine known as the Standard Roller, and it was a machine which was patented in India and introduced and worked in Ceylon but not patented here. It was, therefore, open to anybody to a certain extent to adopt the principles embodied in it; not being patented in Ceylon, no infringement of it could be prosecuted in Ceylon; but what the plaintiff contended in this present action was that the defendants in their Triple Action Roller appropriated a great improvement which plaintiff made in his Excelsior machine over his old and antiquated Standard. Finding the Standard was defective in many important particulars plaintiff improved it and he patented the improvement, and this was the patent he now alleged defendants had infringed. He now claimed that the defendants could not adopt that improvement without confessing their obligation to his machine and making arrangements for obtaining his license; while if they embodied the improvement without his license they were liable for infringement. He would ask their lordships for a brief moment to look at the Standard machine and observe how much more cumbersome it looked than the Excelsior. By the side of it the Excelsior looked a model of simplicity. Now, the distinctive principles alleged to have been infringed in the case of the Excelsior machine did not appear in the Standard, that was to say, there was no motion communicated to the upper rolling surface through the case or jacket surrounding it, and the improvement effected by the Excelsior was to detach the driving mechanism from the upper rolling surface and attach it to the jacket which enclosed the upper rolling surface whereby the upper rolling surface was left free to move up and down so as to accommodate the capacity of the rolling chamber, so to speak, to the quantity of the leaf and the different stages of its rolling. There must be in every machine some means of confining the leaf; that was supplied by the case or jacket; then there must also be some means of contracting the rolling chamber and this was done in the Standard by screwing up the under table by means of a chain working on a pulley. A cooly had to stand at the top and work up the table as the tea got rolled. Another objection to the Standard was the difficulty in regard to feeding the machine with leaf. Then too, in the case of a large machine the case or jacket weighed several cwt., and as it was pushed about it had to be strengthened by metal bands to take off the friction, because it rested on the table. Another objection was that there was no ventilation for the leaf in the rolling chamber, while oil used in lubricating the machine often dropped in and damaged the leaf. These were some of the principal objections. Seeing the defects of this machine and also recognising that it was very expensive both to work and to make, Mr. Jackson patented the Excelsior which possessed advantages not only in point of cost but also in efficiency and in ease of working. The main point of difference was quite clear; the upper surface was left free to

work vertically. In the Standard it was the lower surface that had to be moved to reduce the rolling space; in the case of the Excelsior it was the upper surface which was made movable vertically in order to admit the leaf for rolling and to allow of the pressure on the leaf being regulated. Another advantage gained by the new machine was that the upper table while carried so near to the lower table as to prevent leakage of leaf yet did not touch the lower table and the immense amount of friction present in the Standard was taken away, with the result at once to be anticipated and expected that the machine was easier to drive; it took less motive power to drive it than was the case with the Standard and it was not so stiff or cumbersome, while the oil could not have access to the tea, feeding was far more easily accomplished and ventilation was secured to a much greater extent than could be done in the Standard, and there were many other advantages which it was not necessary to point out. One great improvement was that the driving machinery was taken off from the upper rolling surface and attached to the case or jacket. That improvement had been taken by the defendants and applied to the Triple Action Roller,—that was the appropriation plaintiff complained of. Passing on counsel drew attention to the Triple Action Roller, pointing out that while the case in the Triple Action was round and in the Excelsior square yet the function in each case was to hold the leaf and to confine it between the two rolling surfaces, and the one point in the Triple Action machine which justified its name over and above what appeared in the Excelsior, was the revolution of the upper rolling surface. He asked the Court to picture the machine made square instead of round and then to consider the action on the leaf. The two machines worked so as to produce the same action on the leaf.

The CHIEF JUSTICE asked if this was really the case; if the two machines had exactly the same effect on the leaf?

Mr. WENDT replied that this was so if the rotary motion of the Triple Action's upper surface was left out of consideration. Opinion was divided as to whether that in itself was an advantage; but, leaving that alone, the action was the same. Of course the machines sought to imitate the action of the human hand in rolling the leaf. Hands were used in China still and these machines were made to imitate the rolling there. The effect of these two machines was the same.

The CHIEF JUSTICE remarked that it seemed to him that the motion of the one was distinct from the other; one being rectilinear whereas the other was circular.

Mr. WENDT said this was so in the result but the motion of the two rolling surfaces by themselves was the same, namely, circular which would be demonstrated if a pencil were attached to either surface and made to mark a line on a piece of paper. In addition the defendants had provided what they claimed as an improvement, namely, rotary movement of the upper surface. The upper rolling surface was given a rotary motion on its own axis while at the same time to quote the defendants words, it had the eccentric motion imparted to it by the hollow cylinder corresponding to the jacket in the plaintiff's machine. As the plaintiff said the rotary motion of the upper rolling surface might or might not be an improvement. Let it be so; it was open to anyone to apply that rotary motion to anybody else's machine so long as permission to do so had been granted; but what the plaintiff contended in this case was that the defendants had adopted this principle of giving the eccentric motion to their rolling surfaces from the plaintiff's machine. This induced him to pause and say that the Standard was said to have been common property in Ceylon before the Excelsior was patented; but this improvement could not possibly be applied to that common property for in the Standard the upper rolling surface was kept in one position by sliding on two parallel rods. Defendants could not possibly have applied the rotatory motion there-
